EdTech has transformed education and learning in the last few decades by offering multiple means to represent information, express knowledge, and engage in learning [2]. Moreover, EdTech has played a crucial role in supporting inclusive education by addressing multiple barriers to learning and by providing tools and opportunities to all students, including students with special educational needs and disabilities (SEND). For instance, EdTech has supported fair and optimized access to the curriculum while developing students' independence, agency, and social inclusion [2]. In addition, it has facilitated personalized learning, enhanced communication, and interaction among peers and teachers, and strengthened social skills [2]. However, as noted in the UNESCO (United Nations Educational, Scientific and Cultural Organization) report [2], the overall benefits and drawbacks of the implementation of EdTech are still not fully understood. Several factors contribute to this lack of understanding. First, the effectiveness of EdTech tools varies by the socioeconomic level of the students and by the income level of the country. It also depends on teacher willingness to adopt these tools and their readiness to use them as well as on the education stage. In fact, students at different stages show distinct behavior habits in terms of web-based learning experiences [3]. Third, the costs associated with implementing and maintaining EdTech, both in the short term and in the long term, may be higher than initially anticipated, posing affordability challenges, especially in poorer countries. These costs include the cost of the EdTech tools as well as the cost of training teaching staff members, which is necessary for the effective use and the appropriate selection of technologies for specific students. Finally, not all technologies are suitable for students with different types of SEND. To be effective, these technologies must be tailored to each student's specific learning needs.

With such numerous factors affecting the effectiveness of EdTech and the wide range of software applications, devices, and other technologies available on the market, teachers and policy makers can easily feel overwhelmed. Therefore, systematic reviews are needed to understand the available options and to help them make informed decisions for effective and manageable employment of EdTech in education to facilitate the inclusion of students with SEND. In recent years, a few systematic reviews have examined the use of EdTech for students with SEND [1,4-6]. Despite the importance of these studies, some are limited in their scope and in the variety of EdTech tools examined, while others encompass all educational levels, preventing a focused analysis of EdTech effectiveness for specific educational stages. In addition, only one study included research published after the COVID-19 pandemic.

The systematic review by [4] investigated the technology practices in special education contexts and included 126 studies published between 2014 and 2018. The results revealed that the most examined technology was games, and the most studied outcome was the improvement of learners' cognitive abilities. The majority of the studies included precollege students with learning disabilities and focused on natural sciences. Interventions were primarily conducted in formal educational environments and were mainly implemented over 5-10 weeks. Based on their results, the authors recommended providing a greater level of detail in reporting research findings and placing more emphasis on promoting life, job, and social skills.

The study by [5] investigated the impact of using augmented reality in the education of students with SEND. The review included 18 studies published between 2016 and 2021. The authors noted a decrease in studies from 2020 onwards, which they attributed to the COVID-19 pandemic and to the consequent closure of educational centers. The majority of the included studies used quantitative methodologies. Most of these studies focused on primary and secondary school students, with very few examining early childhood education or higher education. The experiences were primarily conducted with students with intellectual disabilities, followed by students with autism, learning difficulties, and hearing impairments. The use of augmented reality showed positive results in the learning of students with SEND. Improvements were observed in academic performance, motivation, communication, social interaction, and level of autonomy. However, the authors identified several limitations to the use of augmented reality in the education of SEND. These included low levels of teacher training, limited availability of augmented reality technology, lack of support from educational institutions, and technical and accessibility issues.

The study by [6] presented a systematic review investigating technology-enhanced and game-based learning activities used with children with SEND. The authors included 18 studies published between 2009 and 2019. They reported that about one-third of the studies involved participants with intellectual disabilities, another third included autistic participants, and the remaining studies involved participants with Down syndrome, motor impairments, visual impairments, and hearing impairments. The primary goal of the game-based activities was to support students' cognitive skills. These activities covered a wide range of academic areas, including mathematics, functional skills, and communication. The results of the included studies were mixed, with some interventions improving the learning of participants and others promoting their motivation.

Finally, the systematic review by [1] investigated the use of assistive technology among primary school students with disabilities in low- and middle-income countries. The study included 51 studies published between 2007 and 2020. The findings showed little evidence of the efficacy of educational interventions, with learning outcomes often considered secondary to the technological aspects of the studies. The authors reported a considerable variation in the number of studies addressing different types of impairments, with two-thirds of the studies involving students with sensory impairments. In addition, teachers and parents were often excluded from the process of using and evaluating EdTech. A consistent theme reported in the included studies was the reluctance of teachers to adopt EdTech solutions in their everyday teaching practices. Most of the studies were case studies or small-sample multiple baseline studies and rarely included control groups.

The current systematic review aims to summarize the current understanding of how EdTech supports the learning of students with SEND in inclusive primary schools in high-income countries. Moreover, this study will allow the investigation of the effects of the COVID-19 pandemic on the use of EdTech in this specific setting.

Review Questions

This systematic review seeks to answer the following questions:

1. How can EdTech support students with SEND in primary school settings in high-income countries?
2. What EdTech interventions are used to support students with SEND in high-income countries?
3. What are the gaps in the literature, and what is the potential for further development in this field?
4. How has the COVID-19 pandemic impacted the use of EdTech in primary inclusive classrooms?

Methods

Study Registration

The protocol for this systematic review follows the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) checklist [7,8] and the Generalized Systematic Review Registration Form [9]. The PRISMA-P checklist used for the development of this systematic review protocol is provided in Multimedia Appendix 1. The systematic review protocol was preregistered before the analysis of the data in the Open Science Framework in July 2024 and was last updated in December 2024 [10].

Inclusion Criteria

To be included in the systematic review, studies must meet the following criteria.

Population

- Students with SEND.
- Attending primary school.

Setting

We will include studies conducted in high-income countries, as classified by the World Bank [11] and based on the World Bank's Gross National Income per capita thresholds for the 2024-2025 fiscal year.

Study Design

We will include qualitative and quantitative studies exploring the design and the use of EdTech tools with students with SEND. We will exclude reviews of the literature.

Publication Date

We will include studies published between 2016 and 2024. This timeframe encompasses 4 years before the COVID-19 pandemic, which provides a baseline, and 4 years after, allowing us to assess the immediate and evolving effects of the pandemic. Moreover, focusing on this timeframe complements existing literature, which already covers earlier years, and provides a comprehensive and up-to-date perspective on the subject.

Publication Type

We will include peer-reviewed journal articles and peer-reviewed conference proceedings. While we originally considered including gray literature, such as reports from nongovernmental organizations, we realized that these sources would require a different approach to data extraction and synthesis, demanding additional time and resources that are not available to our research team. Similarly, Master and PhD theses will be excluded. Although these documents can be valuable resources, they may not be subjected to the same level of scrutiny as peer-reviewed articles, depending on the country in which they are conducted. Their length and the challenge of assessing them raise concerns about data extraction and synthesis of the findings for the systematic review. Moreover, their limited accessibility and dissemination could complicate replicability and comprehensive data extraction. Finally, we assumed that high quality studies are typically published in a peer-reviewed journal, supporting our decision to exclude these sources.

Language

We will include only studies available in the English language.

Exclusion Criteria

Studies that do not involve participants with SEND will be excluded.

In addition, studies focusing on individuals outside the primary school age range (5 years to 11 years) will not be considered. This exclusion criterion will be based on the mean age of the sample of students with SEND, which has to fall within this range.

Research conducted in countries other than high-income nations, as classified by the World Bank [11], will also be excluded.

Studies conducted in contexts other than the classroom settings, such as hospitals, clinical settings, or participants' homes will be excluded.

Furthermore, non–peer-reviewed studies and gray literature will be excluded. Previous reviews of literature will also be excluded.

Finally, studies not available in English will be excluded.

Search Strategy

Literature search strategies were developed using keywords from previous relevant systematic reviews, with guidance from a specialist librarian at UCL. The librarian provided recommendations on both the keyword list and database selection. The databases searched include ACM, Directory of Open Access Journals, British Educational Index, ERIC, Google Scholar (first 100 records), IEEE, PsycINFO, Scopus, and Web of Science. To ensure comprehensive coverage, the electronic database search will be supplemented by scanning the reference lists of studies that meet the inclusion criteria.

Starting from the list of keywords used by [1], the list of keywords was optimized by including synonyms and relevant terms derived from the research questions. The search strategy underwent several iterations to refine the terms and optimize the query string. The desirability of reducing the number of keywords or adding new terms to the query was evaluated based on the effect on the number of hits [12]. The terms evaluated were not considered necessary and hence deleted if the number of hits increased greatly and included a high ratio of nonrelevant references. To further validate the search results, we ran the search using alternative search terms to confirm that the search string captured the relevant studies. Search terms were limited to the title, the abstract, and the keywords of the papers, when possible. Alternatively, they were limited to the abstract of the paper only. When possible, the search was restricted to specific subject areas (such as “psychology” or “education”) or educational levels (such as “primary school”). The search strategy was conducted on July 26, 2024, by ER. Table 1 displays the search strategy for each database.

Table 1. Search strategy formulated for each database included in the study.

Screening

Rayyan [13], a web-based literature review software, will be used to remove the duplicates and to assist with the screening process. The titles and abstracts of all the records will be screened for relevance against the inclusion criteria by ER. Following this, the same reviewer will evaluate the full text of the articles deemed eligible. The reference list of all the studies that ultimately will meet inclusion criteria from the database search will be screened for any additional records that may have been missed.

An independent reviewer will screen a subsample of all records to establish the reliability of the screening process. The percentage of records to be independently screened will be

determined based on the total number of records, according to the following rule: if there are more than 201 records, 5% will be screened; if there are between 100 and 200 records, 10% will be screened; and if there are 100 or fewer records, 20% will be screened. Disagreements will be discussed and resolved during agreement meetings through consensus or by consulting a third reviewer. The rationale for excluding records that do not meet the eligibility criteria will be documented.

Data Extraction

The data extraction process will begin with a pilot stage, during which ER and MB will independently extract data from a randomly selected sample of the included studies. The sample size will be determined based on the total number of studies included at this stage of the review, following the same criteria used for the screening process. The purpose of the pilot phase is to ensure adherence to standardized procedures and to validate and, if necessary, update the data extraction criteria. After the pilot stage, ER will complete the final data extraction for all included studies, using Microsoft Excel to collect and organize the information.

The provisional list provided in Textbox 1 outlines the data to be extracted. Based on the pilot stage, this list and the corresponding coding rules will be finalized. If significant updates are made to the list of entities to be extracted, MB will independently review the data extraction to ensure the reliability of the final data extraction process. The sample size will be determined based on the total number of studies included at this stage of the review, following the same criteria used for the screening process.

The study's characteristics include the authors, publication year, and the country of data collection. It also includes the study design (cross-sectional or longitudinal) and type of study based on the category used in the Mixed Methods Appraisal Tool (MMAT) [14]. For interventions and single-case research, information about the length and framing of the intervention will also be extracted. The intervention's framing will be coded based on the Multi-Tiered System of Support model, which operationalizes how teachers implement the Universal Design for Learning model and includes three categories: (1) core classroom instruction, (2) targeted small group instruction, or (3) intensive individual intervention [15].

The SEND sample characteristics cover sample size, participant age, sex, socioeconomic status, and the diagnosis or disability categorization.

EdTech characteristics include the terminology used to refer to the tool described in the study (eg, "information and communication technology" or "assistive technology"), cost, level of technology (low-tech or high-tech), and the type of EdTech tools used, categorized according to the World Bank [16], as shown in Textbox 2.

Textbox 1. Provisional list of data to be extracted

Characteristics of the study

- Authors
- Year of publication
- Country where the data was collected
- Study design
- Type of study
- Length and framing of the intervention (limited to intervention studies and single-case research)

Characteristics of the sample with SEND

- Sample size
- Chronological age of participants
- Sex of participants
- Socioeconomic status
- Diagnosis or disability categorisation

Characteristics of Educational Technology (EdTech)

- Use of EdTech terminology
- Overall cost of the EdTech tool
- Level of technology of the EdTech tool
- Type of EdTech employed

Textbox 2. Type of education technology (EdTech).

Type of EdTech

- Augmentative and alternative communication
- Accessible textbooks
- Assistive hearing and listening technology
- Braille reading and writing equipment
- Mainstream accessible software and applications
- Mobility technology
- Personal electronic devices
- Platforms and applications for learning support
- Technology for teaching support
- Technology for vision enhancement
- Text-to-speech technology

Outcomes

The primary outcome of this systematic review will be the overall effectiveness of EdTech tools used in the inclusive classroom, defined as their impact on a range of factors including academic achievement, student engagement, social inclusion, accessibility, and other relevant outcomes that contribute to an inclusive learning environment.

Assessment of Risk of Bias in the Included Studies

To assess the risk of bias in the studies included in this systematic review, we will use the MMAT [14]. The MMAT is a generic critical appraisal tool that was developed for the appraisal of multiple types of studies including qualitative studies, quantitative randomized controlled trials, quantitative nonrandomized studies, quantitative descriptive studies, and mixed methods studies. As the present systematic review includes studies using a range of methodologies, the MMAT was deemed the most suitable approach for ensuring quality and consistency in the evaluation of the risk of bias. The assessment consists of 2 screening questions and 5 category-specific items. Each item can be rated as “yes” if the criterion is met, “no” if it is not met, or “can’t tell” if the study provides insufficient information to score the criterion as met or not met. The MMAT has been applied in previous research, such as in systematic reviews to assess the methodological quality of the included studies investigating the use of EdTech for health and social care practitioners and the use of gamification in education [17,18].

All included studies will be evaluated for quality by one reviewer of the research team. In addition, an independent reviewer will reassess 20% of those studies to ensure consistency and reliability in the evaluation process. Disagreements will be resolved through discussion, and if consensus cannot be reached, a third reviewer will be consulted.

Data Synthesis

We will present the collated results in a structured format, aligned with the research questions of the systematic review. This review will use a mixed methods analysis, incorporating both quantitative and qualitative approaches to analyze the results from the included studies.

For the interventions, we will assess the primary outcome by comparing pre- and posttest scores of students with SEND using specific EdTech tools. Tables will be created to describe the characteristics of the studies, populations, and EdTech tools used.

Qualitative data will be analyzed using content analysis to synthesize and interpret key issues and themes related to Review Question 1 across the studies. If a sufficient number of comparable studies are included, a subgroup analysis will be conducted. Potential subgroups may be based on the type of EdTech used, the population involved, or the country where the study was conducted.

Assessment of Meta-Biases

We anticipate that assessing publication bias may not be feasible due to the heterogeneous nature of the included studies. Similarly, assessing outcome reporting bias may be challenging because of the potential lack of registered protocols for these studies. However, we will provide a narrative discussion on the potential for publication bias, focusing on whether negative results were excluded or difficult to identify, and we will highlight any inconsistencies in outcome reporting where possible.

Results

As shown in Figure 1, a database search was conducted in July 2024, identifying 547 records. We expect to complete the screening process by November 2024 and submit the manuscript for peer review by the end of January 2025. The results of the completed study will be submitted to a journal relevant to the SEND population, and findings will be presented at relevant conferences and shared with stakeholders, such as nongovernmental organizations, education and health care organizations, assistive technology developers, and policy makers.

Discussion

Principal Findings

Many reviews have already been conducted on the use of EdTech with students with SEND. However, these reviews are limited by their focus on specific tools, such as augmented reality or educational game-based activities. In addition, some reviews encompass all educational levels, which prevents a detailed examination of the effectiveness of these tools for specific educational stages (such as primary, secondary, or higher education). These limitations reduce their usefulness for making targeted decisions about EdTech implementation. Furthermore, some reviews have a narrow scope regarding publication years, covering studies only up to 2021. It is essential to have current insights into classroom practices, as technology and devices used just 5 years ago may now be outdated or unavailable, and new EdTech devices may have been introduced and evaluated. To fill this gap, our systematic review will collect and analyze data on the use of EdTech in inclusive primary school settings in high-income countries and will also discuss findings in comparison with previous reviews of literature in this field. Finally, this study will describe the impact of the COVID-19 pandemic on the use of EdTech in the field of research education. We anticipate that the review will reveal an increase in the use of EdTech in the inclusive classroom following the COVID-19 pandemic. These findings are expected to inform the use and the design of inclusive EdTech and assistive technology tools to support students with SEND in the primary classroom and to establish best practices for the seamless integration of EdTech, ultimately producing positive outcomes for these students.

In addition, one of the outcomes of our systematic review will be the creation of an updated database that catalogs all studies investigating the use of EdTech in inclusive primary schools in high-income countries. This database will offer accessible, current evidence on how EdTech supports students with SEND in this setting. The final database, which will be published in the Open Science Framework platform and as supplementary material following the publication of the systematic review, aims to facilitate evidence-based decision-making, support the development of guidelines, interventions, and policies, and identify gaps in the current research landscape. It is expected to serve as a valuable resource for researchers, educators, assistive technology developers, policy makers, and other stakeholders.

Limitations

While we will use a comprehensive search strategy, it is possible that relevant studies could be overlooked. In addition, our search is restricted to English-language and peer-reviewed publications, potentially excluding studies in other languages and unaudited studies and thereby limiting the comprehensiveness of the evidence available. Finally, a limitation of this systematic review is that it may not be feasible to meta-biases. As a result, the confidence in the conclusions drawn from this review may be somewhat limited, and this limitation should be considered when interpreting the findings.

Conclusions

To our knowledge, this will be the first systematic review to describe the impact of the COVID-19 pandemic on the use of a wide range of EdTech to support the learning and inclusion of primary school students with SEND in high-income countries. This review aims to facilitate evidence-based decision-making and contribute to the future improvement of guidelines for the effective use of EdTech to support inclusion in primary school settings. Such knowledge is crucial for promoting educational equity, enhancing learning outcomes, and supporting the diverse needs of all students.

Acknowledgments

This research was funded by the EPSRC ICT Public Engagement Grant (EP/W033674/1). The funder had no role in the study design, analysis, and interpretation of data, writing of the manuscript, or the decision to submit the manuscript for publication.

Data Availability

The dataset generated during this study is available in the OSF repository [10] and will be published as supplementary material alongside the main systematic review paper.

Authors' Contributions

MB and ER contributed to conceptualization, methodology, and writing–original draft, and editing. ER handled data curation. CH and MB handled funding acquisition. MB performed project administration. CH handled supervision, writing–review, and editing.

Conflicts of Interest

None declared.

Abstract

Background: The COVID-19 pandemic has had a profound global impact, leading to a range of persistent sequelae referred to as post–COVID-19 condition or "long COVID" that continue to affect patients worldwide. Among these sequelae, post–COVID-19 insomnia (PCI) has emerged as a significant issue. Conventional treatments, including cognitive behavioral therapy and pharmacological interventions, face limitations such as variable efficacy, potential side effects, and substantial costs. Recently, acupuncture has gained traction due to its efficacy, cost-effectiveness, and safety profile.

Objective: This study aims to conduct a meta-analysis and systematic review evaluating the efficacy and safety of acupuncture for the treatment of PCI to delineate the optimal modality, intervention frequency, and duration for achieving the most beneficial outcomes, thereby providing a comprehensive understanding of acupuncture's role in managing PCI, contributing to evidence-based clinical practice, and informing clinical decision-making.

Methods: Electronic searches will be performed in 12 databases from inception to October 2024 without language restrictions. This includes both English databases (PubMed, Cochrane Library, Web of Science, Embase, OVID and Scopus), as well as Chinese databases (China National Knowledge Infrastructure, Wan-Fang Data, Chinese Biomedical Literature Database, Chinese Scientific Journal Database, Duxiu Database and the Chinese Clinical Trial Registry Center). Randomized controlled trials on acupuncture for PCI will be included. Primary outcomes will include the response rate and insomnia severity; secondary outcomes will include the Traditional Chinese Medicine Symptom Scale (TCMSS) and adverse event rates. Data synthesis will use risk ratios for dichotomous data and mean differences for continuous data. Study selection, data extraction, and quality assessment will be conducted independently by 2 reviewers. Methodological quality of eligible studies will be evaluated following the *Cochrane Handbook for Systematic Reviews of Interventions* (version 6.3). Meta-analysis will be performed with RevMan 5.3.

Results: Based on the data on response rate, insomnia severity, TCMSS score, and adverse event rates, this study will provide an evidence-based review of the efficacy and safety of acupuncture for PCI treatment.

Conclusions: This systematic review will present the current evidence for acupuncture for PCI, aiming to inform clinical practices and decision-making and to enhance the understanding of acupuncture's role in managing PCI. Furthermore, it will identify research gaps and suggest potential areas for future investigation.

Introduction

Background

The COVID-19 pandemic caused by the SARS-CoV-2 virus has emerged as one of the most significant public health challenges in recent years [1], with over 770 million cases and approximately 6.9 million deaths worldwide [2,3]. Despite the World Health Organization having declared the end of the global public health emergency in May 2023, evolving virus variants continue to impact the world, exacerbating the global effects of the pandemic [4]. Nearly 90% of hospitalized patients with COVID-19 develop post–COVID-19 condition [5,6], commonly referred to as "long COVID" according to the National Institute for Health and Care Excellence, which includes a range of signs and symptoms that continue or develop after the acute phase of the illness [7]. These symptoms include sleep disturbances, depression, fatigue, tinnitus, and anxiety [8,9].

Studies indicate that insomnia has a high prevalence, impacting roughly 20% to 35% of the general population [10-13], and this rate is even higher among health care workers and patients with COVID-19, reaching up to 75% [8]. Substantial evidence indicates that post–COVID-19 insomnia (PCI) frequently persists over the long term [14-17], leading to serious health issues such as increased depression, prolonged work absences, and a heightened risk of hypertension [15,18,19]. Insomnia poses a significant threat to public health, not only by impairing physical, emotional, and social well-being but also by reducing quality of life [20]. It can degrade psychological functioning and decision-making, compromise the immune system, raise the risk of accidents, and cause mood alterations, all while boosting medical expenditures [21,22]. Moreover, the interaction between sleep deprivation and SARS-CoV-2 infection could potentially raise the risk of developing neurodegenerative diseases like dementia [16]. Consequently, PCI has become widely acknowledged as a critical and pressing issue affecting the entire world. The emergence of SARS-CoV-2 subvariants in the postpandemic COVID-19 era, particularly the highly mutable Omicron lineage and its numerous subvariants, presents new challenges to public health interventions [23].

Current standard treatments for PCI include cognitive behavioral therapy for insomnia (CBT-i) and pharmacotherapy [24,25]. Although these methods have demonstrated efficacy, they are not without limitations. For instance, the 2017 clinical practice guidelines of the American Academy of Sleep Medicine indicate that CBT-i alone may not be beneficial for all people with insomnia due to issues like noncompliance, treatment unresponsiveness, access barriers, and financial constraints [25]. Pharmacological therapies for insomnia comprise benzodiazepines, nonbenzodiazepines, antidepressants, melatonin receptor agonists, and other sedatives [24,26]. While these medications can offer short-term relief, their long-term, routine use is not recommended due to the risks of developing tolerance, dependency, and withdrawal issues [20,26-28]. Moreover, these medications can lead to rebound insomnia, residual daytime sedation, cognitive and memory impairments, and motor incoordination, particularly increasing the risk of falls among older people [20,26-29]. Given these concerns, there is a pressing need to find alternative therapeutic approaches that are both efficacious and safe for treating PCI.

In recent years, complementary and alternative medicine (CAM) has become widely used to address insomnia in various countries, including the United States, Australia, and numerous Asian nations [30-32]. Acupuncture, recognized as one of the most popular and safest CAM therapies [28,33], has a long-standing history of treating sleep disorders dating back to ancient times [26]. Based on traditional Chinese medicine, acupuncture works by inserting fine needles into acupoints throughout the body. It seeks to reestablish the equilibrium between yin and yang, thereby facilitating the body's return to a state of physiological homeostasis [34-36]. A multitude of studies indicate that acupuncture is highly effective in improving both sleep quantity and quality [37-42]. The underlying mechanisms include regulating neurotransmitters such as gamma-aminobutyric acid [43-46] and serotonin [47-50], increasing melatonin levels [51-53], and modulating the hypothalamic-pituitary-adrenal axis and the expression of corticotropin-releasing hormone and adrenocorticotropic hormone [54-57], thereby improving sleep quality. Furthermore, acupuncture can also regulate inflammatory cytokines such as interleukin-1, interleukin-6, and tumor necrosis factor-α [58-62], and it can influence the gut microbiota to regulate sleep-wake behavior [63,64].

Much of the research supporting the use of acupuncture for insomnia is constrained by the limitations of low- or moderate-quality evidence and inconsistent reports regarding its clinical efficacy and safety. Furthermore, the effects of acupuncture on PCI remain largely unknown. Through an extensive literature review, we identified a notable absence of systematic reviews specifically addressing the efficacy of acupuncture for PCI. In light of this gap, we will conduct a meta-analysis and systematic review to assess and synthesize the available evidence on the efficacy and safety of acupuncture for PCI. This review aims to establish a robust theoretical foundation for clinical practice, thereby providing credible evidence on the therapeutic potential of acupuncture for PCI.

Objectives

This review has 3 objectives: (1) to evaluate the efficacy and safety of acupuncture for the treatment of PCI in comparison to comfort therapy (such as placebo, sham acupuncture, or a blank control) or other therapies (such as Western medicine or nondrug therapies); the results will provide a comprehensive understanding of acupuncture's role in managing PCI, thereby contributing to evidence-based clinical practice and informing clinical decision-making in practice; (2) to assess the methodological quality and the strength of the evidence supporting the use of acupuncture for PCI, offering a thorough

appraisal of the existing literature; and (3) to delineate the optimal modality, intervention frequency, and duration to achieve the most beneficial outcomes.

Methods

Overview

This study will be conducted following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols (PRISMA) statement [65]. This protocol has been prepared in accordance with the Cochrane recommendations and registered on PROSPERO (CRD42024499284).

Study Eligibility Criteria

The inclusion and exclusion criteria for this review are detailed in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Types of studies
  - All randomized controlled trials (RCTs) focusing on the treatment of insomnia after COVID-19 using acupuncture therapy
  - Studies involving single acupuncture therapy, as well as those comparing acupuncture with other interventions
  - Studies published in English or Chinese
  - Studies published from the inception of the database up to October 2024
  - No restrictions on publication status or type
- Types of participants
  - Participants who developed insomnia following COVID-19 infection without a prior history of insomnia who were subsequently enrolled in an RCT; this will include patients with confirmed COVID19 or asymptomatic SARSCoV-2 infections based on the results from nucleic acid testing, antigen testing, and clinical criteria
  - Participants meeting the diagnostic criteria for insomnia, including the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* [66], *Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition* [67], *International Classification of Sleep Disorders, Third Edition)* [68], and *Chinese Classification and Diagnostic Criteria of Mental Disorders, Third Edition* [69] or equivalent standard diagnostic criteria
  - No restrictions on gender, age, race, onset time, or source of cases
- Types of intervention
  - Simple acupuncture therapy
  - Trials where acupuncture is used as an adjunct to other interventions (eg, behavior therapy, psychotherapy, or pharmacotherapy) only included if the control groups receive the same additional interventions
  - No specific restrictions on acupoints or course of treatment; the selection of acupoints and acupuncture methods should be derived from traditional Chinese medicine
  - The specific length, thickness, and model of the acupuncture needle will not be considered in this review
- Types of comparisons
  - Comfort therapy (placebo, sham acupuncture, or blank control)
  - Other therapies (Western medicine or nondrug therapy)
- Types of outcome measures
  - The primary outcomes will include response rate and insomnia severity as measured by validated instruments (eg, the Insomnia Severity Index, Pittsburgh Sleep Quality Index, or Athens Insomnia Scale)
  - The secondary outcomes will include the Traditional Chinese Medicine Syndrome Score Scale score and adverse events

Exclusion criteria

- Non-RCTs, such as reviews, animal experiments, commentary articles, letters, and case reports
- Participants with primary insomnia or a serious underlying disease that makes them unsuitable for acupuncture treatment
- Studies that explored interventions using nontraditional acupoints, such as ear acupuncture, scalp acupuncture, and other methods
- Duplicate publications
- Studies found in gray literature
- Studies with incomplete data

Electronic Searches

A search strategy will be designed and conducted following the guidelines outlined in the *Cochrane Handbook*. The meta-analysis will be reported based on the PRISMA guidelines.

Electronic searches will be carried out by 2 independent researchers (YL and JZ) from initiation until October 2024. English databases (PubMed, Cochrane Library, Web of Science, Embase, OVID, Scopus) and Chinese databases (China National Knowledge Infrastructure, Wan-Fang Data, Chinese Biomedical Literature Database, Chinese Scientific Journal Database, and Duxiu Database) will be included in the search. The Chinese Clinical Trial Registry Center will also be searched for ongoing

trials. There will be no restrictions on countries or publication types.

The search will use keywords such as *COVID-19, 2019-nCoV infection, SARS-CoV-2 infection, acupuncture therapy, acupuncture treatment, pharmacoacupuncture treatment, sleep initiation and maintenance disorders, sleeplessness*, and *insomnia disorder*. To ensure a comprehensive search, a combination of subject headings (Medical Subject Headings) and free words will be used, regardless of the language or type of publication. The search will be conducted across all databases to identify all relevant articles. An example search strategy for the PubMed database is provided in Multimedia Appendix 1.

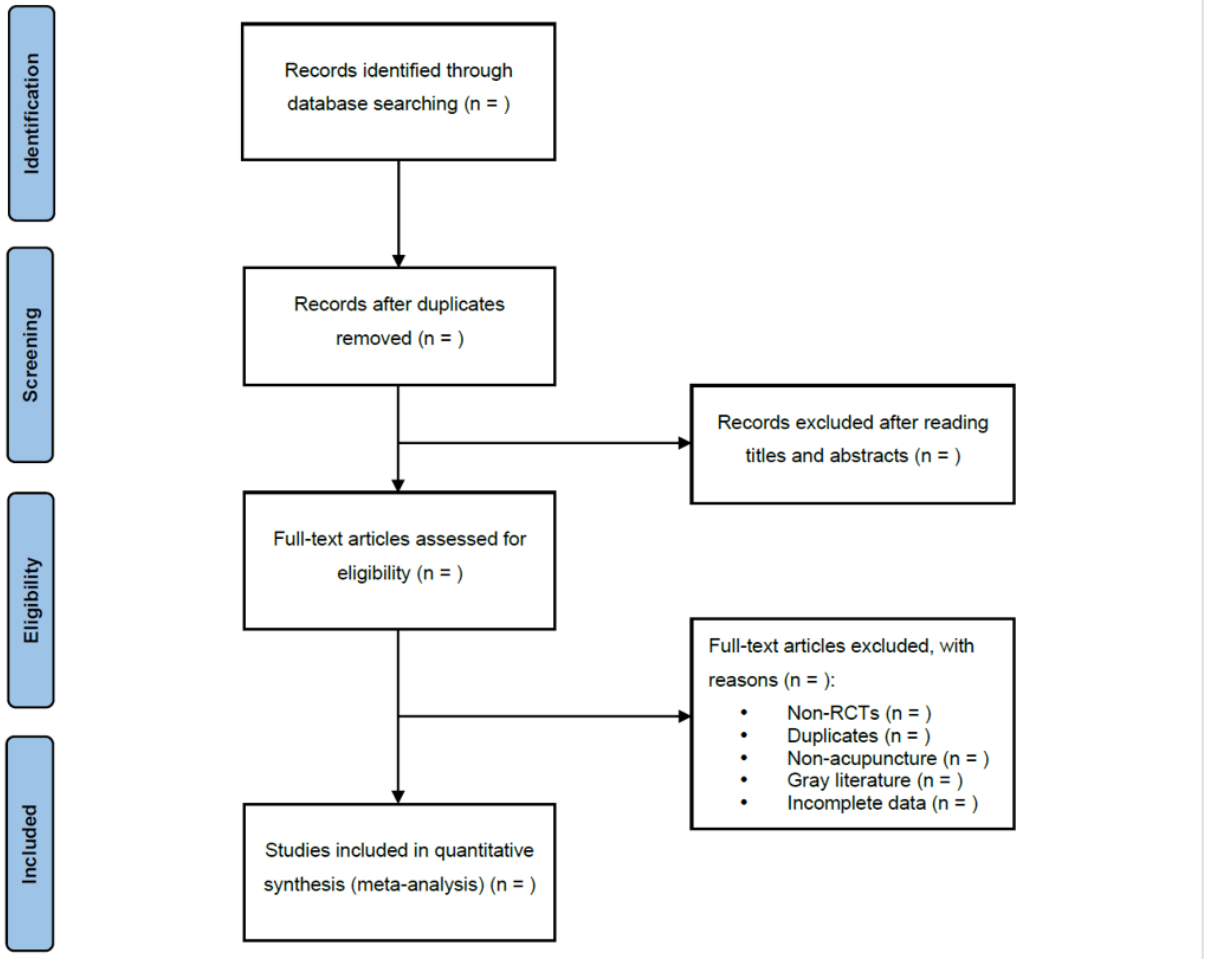
Similar search strategies will be used for the other databases. Additionally, in the case of studies for which the full text is not available, efforts will be made to contact the first author or corresponding author to obtain the necessary full text.

Study Selection and Data Collection

Selection of Studies

All reviewers have undergone training to ensure a fundamental comprehension of the context and purpose of the review. In this step, EndNote X9 (Clarivate) will be used to screen the search results. Two reviewers (YL and JZ) will independently conduct the screening process and cross-check the results. Based on the predefined inclusion and exclusion criteria, relevant studies will be selected after reviewing their titles, abstracts, or full texts. In instances of duplicate publications, the original publication will be selected. Should there be any incomplete data or ambiguous details, efforts will be made to contact the first author or corresponding author for clarification. In cases where disagreements arise, a third reviewer (KS) will be consulted, and a final decision will be reached through discussion. A comprehensive overview of the selection process will be depicted with a PRISMA flow chart (Figure 1).

Figure 1. Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow chart. RCT: randomized controlled trial.



Data Extraction and Management

Two reviewers (ZW and LL) will independently perform data extraction using the provided data extraction form (Multimedia Appendix 2). Any disagreements that emerge during the process will be addressed through discussion between the 2 reviewers. If a resolution cannot be achieved, the input of a third reviewer (HX) will be sought. The following information will be recorded using a standardized data extraction form: (1) basic information on the study (first author, year, and country of publication); (2) study characteristics (study inclusion criteria, sample size, and participants' details, including age, gender, complications, severity, and course of insomnia); (3) details of the study intervention and control intervention, including modality, frequency, and treated acupoints; (4) a risk of bias assessment; and (5) outcome data, adverse effects, and drop-out rate.

EndNote will be used by the reviewers to facilitate data management and to identify duplicate publications. In cases where 2 or more reports describe the same trial, only one of these publications will be considered for inclusion in the analysis.

Assessing Risk of Bias in Included Studies

The methodological quality of selected studies will be assessed using the Cochrane Risk of Bias 2.0 tool. Two reviewers (HX and CL) will independently assess the risk of bias for each included randomized controlled trial according to the guidelines provided in the *Cochrane Handbook for Systematic Reviews of Interventions* (version 6.3). The assessment will cover the following domains: (1) bias arising from the randomization process, (2) bias due to deviations from the intended intervention, (3) bias due to missing outcome data, (4) bias in measurement of the outcome, and (5) bias in selection of the reported results.

Each study will be classified as "low risk," "high risk," or "some concerns" based on the evaluation. Should any disagreements arise, a third reviewer (GL) will be engaged to facilitate consensus.

Measures of Treatment Effect

Statistical analysis will be conducted using RevMan (version 5.3; Cochrane Collaboration), with forest plots being used to visually represent the comparative efficacy of the treatments. For continuous variables, the mean difference (MD) will be used to express the treatment effect, whereas for dichotomous data, the risk ratio (RR) will be used. For each treatment effect, the estimated value and 95% CIs will be determined and reported within the analysis.

Dealing With Missing Data

For studies with missing or ambiguous data, efforts will be made to contact the first author or corresponding author for assistance. Should the missing data remain unobtainable despite attempts to contact the authors, the study will be excluded from the analysis.

For studies with missing data, the intention-to-treat analysis will be used to conduct statistical and omission analysis. Intention-to-treat analysis helps maintain the integrity of the original randomized allocation of participants, even in cases where some data may be missing. This approach guarantees that participants are evaluated based on their original randomized groups, irrespective of any missing data.

Assessment of Reporting Biases

Should more than 10 studies report on the same outcome measure, a funnel plot and an Egger regression test will be applied to assess the potential for reporting bias.

Data Analysis

RevMan will be used for the calculation of the RR for dichotomous data and the MD for continuous variables. For each effect, the estimated values and the 95% CIs will be determined.

The RR is calculated as follows:

where a and b are the number of events and nonevents in the intervention group, and c and d are the number of events and nonevents in the control group.

The MD is calculated as follows:

where  and  are the means of the intervention and control groups, respectively.

Heterogeneity will be assessed using the I^2 statistic, calculated as follows:

where Q is the Cochrane Q statistic and k is the number of studies.

If the research results exhibit low heterogeneity (I^2<50%), a fixed-effect model will be applied for the meta-analysis. On the other hand, in case of significant heterogeneity (I^2>50%), a random-effects model will be used for the meta-analysis, after which, further analysis will be conducted to ascertain the sources of heterogeneity.

When the data are not amenable to quantitative synthesis, a narrative summary will be provided to elucidate the findings of the included studies.

For trials that report only pre- and postintervention values, the mean change will be derived by computing the difference between post- and preintervention measurements. Consequently, the SD for these changes will be estimated.

Subgroup Analysis

When significant heterogeneity is observed, a subgroup analysis will be performed to investigate the possible sources of this variability. The following factors will be examined as potential subgroup variables: age, gender, duration of COVID-19 infection, severity of insomnia, the type of acupuncture intervention, treatment frequency and duration, and other relevant parameters.

When sufficient data are available for each subgroup, a quantitative subgroup analysis will be performed to assess the influence of these factors on the treatment effects. Nonetheless, if the data for subgroup analysis are inadequate, a qualitative synthesis will be conducted. In this approach, the results from individual studies will be summarized and compared without a formal quantitative synthesis.

Sensitivity Analysis

If significant heterogeneity persists even after the subgroup analysis, a sensitivity examination will be implemented. This process involves reconducting the meta-analysis after discarding studies of low quality or those with possible biased sources.

The comparison of the meta-analysis results before and after sensitivity analysis allows for a thorough assessment of the

findings' stability and reliability. This approach aids in understanding the impact of individual studies on the total results, offering a more in-depth insight into the meta-analysis outcomes.

Grading the Quality of Evidence

Researchers will assess the quality of evidence using the Grading of Recommendations, Assessment, Development, and Evaluation (GRADE) approach. The quality of evidence will be classified into 4 levels: very low, low, moderate, or high.

The GRADE methodology facilitates a systematic and transparent assessment of the certainty and strength of the evidence, thereby enabling researchers to present a comprehensive and reliable summary of the evidence in a distinct and dependable way.

Ethical Considerations

Ethics approval is not required since this protocol is solely for a systematic review and does not involve private data.

Dissemination

The results will be disseminated electronically through publication in a peer-reviewed journal or presented at a relevant conference.

Results

The study will be conducted following the methodology in the *Cochrane Handbook for Systematic Review of Interventions*. Two independent researchers will perform comprehensive searches across 12 databases, encompassing English databases (PubMed, Cochrane Library, Web of Science, Embase, OVID, and Scopus) and Chinese databases (China National Knowledge Infrastructure, Wan-Fang Data, the Chinese Biomedical Literature Database, the Chinese Scientific Journal Database, the Duxiu Database, and the Chinese Clinical Trial Registry Center). Focusing on the outcomes such as response rate, insomnia severity, TCMSS score, and adverse event rates, this study will deliver an evidence-based review of the efficacy and safety of acupuncture for PCI treatment.

Discussion

Overview

The COVID-19 pandemic has become one of the most formidable public health crises in recent years. As the persistence of post–COVID-19 condition continues, a considerable number of individuals have been grappling with PCI. This issue is escalating and poses a critical challenge to public health, placing a substantial economic burden on society. Not only does PCI negatively impact physical and mental well-being, but it also contributes to a decline in social functioning and a lower quality of life [20]. PCI is often accompanied by other symptoms, such as anxiety and depression [70]. Although CBT-i and pharmacological interventions are widely used in clinical settings, they face certain constraints, such as variable efficacy, adverse effects, and high costs. These limitations have sparked a surge of interest in CAM therapies.

As a significant component of CAM therapies, acupuncture has gained increasing recognition for its effectiveness, affordability, and favorable safety profile. It is rooted in the basic theory of traditional Chinese medicine, which emphasizes the interconnectedness of nature and humanity, viewing the body, mind, and spirit as a unified whole [71,72]. Considering that PCI affects both physical and mental health, acupuncture's natural, potent, and low-risk attributes, along with its holistic approach, make it a compelling alternative for individuals with PCI. However, given that PCI is a relatively novel condition, it is imperative to conduct a thorough analysis of acupuncture's therapeutic efficacy and safety as a treatment option.

This paper presents the protocol for a systematic review that constitutes the first quantitative analysis of the efficacy and safety of acupuncture for PCI. Through a meticulous evaluation of evidence gleaned from published randomized controlled trials, we aim to provide a comprehensive appraisal of acupuncture's impact on PCI. Furthermore, the study endeavors to delineate the optimal modality, frequency of intervention, and duration of treatment to achieve the most favorable outcomes. The findings from this meta-analysis and systematic review are expected to offer valuable insights to clinical practitioners, establishing a robust theoretical foundation and essential reference for the application of CAM therapies in PCI treatment. This evidence may significantly enhance the quality of informed clinical decision-making, particularly in the selection of therapeutic strategies for patients with PCI.

All amendments to this protocol will be meticulously recorded, including the amendment date, a description of the changes, and the corresponding rationale.

Limitations

Due to language barriers, some relevant electronic databases might not be included, potentially limiting the comprehensiveness of the findings.

Conclusion

This review will offer a thorough synthesis of the literature on acupuncture as a treatment for PCI, thereby enriching the current scientific discourse on this subject. By examining the evidence base, the review will deliver significant insights aimed at optimizing clinical practices in practical health care environments. It will also present health care professionals with a novel viewpoint on the use of complementary and alternative medicine in addressing PCI, facilitating more informed clinical decision-making.

Acknowledgments

The authors would like to express their gratitude to the anonymous reviewers for their perceptive comments and constructive suggestions.

Abstract

Background: Intestinal protozoal infections caused by *Entamoeba histolytica*, *Giardia lamblia*, and *Cryptosporidium parvum* are prevalent in Malaysia. They cause severe diarrheal diseases with symptoms such as bloody stools, abdominal pain, stomach discomfort, and bloating. These infection outbreaks have been reported in diverse socioeconomic backgrounds and geographical regions usually during the rainy season or in areas with poor sanitation. Despite the importance of these infections, data on its overall prevalence, risk factors, and diagnostic methods remain limited.

Objective: The aim of this study is to systematically review and synthesize evidence on the risk factors, prevalence, and detection methods for intestinal protozoal infections in Malaysia, offering insights that are applicable to other tropical and low-income regions.

Methods: Studies on intestinal protozoal infections among Malaysian patients published after January 2010 up to November 2024 will be eligible for inclusion. The eligibility criteria include studies investigating infections caused by *E. histolytica*, *G. lamblia*, and *C. parvum* using validated diagnostic methods such as microscopy, molecular techniques, or immunoassays. Case reports, reviews, and studies without original data will be excluded. Comprehensive database searches will be conducted in PubMed/MEDLINE, Scopus, ProQuest, Web of Science, Google Scholar, and the Cochrane Library. The reference lists of selected papers are also checked. A standardized data extraction form will be used to record study characteristics, outcomes, and associated variables. Risk of bias will be assessed using the Joanna Briggs Institute tools and Newcastle-Ottawa Scale approach. Data synthesis will utilize a random effects model to estimate pooled prevalence and identify risk factors associated with these infections. Subgroup analyses will examine variations by geographic region and diagnostic method. Statistical heterogeneity will be assessed using I^2 statistic and meta-regression. Publication bias will be assessed using Egger and Begg funnel plot test. The results are reported in accordance with PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines.

Results: This systematic review was funded in June 2024. Database searches were started in July 2024, and we identified 1652 papers as of December 2024 for screening. Completion of study screening is anticipated by May 2025, with data extraction and analysis expected to conclude by December 2025.

Conclusions: Our study will address critical knowledge gaps in the epidemiology and risk factors of intestinal protozoal infections in Malaysia. Study limitations include potential bias in study selection, heterogeneity in diagnostic methods, and differences in the reporting quality of the included studies. Our findings will provide valuable insights into the prevalence of these infections,

the associated risk factors, and the diagnostic techniques employed, which should strengthen public health measures, improve diagnostic procedures, and guide future research to reduce the prevalence of intestinal protozoal infections in Malaysia.

Introduction

Intestinal protozoal infections are the most common parasitic infections and are a serious global health concern. An estimated 3.5 billion people are affected, with approximately 450 million individuals currently experiencing intestinal protozoal infections [1]. The typical intestinal protozoal infection cases are reported from *Entamoeba histolytica*, *Giardia lamblia*, and *Cryptosporidium parvum*. The transmission of these protozoa occurs via the oral-fecal route, which involves either indirect or direct contact with the infection. This includes various modes of transmission such as human-to-human, zoonotic, waterborne, and foodborne transmission [2,3]. The most common symptoms of an intestinal protozoal infection include nausea and watery diarrhea, which are caused by the release of enterotoxins, and are often accompanied by inflammation in the stomach, small intestine, and large intestine [3]. Individuals infected with *E. histolytica*, the causative agent of amoebiasis, show characteristic symptoms such as abdominal pain, bloody diarrhea, fever, and in severe cases, liver abscesses. *G. lamblia* causes giardiasis, which is characterized by watery diarrhea, abdominal pain, flatulence, and weight loss. Similarly, *C. parvum*, which is responsible for cryptosporidiosis, primarily manifests with watery diarrhea accompanied by stomach cramps, nausea, vomiting, and fever, with an increased risk in immunocompromised individuals. These different clinical signs emphasize the importance of targeted diagnostic approaches and tailored therapeutic interventions, with the severity of the disease depending on the immune status of the affected individuals [4,5]. The causes can be difficult to determine because the majority of enteric pathogens cause similar symptoms. There can be multiple infectious agents that can cause acute gastroenteritis, and contamination may come from food, water, the environment, or animals. Therefore, it is difficult to make accurate and fast reports via epidemiological analysis [6,7].

The primary method for detecting intestinal protozoa is the microscopic analysis of stool samples, which is laborious and requires specialized personnel. Molecular approaches such as real-time polymerase chain reaction offer increased sensitivity and efficiency and require only 1 sample for testing. Immunodiagnostic approaches targeting parasite antigens or host antibodies improve sensitivity and specificity. Despite advances, there is no one-size-fits-all strategy for diagnosis, which requires careful evaluation of aspects such as the suspected parasite, the nature of the sample, and the resources available [8]. A comprehensive approach may involve a combination of microscopic, molecular, and immunodiagnostic approaches to ensure accurate detection and treatment of intestinal protozoal infections.

Currently, intestinal protozoa, including *E. histolytica*, infect nearly 50 million individuals annually, leading to 100,000 deaths. Moreover, *Entamoeba* infection affects 50% of the global population, notably in Central and South America, Africa, and Asia, with rates up to 25% in certain limited-income and heavily indebted poor countries [9]. Giardiasis, caused by *G. lamblia*, is prevalent in the United States, the United Kingdom, Africa, Asia, and Latin America, and affects approximately 200 million people annually. In temperate countries such as Spain, the United Kingdom, and France, the prevalence in children is approximately 1.1%-2.1% [10,11]. *Cryptosporidium spp.* infection is widespread in the United States and tropical countries, with rates as high as 13% in India and 7.3% in Thailand [12,13]. These infections impose a significant burden, especially in heavily indebted poor tropical nations and parts of Central/South America, Africa, and Asia. Addressing sanitation and hygiene is crucial in prevention efforts.

In Malaysia, helminths and protozoa are the most common types of parasites causing diarrheal diseases. Diarrheal diseases are the leading cause of death in children younger than 5 years, with a mortality rate of 0.8% in 2019 [14]. The occurrence and wide distribution of intestinal protozoal infections in Malaysia represent significant events in the epidemiology of infectious diseases. Unfortunately, only limited data are currently available on the epidemiology and the risk factors associated with these diseases. Moreover, overall data on the diagnostic approach used to detect intestinal protozoal infections in Malaysia are lacking [15]. To address this knowledge gap, we will conduct a comprehensive systematic review with meta-analysis, aiming to synthesize the available data and overcome the limitations of individual studies. This study will be conducted to gain a better understanding of the prevalence and distribution of different intestinal protozoal infections, risk factors associated with intestinal protozoal infections among patients, and update on the diagnostic methods primarily used to detect intestinal protozoal infections, with a specific focus on the Malaysian population. Although this study focusses on Malaysia, the outcomes are also relevant for other tropical regions with similar socioeconomic, environmental, and health challenges. These findings can guide strategies to manage intestinal protozoal infections in regions such as Southeast Asia and beyond.

Methods

Patient and Public Involvement Statement

This protocol was not developed with the involvement of patients.

Study Design

The systematic review and meta-analysis will be reported in accordance with PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement, which was considered in the development of this protocol (Multimedia Appendix 1) [16]. This protocol is registered with PROSPERO (International Prospective Registry of Systematic Reviews; registration CRD42023456199). The methodology chosen for this study is designed to be replicable in different settings. Although the focus is on Malaysia, the search strategy and data extraction can also be applied to other regions to gain comparable insights.

Study Area

We will include studies published on intestinal protozoal infections among patients in Malaysia, except for case reports, reviews, and studies without original data, and the studies will be divided according to region. Malaysia is an ideal case study for the study of protozoal infections due to the unique intersection of tropical climate, diverse population, and varied socioeconomic conditions. These factors combined with the limited epidemiological data underscore the urgent need for comprehensive research in this context.

Types of Participants

We will include primary studies that investigate patients without age restrictions that provide estimates of any symptoms of intestinal protozoal infection (eg, amoebiasis, giardiasis, cryptosporidiosis). We will include studies that explicitly describe the detection methods and definitions of intestinal protozoal parasites. Studies on intestinal protozoal infections in which at least one of the 3 protozoa were detected will be included. We will exclude case reports, reviews, and studies without original data. If we find multiple studies with the same data, then we will use the study with the largest sample size. The results will be presented in tables and figures.

Types of Outcome Measures

This meta-analysis will have 2 main outcomes. The primary outcome will be the prevalence of intestinal protozoal parasites in Malaysia. The second aim is to investigate the risk factors associated with the diseases and the update on the primarily used detection methods for intestinal protozoa, that is, *C. parvum*, *E. histolytica*, and *G. lamblia*.

Information Sources

The following electronic databases of scientific literature that have been peer-reviewed, as recommended by Siddaway et al [17], will be carefully searched without language restrictions and limited to human research only: PubMed/MEDLINE, Scopus, ProQuest, Web of Science, Science Direct, Google Scholar, and Cochrane Library databases. A manual search of reference lists of identified papers will be added to the electronic searches. The authors of the research will be contacted for explanation or to provide any additional crucial missing metadata when necessary. Google Scholar will be used meticulously to search for relevant literature, including grey literature and unpublished data, to compile a thorough understanding of the prevalence rates, socioeconomic impact, and various diagnostic techniques employed for these infections within the Malaysian population. Studies completed after January 1, 2010, with no language constraints will be considered.

Search Strategy

The proposed search term for the first theme will be developed in MEDLINE by using medical subject headings (MeSH) combined with free-text terms around the 3 search components for intestinal protozoal infection, that is, giardiasis, cryptosporidiosis, and amoebiasis. The second theme will be prevalence, including epidemiology, incidence, epidemiological studies, and observational studies. The third theme will be risk factors and detection methods of intestinal protozoal infection and other similar names used (see detailed list in Multimedia Appendix 2) and then adapted for use in the other databases. The search, the evaluation of the titles and abstracts, and the review of the complete texts will be performed independently by an author. After removing duplicates and irrelevant entries, the reference lists of the studies received were checked for further studies that were not found in the database search.

Eligibility Criteria

The selection or exclusion of studies is based on the criteria proposed in Table 1. Studies published after January 2010 up to November 2024 will be eligible for inclusion. The literature search is limited to papers published after 2010, highlighting the significant change in the diagnostic process when molecular techniques began to replace traditional microscopic methods for detecting intestinal protozoal infections. This time frame allows for studies that include both the transition period and the continuous use of microscopy, including the more recent implementation of molecular techniques. This methodology allows for a full assessment of the evolution of diagnostic methods across time. We will not apply any language restrictions as part of the eligibility criteria. The PICO (Population, Intervention, Comparison, Outcome) classification technique is a popular method for creating search methods and describing meta-analyses.

The study population includes individuals with intestinal protozoal infections identified through positive laboratory test results, physician diagnoses, self-reported infection status, treatment registries, or other medical records. Both asymptomatic and symptomatic cases will be included, with no restrictions on age, gender, ethnicity, or geographical location within Malaysia. Eligible populations encompass mixed communities, outpatients, inpatients, and residential settings, spanning diverse socioeconomic backgrounds. This inclusion criterion ensures a representative sample of intestinal protozoal infections across Malaysia.

Table 1. Criteria for inclusion and exclusion.

Category	Included	Excluded
Population	Both asymptomatic and symptomatic cases from diverse socioeconomic backgrounds, including all ages, genders, ethnicities, and geographical locations in Malaysia (including non-Malaysians) will be considered, with identification based on laboratory tests, physician diagnoses, or medical records	Both asymptomatic and symptomatic cases conducted outside Malaysia or non-Malaysian settings will be excluded, including cases from mixed communities, outpatient, inpatient, and residential settings, regardless of age, gender, ethnicity, or non-Malaysians
Intervention/exposure	Studies conducted on the 3 common intestinal protozoal parasites (*Entamoeba histolytica*, *Giardia lamblia*, and *Cryptosporidium parvum*) and using any of these methods: microscopic examination, immunoassay technique, and molecular methods	Studies excluding these 3 intestinal protozoa (*E. histolytica*, *G. lamblia*, and *C. parvum*) and other intestinal protozoa parasites unrelated to this study or using other detection methods as mentioned
Study design	Quantitative studies, cross-sectional studies, cohort, and case controls will be included	Case reports, reviews, and studies without original data will be excluded
Outcome	Diarrhea and presence of intestinal protozoa	Nonenteric infection and studies without detection method mentioned

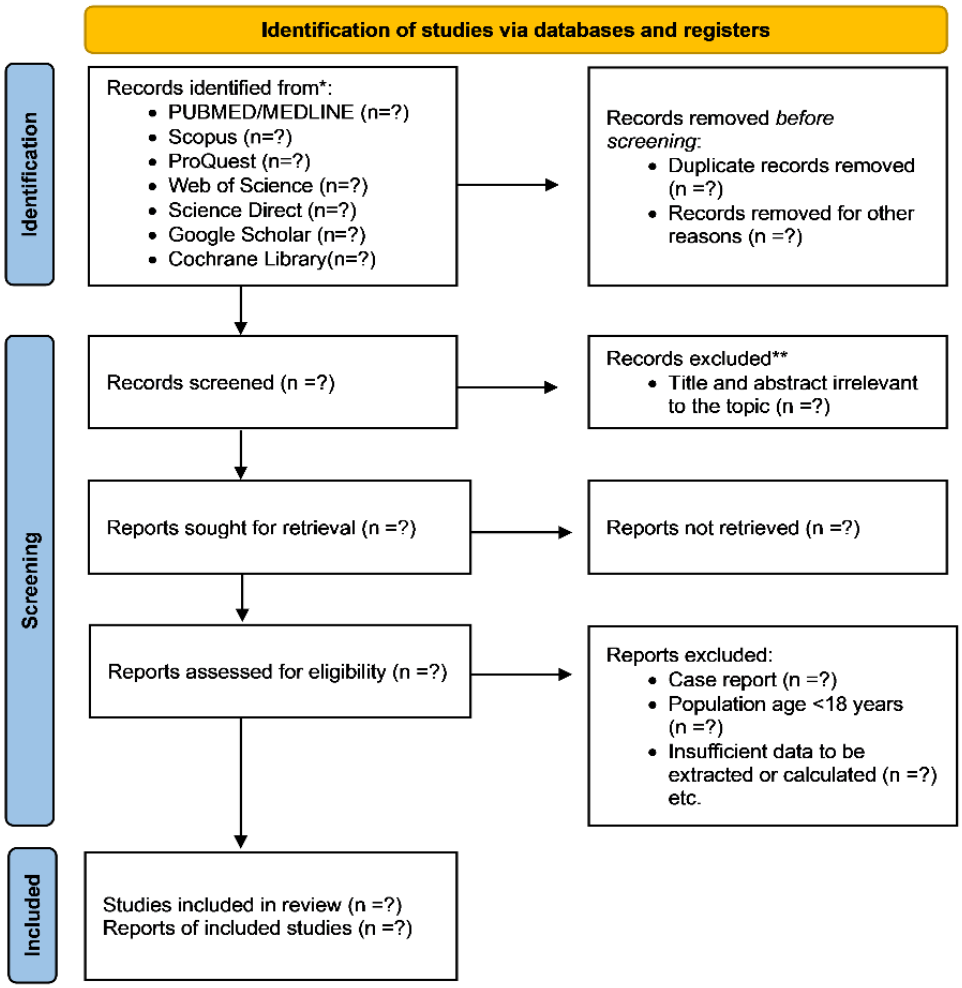
The primary outcome measure is self-reported diarrhea, which is commonly defined as the occurrence of 3 or more watery stools or bloody diarrhea within a 24-hour period. This information is reported by the patient's family or caretaker and covers a 2-week period preceding the assessment. Additionally, laboratory confirmation of diarrheal illness involves the identification of specific pathogens in the patient's stool. This confirmation can be achieved through microscopic examination or culture techniques. Furthermore, the presence of intestinal parasites is confirmed through laboratory procedures, including microscopy, serological tests, or molecular methods.

This study will focus on the prevalence of intestinal protozoal infections in Malaysia, exploring the epidemiology, diagnostic methods, and contributing factors to these infections. This research aims to investigate the extent to which individuals in Malaysia are affected by these parasitic infections and the various factors contributing to their occurrence, shedding light on their epidemiology and diagnostic methods. We will consider both randomized and nonrandomized controlled trials, along with observational studies that have examined the connection between the exposure and outcome of interest. We will collect data on the measures of association. However, we will put a lower priority on unadjusted measures (please refer to the "Risk of bias assessment for eligible studies" section for details).

Screening and Selection Procedure

In the research methodology, citations retrieved from diverse search engines will be imported into EndNote and subjected to a deduplication process to eliminate redundant entries. The exclusion criteria are usually unrelated, duplicate, unavailable full texts, or pure abstracts. These exclusions should be stated in advance to prevent any biases. The inclusion criteria would be studies with the target patients, interventions studied, or the comparison between the 2 interventions studied. These are publications that contain information relevant to our study subject. The most critical aspect is that the information provided is clear and adequate to answer the problem, whether positive or negative. Then, the required data will be meticulously extracted by the primary researcher (NSM). To ensure accuracy and reliability, the extracted information from all papers will undergo a thorough cross-checking process conducted independently by 2 other researchers (HA-T and SMW). The goal of this review is to confirm the consistency of the data, identify and mitigate potential biases, and correct minimal errors. The validated studies will be organized and stored in a structured spreadsheet program specifically designed for systematic data extraction. Following this, the collected data will undergo a series of rigorous assessments to evaluate the adequacy of the studies, ensuring a solid and reliable basis for subsequent analysis and interpretation. We will record the selection process in sufficient detail to complete a PRISMA flow diagram shown in Figure 1 [18,19].

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram for systematic review and meta-analysis. *Reporting the number of records identified from each database or register searched (rather than the total number across all databases/registers). **Indicate how many records were excluded by a human and how many were excluded by automation tools.



Data Extraction

We will use a standardized data extraction created in the online Microsoft Excel spreadsheet for study characteristics and outcome data. The data capture sheet will consist of a screening checklist consisting of study details (author, year of publication, period of study, place the study was performed), study characteristics (sample size, mean age, and age range of participants), risk factor analysis (socioeconomic status, population characteristics, geographical area), and outcome (presence of intestinal protozoa status; odds ratios, prevalence ratios, relative risks or hazard ratios [95% CI] with their related variability [SD or SE]). Please see "Eligibility criteria" section and Table 1 for the list and definitions of the aforementioned exposures and outcomes. Any significant limitations of the study will be identified, and any further relevant information will be requested from the corresponding author if necessary.

Data Synthesis

The data will be analyzed using STATA software (version 17.0; William Gould) and REVMAN software (The Cochrane Collaboration). To accurately report the content of each paper under consideration and to explore the relationships between outcomes and risk factors, the data will be summarized in a tabular form and the main findings of each paper will be presented, including descriptive analysis of gender, age, region, and others. We will also calculate the overall prevalence of intestinal protozoal infections among patients by using a random effects model to allow heterogeneity across the included studies and later divide the studies into regions. This study will include a qualitative or narrative analysis to summarize the key features and overall quality of the publications. In addition, a comprehensive assessment of potential bias will be performed for each paper (see the "Assessment of Risk of Bias for Eligible Studies" section). All meta-analyses will be conducted using the random effects model because of the expected epidemiologic and clinical heterogeneity. Because the underlying effects of the different studies are assumed to be normal, we will use random effects modelling to account for variation within and between studies.

Risk of Bias Assessment for Eligible Studies

Risk of bias (quality assessment) will be performed using the Joanna Briggs Institute critical appraisal tools [20]. The primary author and 2 independent reviewers will evaluate each study individually at both the outcome and study levels to provide an

overall assessment of the risk of bias. Each reviewer will examine each study as yes, no, unclear, or not applicable for bias (Multimedia Appendix 3). The quality of the included studies will be assessed using the Newcastle-Ottawa Scale, which is specifically designed to evaluate observational and cohort studies [21]. This tool will ensure a consistent and balanced evaluation of the methodological quality of all studies included in the review, accommodating the variability between experimental and observational study designs (Multimedia Appendix 4).

Assessment of Heterogeneity

We will visually inspect the forest plots for any evidence of heterogeneity. The pooled estimates will be visually assessed using forest plots to determine the degree of heterogeneity between studies. We will also measure statistical heterogeneity by using the I^2 statistic to estimate the difference between studies [22]. The I^2 statistic quantifies the proportion of variability observed in the prevalence estimates that can be explained as genuine variations in treatment effects rather than random sampling error. The I^2 statistic is bounded in the scientific literature by a range of 0% to 100%. Values between 0% and 25% indicate low heterogeneity, while values between 75% and 100% indicate substantial heterogeneity [23]. We will investigate potential sources of heterogeneity by using subgroup analyses and meta-regression. The possible causes will be explored and evaluated in terms of their methodological characteristics to determine whether the degree of heterogeneity can be explained by differences in these characteristics and whether meta-analysis is appropriate. The overall prevalence and 95% CIs estimate of the outcome (presence of intestinal protozoa status; odds ratios, prevalence ratios, relative risks or hazard ratios), with their related variability (SD or SE) will be presented in forest plots. If the selected studies are acceptable for quantitative synthesis, the data will be pooled in a meta-analysis to combine the primary exposures across studies and to provide a summary of effects according to study design/measurement of effects. Where possible, we will also conduct subgroup analyses by age group, detection methods (microscopy, immunoassays, and molecular techniques), study design (ie, cross-sectional or prevalence studies), and geographical region (Peninsular Malaysia and East Malaysia) to assess differences between the strength of association by geographical location and the potential impact of contextual confounders, which may vary by region.

Meta-Biases

To assess the possibility of publication bias, we plan to use funnel plots [24], a widely used graphical tool in meta-analyses, to visually check the symmetry of the data distribution. In addition, we will apply statistical tests such as Egger and Begg funnel plot test [25], which are specifically designed to detect asymmetries in funnel plots and provide quantitative measures of publication bias. In addition, we intend to perform a comparative analysis between the outcomes derived from the fixed effects model and the random effects model. This comparative evaluation will allow us to assess the possible presence of small sample bias in the published literature. Specifically, we aim to determine whether the effects of the studied exposure appear to be more pronounced in studies with smaller sample sizes, indicating a possible bias in favor of smaller studies in the existing literature. By applying these comprehensive analyses, we aim to ensure the robustness and reliability of our results and to rule out potential biases that could affect the interpretation of the results.

Ethical Considerations

No primary data will be collected; thus, no formal ethical approval is required. The results will be disseminated though a peer-reviewed publication and conference presentation.

Results

This systematic review was funded in June 2024. Database searches were started in July 2024 using specific databases such as PubMed, Scopus, ProQuest, Web of Science, Science Direct, Google Scholar, and Cochrane Library databases. As of December 2024, 1652 studies have been identified for title and abstract screening. The screening phase is expected to be completed by May 2025. Data extraction and synthesis will be performed. Data analysis is expected to be completed by December 2025. The results will be published in peer-reviewed journals and presented at conferences in early 2026.

Discussion

Currently, there are few epidemiological data on the prevalence of intestinal protozoal infections in the Malaysian population. A comprehensive study of the prevalence and distribution of intestinal protozoal infections is critical to understanding their public health impact and implementing effective control measures. Given the lack of available data, it is important that Malaysia conduct detailed epidemiological studies that will allow a more thorough assessment of the prevalence, risk factors, and distribution of these intestinal protozoa. Such studies would not only make an important contribution to the scientific knowledge base but also facilitate the development of targeted interventions and public health strategies to reduce the burden of these infections in the region. The results of this study will show that local data are consistent with global data, indicating that socioeconomic factors and diagnostic limitations are key barriers to the treatment of intestinal protozoal infections. For example, the diagnostic challenges in Malaysia mirror those observed in other tropical regions such as sub-Saharan Africa and South Asia. By addressing these gaps, this study provides a framework that can be transferred to other regions with similar public health problems.

The theory under study is that several factors, particularly in vulnerable populations such as low-income societies with poor sanitation and immunocompromised patients, may increase the risk of infection with intestinal protozoa and that differences in the validity of different diagnostic techniques may lead to different rates of detection of intestinal protozoa, that is, false positive or false negative results. The above hypothesis proposes that the combination of various contextual risk factors may jointly contribute to an increase in the overall prevalence of intestinal protozoal infections in the studied population.

In our study, we will conduct a thorough and systematic review, including a meta-analysis, to integrate the available data and address the limitations of individual studies. Our main objective is to better understand the prevalence and geographic distribution of intestinal protozoal disease. In addition, we will investigate the factor analysis that contributes to this infection and its relationship with its detection method. Our work, by synthesizing this extensive information, will provide a more nuanced and comprehensive view of intestinal protozoal infections and add significantly to the current body of knowledge in the field of infectious diseases and public health. No changes to the current protocol are envisioned. If critical changes prove necessary, they will be documented in the published review. Our findings will be published in a peer-reviewed scientific journal. In addition, they will be disseminated to relevant health care organizations.

A limitation of this study is that data on symptoms of intestinal protozoal infections are currently extracted from medical records, which may lead to underreporting due to gaps in documentation. Although documented medical records are often used as the main source of data, this approach has limitations. This method is consistent with real-life situations where diagnostic assessment often depends on accessible clinical data. Implementing a model that requires additional prospective assessments of patients beyond conventional clinical care procedures may be impractical, particularly in a health care setting where such assessments are often not mandatory. It is crucial to understand that the proposed model is preliminary and should not be used in clinical practice without additional validation. Another striking feature of our research design is the possibility of selection bias due to differences in duration of symptoms or time since exposure to protozoal infections at the time of study entry. By excluding individuals with recent protozoal infections who may have different clinical characteristics or outcomes, we aim to create a model that applies only to those who may have overcome the acute phase of infection.

In addition, future research should investigate the serial examination of clinical symptoms and use dynamic modelling techniques to enable the application of the model across different stages of infection. A comparison of the performance of the model we developed with established diagnostic algorithms or clinical guidelines in similar patient populations would also be crucial for validation. However, it should be noted that certain diagnostic indicators required for established algorithms may not be routinely assessed during standard clinical care, necessitating additional assessments beyond the scope of our study.

Even after further validation, predictive models for intestinal protozoal infections are primarily ambiguous, and the goal is to provide guidance to health care providers regarding potential infection outcomes and not to replace clinical assessment. Once the models are externally validated, a clinical decision aid should be available to better identify individuals at high risk for protozoal infections, thereby improving patient care and regulating appropriate diagnostic techniques. The future development of such a decision aid would require collaboration with health care professionals and researchers to ensure its effectiveness and appropriateness in clinical practice.

Acknowledgments

We thank the Institute of Medical Molecular Biotechnology, Faculty of Medicine and Universiti Teknologi MARA, for their tremendous assistance. This research received funds from Ministry of Higher Education (600-RMC/PRGS 5/3 (004/2024).

Abstract

Background: There has been a surge in mental health apps over the past few years. While these have great potential to address the unmet mental health needs of the population, the recent proliferation of mental health apps in the commercial marketplace has raised several concerns, such as privacy, evidence-based, and quality. Although there is mounting research on the effectiveness of mental health apps, the majority of these are not accessible to the public and most of those available have not been researched. Despite the rapid growth of the digital health market in India, there are no comprehensive reviews of publicly available mental health apps for Indian users. Hence it becomes important to review mental health apps freely available to potential end users in terms of their scope, functions, and quality.

Objective: This study aims to systematically evaluate mental health apps available to Indian users in app stores.

Methods: This systematic review of mental health apps will be performed following the Target user, Evaluation focus, Connectedness and Health domain approach and the PASSR (Protocol for App Store Systematic Reviews) checklist. Fifteen key search terms covering various mental health conditions and therapies will be used on the Android and iOS stores. The identified apps will be further screened and reviewed based on the inclusion and exclusion criteria. The pool of eligible apps will be downloaded for detailed review. The following steps will be adopted to streamline the review process and interrater consistency. Six apps will be randomly selected from the downloaded apps, for joint discussion and review by a team of 4 primary reviewers and 2 mentors. Following this, a new set of 6 randomly selected apps will be rated independently by the primary reviewers and the differences in ratings will be jointly discussed for generating consensus. Subsequently, the primary reviewers will individually review the remaining apps in the list. Data will be extracted based on predecided parameters such as privacy policy, basic purpose, type of developer, nature of intervention strategies, and guided versus unguided nature. Additionally, the apps will be reviewed for quality using the Mobile Application Rating Scale. The data analysis and synthesis strategy will incorporate descriptive statistics based on quality evaluation using the Mobile Application Rating Scale and examining the content of the apps for generating descriptive information.

Results: The initial screening of mental health apps available for Indian users on the Google Play Store and Apple App Store was initiated in October 2024. We expect to complete the detailed systematic review by April 2025.

Conclusions: This study will offer a comprehensive review of mental health apps available in digital marketplaces for Indian users and has implications for end users, policy makers, developers, and mental health professionals.

KEYWORDS

mental health apps; mHealth; review of apps; smartphone apps; MHApps for Indian users; India; mobile phones

Introduction

Background

According to the National Mental Health Survey (2017-2018), approximately 10% of Indian adults experience a diagnosable mental health condition, and the treatment gap for most such conditions exceeds 60% [1]. For example, the treatment gap for depression in India is 85.2%. Factors contributing to this gap include the stigma surrounding mental health issues and their treatment, the uneven distribution of mental health services, affordability challenges, and the scarcity of trained mental health professionals [2]. Some of these same factors have also become the drivers of the growth of digital mental health solutions in India.

There has been an increasing popularization of telehealth and digital mental health services in India [3,4]. This has been fueled by several factors such as the rapid proliferation of smartphone users, increasing internet penetration, the emergent needs and familiarity with digital services during the COVID pandemic, government initiatives promoting digital literacy, digital health, and specifically telemental health, rising number of startups in the mental health space apart from improved awareness about mental health and felt needs for convenient and accessible solutions [4-8].

India's smartphone penetration rate was 71% in 2023 [9]. Mental health apps have seen a 30% increase in downloads, with over 200,000 new users in the year 2023 alone. India's digital mental health market is projected to grow at a compound annual growth rate of 28.16% and is expected to reach a projected revenue of US $62.86 million by 2032 [10].

The last few years have seen a mushrooming of mental health apps, several of which have been developed with peripheral involvement or lack of involvement of mental health professionals, and this can raise significant concerns about the validity and appropriateness of suggestions, messages, and recommendations contained in the apps [11]. Inadequately customized recommendations can delay seeking professional help and extend the period of reliance on self-help alone even when the nature and severity of the problem warrants professional help.

Globally, the last decade has also seen a plethora of scoping reviews, systematic reviews, and meta-analyses of effectiveness and efficacy studies, including a few from India on mental health apps. 1009 psychosocial wellness and stress management apps with varied content were reviewed by Lau et al [12]. Almost all were designed as purely self-help apps, with less than 2% meant to serve as a supplement to in-person therapy or involving therapy via a web-based platform. It was noted that only 4.66% of apps targeted individuals with psychiatric disorders. This review also highlighted that only 2% of the apps in app stores were supported by original research publications. Another review aimed to document the proportion of mental health apps offering comprehensive therapeutic treatments for anxiety and depression available in the app stores and developed using evidence-based frameworks. The authors found that out of the 293 apps shortlisted as offering a therapeutic treatment for anxiety and/or depression, 55.3% mentioned an evidence-based framework in their app store descriptions. However, only 6.2% had published evidence of their efficacy [13].

Alqahtani and Orji [14] examined more than 13,000 user reviews of 106 publicly available mental health apps in app stores. Their review highlighted the value placed by end users on the user interface, user-friendliness, and adaptive functionalities. Lack of variety of content, low scope for personalization, lack of customer service, trust, and privacy issues were cited as some of the pitfalls [14]. In another review, 104 mental health apps on Google Play and App Store were examined through sentiment analysis of 88,125 user reviews, using machine learning and thematic analysis. The emergent negative themes spanned usability, content, ethics, customer support, and billing issues. The positive themes included appealing interface, app stability, customizability, high-quality and diversity of content, personalization, privacy and security, and low subscription cost [15].

Some of the recent research papers on mental health apps continue to use App Store star ratings as a proxy for quality and satisfaction, although there are growing concerns with this metric. Despite the potential clinical applications and benefits, the app marketplace, with an estimated 3,00,000 health apps and 10,000 focused on mental health, poses enormous challenges to users who wish to explore and find apps that may suit their needs [16]. Insufficient regulation of health apps in the commercial marketplace can result in several apps making unsubstantiated claims, offering inaccurate and potentially dangerous information, or posing threats to user privacy. Recent research has shown that the measures that are currently used in the app marketplace for the purpose of evaluating apps (eg, app downloads or star ratings) do not provide adequate representation of apps in terms of important metrics such as security, engagement, or effectiveness [17,18].

Studies on mental health apps and reviews from India have been scarce. An overview of smartphone apps aimed at suicide prevention available for Indian users on Google Play Store found that only 11.62% of 43 apps reviewed provided information about a formal evaluation process or study [19]. It was also noted that only about 16% of the apps intended for direct use by people at suicidal risk had an initial screening aspect. Only 4 of these 43 apps were developed in India. In a review of free apps for depression available for Android phone users in India, 278 apps were identified in the first step and information on coping with depression and stand-alone screening

tools formed the 2 largest types of free apps. Features of interactive self-care apps (N=33) were reviewed further, and this exercise showed that less than 10% of the apps incorporated explicit delineation of their scope or initial screening for suitability. Slightly more than one-third of these apps included content aimed at encouraging professional help-seeking when needed or an explicit mention of their theoretical or empirical basis. Challenges for potential users were highlighted [20].

A recent survey of smartphone users in India highlighted that most of them (69%) were not aware of any mental health apps [21]. In another study involving persons with severe mental illness seeking treatment in a tertiary care setting in India and their caregivers, it was noted that health app use was low, with costs, lack of familiarity, and language being significant barriers to use [22]. An Indian study examined mental health apps in the Google Play Store between 2016 and 2020 by extracting data using various software programs. The keywords used for the search included: “mental health,” “mental illness,” “mental disorders,” “cure of mental disorder,” and “healing of mental illnesses.” As per the content analysis of the apps, the apps targeted various mental health concerns ranging from depression, anxiety, stress, posttraumatic stress, sleep, obsessive compulsive disorder, substance use, and panic symptoms to schizophrenia. This review examined basic content, number of downloads, mention of interactivity, and pricing and ratings of apps. It was observed that most app users did not leave their opinions or share their experiences, and thus, 70% of app ratings were based on a small number of users (100 or fewer users). The intervention approaches mentioned in this review ranged from relaxation, stress management, symptom tracking, calming audio, keeping a diary, interpersonal support meditation, and mood tracking. Connecting to mental health professionals as a strategy was mentioned in less than 2% of the instances. This study did not focus on examining the quality and appropriateness of content, usability, or empirical evidence-based [23].

The need for mental health app libraries independent of commercial biases has been advocated [24-26]. Lagan et al [17] systematically evaluated 278 mental health apps using the Mhealth Index and Navigation Database framework, which comprises 105 questions across 6 categories, namely, app origin or accessibility, privacy or security, inputs or outputs, clinical foundation or evidence base, features or engagements, and interoperability. The most common features offered by the 278 apps were mood tracking and journaling, with much fewer ones offering comprehensive therapeutic interventions that may be useful for addressing the diversity of user needs. Less than 25% of apps were supported by a feasibility or efficacy study [17].

From end users’ perspectives, when selecting apps, they rely mainly on ratings and reviews in app stores or on advice given through social media or word of mouth [27]. However, the lack of involvement of mental health experts in app development and insufficient attention to evidence-based development are factors that can limit the effectiveness of the apps or even pose a risk for harm due to unscientific suggestions or lack of information on limitations of app-based interventions and need for direct professional consultations.

It has been observed that many apps in commercial app stores, including low-quality ones, make it difficult for users to identify a suitable app for various mental health conditions, and evidence-based is often lacking, even for top-rated apps in app stores [28,29].

Rationale for the Review

Studies have highlighted that most well-researched apps are not easily accessible to the public, while a bulk of apps available in app stores are not backed by research evidence or do not involve qualified mental health professionals in their conceptualization, development, or validation [30]. In contrast to the reviews on research studies on the efficacy or effectiveness of mental health apps, there have been fewer studies that have directly reviewed mental health apps themselves, which are available for end users in app stores.

Apart from the lacuna mentioned earlier, data security and privacy concerns are some of the factors that restrict the potential of this field, as mental health apps use sensitive information pertaining to personal concerns, thoughts and moods, and sleep patterns. High attrition rates and inconsistent or infrequent usage of apps are challenges noted across the globe that reduce the potential effectiveness of the apps for users, and this is particularly true of mental health apps that are completely unguided as these do not involve any human interface or assistance for use. The other challenges surrounding mental health apps in India include the diversity of languages spoken across the country and the sociocultural factors that can make it difficult to develop apps that cater to the population's diverse needs.

There is a dearth of systematic reviews of mental health apps available in app stores for Indian users. Reviews that rely on the number of downloads, user ratings, or merely app store descriptions are unlikely to be helpful in guiding the consumers of mental health apps in making informed decisions. This study is designed to address these gaps by conducting a systematic review of mental health apps accessible to Indian users, using a standardized framework for assessment. This systematic review is expected to help in the creation of a user-friendly platform to guide consumers of mental health apps in India. This is especially important as the commercial marketplace offers a confusing array of options with a plethora of apps, a diverse range of content, a lack of clarity on scope or indications for the use of specific apps, and a lack of noncommercial platforms providing detailed information that can assist users in choosing apps that serve their needs.

Hence, we aim to conduct a comprehensive and systematic review of smartphone-based mental health apps available in app stores that are accessible to Indian end users in order to (1) describe these apps in terms of characteristics such as purpose, nature of the intervention, mental health conditions focused upon, involvement of mental health professionals in development, mention of empirical basis, nudges to seek professional help as well as (2) evaluate and document the quality of these apps.

Methods

Ethical Considerations

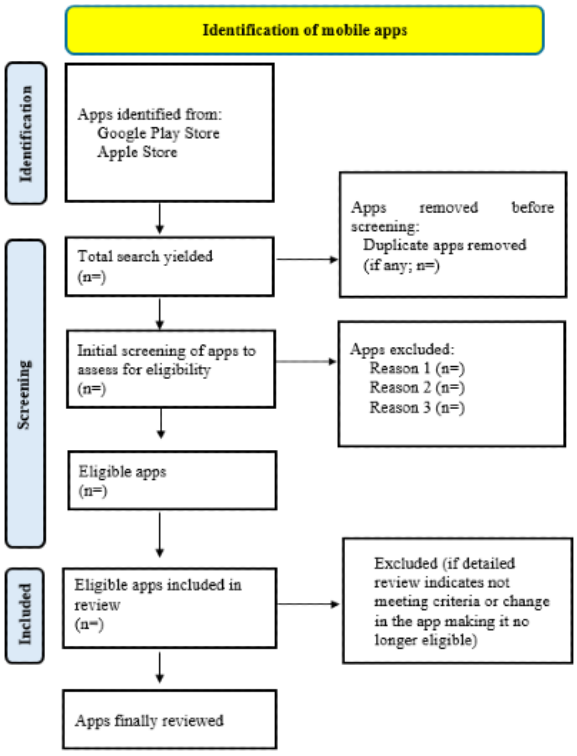
The systematic review has been registered on the International Platform of Registered Systematic Review and Meta-analysis Protocols (INPLASY2024100035). An exemption from the Institute Ethics Committee (Behavioural Science Division), NIMHANS (No. NIMHANS/EC/[BEH.SC.DIV.] MEETING/2024) was sought and obtained for this review.

App Review Approach

An approach called Target user, Evaluation focus, Connectedness and Health domain (TECH) has been developed to formulate research questions and determine eligibility criteria for systematic reviews of commercially available health apps. This is because formats such as Population, Intervention, Comparison, and Outcome (PICO) and Sample, Phenomenon of Interest, Design, Evaluation, Research (SPIDER) are appropriate primarily for a systematic review of studies examining the effectiveness of interventions and for systematic qualitative review, respectively [31]. Here TECH refers to (1) target user (the specific population in question); (2) evaluation focus (eg, app characteristics, quality, usability, techniques, or components); (3) connectedness (whether the app connects with other apps or services); and (4) health domain (eg, specific health condition or concern being focused). This approach is aimed at helping in the development of the research question and for guiding eligibility criteria for the review of apps. Applying the TECH approach in this study context, the target population broadly consists of Indian adults interested in exploring or using apps to understand or manage mental health concerns. The evaluation focus is kept intentionally broad to include descriptive information on app characteristics, content, and quality. The review intends to include stand-alone apps as well as those that may connect to services but apps that connect to wearables or other apps would fall beyond the purview of this review. The health domain focused upon in the review is broad and includes various mental health concerns and conditions, The eligibility criteria mentioned subsequently drew upon these elements of the TECH approach.

Since this is proposed to be a review of mental health apps and not a systematic review of research studies on mental health apps, the Protocol for App Store Systematic Reviews (PASSR) checklist will be used (see flow diagram in Figure 1) [13]. It is a combination and adaptation of the items from A Measurement Tool to Assess systematic Reviews (AMSTAR) and Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) checklists that can be applied to the systematic search of app stores for any category of apps [32,33].

Figure 1. Flow diagram depicting the exclusion of apps at different stages of the review.



Inclusion and Exclusion Criteria

The inclusion criteria for the review of apps are as follows:

- Apps available in Google Play Store or Apple App Store for Indian adults.
- The store description of the app indicates they are offering guidance on mental health problems or therapy, information, self-help, or support and are thus relevant for the review.
- Apps available in English.
- Free apps and partially free apps (for those involving in-app purchases, what is freely available will be reviewed).

It should be noted that the number of apps that are available in any Indian language that do not have an English version will also be documented but not included in the detailed review.

The exclusion criteria for the review of apps are as follows:

- Mental health apps that are fully paid and do not have a free trial period.
- Apps available solely in a non-English language.
- Apps meant for exclusive use by health professionals (eg, for training or education).
- Apps that require any additional wearable devices or sensors.
- Apps that are solely focused on enhancing wellness without the context of mental health concerns (eg, improving time management, improving productivity, managing relationships).
- Apps available only for research participants of a given study.

The keyword-driven search was carried out during October 2024 and November 2024. Apps that are no longer available to download in January 2025 for a detailed review will be excluded.

The aforementioned search criteria have been set in order to ensure that the research objectives can be adequately addressed while also taking into account feasibility considerations for this comprehensive review. The search will be carried out on Google Play stores and Apple iOS stores as these together comprise about 99% of the Indian market share [34]. Most of the mental health apps for Indian users are in English language. Any app in an Indian language that has an English version will be included for review. India is a multilingual country with 121 languages [35]. Apps available only in a non-English language will be documented but excluded from detailed review as that would require expertise in the given language. There is a very huge and broad range of apps that are on themes related to well-being and these deserve a separate review exercise. The review is restricted to apps that focus on one or more mental health conditions to ensure a focus and enhance the feasibility of the study. Apps that require additional wearable devices are not included in this review as they can have accessibility or affordability issues. These are also likely to be vulnerable to cyberattacks and may require smart intrusion detection systems [36]. Also, apps directed at health professionals would be excluded as the purpose of the review is to evaluate apps for the public.

App Search Strategy

The keywords used in this study are “Mental health,” “Depression,” “OCD,” “Addiction,” “Schizophrenia,” “Anxiety,” “PTSD,” “Bipolar,” “BPAD,” “CBT,” “ACT,” “DBT,” “Cognitive Behaviour Therapy,” “Acceptance and Commitment Therapy, and “Dialectical Behaviour Therapy.”

The selection of these 15 keywords was guided by the purpose of this study which was to cover a broad range of common and prevalent mental health concerns, common psychotherapy interventions as well and their commonly used acronyms. Further, a broad scan of review studies in the last 5 years on mental health apps, as well as an initial scanning of the apps in the app stores helped in finalizing the keywords.

The following search strategy will be adopted:

- Searches will be conducted in each store (marketplace) with each of the aforementioned keywords.
- Will use a clean or reset device to search the data store with a new Gmail or iOS ID.
- Details of the search dates will be recorded.
- The entire search process will be screen-recorded for reference while ensuring slow scrolling from the top to the end of the screen. To avoid missing any apps, scrolling will continue past any advertisements until all content is thoroughly recorded.
- Before the second key term search, the Play Store or Apple App Store history from settings will be cleared and reset.
- All the listed apps in the screen recordings will be carefully entered on a Microsoft Excel sheet.
- If an app is available both on the Google Play Store and Apple Stores Android and iOS phones, the version on the Google Play Store will be reviewed, and the app will be counted only once.
- Four mobile devices (2 Apple and 2 Android devices) will be used for the search.

Initial Screening

After lists of apps on the 2 stores are generated, duplicates will be removed, and the remaining apps will be screened for eligibility using the selection criteria. This screening task will be divided among 4 members of the review team. Any doubts regarding inclusion will be resolved through joint discussions.

The apps meeting the inclusion criteria will be downloaded for detailed review. At this stage too, if any apps are found to be nonrelevant or not meeting any of the inclusion criteria will be excluded from further review.

From the final pool of apps, 6 apps will be randomly selected for joint discussion and review by a team consisting of 4 primary reviewers along with 2 clinical psychology faculty serving as mentors (with more than 10 years of overall experience and familiarity with app review processes). Following this, a new set of 6 randomly selected apps from the remaining ones will be rated independently by the primary review team and the differences in review ratings, if any, will be discussed with all the team members, including the mentors, to arrive at a consensus. This process is adopted to streamline the review process and increase interrater consistency in review and ratings through training and the use of a panel of primary reviewers and mentors. In the last step, the primary reviewers will individually review the remaining apps in the list. In addition, 2% of all the apps, (depending on the number of finally selected eligible apps) will be randomly selected and reviewed collectively by the mentor team in order to note the concordance with the ratings by the primary reviewers.

Data Extraction

The detailed review of downloaded apps will involve documenting the following aspects in Table 1.

Table 1. Information of apps planned to be extracted.

Serial number	Information parameter	Coding format
1	• Privacy-related: • Privacy policy accessible to users • Privacy terms clearly explained • Mention of data-sharing policy with third parties • Mention of data retention duration • Mention of provision for deletion of user account	• Yes or no
2	• Payment requirements	• Completely free to use • Fully paid • Involves in-app purchases
3	• Nature of developer	• Company • Not-for-profit organizations • Academic bodies • Government agency • Insufficient information available
4	• Country of origin	• Mentioned name of the country • Insufficient information available
5	• Release	• Date of first release • Insufficient information available
6	• Update	• Date of last update • Insufficient information available
7	• Downloads	• Number of downloads
8	• Rating	• Number of reviews • Average review rating
9	• Log-in requirements	• Yes or no
10	• Language	• English • Non-English • If in any Indian language
11	• Mental health professionals' involvement in development of the app	• Clearly specified • Generally mentioned • Not mentioned
12	• Empirical research on the app mentioned	• Yes or no
13	• Target users: • Specified minimum age (if any) • Any special group (eg, veterans)	• Yes or no
14	• Basic purpose of the app (as ascertained from the content and features)	• Free text (eg, providing information, psychoeducation, screening, self-help, synchronous or asynchronous chat-based support, therapy or counseling support, artificial intelligence–based counseling, peer-support, symptom monitoring, tracking)
15	• Mental health condition	• Single mental health condition focused • Multiple mental health conditions focused • Not mentioned
16	• Type of intervention: • Type of therapy mentioned • Guided or unguided	• Free text (like CBT[a], DBT[b], and mindfulness) • Yes or no

Serial number	Information parameter	Coding format
17	• Components of the intervention	• Single component or multiple components
18	• Empirical basis of the intervention	• Mentioned or not mentioned
19	• Nature of the intervention • Attempts to dispel common myths related to mental health and illness	• Yes or no
20	• Crisis management • Mentioned helpline, emergency service details, or directories • Basic crisis support strategies	• Yes or no
21	• Sociocultural appropriateness of examples used (case study)	• Yes, no, or could not be ascertained
22	• Inclusion of pointers on when to seek professional help	• Yes or no
23	• Inclusion of nudges to seek professional help when needed	• Yes or no
24	• Any special feature	• Yes (a brief description of the feature) or no

[a]CBT: cognitive behavior therapy.

[b]DBT: dialectical behavior therapy.

Some modifications and refinements in the data extraction parameters and process may be considered if required depending on the review of the initial 15 apps by the primary reviewers.

Evaluation of Quality of Apps Using Ratings From the Mobile Application Rating Scale

In addition to documentation on the earlier aspects, primarily related to the content, the apps will also be evaluated using the Mobile Application Rating Scale (MARS). This scale consists of 19 items across 4 domains, that is, engagement, functionality, aesthetics, and information quality [37]. Each item is rated on a 5-point Likert scale: (1) inadequate, (2) poor, (3) acceptable, (4) good, and (5) excellent. The total score and the 4 objective domains have high internal consistency. An additional 4-item subjective quality scale is also available, though it is not counted toward the total. MARS has been one of the most widely used tools across nations for the evaluation of the quality of mobile health (mHealth) apps, including mental health apps [38-40]. A recent study documented the validity of MARS by using pooled MARS data from 15 international reviews assessing the quality and content of mHealth apps in various health conditions [41].

Strategy for Data Analysis and Synthesis

The analysis will involve the use of descriptive statistics such as frequencies, percentages, mean, and SDs. This would be in addition to the qualitative analysis of the apps as mentioned earlier through the use of MARS ratings. In addition to the overall findings, an attempt will be made to synthesize and present subgroup-wise findings based on apps with a different focus in terms of the nature of mental health conditions (eg, severe vs common mental health conditions) and those with single versus multicomponent interventions, provided there is a sufficient number of apps to form such subgroups. This study is focused on reviewing apps themselves rather than reviewing studies about apps and hence the traditional methods for assessing the risk of bias are not applicable. There is a scarcity of guidelines to assess the risk of bias in studies evaluating apps on app stores. An attempt will be made to describe the potential risk of bias at the stage of inclusion of apps for review, their detailed review by independent reviewers, and the handling of missing data while reporting findings. The risk of bias will also be documented by mentioning whether any apps being reviewed have been examined by any member of the research team for effectiveness or efficacy [13].

Results

The search for mental health apps in virtual stores has been completed. The initial screening has been completed. The initial search yielded 5827 apps, comprising 3708 apps on the Android Play Store and 2119 apps on the Apple App Store. We expect to complete the detailed systematic review by April 2025.

Discussion

Significance of the Systematic Review of Mental Health Apps

In the background of a huge treatment gap, mental health apps can contribute in numerous ways to strengthen mental health care systems, empower communities with low-intensity, affordable, and accessible options for self-care for milder problems as well as enhance mental health literacy and reduce barriers to seeking mainstream mental health services; provided that the challenges related to quality, security, congruency to user needs, and user engagement are appropriately addressed [42-44]. As pointed out earlier, the current regulatory frameworks for mental health apps are still evolving and there is a plethora of apps in the commercial marketplace with little information available on their evidence or use of evidence-based content [18,20]. Hence, a review like the present one can be a stepping stone to exploring the nature of apps and subsequently

coming up with suggestions and recommendations to improve the safety and quality of apps [45]. The review is not focused on outcome research on apps; instead, it delves into examining apps in terms of the nature of content, their scope, and quality. As previous research indicates, the popularity of apps and user experience do not necessarily predict sustained engagement and hence the need for systematic evaluation of apps on a comprehensive set of parameters including sociocultural appropriateness, as planned in this review [29,46,47]. It is important to highlight that the potential impact of the review is not to come up with a list of apps that are "flagged as not useful," instead it attempts to draw the attention of the public, developers, and mental health professionals to make informed decisions for choosing, using, designing, and studying mental health apps judiciously to maximize their potential for serving the mental health needs of the population.

Future Plans

Following the systematic review of the mental health apps in app stores, an attempt will be made to categorize them based on various parameters that may be relevant for potential end users as well as professionals who search for relevant apps on stores for specific purposes (eg, target group, main purposes, level of interactivity, functions, and scope and limits of the app). The outcome of this process will be made available to the public and professionals in a web-based portal in an easy-to-use search or filter format.

Strengths and Limitations

This would be one of the first systematic reviews of mental health apps available in app stores for Indian users, using a comprehensive set of keywords related to mental health conditions and therapies. Also, this review would go beyond app store descriptions and indices such as user reviews and number of downloads and would entail examining the actual content, functionalities, and features of the apps through engaging a panel of raters, including mental health professionals. Unlike literature searches, searching apps in app stores have some limitations. The search can be challenging as the order in which the search results are displayed can be variable and the usual filter functions like those when reviewing research are not available. Moreover, the initial screening would be guided by the app store descriptions that may not always provide clear information being sought by the reviewers and hence may result in the exclusion of some relevant apps, although an attempt will be made to err on the side of overinclusiveness, during the initial round of screening.

Conclusions

The review will provide a comprehensive and critical review of the smartphone apps on mental health that are available for Indian end users. The review findings are likely to have implications for end users, policy makers, developers, and researchers in the field of mental health apps.

Acknowledgments

This study was funded by the Indian Council of Medical Research as part of funding support for the Centre for Advanced Research in Digital Interventions for Mental Healthcare, National Institute of Mental Health and Neuro Sciences.

Authors' Contributions

SM conceptualized and designed the protocol, contributed to the development of selection criteria, supervised the drafting, revising of the manuscript, and finalized the same; RT conceptualized and designed the protocol, contributed to the development of selection criteria, supervised the drafting and helped in the editing of the same; P Sengupta and AK contributed to the drafting of the manuscript and also revised the same along with planning for data analysis. AF and P Sharma reviewed the literature and were also involved in the process of data collection and analysis and contributed to writing up portions of the manuscript; P Sudhir and GNR supervised the analysis plan, writing of the manuscript, and its revision; TKS was involved in the review and write up of technological aspects, contributed to revisions of the manuscript while RS provided supervisory support and helped in finalization of the manuscript. All authors reviewed the final manuscript.

Conflicts of Interest

Abstract

Background: Long-chain omega-3 polyunsaturated fatty acids (LCPUFAs) are essential fatty acids that protect cellular structures and provide energy, particularly for fetal growth and development. The maternal supplementations of omega-3 LCPUFA may affect the rate of intelligence in early childhood development.

Objective: This systematic review aims to synthesize available evidence on the impact of omega-3 LCPUFA supplementation during pregnancy toward intelligence in early childhood development by analyzing the outcomes specifying the aspects of intelligence such as neurodevelopment, social-emotional, language, attention, behavior, cognition, vision, hearing, and motor skills.

Methods: We will only include randomized controlled trials on pregnant women supplemented with omega-3 LCPUFA interventions and the outcome measured is the children's intelligence. Based on the World Health Organization's definition of early childhood, we will include children aged 8 years or younger. Children's intelligence can be indicated using several tools measuring their intelligence index, such as neurodevelopment, social-emotional, language, attention, behavior, cognition, vision, hearing, and motor skills. Irrelevant and unavailable studies will be excluded. A systematic search will be conducted in 3 electronic databases, namely PubMed, Scopus, and Cochrane using relevant and synonymous terms. Study screening and selection will be conducted by the authors based on eligibility criteria. Upon encountering conflicting decisions, a discussion will be held to reach a consensus. The screening and selection process will be recorded using a PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart. The included studies will be subjected to bias and quality assessment in accordance with the Critical Appraisal Skills Programme (CASP) and Grading of Recommendations Assessment, Development, and Evaluation (GRADE) assessment tool for randomized controlled trials.

Results: An initial search was conducted on November 1, 2023, which returned 1998 studies for screening. The extracted data will be classified into groups and subgroups according to the indicator of intelligence measured in the study. Next, the extracted data will be summarized using tables of evidence. Whenever possible, a meta-analysis of homogeneous groups of studies will be conducted using statistical software such as RevMan (version 5.4; Cochrane Collaboration). Studies with significant heterogeneity will be discussed narratively. The systematic review is estimated to be published in November 2025.

Conclusions: This systematic review will systematically pool the evidence on the potential use of omega-3 LCPUFA supplementation to improve children's intelligence status. This review is also important in addressing any existing knowledge gaps on this topic. Finally, a deeper understanding of the association between the consumption of omega-3 LCPUFA

supplementation during pregnancy and children's intelligence will aid policy makers, health care practitioners, and mothers with more informed evidence-based decisions.

KEYWORDS

antenatal; long-chain omega-3 polyunsaturated fatty acids supplementation; pregnant women; systematic reviews; pregnant; pregnancy; maternal; maternity; infant; babies; nutrition; fish oil; docosahexaenoic acid; eicosapentaenoic acid; supplements; cognition; attention; motor skills; languages; behaviors; vision; neurodevelopment

Introduction

Long-chain omega-3 polyunsaturated fatty acids (LCPUFA), also known as omega-3 fatty acids are a part of polyunsaturated fatty acids (PUFA). It is characterized by multiple double bonds (C=C), with the first double bond located on the third carbon chain counting from the terminal methyl group (omega carbon). The 3 forms of this type of PUFA include alpha-linolenic acid (ALA), docosahexaenoic acid (DHA), and eicosapentaenoic acid (EPA). As the body lacks the necessary enzymes to synthesize ALA, it must be acquired through food or supplements, making it an essential fatty acid. Although ALA can be converted to DHA and EPA, the efficiency of its conversion is rather low, hence it is recommended to consume foods that are rich in DHA and EPA [1,2]. The primary source of ALA is plant oils such as canola oils, soybeans, and flaxseed while DHA and EPA are mainly found in fatty oil–enriched fish, which includes sardines, mackerel, and salmon [3,4].

In addition to being essential for the structural integrity of cell membranes, omega-3 LCPUFA also operates as a source of energy and bioactive lipid mediators [5,6]. These functions are critically essential for fetal growth and development, particularly for DHA as DHA plays a key role as part of the cell membrane components in the fetal brain and retina [7]. Placental transfer is the primary source of DHA accumulation in utero, which is involved in neurotransmitter metabolism, neural, and visual functions [8]. Thus, the consumption of omega-3 LCPUFA, in general, is essential to promote optimal fetal growth and maturation for several vital organs, notably the brain and eyes [9]. According to Khalid et al [10], the fetal brain and eyes that were developed in a systematic fashion in response to an adequate intake of omega-3 LCPUFA have some influence on optimal cognitive and visual acuity development in early childhood [10]. DHA prevents cognitive aging by reducing brain apoptosis through upregulating the expression of antiapoptotic proteins or downregulating the apoptotic proteins, thus enhancing early memory and learning ability related to intelligence [11].

According to the World Health Organization, the definition of early childhood corresponds to the period from prenatal development to 8 years of age [12]. While the key factors that determine intelligence in these age groups are hotly debated and vastly described, some genetic and modifiable environmental and nutritional factors contributed to the high intelligence quotient in early childhood [13,14]. Consumption of daily omega-3 LCPUFA during pregnancy as part of maternal nutritional benefits, has been linked to increased early childhood intelligence, according to multiple clinical studies [15-17]. However, as opposed to other clinical studies, randomized controlled trials (RCT) have shown that the most promising outcomes as the confounding factors will be removed in the early phase of the trial to obtain a solid causality that influences the development of early childhood intelligence.

Throughout the years, RCTs related to the consumption of omega-3 LCPUFA have reported varying degrees of results, and several systematic reviews have made an effort to assess the corpus of literature as a whole. The recent Cochrane-based systematic review of omega-3 LCPUFA conducted by Middleton et al [18] has concluded the necessity of conducting a series of follow-ups for completed RCTs for both mothers and children to understand the growth, metabolic, and neurodevelopmental pathways as the RCT outcomes varied by different types of omega-3 LCPUFA, along with the timing, doses, and characteristics of women [18]. This is also supported by a previous systematic review conducted by Gould et al [19]. However, the evidence from these reviews does not conclusively show that the consumption of omega-3 LCPUFA during pregnancy influences the improvement of cognitive and visual development in childhood. This systematic review aims to synthesize available evidence on the impact of omega-3 LCPUFA supplementation during pregnancy toward intelligence in early childhood development as compared to placebo by using a similar approach with added keywords based on the previous systematic review by Gould et al [19] and Middleton et al [18]. The outcome of children's intelligence can be assessed using various tools that measure factors like cognition, attention, motor skills, language, behavior, vision, hearing, social-emotional, and neurodevelopment.

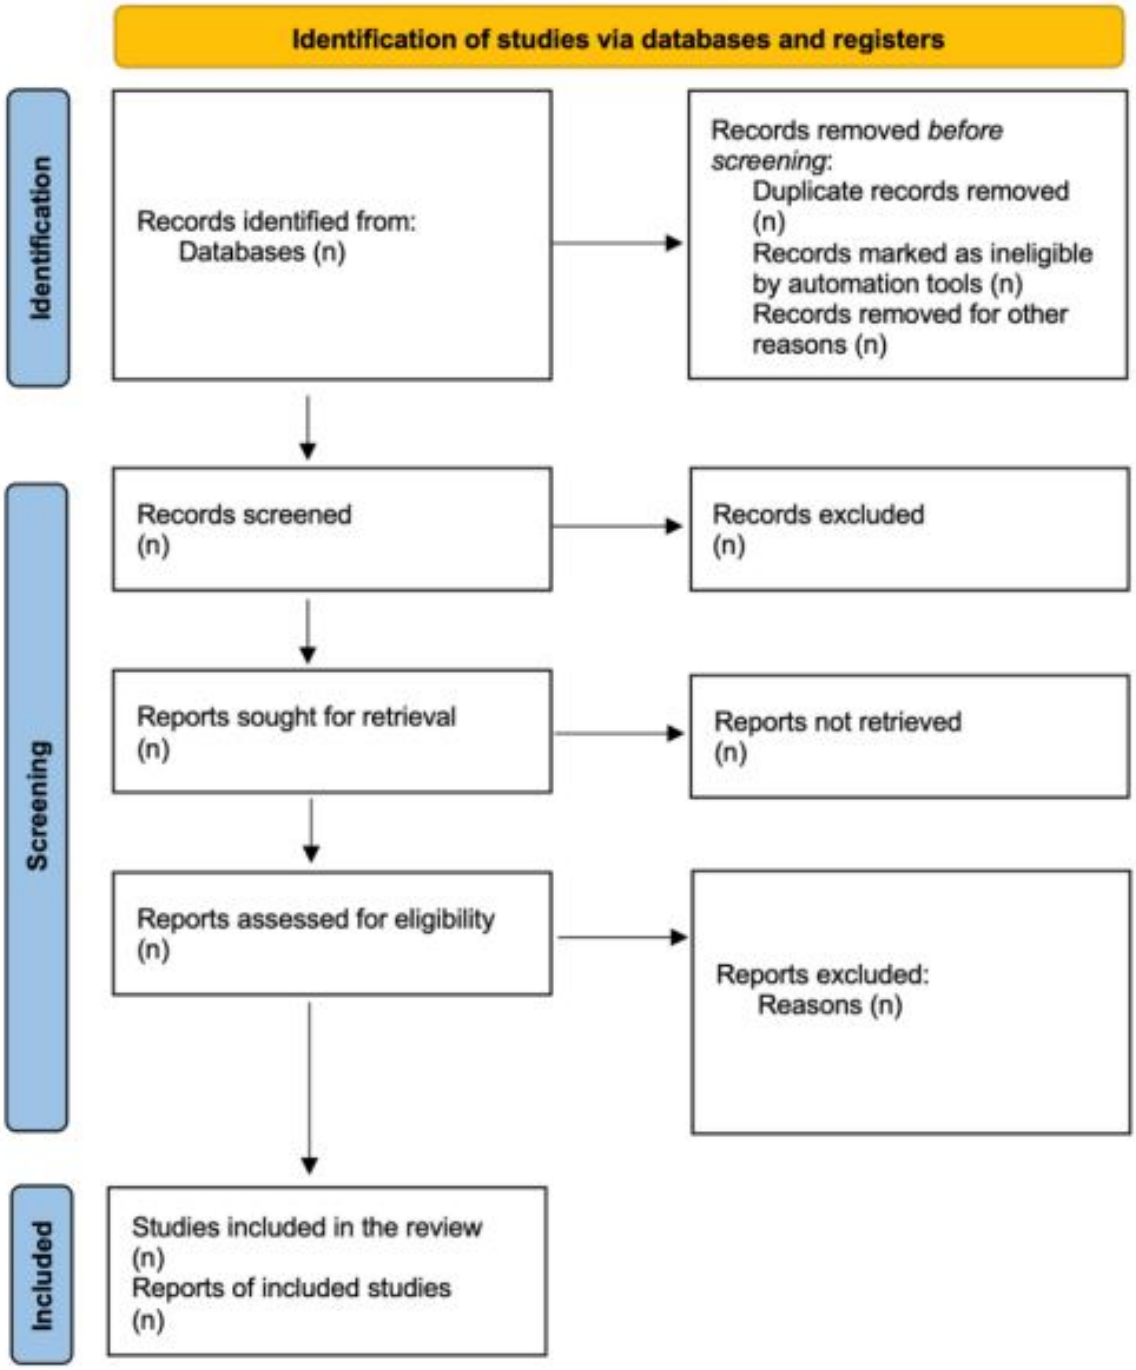
Methods

Overview

We will conduct a systematic review in accordance with the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) [20]. We will ensure adherence to the PRISMA 2020 guidelines throughout the review process by following their checklist (Multimedia Appendix 1) and flow diagram (Figure 1). All processes will be recorded systematically, precisely, and transparently. The systematic review flow diagram will be divided into three processes: (1) identification, (2) screening, and (3) inclusion. The identification

of studies will be categorized into 2 sections, via databases, registers, and other methods. Records identified from each section will be documented accordingly. The final selection process will display the total number of studies that are eligible to be included in the review. To avoid the potential confounding factors that may affect the relationship between omega-3 LCPUFA supplementation and childhood intelligence, such as socioeconomic status, maternal education, and prenatal care, several review strategies will be used in the methodology phase. First, several effect models, such as fixed effects and random effects models will be reviewed in all studies to account for unmeasured individual-level confounding that might vary over time to help in estimating the causal effects of omega-3 LCPUFA supplementation. Second, during the screening phase, only studies where the participants are randomly assigned to either the treatment group (omega-3 LCPUFA supplementation) or the placebo group will be accepted. This randomization ensures that confounders are evenly distributed between the groups, thereby reducing their potential influence on the study results.

Figure 1. PRISMA flow diagram.



Eligibility Criteria

We will use the Participant, Intervention, Control, Outcomes (PICO) model in constructing eligibility criteria for study inclusion in the review.

Study Selection

We will include individual and clustered RCTs that studied the children's intelligence status between the supplementation of omega-3 LCPUFA during pregnancy compared to placebo or other supplemented intervention or standard perinatal care. Other types of study designs such as unpublished studies, gray literature, reviews, letters, short communications, conference papers, conference abstracts, abstracts, in vitro or in vivo, prospective or retrospective cohort, case-control, quasiexperimental and nonrandomized clinical trials will be excluded. We will include studies published in English. For studies in other languages, we will seek translations, if available.

Population

Our systematic review will focus on studies involving healthy pregnant women who received omega-3 LCPUFA supplementation. These pregnant women must be free from major confounding factors that are not representative of the general population of pregnant women. Additionally, we will consider the outcomes for their children who are aged 8 years or younger, assessing the impact of omega-3 LCPUFA supplementation on the children's intelligence using validated tools. The studies selected will exclusively involve mothers without chronic health conditions as well as children who have not been diagnosed with congenital anomalies, gastrointestinal issues, or metabolic disorders.

Intervention

In the review, we will evaluate the omega-3 LCPUFA supplementation in pregnant women as the intervention. We will not put a restriction on the dose. We will follow the study authors on the dose of omega-3 LCPUFA supplementation. Any RCTs that involve the supplementation before pregnancy or during the postnatal period will be excluded.

Comparison

We will include studies that compare the intervention with pregnant women receiving placebo or other supplement interventions.

Outcomes

We will include studies that measured the intelligence status of children using validated inventory or tools, for example, but not limited to, The Bayley Scales of Infant and Toddler Development, Third Edition, and Kaufman Assessment Battery for Children, Second Edition. The intelligence status may be based on several indicators such as cognition, attention, motor skills, language, behavior, vision, hearing, social-emotional, and neurodevelopment. The children included in the outcome group must be aged 8 years or younger. Studies that did not measure the intelligence status of the children, or studies that used children older than 8 years as an outcome group will also be excluded.

Data Sources, Search Terms, and Search Strategy

The authors have agreed to use 3 prominent journal databases as sources. The selected databases are PubMed, Scopus, and Cochrane Library. These databases were selected since they can fulfill every performance criterion as a search system [21]. All authors participated in a discussion to determine relevant terms and keywords that will be used in database searching. MeSH (Medical Subject Headings) terms will also be used in the search. Advanced search in each database will be performed using Boolean operators such as "AND" and "OR" to build search strings. Databases will be searched from inception to the most recent study publication. Any unpublished studies upon the final search date will not be included. No search filters will be used during the database search. The query search string will be adjusted following the interface provided by the databases (Multimedia Appendix 2).

Data or Reference Management

All studies identified in the final hit will be downloaded using NLM or RIS format. A reference manager software, EndNote (Clarivate) will be used to combine studies identified in the 3 databases. In-apps feature using the reference manager will be used to identify and remove duplicates.

Study Screening

Study screening will commence once database searches have been fully accomplished. A data selection form will be developed using Microsoft Excel and a systematic review tool. We will use Rayyan software (Qatar Computing Research Institute) to streamline the screening process, as it is a widely recognized tool designed for systematic reviews. All identified studies will be uploaded to the Rayyan review panel. Any duplicates identified by Rayyan will be removed. Before the process of selection, at least 5 randomly chosen studies will be pilot-tested to ensure all reviewers are familiar with the software. The references can be filtered by category, which makes the extraction process a lot easier. Collaborators or other reviewers will be invited to join the page and blind will be turned on in collaboration reviews to remove the risk of bias. References can be included by clicking "Include," excluded by clicking "Exclude," or "Maybe," if not sure. The label and reason box can be used to include labels and reasons for exclusion. The probability of the references (included, excluded, or undecisive) will be calculated by Rayyan. Undecided references will have a rating from 1 to 5, where 5 is most likely to be incorporated.

The screening process will be conducted in two phases: (1) title and abstract screening, and (2) full-text screening. Two reviewers (IHAS and MAMF) will be assigned to screen the titles and abstracts based on the eligibility criteria. Following that, the other 2 reviewers (SM and WASM) will conduct the second screening process by evaluating the full-text studies to be included in the review. If both reviewers have different opinions or judgments, a third reviewer (HYL) will be called upon to unravel the disagreements.

Data Extraction

A data extraction form will be constructed in an Excel (Microsoft Corp) sheet and the following information will be gathered from the relevant selected studies such as title, last

name of the first author, year of publication, duration of intervention, study design, single or multicenter, country, source of funding, aims, population (inclusion and exclusion criteria), intervention, indicator, index test, comparison, reference standard, primary and secondary outcomes (including tools and period of measurement), and results. Two reviewers (IHAS and MAMF) will extract the data of eligible studies independently. The other 2 reviewers (SM and WASM) will recheck the data extracted. Any discrepancies will be resolved by discussion to achieve a consensus. Any missing data, incomplete information, or variation in results will be obtained by contacting the corresponding author of the study.

Risk of Bias and Quality Assessment

Assessment of risk of bias will be conducted by 2 independent reviewers (IHAS and MAMF). A third reviewer (HYL) will be the referee for any uncertainties or disagreements in the discussion. All included RCTs will be assessed for study quality and potential biases using the Critical Appraisal Skills Programme (CASP) checklist for RCT. CASP is a checklist widely used for RCT evaluation, chosen for its simplicity, structured approach, and focus on key domains of study quality. This tool considers the following four domains of biases: (1) arising from the validity of the study design for RCT; (2) the soundness of the methodology applied; (3) measurement of the outcome; and (4) whether the results will provide any benefit to the targeted population. Each domain will be judged as "yes," "no," or "can't tell." If necessary, the authors will be contacted to obtain or clarify any information needed. The Grading of Recommendations Assessment, Development, and Evaluation (GRADE) tool will be used to assess the quality and certainty of the evidence for the outcomes analyzed in the meta-analysis. A summary of the risk of bias will be compiled into a table along with the justification for each judgement.

Data Synthesis

Meta-analysis will be performed when there are at least 2 studies reporting on the same outcome of interest between the omega-3 supplementation (intervention) and placebo (control), otherwise, a narrative summary approach will be presented. In the case of RCT with more than 2 arms, each arm will be treated separately. Data extracted from each study will be pooled and analyzed using the RevMan (version 5.4; Cochran Collaboration) software. For outcomes of interest measured in continuous or scale, sample size, means, and corresponding SDs will be used in pooling the effect size of the outcomes across the included studies. The pooled effect estimates for continuous outcomes will be expressed as mean differences with 95% CIs for studies using a similar outcome assessment tool, meanwhile, standardized mean differences with 95% CIs will be expressed for studies using different outcome assessment tools. For outcomes of interest measured in dichotomous or binary, the number of events and total sample size will be used in pooling the effect size of the outcomes across the included studies. The pooled effect estimates for dichotomous outcomes will be expressed in odds ratio with 95% CI. In cases where the data reported in the included studies are not usable (ie, cannot be pooled with other data), the corresponding author of the study will be contacted for access to data or revised statistics. If the corresponding author is uncontactable, or the data are unavailable, we will retain the study as eligible but restricted for meta-analysis. In view of inconsistencies between results in the existing literature highlighted by Gould et al [19] and Middleton et al [18], meta-analysis will later identify patterns of agreement and disagreement, thus offering insights into the reasons behind conflicting results.

The overall effect estimates that have a P value less than .05 will be interpreted as statistically significant. Heterogeneity will be assessed using the I^2 statistic, which represents the percentage of the total variation present between studies included. The I^2 statistic values of over 50% will be considered substantial heterogeneity. To address the variability of dosage, duration, and types of PUFA supplementation, random effects models will be used during analysis to manage heterogeneity. This will ensure a robust analysis of our findings. Sensitivity analysis will be performed when heterogeneity is high to address potential confounding factors and strengthen the study's robustness. We will group the outcomes according to the same assessment tools. Subgroup analyses for outcomes will be conducted when 2 or more studies are available per subgroup of interest. The following prespecified subgroups will be considered: maternal age, duration of intervention, presence of co-interventions (by itself or combined with complementary interventions), baseline nutritional status in mothers, sex of infant, country or geographic region, and risk of bias (low, high, or some concerns). If the dosage of the supplementation varies significantly, we will also do a subgroup analysis based on the dose group if we can pool studies with the same outcome.

Funnel plots will be conducted for the detection of publication bias if there are 10 or more studies available for an outcome. Publication bias is unlikely if data forms a symmetric inverted funnel shape around the mean effect estimate. As the funnel plots will be presented graphically, subjective judgments are required, which might differ from one person to another in interpreting the result. In addition, the Egger test will be conducted to determine funnel plot asymmetry. The presence of publication bias will be considered if the P value of the Egger test is less than .05.

For outcomes with insufficient data or extreme heterogeneity that cannot be analyzed by meta-analysis, a narrative synthesis will be provided.

Registration and Reporting

This systematic review and meta-analysis protocol has been registered on the International Prospective Register of Systematic Reviews (PROSPERO, CRD42023463910) and in the National Medical Research Register Malaysia (03507-WSF). In the event of protocol amendments, the date of each amendment will be accompanied by a description of each change and the rationale on PROSPERO. In preparing this protocol, we followed the PRISMA 2020 checklist (Multimedia Appendix 1). This systematic review will be reported in accordance with the Cochrane Handbook for Systematic Reviews of Interventions [22] as well as the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analysis Protocols) guidelines (Multimedia Appendix 3) [23].

Ethical Considerations

As this systematic review and meta-analysis uses secondary data, ethical approval is not required, and an exemption letter for ethical approval is obtained as per requirement by the Ministry of Health, Malaysia.

Results

After discussing and finalizing the search keywords and search strategy, 1 author conducted the initial search. The first keyword search was run on November 1, 2023. The first database, which is PubMed, yielded 530 hits whereas the second database from Cochrane found 306 hits. The most hits were from Scopus with 1162 hits. In total, our first database search yielded 1998 hits. All references were then imported into a reference manager specified in the search strategy section. All hits will be pooled and screened for duplicates using automation tools. Then, the titles and abstracts will be extracted for the first screening by the authors. We aim to finish extracting and analyzing data from chosen studies and prepare the report by November 2025.

Discussion

Principal Findings

In our planned systematic review, we intend to investigate the existing body of literature concerning the effects of maternal omega-3 LCPUFA supplementation on the cognitive development, specifically the IQ, of children in early childhood. The justification for maternal omega-3 LCPUFA supplementation, often promoted as a means to enhance a child's cognitive development, remains a topic of ongoing debate. Given the extensive systematic review conducted in 2018, this systematic review aims to provide a more rigorous analysis of the available evidence [18]. While previous findings suggest a positive association between omega-3 LCPUFA supplementation during pregnancy and children's IQ, it is important to note that the existing evidence is characterized by relatively low quality due to limitations such as small sample size. Hence, our objective is to enhance the quality of evidence through this review. A consistent body of research indicates a significant link between maternal omega-3 LCPUFA supplementation during pregnancy and a substantial enhancement in the IQ of the children [24,25]. Despite the overall indication of support for the beneficial effects of maternal omega-3 LCPUFA supplementation, it is important to acknowledge the presence of factors that can influence the outcomes [26,27]. Therefore, in our systematic review, we will also look at the variations in indicators of the intelligence status of the children based on several indicators such as cognition, attention, motor, language, behavior, vision, hearing, social-emotional, and neurodevelopment, which may contribute to heterogeneity in the results. The systematic review will adhere strictly to the protocol, and any deviations will be documented and reported in the published manuscript.

The implications of these findings for public health are significant. A more tailored approach to prenatal nutritional guidance, as suggested by Cetin et al [28], may be warranted to ensure optimal cognitive development in early childhood [28]. This, in turn, could have long-term cost-saving benefits for health care systems by potentially reducing the societal burden of cognitive impairments.

Comparison With Prior Work

Previous systematic reviews were published more than 5 years ago and the findings were varied [18,19]. Given the potential impact of maternal omega-3 LCPUFA supplementation on child IQ, there is a strong case for revisiting and possibly refining dietary recommendations for pregnant women. Thus, this review builds on these works by incorporating updated evidence and conducting subgroup analyses to address key factors, such as timing, dosage, and source of supplementation.

Limitations

We will thoroughly examine the limitations and potential sources of bias in the included studies. Despite our review's rigorous evaluation of evidence quality, there may still be sources of bias, such as publication bias or unaccounted confounders, that influence the overall results. To address potential publication bias, we will include a funnel plot analysis to visually assess the presence of asymmetry. Furthermore, the quality and design of the individual studies may vary. It is important for researchers and policymakers to recognize these limitations when interpreting the findings and consider them when making recommendations.

Future Research

This systematic review will address the necessity for further research in this area. It will also help future studies to address the identified limitations and clarify the optimal timing, dosage, and duration of maternal omega-3 LCPUFA supplementation to maximize the potential benefits on child IQ. Additionally, the long-term effects of maternal supplementation in children beyond the age of 8 years warrant exploration. This will not only deepen our understanding of this complex relationship but also help refine practical recommendations for expectant mothers, contributing to the well-being of future generations.

Conclusions

In conclusion, the systematic review will provide valuable insights into the potential impact of maternal omega-3 LCPUFA supplementation on children's IQ. If the evidence suggests a positive association, further research is needed to address limitations, confirm findings, and refine recommendations. The results will be disseminated by publishing the review, presenting at conferences, and sharing with stakeholders such as policy makers, nutritionists, and doctors, following PRISMA guidelines for transparent reporting. The implications for public health are substantial, and addressing these gaps can lead to a more comprehensive exploration of the impact of omega-3 LCPUFA supplementation during pregnancy on children's intelligence. Thus, this systematic review can provide a thorough understanding of the topic and offer valuable insights for future research and practice.

Acknowledgments

The authors would like to thank the Director General of Health Malaysia for his permission to publish this manuscript. The authors also would like to thank Datuk Nor Asiah Muhamad and Izzah Athirah Rosli from the Sector for Evidence-Based Healthcare, National Institutes of Health, Malaysia for reviewing the manuscript. The authors attest that there were no generative artificial intelligence was used in the manuscript generation, figures, or other informational content of this manuscript.

Data Availability

All data generated and analyzed in this systematic review are available upon request from the corresponding author.

Authors' Contributions

HYL, MAMF, SM, IHAS, and WASM designed the systematic review and wrote the original draft; HYL and WASM designed the systematic review and approved the final manuscript. All authors are researchers involved in clinical nutrition research, with several years of experience in nutrient analysis and clinical nutrition at the Institute for Medical Research, Malaysia.

Abstract

Background: Physical activity (PA) is crucial for youth health, but up to 74% of adolescents fail to meet recommended levels, especially during summer when structured supports associated with school are not available. The social and built environments significantly influence youth PA; yet, their complex interactions remain poorly understood. This study aims to evaluate the feasibility of combining ecological momentary assessment (EMA) and social network analysis to examine bidirectional influences among youth PA, built environments, and social networks during summer.

Objective: The objectives are to (1) evaluate the feasibility and acceptability of the combined EMA and Social Network Analysis protocol, and (2) identify phenotypes using person-level, microtemporal, and dynamic overlap between social and built environments.

Methods: This mixed methods feasibility study with an exploratory observational component will recruit 120 youth aged 12 years to 15 years from an urban school district in Central Texas, US. Participants will first complete a baseline survey to report their general social network patterns and environmental perceptions. Then participants will wear an ActiGraph LEAP accelerometer and respond to EMA prompts via smartphone for 7 days. EMA will assess real-time perceptions of social networks and surrounding built environments, which will be time-matched with accelerometer-assessed PA data. GPS coordinates will be collected with each EMA prompt to assess features of the built environment. Follow-up semistructured interviews will assess protocol acceptability.

Results: This study has been funded by the National Heart, Lung, and Blood Institute. Data collection is expected in the summers of 2025, 2026, and 2027.

Conclusions: This innovative approach combines EMA, SNA, accelerometry, and GPS data to provide unprecedented insights into the dynamic interplay between social networks, built environments, and youth PA during summer. Findings will inform the development of more targeted, effective interventions to promote PA among youth. While limitations include potential participant burden and generalizability, the study's strengths in capturing real-time, contextualized data make it a valuable contribution to understanding youth PA determinants.

Introduction

Background

Physical activity (PA) is crucial for youth health and development, offering a wide range of physical, psychological, and social benefits [1]. However, roughly 74% of young people fail to meet recommended PA levels [2], putting them at risk for various health issues both in the short and long term [1]. Summer presents a unique challenge for youth PA, as it represents a significant departure from the social and built environment supports typically offered by schools [3,4]. During the academic year, schools provide structured physical education classes, organized sports, and supervised recess periods, all of which contribute to youth PA levels [3,4]. The absence of these supports during summer leads to substantial changes and variability in how youth experience and are influenced by their social and built environments [5,6].

The social and built environments have been identified as key modifiable factors influencing youth PA, with research suggesting complex and nuanced relationships between these environmental factors and PA behaviors [7]. The social environment encompasses interpersonal relationships, social networks, and community norms, while the built environment includes physical structures, facilities, and design elements that can either facilitate or hinder PA. Despite growing research in this area, our understanding of how different layers of the social ecological model impact youth PA remains unclear, particularly during the summer months when the structured supports provided by schools are absent [8,9]. This knowledge gap hinders the development of effective interventions to promote PA among youth, especially during critical periods like summer. Moreover, there is considerable variability between youth in terms of the social and built environment factors they are exposed to during the summer months, as well as the impact these factors have on their PA levels [3,4,8]. For instance, some youth may be more affected by built environment barriers (eg, lack of safe parks or playgrounds) despite having a supportive social environment (eg, friends who enjoy physical activities), while others may face disparities in both domains [1,10,11]. This heterogeneity in experiences and influences underscores the need for more sophisticated research approaches that can capture and analyze these complex relationships.

Recent reviews of existing evidence highlight a significant need for more nuanced measurement approaches, including the use of intensive longitudinal data (ILD) to understand the complex variability (both within and between-subject) as well as the independent and mutual effects of social and built environments on youth PA [7,12,13]. Traditional cross-sectional or even longitudinal studies with infrequent measurement points may fail to capture the dynamic nature of these relationships and the day-to-day variations in youth PA behaviors [12,13]. ILD, on the other hand, allows for the collection of frequent, real-time data that can reveal patterns and associations that might otherwise be missed [12,13]. One promising approach to capturing this variability is through the identification of "phenotypes," individual-specific webs of links between social and built environmental determinants [14,15]. These phenotypes have the potential to identify overlaps in ILD and salient intervention targets for health behavior [14-16]. By understanding these phenotypes, researchers and practitioners may be able to develop more personalized and effective interventions to promote PA among youth, considering the unique combination of social and built environment factors that influence an individual's behavior.

Ecological momentary assessment (EMA) has emerged as a valuable method for collecting ILD by gathering real-time self-reports of behaviors, contexts, and perceptions in naturalistic settings [12,13]. EMA typically involves prompting participants multiple times throughout the day to report on their current activities, feelings, and surroundings, providing a rich, contextual dataset that captures the ebb and flow of daily life. This approach offers several advantages over traditional retrospective self-report measures, including reduced recall bias and the ability to capture within-person variability over time [12,13]. However, previous EMA measures of the social environment have been limited to the presence of others or coparticipation in PA, which may not fully capture the complexity of social influences on youth PA [7,13,17]. Social network analysis (SNA) offers the potential to provide more nuanced information, such as dyadic and personal network measures of social bridging, bonding, norms, and influence [17,18]. SNA allows researchers to map and analyze the structure and composition of an individual's social network, providing insights into how social connections and interactions may influence PA behaviors. By combining EMA and SNA approaches, researchers may be able to gain a more comprehensive understanding of the dynamic interplay between social factors and PA in youth's daily lives.

To examine these influences on a more granular level, this project aims to evaluate the feasibility of combining EMA and SNA techniques to collect ILD describing social and built environment associations with youth PA during the summer. This innovative combination of EMA and SNA techniques represents a data-intensive approach, necessitating an evaluation of its feasibility and acceptability in terms of validity, reliability, and respondent burden. The integration of these methods has the potential to provide unprecedented insights into the complex relationships between social networks, built environments, and PA behaviors among youth. For example, EMA data may show a youth's PA spikes when they are with a specific friend, but only if they are within a half-mile radius of a park, as indicated by GPS data. SNA reveals this friend is not particularly active themselves, but rather may be influential in triggering PA in groups, potentially exposing the youth to varied activity opportunities. This complex interplay suggests that interventions targeting both social network dynamics and built environment access could be more effective than addressing either in

isolation, highlighting the value of integrating EMA and SNA approaches to understand youth PA patterns.

This complex framework also presents challenges in terms of data collection, participant compliance, and analytical complexity. The intensive nature of the EMA protocol, combined with the detailed social network data collection, may lead to significant participant burden, potentially resulting in missing data, reduced compliance over time, or even selective attrition of certain participant subgroups. Moreover, the frequent prompts and awareness of being monitored could introduce reactivity, where participants alter their behavior or reporting patterns, while the complexity of the data collected across multiple platforms (EMA, GPS, and accelerometry) presents substantial challenges in data integration, cleaning, and analysis, requiring sophisticated statistical approaches to handle the multilevel, time-varying nature of the data. By conducting a feasibility study, researchers can identify potential barriers and refine the methodology before implementing it on a larger scale. This study seeks to address the critical need for more comprehensive and nuanced understanding of the complex interplay between social and built environments and their impact on youth PA during the summer months. The findings from this research could inform the development of more effective, targeted just in time adaptive interventions to promote PA among youth, ultimately contributing to improved health outcomes and reduced health disparities in this population.

Study Aims

The study has 2 primary aims. Aim 1 is to evaluate the feasibility and acceptability of an EMA protocol that combines the collection of social network characteristics using SNA and built environment characteristics corresponding to PA among youth during the summer. This aim will assess metrics such as EMA response rates, accelerometer wear time, and qualitative feedback from participants to determine the viability of the combined EMA-SNA approach. Aim 2, which is exploratory, seeks to identify and classify phenotypes by using microtemporal dynamic overlaps between social and built environments. Aim 2 will examine these phenotypes and their association with PA among youth in summer. These aims will use cluster analysis to identify subgroups of social and built environment patterns within the sample followed by dynamic structural equation modeling (DSEM) to analyze the bidirectional dynamics of social and built environment factors and PA [19,20]. These aims will provide a comprehensive assessment of the proposed methodology's feasibility and potential for uncovering nuanced relationships between environmental factors and youth PA during summer.

Methods

Study Design

This study will use a mixed methods approach to evaluate the feasibility and acceptability of combining EMA and SNA techniques for assessing social and built environment influences on youth PA during summer. The research design involves recruiting 120 youth aged 12 years to 15 years (entering the seventh to the ninth grades) from a local school district. An initial cohort of 20 youths will be recruited in year 1 of the project to assess initial feasibility and pilot the measures. Participants will be divided into 2 cohorts (n=50 each) across years 2 and 3, with each cohort further split into 5 groups (n=10) to facilitate data collection throughout the summer.

Conceptual Framework

The conceptual model guiding this study is grounded in a social ecological model, recognizing that youth PA is influenced by multiple, interacting layers of environmental factors [21,22]. At its core, the model posits that youth PA is shaped by a dynamic interplay between social and built environment elements, with each exerting both independent and synergistic effects on PA behaviors [7,23]. The social environment component encompasses the structure and quality of social networks, including aspects such as social bridging, bonding, norms, and influence [17,18,24]. These social factors are theorized to provide support, motivation, and opportunities for PA, but may also act as barriers in some contexts [25,26]. The built environment element includes physical structures, facilities, and urban design features that can either facilitate or hinder PA [27,28]. This includes factors such as neighborhood walkability, access to recreational spaces, and perceived safety [29-31].

Critically, the model emphasizes the reciprocal nature of these relationships, acknowledging that youth's PA behaviors can, in turn, influence their perceptions and interactions with both social and built environments [32,33]. This bidirectional conceptualization allows for a more nuanced understanding of how environmental factors and PA behaviors coevolve [7]. The model also incorporates the concept of phenotypes, representing individual-specific patterns of associations between social and built environment factors and PA [14,34]. These phenotypes are theorized to capture the heterogeneity in how youth respond to and interact with their environments, reflecting the complex, person-specific nature of PA determinants [35,36]. By integrating these various components, the conceptual model provides a comprehensive framework for understanding the multifaceted influences on youth PA, particularly during the unique context of summer months when typical school-based structures are absent [8,9].

Participants and Procedures

The study will recruit 120 youth participants aged 12 years to 15 years (entering the seventh to ninth grades) from a local school district. This age range was selected based on previous research indicating significant declines in PA and increases in peer influences during this developmental period [37,38]. Recruitment will be stratified to ensure equal numbers across sex and grade levels. Participant recruitment will occur through a partnership with a school district in central Texas, United States, which serves a diverse student population. The district-wide demographics include 72% of students classified as being at risk of dropping out of school and 77% eligible for free or reduced-price lunch. The student population is approximately 60% Hispanic or Latinx, 18% Black or African American, and 19% White. Recruitment will occur in 2 phases. First, a feasibility and pilot cohort (n=20) will be recruited in year 1. Next, 2 additional cohorts (n=50 each) will be recruited over years 2 and 3 to manage researcher burden and resource allocation. Each cohort will be further divided into 5 groups

(n=10) to facilitate data collection throughout the summer with 1 group participating in data collection each week. Participants will be asked to provide a list of weeks that they would be able to participate in the program to avoid scheduled family vacations and other activities that would alter their normal activity level. Participants will then be assigned a week at random from their available weeks. An informational sheet will be sent to eligible youth and their guardians in cooperation with the school district.

The study protocol consists of three main components: (1) an initial survey, (2) a 7-day EMA period, and (3) a follow-up interview. During the initial study visit, participants will complete researcher-administered surveys assessing their personal social networks and perceptions of the built environment around their home. They will also receive training on the use of the EMA application and the ActiGraph LEAP accelerometer. For the 7-day EMA period, participants will wear the ActiGraph LEAP accelerometer on their nondominant wrist 24 hours per day. They will respond to EMA prompts via a smartphone application 6 times daily over 12 hours [39]. The application (LifeData) will be downloaded onto their personal phones (Android or Apple). If the adolescent does not have a phone, a research device will be provided with all other functionality disabled. Prompts will be delivered at random during six 2-hour windows across the day with no prompt being sent within 30 minutes of the previous prompt. The prompting schedule will be adjusted to accommodate each participant's sleep and wake schedule, with 3 options available (8 AM to 8 PM; 9 AM to 9 PM; and 10 AM to 10 PM). Each prompt will include short questionnaires (2-3 mins) assessing momentary perceptions of social and built environments. Following the 7-day EMA period, participants will return for a follow-up visit to return the equipment and participate in a qualitative interview. This interview will assess the acceptability of the EMA and accelerometry protocols and gather additional contextual information about their experiences during the study period.

Survey Variables

The survey component of this study will assess various aspects of the social and built environments and demographic information. These measures are collected during the initial study visit and provide baseline data for each participant.

Demographic Information

Participants will provide demographic information, including age, sex, race, ethnicity, household income (reported by parents or guardians), parental education level, and home address (for Geographic Information System analysis). These data will be used to characterize the study sample and explore potential moderating effects on the relationships between social networks, built environments, and PA.

Social Network Characteristics

To assess social network characteristics, participants will be asked to list up to 10 people (also termed alter) they interacted with most in person over the last 7 days, a method previously used in personal network research [17,18,24]. For each person listed, participants will provide information on relationship type, frequency of contact, perceived frequency of the alter's PA, frequency of coparticipation in PA, perceived closeness, and likelihood of joining the alter in new activities or PA. Participants will also report if each pair of alters knows each other, allowing for the analysis of network structure [17,18]. These data will be used to calculate various social network measures, including social bridging (network size, effective size, and diversity), social bonding (density, proportion of frequent contact, and mean closeness of connection), social norms (frequency of coparticipation in PA and mean perception of alter PA), and social influence (proportion of likely influencers and mean suggestibility) [17,18,40]. In addition, individuals listed in this survey will also be included in EMA prompts as potential responses to items regarding the social environment. In this manner, SNA alters perceptions can be combined with EMA prompt answers to offer opportunities to connect the data set and better explain the social environment as collected by the EMA prompts.

Built Environment Perceptions

To assess built environment perceptions, the Neighborhood Environment Walkability Scale–Youth (NEWS-Y) will be used [31]. This scale, adapted from the adult version and validated for use with youth aged 12 years to 18 years, assesses several domains of neighborhood walkability including PA resource access, land-use mix, walkability, neighborhood aesthetics, safety (crime and traffic), walking and bicycling facilities, street connectivity, and residential density [29]. These measures provide a comprehensive assessment of youth perceptions of their neighborhood-built environment.

EMA Items

The EMA protocol is designed to capture real-time data on participants' social context, built environment perceptions, and PA. EMA prompts will be delivered 6 times per day over a 12-hour period for 7 consecutive days, using a smartphone application [41,42]. Prompts will be delivered at random during six 2-hour windows across the day with no prompt being sent within 30 minutes of the previous prompt. Each EMA prompt is designed to be completed in 2-3 minutes to minimize participant burden while still capturing key variables of interest. The combination of these EMA items with the continuous accelerometer data and GPS coordinates will provide a rich, contextualized dataset for examining the dynamic relationships between social and built environments and youth PA during summer [36,42]. The specific items included in the EMA prompts are in Table 1.

Table 1. Domains, ecological momentary assessment prompts, and response options.

Domain	Ecological momentary assessment prompt	Response option
Current activity	• "What were you doing right before the beep went off [Choose your main activity]?"	Reading/computer/phone, watching TV/movies, eating/drinking, physical activity/exercising, socializing/hanging out, and others.
Social context	• "WHO were you with just before the beep went off?"	Free response for person(s) listed in the network, other friends, siblings, parents, other family members, others, or people they did not know. (Select all that apply)
Social bridging	• N/A[a]	Measured by the diversity of social context and frequency of persons not known.
Social bonding	• "How close (emotionally) do you feel to those around you at this moment?"	Visual analog scale anchored from "not at all" to "extremely close"
Social norms	• "How physically active do you think the people around you are normally?"	Visual analog scale anchored from "not at all" to "extremely active"
Social influence	• "If someone you are with suggested doing something physically active, how likely would you be to join?"	Visual analog scale anchored from "not at all" to "extremely likely"
Built context	• "Where were you just before the beep went off?"	Home (indoors), home (outdoors), care program (indoors), outdoors (not at home), car/van/truck, and other
Safety	• "How safe do you feel in the current setting?"	Visual analog scale anchored from "not at all" to "extremely"
Pleasantness	• "How pleasant is the physical setting?"	Visual analog scale anchored from "not at all" to "extremely"
Space to be active	• "How much space is there to be physically active where you are right now?"	Visual analog scale anchored from "none" to "a lot"
Affective and feeling states	• "Right now, how SAD do you feel?" • "Right now, how HAPPY do you feel?" • "Right now, how FATIGUED do you feel?" • "Right now, how ENERGETIC do you feel?" • "Right now, how RELAXED do you feel?" • "Right now, how TENSE do you feel?" • "Right now, how STRESSED do you feel?" • "Right now, how FRUSTRATED do you feel?" • "Right now, how NERVOUS do you feel?"	Visual analog scale anchored from "not at all" to "extremely"
Interesting or engaging	• "What is the most interesting/engaging part of the surrounding environment to you right now?"	Free response

[a]N/A: Not available.

Activity Level

Participants will report their current activity at the time of each prompt. Options will include sedentary activities (eg, sitting and lying down), light activities (eg, standing and walking slowly), moderate activities (eg, brisk walking), and vigorous activities (eg, running and sports). This item has been validated against accelerometer measures in previous youth studies [43].

Social Context

To assess momentary social context, participants will respond to questions about who they are with now, the number of people present, how close (emotionally) they feel, their perception of how active those around them are being, and their perception of susceptibility to PA suggestions. Previously mentioned individuals from the initial SNA survey will be provided as response options in these prompts to further understand social influence and norms. These items are designed to capture both the presence of others, social norms related to PA, and susceptibility to influence in the immediate environment.

Built Environment Perceptions

Participants will be asked about their current physical location and their perceptions of the immediate built environment. Questions will address the type of location, perceived safety of the current environment, pleasantness of the surroundings, and availability of space to be physically active. These items are adapted from previous EMA studies on built environment perceptions and PA [36,41].

Mood and Motivation

To capture psychological factors that may influence PA, participants will be asked about their current mood (using a brief affect scale). These items allow for the examination of how momentary psychological states may interact with social and built environment factors to influence PA [41].

Qualitative Inquiry

To complement the quantitative data collected through surveys, EMA, and accelerometry, this study incorporates a qualitative component to gain deeper insights into participants' experiences and perceptions. Following the 7-day EMA period, semistructured interviews (Multimedia Appendix 1) will be conducted with all feasibility participants (n=20). These interviews will serve multiple purposes: (1) to assess the feasibility and acceptability of the EMA and accelerometry protocols; (2) to gather contextual information about participants' experiences during the study period, such as whether they encountered difficulties answering prompts while engaged in physical activities, if the device interfered with their sleep, or if they felt compelled to alter their behavior due to being monitored; and (3) to explore any anomalies or patterns observed in the quantitative data. The interviews will probe participants' thoughts on answering EMA questions in real time, any privacy concerns they may have had, and their overall experience with the study protocol. In addition, an adapted version of the System Usability Scale will be integrated into the interview to further assess the acceptability and usability of the protocol [44]. These interviews will be audio-recorded, transcribed verbatim, and analyzed using thematic analysis to identify key themes related to the study's feasibility.

Analysis Plan for Feasibility Assessment (Aim 1)

The feasibility assessment will examine multiple quantitative metrics including EMA response rates, with a target of at least 70% completion, accelerometer wear time aiming for 5 or more valid days with more than 10 hours per day, and participant retention rates targeting 80% or higher. We will calculate descriptive statistics including means, SD, and 95% CIs for these metrics. In addition, we will assess patterns of missing data and examine whether compliance varies systematically by participant characteristics using logistic regression models.

Qualitative Analysis Approach

The qualitative analysis will follow the Braun and Clarke [45,46] reflexive thematic analysis framework, which emphasizes the active role of researchers in identifying patterns of meaning across the dataset. The analysis process will begin with data familiarization, during which 2 trained researchers will independently immerse themselves in the data through repeated reading of interview transcripts. This will be followed by systematic initial coding using NVivo (Lumivero) software, with researchers generating codes across the entire dataset and paying particular attention to data related to protocol feasibility and acceptability. The researchers will then develop themes by sorting codes into meaningful patterns and creating a preliminary thematic framework that captures key aspects of participants' experiences. These themes will undergo refinement through review in relation to both coded extracts and the full dataset to ensure they form coherent patterns and accurately represent the data. Clear definitions will be developed for each theme to identify the essence of what each captures about participants' experiences with the protocol. The final analysis will be synthesized into a coherent narrative, supported by illustrative quotes.

Ensuring Qualitative Rigor

To enhance the trustworthiness of our findings, we will implement several complementary strategies [45,47]. For credibility, we will use of investigator triangulation, with multiple researchers independently coding data and comparing interpretations, along with member checking conducted with a subset of participants to verify our interpretations reflect their experiences. To establish dependability, we will maintain a detailed audit trail documenting analytical decisions and theoretical development throughout the analysis process. Confirmability will be addressed through researchers' engagement in reflexive journaling to document their positionality and potential biases, with regular team meetings including discussions of how researchers' backgrounds and perspectives might influence interpretation. For transferability, we will provide rich, detailed descriptions of the study context and participant characteristics to allow readers to assess the applicability of findings to other settings.

Integration of Quantitative and Qualitative Findings

The mixed methods analysis will use a convergent parallel design where quantitative and qualitative data are analyzed separately and then merged to provide a comprehensive understanding of protocol feasibility [48]. Areas of convergence and divergence between quantitative metrics and qualitative experiences will be explicitly examined and discussed. This integrated analysis will inform decisions about protocol modifications and provide crucial insights for implementing these methods in larger-scale studies. The combination of rigorous quantitative metrics with rich qualitative insights will allow us to not only assess the technical feasibility of our protocol but also understand the lived experiences of participants engaging with these novel data collection methods [48].

Analysis Plan (Aim 2)

To address the challenge of integrating data collected at different frequencies and levels of analysis, a multistep data processing approach will be used. Initially, accelerometer and GPS data will be aligned using timestamp information, creating a continuous stream of location-tagged PA data. For each EMA prompt, a time window of more than 30 minutes will be established, extracting the corresponding accelerometer and GPS data. This window allows for the capture of PA and location information immediately before and after each self-report, providing context for the EMA responses. Social network data from the initial survey will be treated as a stable characteristic for each participant throughout the study period, with key network metrics (eg, network size and density) linked to each EMA prompt. To account for potential temporal dynamics in social networks, EMA items assessing momentary social context will be used to create time-varying indicators of social influence. The resulting dataset will be structured hierarchically, with EMA prompts nested within days, and nested within participants. This approach allows for the examination of associations between social network characteristics, built environment features, and PA at various temporal scales, from momentary fluctuations to day-level patterns, while accounting for the different data collection frequencies and levels of analysis.

The analysis plan for this study incorporates a range of statistical techniques to address the research aims and account for the complex, multilevel nature of the data. For aim 2, which seeks to identify within-day phenotypes, a multistep analytical approach will be used. Associations will be explored at the hour, day, and person levels to determine which temporal associations are strongest. First, intraclass correlation coefficients (ICCs) will be calculated to estimate the impact of clustering (occasions within days, days within individuals) [49]. DSEM will then be used to analyze the within-person time-series data, accounting for the intensive longitudinal nature of the data and examining the bi-directional effects of social and built environments and PA [19]. DSEM allows for the decomposition of variance in PA into within-person and between-person components, estimating autoregressive parameters and cross-lagged parameters. To identify phenotypes, within-person standardized model estimates from the DSEM model will be used in an individual-level cluster analysis, using Ward's Method with Euclidean distance for hierarchical agglomerative clustering [20]. Validity of the clusters will be assessed using ANOVAs and chi-squared tests to examine univariate differences between clusters in terms of PA. Sensitivity analyses will be conducted with varying clustering methods, item rescaling, and time points included to assess the robustness of the cluster profiling [50]. Throughout the analysis, considerations will be made for potential sex and age differences, with exploratory moderation tests conducted. Missing data will be handled using maximum likelihood estimation in the multilevel models. All analyses will be conducted using appropriate statistical software packages, with a significance level set at $P<.05$, adjusted for multiple comparisons where necessary using the Bonferroni correction.

Sample Size Justification and Power Analysis

Our sample size determination was guided by multiple considerations. For aim 1 (feasibility and acceptability), the planned sample size of 20 participants aligns with recommendations for feasibility studies [51]. We will recruit 20 participants in year 1 for initial protocol testing, followed by 2 cohorts of 50 participants each in years 2 and 3. This sample size will allow us to estimate compliance rates with a margin of error of ±9% (assuming 95% CIs), which is adequate for assessing protocol feasibility. For aim 2 (identifying phenotypes), we conducted power analyses using Monte Carlo simulations for DSEM. Based on these simulations, assuming moderate effect sizes ($\beta=0.3$) and ICCs of 0.2, a sample of 100 participants providing 42 observations each (6 prompts per day for 7 days) will provide 80% power to detect significant cross-lagged effects at $\alpha=.05$.

While the study is primarily powered for overall effects, we acknowledge limitations in detecting sex differences. Given our balanced recruitment by sex (50 participants per group), post-hoc power analyses indicate we would only be able to detect large effect size differences ($d>0.7$) between males and females with 80% power. However, previous research in youth PA suggests that while absolute activity levels may differ by sex, the underlying mechanisms of social and built environment influences are generally consistent across sexes [52]. Therefore, while we will explore potential sex differences as secondary analyses, our primary focus is on identifying overall patterns and phenotypes that can inform future intervention development.

Ethical Considerations

This study was approved by the institutional review board at Texas A&M University (STUDY2024-0473). The study will be performed in accordance with the ethical standards as laid down in the 1964 Declaration of Helsinki and its later amendments. All participants will be asked to provide assent to participate. In addition, guardian permission will also be required for all participants. Data will be deidentified using unique study IDs to protect participants privacy. Participants will receive compensation for their involvement, with a tiered incentive structure to encourage compliance. They will receive US $25 gift cards for the initial survey, return devices after the EMA protocol, and participate in qualitative interviews. An additional US $25 will be provided for meeting compliance benchmarks of at least 5 days of valid accelerometer data (more than 10 hours/day) and at least a 70% response rate for EMA prompts, for a potential total of US $100 throughout the study.

Results

The study received funding from the National Heart Lung and Blood Institute in May 2024. Data collection is expected to occur during the summers of 2025, 2026, and 2027. Findings are expected to be published in the fall of 2027.

Discussion

Principal Findings

This study will yield several important findings. First, regarding aim 1, we expect to demonstrate the feasibility and acceptability of combining EMA and SNA techniques to assess social and built environment influences on youth PA during summer. We also expect to identify potential challenges and areas for improvement in the protocol, which will be valuable for future studies using these methods. For aim 2, we anticipate identifying distinct phenotypes that represent different patterns of associations between social and built environment factors and PA. These phenotypes may reveal subgroups of youth who are more or less influenced by specific social or built environment characteristics. For example, we may find a subgroup for whom social network factors are particularly influential on PA, and another for whom built environment features play a more prominent role [7]. We expect these phenotypes to provide insights into the heterogeneity of environmental influences on youth PA, potentially informing more targeted and personalized intervention strategies.

Strengths

This study has several notable strengths. The combination of EMA and SNA techniques represents an innovative approach to capturing the dynamic interplay between social and built environments and youth PA. This method allows for the collection of rich, contextual data in real-time, reducing recall bias and capturing within-person variability [12]. The use of objective PA measures through accelerometry, coupled with GPS data, provides a comprehensive picture of youth PA

patterns and their environmental contexts [53]. In addition, the mixed-methods approach, incorporating both quantitative and qualitative data, allows for a more nuanced understanding of youth experiences and perceptions. The focus on the summer period addresses an important gap in the literature, as this is a time when youth PA patterns may differ significantly from the school year [8]. Finally, the application of advanced analytical techniques such as DSEM and phenotyping represents a cutting-edge approach to understanding the complex, individual-specific nature of environmental influences on PA [14,19].

Limitations

Despite its strengths, this study has limitations that should be acknowledged. The sample size, while appropriate for a feasibility study, may limit the generalizability of findings, particularly in the identification of phenotypes. The focus on a single geographic area may also limit generalizability to youth in other regions with different social and built environment characteristics. While our sample size is appropriate for our primary aims, we acknowledge limited power to detect sex differences in environmental influence patterns. However, existing literature suggests that fundamental mechanisms of social and built environment influences on physical activity are largely consistent across sexes during early adolescence, even though absolute activity levels may differ. Future larger-scale studies may be needed to fully explore potential sex-specific patterns in these relationships. The intensive nature of the EMA protocol, while providing rich data, may introduce participant burden and potentially affect compliance rates or typical behavior patterns. There is also a possibility of reactivity, where participants may alter their behavior due to awareness of being monitored. In addition, while the study captures a week of data for each participant, this may not represent typical summer PA patterns, which could vary over the course of the entire summer. Finally, while the combination of EMA and SNA provides detailed information on social networks and momentary social contexts, it may not capture all relevant aspects of social influence on PA. Similarly, the built environment measures, while comprehensive, may not account for all relevant features that influence youth PA.

Conclusions

This study represents an important step forward in understanding the complex interplay between social and built environments and youth PA during summer. By employing innovative methodologies and advanced analytical techniques, we expect to gain unprecedented insights into the dynamic, individual-specific nature of these relationships. The findings from this study have the potential to inform more targeted and effective interventions to promote PA among youth, particularly during the critical summer months. While limitations exist, they are outweighed by the strengths of this study's design and its focus on an understudied time period makes it a valuable contribution to the field. Future research can build upon these methods and findings to further elucidate the multifaceted influences on youth PA and develop strategies to promote active, healthy lifestyles among diverse youth populations.

Acknowledgments

The present study was supported by the National Heart, Lung, and Blood Institute under a K01 grant (K01HL169818).

Authors' Contributions

TP conceptualized the study, developed the methodology, and wrote the original draft of the manuscript. GD provided technical expertise on Ecological Momentary Assessment (EMA) methods and contributed to the study design and EMA protocol development. KdH offered expert guidance on Social Network Analysis (SNA) techniques, assisting with the social network measures and analysis plan. CL contributed expertise on spatial analysis, advising on the integration of GPS data and geospatial analysis of the built environment. KPP assisted with the overall study design and methodology. All authors reviewed and edited the manuscript, providing critical feedback and approving the final version for submission**.**

Abstract

Background: Contactless monitoring of vital signs, especially the breathing of children, in the hospital is performed on a priority basis because their organs and immune system are immature. Therefore, continuous monitoring of their vital signs with a sensor that is directly attached to their body is not possible, as it irritates the sensitive newborn skin and causes discomfort. A contactless frequency-modulated continuous-wave (FMCW) radar-based device can wirelessly monitor the breathing rate and pattern of a child in the hospital or at home. Signal-processing capability can be added to this device to process breathing data and analyze the apnea condition arising due to irregular breathing patterns.

Objective: This study will develop a contactless FMCW radar-based system to accurately monitor the breathing rate and pattern of neonates and infants in hospitals and at home in order to provide a noninvasive, nonintrusive and contactless alternative to conventional sensor-based methods and address a critical need in neonatal care, potentially improving health outcomes for vulnerable infants.

Methods: The radar transmits a signal toward the body, and the time taken by the signal received to travel from the body to the receiving antenna is analyzed. This time is proportional to the distance between the radar and the body, and the breathing pattern is recognized as a slight, periodic variation in this distance. We will use this concept with multiple antenna systems to monitor the breathing of neonates with improved sensitivity. The radar-based device will be installed, in addition to conventional breathing monitors, in the neonatal intensive care unit. The signals received at the radar and the respiration signals from conventional monitors will be recorded in a database. Signal-processing techniques will be applied to extract breathing signals from the signals received at the radar.

Results: This study was funded in January 2023 by the Science and Engineering Research Board (SERB) of India. The device was designed by May 2024, and a working proof-of concept was verified in the Indian Institute of Technology (IIT) Ropar laboratory. Implementation of the proposed method for initial study began in December 2024. Results are expected to be published in the first quarter of 2025.

Conclusions: The contactless FMCW radar-based system will provide reliable estimation of the breathing rate and pattern, which is close to the conventional reference device values most of the time. Our device will also provide a seamless breathing-monitoring system to be used both in hospitals and at home for newborns and premature babies until they are fully healthy and fit.

KEYWORDS

radar; contactless vital monitoring; breathing rate monitoring; vital signs; health monitoring

Introduction

In recent times, we have seen advancements in the medical sector, especially in health monitoring, by replacing conventional medical equipment with wireless equipment, which is convenient and accurate for usage. Such advancements have made some vital sign monitoring possible at the home of the patient/subject. As an advanced health-monitoring system, smart homes monitor not only temperature and the environment but also some critical vital signs [1]. Continuously monitoring the breathing rate benefits patient management by early detection of health deterioration and breathing irregularities, if any. For monitoring children and newborns, it is convenient if performed at home. Nearly 15 million infants born prematurely in the world every year need to be monitored until they are healthy and fit [2]. In these children, basic vital parameters, such as breathing, the heart rate, and oxygen saturation, are especially monitored. Initially, these parameters are monitored by a sensor that is directly attached to their body [3], which, however, causes skin irritation and may also lead to pressure necrosis. Regularly observing a patient's vital signs aids medical professionals in identifying early abnormalities and assessing the progression of an illness, as well as evaluating the effectiveness of a treatment method. Contactless monitoring of a patient's vital signs, minimizes inhibition, reduces the risk of infection, and eliminates any discomfort to their skin [4]. Radar is already a promising technology for wireless health parameter monitoring due to its low power, low cost, and security purposes. In this paper, an FMCW radar-based device [5] is proposed to investigate breathing patterns in infants in different scenarios. The device is intended to be used in the hospital or at home for monitoring purposes. Using the proposed design, we will eliminate the requirement of a cannula, which is usually attached to the patient's nose for flow-based breathing-monitoring purposes. Another method that is used as an alternative to interpolate normal breathing is a pulse oximeter, which is attached to the patient's finger for oxygen saturation measurement that correlates with normal/abnormal breathing. Such methods come with the requirement of one or the other kind of attachment to the patient's body, which might create irritation or discomfort for the patient. Thus, we will use a contactless monitoring device for breathing pattern/rate measurement. In this paper, the feasibility of radar technology as a possible means of continuously monitoring vital signs without physical contact will be studied. Radar means detecting an object and estimating its parameters based on its distance from the radar. Continuous-wave radar is used in the microwave range of the spectrum, which means transmit frequencies are within tens of gigahertz [6]. The contactless FMCW radar-based model is based on wireless technology, which includes radio frequency for the transmission of signals and reception after reflection so that direct contact with the patient is not needed, providing an advantage over conventional methods by monitoring health parameters remotely, which is suitable in emergencies and allows health care providers to assess the patient's condition without being physically present at that place.

In this study, we propose a device for contactless breathing rate monitoring. In particular, this device is targeted to be used for the contactless breathing monitoring of newborns to reduce discomfort and potential infection risks due to wired sensor devices by implementing a radar system that will be kept at some distance from the babies so that they do not face any problem during the monitoring of vital signs, especially the respiration rate. For this purpose, we will use the radar for measuring inhalation and exhalation through the outward or inward movement of the abdominal area. This will be monitored in the form of changes in the distance from the radar and the patient being monitored.

Methods

Study Setting

The proposed study will be jointly performed at the Indian Institute of Technology (IIT) Ropar and Government Medical College and Hospital (GMCH) Chandigarh. IIT Ropar is a technology education institute having ~2500 students [7]. The campus also accommodates the staff and faculty members in the on-campus residential facility. The device will be developed at IIT Ropar. The initial study will be conducted on healthy students of the institute who volunteer to be part of the study. The accuracy of the breathing pattern of a healthy human being will be verified. Next, healthy children of the staff and faculty members residing on campus will be enrolled after obtaining informed consent from their parents. Furthermore, a study will be conducted at GMCH Hospital's pediatrics department, which has an inpatient facility for all age groups, including newborn and premature neonates.

Study Design

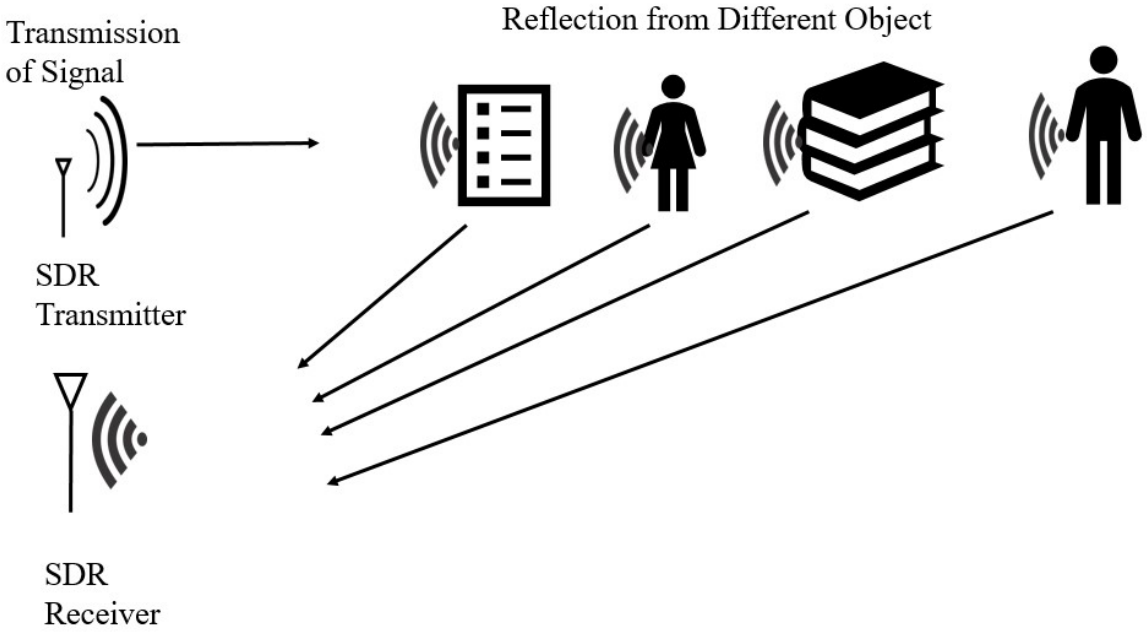
The proposed study is intended to prove the applicability of contactless methods for breathing rate monitoring in neonates. Further, this study will be useful in the detection and management of apnea conditions due to irregularity in breathing patterns. The primary objectives of the study are as follows:

- Designing a device for noncontact breathing rate monitoring using the FMCW radar principle, which transmits a signal with the frequency varying linearly with time. When this signal reflects off an infant's chest, the received signal has a frequency difference (beat frequency) from the transmitted signal. This frequency difference is proportional to the minute movements caused by breathing. Thus, the beat frequency carries information of the breathing pattern. In addition to the breathing pattern, some unwanted reflected components from multiple objects around the patient being monitored are contained in the radar signal, as illustrated in Figure 1. The primary objective is to design algorithms to suppress the effect of reflections from stationary objects.
- Identifying specific signal fluctuations related to the breathing of the patient being monitored and distinguishing these variations from other persons in the room or other body movements, such as those of limbs. Breathing is

periodic, so the beat frequency variation is also periodic. Variation due to limb movements and other people is large and aperiodic. Therefore, signal processing techniques, including filtering, can be used to minimize the effects of unwanted reflections and movements.

- Further extending this setup to analyze breathing signals of multiple persons and separating them.

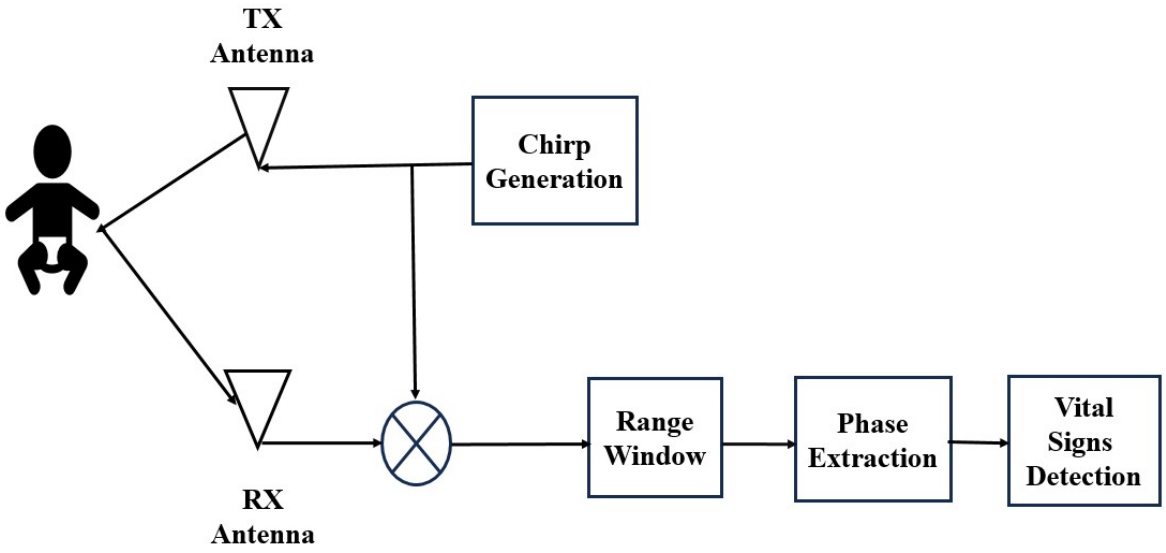
Figure 1. Separating different objects based on reflection. SDR: software-defined radio.



Prototype and Implementation

The main objective of the model is to monitor the breathing of premature and newborn babies without any contact with their bodies. The proposed monitoring device is contactless. Therefore, it will not cause skin injury, irritation, allergy, or infection. Device accuracy is targeted to be more than 90% in all scenarios and more than 98% in a controlled setup [1]. The controlled setup is defined as a laboratory environment or the target patient being instructed to restrict any movement of body parts. This model combines the development of hardware and software, in addition to the testing protocol for the breathing rate. The software contains signal-processing algorithms to clean the received signal after reflection from the target and the other objects or persons in the vicinity, as shown in Figure 2. The waveform is designed and generated to be sent toward the patient being monitored using a software-defined radio (SDR) transmitter [8,9]. The same SDR is used to receive the reflected signal. The broadcast signal is reflected and received with a time delay due to the distance propagated between the device and the target patient. The difference in frequency between the transmitted and received signals, which determines the beat frequency, provides distance information. The distance varies with the state of breathing, such as inhalation results in reduced distance and exhalation results in increased distance due to expansion and contraction of the chest and abdominal region of the patient. The reflected signal's components are reflected from the patient and nearby objects. The reflected signal received at the SDR receiver is converted back to the baseband after dechirping. The dechirped signal is processed further in a general-purpose computer to extract the required breathing signal by mitigating the effects of the reflections from objects other than the patient being monitored. This requires passing the signal through a low-pass filter to obtain the frequency of interest (ie, to retain frequency components that are within the range of the breathing rate). We will also implement the algorithms to separate the reflection from different objects based on their reflection time so that the objects at different distances are separated. Wireless signals travel at the speed of light. Separating these reflections eliminates them from static objects, as their reflections do not change over time [8].

Figure 2. System model design. RX: receiving; TX: transmission.



FMCW Radar and Study Measurement

Effective contactless monitoring of each baby in the hospital was initiated after stability criteria were met, such as respiratory status without serious illness. FMCW radar monitoring is performed continuously during the monitoring period [10]. The benefit of this device is that it can be used in hospitals and homes both. Many times, it is only necessary to monitor the breathing, which can be performed at home with the proposed device without admitting the child to the hospital. For the proposed study and initial trial, the infants will be observed with their chest facing the radar at a distance of roughly 1-1.5 m from the low-vibration tripod to which the radar is attached. A research assistant will track each infant's vital signs for 10 minutes, 3 times a day. The effectiveness of the radar-based breathing rate–monitoring device will be evaluated by comparing the device's measurements with clinical recordings.

Sample Size and Data Analysis

A sample of 20-30 premature newborn babies will be included in the study. Data collection will be performed with the help of the neonatology department at GMCH Chandigarh. The radar-based device will be installed, in addition to conventional breathing monitors, in the neonatal intensive care unit. The signals received at the radar and the respiration signals from the conventional monitors will be recorded in a database. An in-depth analysis of radar signals received from each infant will be carried out. All the factors critical for understanding the complexities of the premature newborn condition and care will be observed, providing the diversity and depth of experience necessary for such research [11]. The main idea is to investigate different effects of collecting radar data from the chest and abdominal region, removing the effect of any interference or movements and reflections from the surroundings. Further analysis and algorithm development will be carried out to extract breathing signals when each infant is with the mother. If monitoring of twins is possible, a minimum safe distance will be required to mitigate the radar interface between them. The basic principle that will guide the data collection protocol will ensure seamless operation at GMCH Chandigarh.

Ethical Considerations

The study was approved by GMCH Chandigarh and the Government of India. Informed consent will be obtained from parents. They will be informed about the purpose of the experiment, the procedure, and benefits. We will ensure that they do not face any type of harm and that they voluntarily agree to participate. Data confidentiality will be ensured, and participants' identities will be protected. Ethical approval (approval number GMCH/IEC/2022/730) was obtained from the GMCH Chandigarh Institutional Review Board (IRB) or Ethics Committee to ensure that the study meets ethical standards and that participants are protected from potential harm.

Results

Data collection and implementation of the proposed device was performed with the help of IIT Ropar and GMCH Chandigarh. The study was funded in January 2023 by the Science and Engineering Research Board (SERB) of India. The device was designed by May 2024, and a working proof-of concept was verified in the IIT Ropar laboratory. Implementation started in December 2024. Initially, we will apply this method to monitor a single child, and then, this study will be extended to monitor multiple infants by modifying the device design and signal-processing algorithms. The main outcome of the proposed method is to obtain breathing patterns of infants at home and in hospitals to predict their health condition based on the breathing patterns. We expect to obtain the results of monitoring a single child by the end of the first quarter of 2025.

Discussion

Summary

The proposed study will develop a device for accurate noncontact monitoring of the breathing rate and patterns of neonates and infants in the hospital and at home using an FMCW radar-based system. The working principle of the device is based on capturing, using radar, the pattern of movements in the chest and abdominal region due to inhalation and exhalation. This

will address the critical need for noninvasive and noncontact continuous respiration monitoring in clinical settings. With the system being noncontact and portable, it can also be used at home to monitor the patient's condition. Unlike wearable devices that may be affected by environmental factors and require direct contact, the proposed system offers a significant advantage over conventional chest-mounted devices that may cause discomfort and privacy concerns. The typical range for an infant's respiratory rate is between 40 and 60 breaths per minute [12]. A breathing rate outside this range indicates that the patient is not healthy. Through the usage of the proposed technology, we plan to demonstrate high accuracy in identifying respiratory irregularities, such as apnea, aligning with the study's objective to enhance neonatal care. Contactless radar systems [13-17] have been proven to be a more convenient option for users compared to wearable devices due to immunity to environmental constraints, wider coverage, the absence of privacy concerns, and importance for heavy-burned and newborn babies, enhancing usability. The ability to detect vital signs, particularly the breathing rate, is typically required to identify human presence in short-range environments. However, the system's accuracy may be affected by movement artifacts, physical abstraction, clothing, cobedding, and positioning. Other constraints related to the proposed method are a trade-off between range and resolution due to bandwidth constraints, and further validation in diverse clinical settings is required. Despite these limitations, the signal-processing techniques will be used to improve the performance and bring about significant advancements in neonatal respiratory care, with broader implications for improving patient care and monitoring in various clinical and home settings. Once the designed device is developed, it will be tested in the neonatology department of GMCH Chandigarh, where breathing rate monitoring will be compared with conventional methods. We will have a database of signals received at the proposed device and those from conventional devices. This database can be used to test various algorithms. Future research will focus on refining the device's accuracy and expanding its applicability to a wider range of patients and conditions. The device design can be modulated to monitor multiple individuals through use of multiple antennas and advanced signal-processing techniques.

Conclusion

An FMCW device can measure submillimeter-range shifts because of its improved precision in measuring displacements. Breathing using an FMCW radar-based device [18-20] is useful for pathologies that are difficult to detect solely with the use of an electrocardiogram (ECG). FMCW devices are cheap and easy to operate. Our model will also have the advantage of better resolution compared to other radar-based model designs and will be based on radio frequency signals from a radar to detect the patient's position and extract respiration data [21-23]. With the help of this system, we can detect the breathing of patients within the range of up to 45 cm and possibly improve spatial resolution and range with additional radar and antenna units.

Acknowledgments

We thank the Indian Institute of Technology Ropar (IIT Ropar) and Government Medical College and Hospital (GMCH) Chandigarh for their help and assistance with data collection. The study was funded by the Science and Engineering Research Board (SERB; grant number SCP/2022/000464).

Data Availability

The data from this trial will be accessible to the public and research community. The research team will decide on the dissemination method once the trial ends and our results are published. Although the data will not be made immediately public, they can be requested from the corresponding author.

Authors' Contributions

All authors have read and approved the final version of the manuscript.

Abstract

Background: Childhood obesity is increasing in Singapore, with most cases persisting into adulthood and leading to poor health outcomes. The current evidence for childhood obesity interventions shows a clear dose-response effect, where effectiveness improves with an increasing number of treatment hours. A minimum threshold of ≥26 hours over a 2- to 12-month period is required to achieve significant outcomes. The Kick Start Move Smart program is the first online community-based multidisciplinary program to treat pediatric obesity in Singapore. It has demonstrated feasibility and acceptability, with 70% of participants completing the recommended ≥26 hours of intervention. Preliminary data show significantly lower BMI and improved quality of life in participants compared to controls. Successful families are positive outliers who developed strategies for health in the context of an obesogenic environment. This positive outlier approach indicates that solutions to challenges that a community faces exist within certain individual members, and these strategies can be generalized and promoted to improve the health of others in the same community. A mobile health (mHealth) app targeting parents is a critical missing link in the currently available interventions to support parental self-management of childhood obesity. Using a combination of behavioral theory and user-centered design approaches is important for designing mHealth apps. One recommended framework is Integrate, Design, Assess, and Share (IDEAS), which aims to facilitate the development of more effective interventions by engaging perspectives from different stakeholders.

Objective: This study aims to (1) describe the co-design protocol of an mHealth app using the IDEAS framework as a low-intensity intervention or as an adjunct to more intensive existing pediatric obesity interventions and (2) assess the usability, acceptability, and engagement of the app by parents.

Methods: A clinician-led co-design approach will be undertaken with a multidisciplinary team using the IDEAS framework. Phase 1 involves stakeholder engagement and the formation of a core committee and a parent advisory board. Phase 2 involves developing the app content through focus group and expert panel discussions. Phase 3 involves developing a prototype app and gathering feedback. Phase 4 involves piloting the minimum viable product by parent users and evaluating its effectiveness through interviews and questionnaires.

Results: In April 2023, a parent advisory board was formed, and stakeholders were engaged as part of phase 1. Phases 2 and 3 were completed in June 2024. Focus group discussions were held with the parent advisory board and stakeholders to identify family strategies and patient-centric outcomes and provide feedback on the app. As of January 2025, the app is complete, and

we are now in the middle of data collection from participants. Participants will provide feedback to the research team, and the app will be updated accordingly.

Conclusions: An evidence-based, theory-driven mHealth app developed using a structured design framework can bridge the gap in delivering multidisciplinary care in community settings for families with overweight children.

KEYWORDS

childhood obesity; mHealth; mobile health; co-design; IDEAS framework

Introduction

Childhood obesity rates are rising in Singapore, with most cases persisting into adulthood and leading to adverse long-term psychosocial and health effects. A recent systematic review and meta-analysis highlighted the importance of access to multidisciplinary interventions for children with obesity. The current evidence for childhood obesity interventions shows a clear dose-response relationship, where effectiveness improves with an increasing number of treatment hours. A minimum threshold of ≥26 hours over a 2- to 12-month period is required to achieve significant outcomes [1]. The Kick Start Move Smart (KSMS) program is the first online community-based program to treat pediatric obesity in Singapore. The pilot evaluation has demonstrated feasibility and acceptability, with 70% of the participants completing the recommended ≥26 hours of intervention. Preliminary data on the effectiveness of the program show significantly lower BMI scores and improved quality of life in program participants compared to the control group. Families who achieved the recommended treatment hours in the program also demonstrated improvements in their child's quality of life, health behaviors (such as increased intake of fruits and vegetables), and BMI. Successful families are positive outliers who developed strategies for health in the context of an obesogenic environment. The theoretical underpinning of the positive outlier approach is that solutions to problems a community faces often exist among certain individuals and that these successful strategies can be generalized and promoted to improve the outcomes of others in the same community [2]. Typically, there is a high degree of heterogeneity in response to lifestyle interventions in pediatric obesity treatment; thus, adopting the positive outlier approach can facilitate the best solutions to support families.

An evidence-based, theory-driven mobile health (mHealth) app that targets parents is a critical missing link in currently available interventions to support parental self-management of childhood obesity [3]. While there has been a rapid growth of mHealth apps to support chronic disease management, achieving meaningful health improvements through the use of mHealth apps remains elusive. Combining approaches from behavioral theory and user-centered design to guide intervention development, coupled with rigorous approaches for evaluation and dissemination, is important to achieve the full potential of mHealth apps. Integrate, Design, Assess, and Share (IDEAS) is one recommended framework, which aims to facilitate the development and dissemination of more effective interventions by engaging the perspectives of different stakeholders [4]. This framework builds on design thinking and integrates user insights throughout the stages of development and the inclusion of theory-driven behavioral strategies.

We hypothesize that codevelopment with health care providers, digital health experts, and successful families to create a high-quality mHealth app for childhood obesity can increase its acceptability and engagement from families. First, we aim to co-design an mHealth app with health care providers, digital health experts, community partners, and successful families using the IDEAS framework. The app will be evidence-based and theory-driven and consist of three core components: (1) consolidation of positive outlier strategies and development of patient-centric outcomes for self-monitoring, (2) synthesis of evidence-based guidelines and integration of theory for behavioral strategies, and (3) incorporation of community resources and integration with community programs. The mobile app is designed to be used independently as a low-intensity intervention or as an adjunct to more intensive existing pediatric obesity interventions to increase overall engagement and effectiveness. Second, we aim to assess the usability, acceptability, and engagement of the mHealth app by parents in the pilot testing phase. Specifically, the usability and acceptability of the mHealth app will be assessed using the validated Mobile App Rating Scale (uMARS) [5] and by self-monitoring of patient-centric outcome measures as determined in the primary aim.

Methods

Overview

A clinician-led co-design approach will be undertaken with a multidisciplinary team of researchers, parents of children with obesity, community stakeholders, and digital health experts using the IDEAS framework [4]. The experience-based co-design principle will be followed to design the mHealth app, including gathering stakeholders to participate in the design process and developing a set of feasible care paths by sharing their experiences [6]. Based on the IDEAS framework and co-design principles, 4 iterative phases for the prototype mHealth app have been developed, which are summarized in Table 1.

Table 1. Phases of the project and their estimated timelines.

Phase	Activities	Duration	Stakeholders (n=21)
1	• Stakeholder engagement • Forming the parent advisory board	• 4 months	• Multidisciplinary health care providers (10/21, 48%) • Parent advisory board (5/21, 24%) • Community stakeholders from Sport Singapore and Health Promotion Board (4/21, 19%) • Digital health experts and app developers (2/21, 10%)

2	• Developing content
	  • Patient-centric outcomes that are clinically relevant
	  • Successful positive outlier strategies
	  • Integration with community resources
	  • Implementation of the app in daily lives
		• 6 months	• Multidiscpilinary health care providers
			• Parent advisory board
			• Community stakeholders

3	• Sharing proposed contents and features based on results from phase 2 and revisions • Sharing prototype app	• 6 months	• Multidiscpilinary health care providers • Parent advisory board • Community stakeholders • Digital health experts and app developers
4	• Evaluating and refining the MVP[a] to assess usability and acceptability and improvement of the app functions	• 9 months	• Parents of children with obesity • Digital health experts and app developers

[a]MVP: minimum viable product.

Ethical Considerations

Ethical approval has been sought from the SingHealth Centralized Institutional Review Board (2022/2035).

Phase 1: Stakeholder Engagement and Formation of the Core Committee and Parent Advisory Board

Stakeholder Engagement

The multidisciplinary team of health care providers will consist of pediatricians, dietitians, nurses, physiotherapists, exercise physiologists, psychologists, and social and medical workers with expertise in childhood obesity, who provide their clinical input in the co-design process. Digital health experts and app developers will also advise on the feasibility of the mHealth app's requirements and involve the vendor at appropriate time points to effectively transform the information into system requirements and design considerations to achieve an optimal design solution. The app's privacy and security features and compliance with the Personal Data Protection Act will also be considered. These features have emerged as fundamental from both clinical and patient perspectives in an evaluation of an mHealth app [7].

Parent Advisory Board to Learn From Positive Outliers

Patient advisory committees have been used in numerous co-design approaches to obtain patient input on a variety of health care processes. This ensures that the posed research questions and selected outcome measures are relevant and important to patients [8]. In this project, we will convene a parent advisory board to inform the mHealth app development. The parent board will consist of at least 5 parents who previously participated in the KSMS pilot study and successfully attended at least 26 hours of the program. The parent advisory board will be part of 2 focus group discussions in phase 2 and 1 focus group discussion in phase 3 of this project.

Formation of the Core Committee

Given the networked nature of the project, which includes the multidisciplinary team, community stakeholders, digital health experts, app developers, and a university partner, the core committee is critical for the project's success. It builds off our 2 years of experience working with multiple stakeholders across institutions for the KSMS program. The core committee will be chaired by the principal investigator with 2 members from the multidisciplinary team, 2 members from community stakeholders, 1 member from the digital health expert team, 1 member from the parent advisory board, 1 member from the partner university, and 1 clinical research coordinator. At defined intervals (intended to be one per quarter and as required), the core committee will meet by teleconference to review the strategic course and resource allocations. The clinical research coordinator, who is also the project coordinator for KSMS, serves as the lead administrator. The core committee is responsible for initiating and reviewing overall project progress and undertaking operational decisions to ensure that the project goals are aligned. This committee plays a vital role in the mHealth app's successful implementation into clinical practice and in ensuring the project's sustainability.

Phase 2: Development of the mHealth App's Contents

Overview

In phase 2, we plan to conduct 2 focus groups with the parent advisory board (5/21, 24%), 1 focus group discussion with community stakeholders (4/21, 19%), and 2 expert panel discussions with the multidisciplinary health care team (10/21,

48%) to develop the 3 main components of the mHealth app, as detailed in the subsequent sections.

Consolidating Contextually Tailored Positive Outlier Strategies and Developing Patient-Centric Outcomes for Self-Monitoring

The 2 focus group discussions with the parent advisory board will identify practices that facilitated their engagement in the intervention and change in health behaviors as well as highlight outcomes that matter most to their families in relation to weight management. These successful positive outlier strategies will be generalized and incorporated into the app with the aim of improving other families' outcomes. Patient-centric outcomes will be incorporated as part of the self-monitored outcome measures for parents. Parents will also provide input on integrating the app into their daily lives. Parents' detailed input on activity and nutrition suggestions will be used to make these recommendations actionable and tailored contextually (eg, based on time and day of the week), increasing the effectiveness of "push" notifications and suggestions.

Synthesizing Evidence-Based Guidelines and Integrating Theory for Behavioral Strategies

The multidisciplinary team of health care providers will consist of pediatricians, dietitians, nurses, physiotherapists, exercise physiologists, psychologists, and social workers trained in pediatric obesity management. Focus groups with the multidisciplinary team will consolidate practices and incorporate evidence-based strategies, guided by expert committee recommendations for pediatric obesity prevention and Singapore's Integrated 24-Hour Activity Guidelines for Early Childhood (0-6 years) [9]. The multidisciplinary team will also review strategies from parent advisory board focus groups and evidence-based guidelines to select optimal theory-driven behavioral strategies for guiding the mHealth app design [10]. Incorporating motivational interviewing (MI) in health care settings has been shown to improve intervention engagement and commitment to the behavioral change process [11]. MI is a person-centered counseling method that supports individual autonomy and uses collaborative and nonauthoritarian interaction to work toward an individual's goal.

Incorporation of Community Resources and Integration With Community Programs

The focus group with community stakeholders aims to integrate currently available community resources (web-based and physical) that are relevant to the target population, such as community-based sports programs designed for families.

Phase 3: Development of the Prototype App

The results of phase 2 will be shared with digital health experts and app developers to outline the required app features and guide the development of multiple prototypes. Studies have shown that developing multiple prototypes in parallel (versus sequentially) leads to a superior final prototype [12]. The prototype will be developed in regulated phases before being shared with the parent advisory board, multidisciplinary team, and community stakeholders to gather their feedback through 3 separate focus groups (one for each stakeholder). The feedback obtained will include user experience, visual design, content, and logic (such as a graphical representation of families' data). Feedback will be gathered from the clinical team on the integration of the app into clinical workflows, its prescription to families, and the visualization of intervention-related data. The digital health experts and app developers will then review the feedback for integration into the prototype app before a final minimum viable product (MVP) is published.

Phase 4: Piloting the MVP and Evaluation

A fully functional MVP will be developed to focus on details beyond the prototype phase. The MVP will be pilot-tested by 10 parents for 4 weeks to detect usability issues before the final prototype is developed. Parents of children aged 4 to 7 years old with obesity will be recruited from outpatient clinics. A sample size of 10 participants in think-aloud studies has been shown to detect 80% of usability issues [13]. At the start of the pilot testing, think-aloud walkthrough interviews will be conducted. Participants will be instructed to use the app as they would any newly downloaded app, verbalizing their thoughts throughout the process. They will be encouraged to freely explore the app and ask questions to provide insights into their user experiences. Following the walkthrough interviews, participants will be asked to use the app for 4 weeks.

At the end of the 4-week period, semistructured interviews and the uMARS questionnaire will be administered. The interviews will consist of open-ended questions on participants' previous experience with mobile apps, general perceptions of the app, its most/least useful features, suggestions for improvement and usage, possible features that could exclude potential users, and factors related to engagement. Inputs on the push notifications will be obtained from parents to optimize their timing and delivery to target behavior change.

Analytics will be integrated into the app to collect a rich dataset, capturing patterns of use, particularly in relation to accessing information and completing patient-centric outcomes as defined in our secondary aims. The usability and acceptability of the mHealth app's "pull" features (educational materials and graphical representations of monitored outcomes) will be evaluated using uMARS, a 20-item measure that includes 4 objective quality subscales (engagement, functionality, aesthetics, and information quality), 1 subjective quality subscale, and 1 perceived impact scale, all measured on a 5-point Likert scale. A score of 4 and above indicates good quality [5].

High usability and acceptability will be defined as a median score of 4 out of 5 in all domains (information, engagement, functionality, aesthetics, impact, and acceptability) for parents. The user engagement aims will be defined as (1) recruited parents accessing ≥70% of the information and (2) completing patient-reported outcome measures over the 4-week period.

Results

This study received funding in February 2023. As part of phase 1, a parent advisory board was formed in March 2023 with parents who had previously participated in the KSMS pilot study and completed at least 26 hours of the program. Stakeholders were engaged in April 2023 to co-develop the mHealth app.

Stakeholders included the multidisciplinary health care team from KK Women's and Children's Hospital, the Health Promotion Board (HPB), and Sport Singapore. Digital health experts and app developers from the National University of Singapore School of Computing were also involved in developing the mHealth app.

Phase 2 was completed between April 2023 and December 2023. The first focus group discussion with the parent advisory board was held in April 2023 to identify positive outlier strategies. A preliminary mock-up app was developed and shared in focus group discussions for feedback with community stakeholders (HPB and Sport Singapore) in May 2023, followed by the multidisciplinary team in July 2023. Discussions were held with community stakeholders between June 2023 and December 2023 to integrate existing community resources and programs into the mHealth app. A second round of individual interviews with the parent advisory board was conducted in October 2023 to identify patient-centric outcomes and review the mock-up app.

Revisions were made to the mHealth app following feedback from the stakeholders and parent advisory board. Focus group discussions and individual interviews were conducted in phase 3 to obtain feedback on the revised mock-up app with stakeholders and the parent advisory board, completed between April and June 2024.

The final stage of the mHealth app development was completed in December 2024 with an MVP app. Participants were recruited to pilot-test the mHealth app and provide feedback from January 2025. Recruitment will resume in April 2025, and feedback will be collected from the participants to enhance the mHealth app.

Discussion

Expected Findings

This study outlines the co-design process of an mHealth app with health care providers, digital health experts, community partners, and families, using the IDEAS framework. We hypothesize that the app, developed through the IDEAS framework, will be usable, acceptable, and engaging for parents in managing childhood obesity.

Patient advisory committees have become increasingly important in health care, offering valuable insights into various health conditions [14]. Engaging parents as active participants in the design of this app is important to ensure that the strategies recommended for other parents will be relevant and meaningful. For patient-centric outcomes, we anticipate focusing on themes related to psychosocial wellness, as seen in other studies [15], especially considering the lower quality of life among Singaporean children with obesity [16].

Some successful positive outlier strategies identified in a United States–based study [15] include (1) making family-centric changes in health behaviors rather than child-centric changes, (2) establishing rules around health behaviors, (3) shared decision-making with health care providers on child weight management, and (4) using community resources for behavioral change. We anticipate some common themes among our local population, especially around family-centric changes, rule implementation on behavior change, and the use of immediate outcomes, which align with findings from our previous study [17]. However, strategies like shared decision-making with health care providers and the use of community resources are less likely to emerge as important themes. This is because obesity is commonly perceived as a lifestyle factor, rather than a chronic disease, with treatment not claimable under private or public health care insurance [18]. These factors may hinder help-seeking for obesity treatment and pose challenges in developing community programs for childhood obesity management. Thus, the development of this mHealth app aims to bridge the gap in available resources for managing childhood obesity.

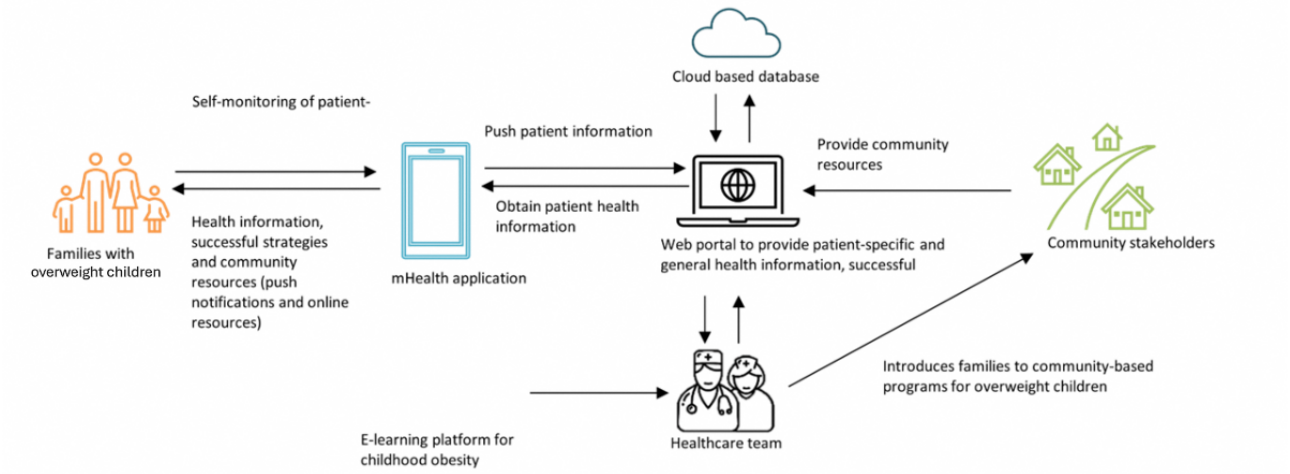
Despite research showing that parents are an integral part of pediatric obesity prevention and treatment, the currently available apps do not target parents or families but focus solely on the child. A review of mHealth apps for pediatric obesity prevention and treatment also found that most apps lacked any expert recommendations. mHealth apps have also been found to lack a theoretical basis for their development, thereby limiting their efficacy [19]. There is currently no mHealth app that integrates the strategies learned from positive outlier families with locally available community resources. Thus, this project will be the first theory- and evidence-informed mHealth app for pediatric obesity management targeted toward parents. The successful development of this mHealth app, through the use of the IDEAS framework, will also provide important information for the future development of mHealth apps for other chronic diseases, such as diabetes mellitus, to facilitate behavioral change and improve patient outcomes.

Currently, primary care providers and patients can only access pediatricians, dietitians, physiotherapists, and exercise physiologists trained in pediatric obesity management when they are referred to tertiary pediatric centers. This reliance on specialized centers can result in these services becoming overwhelmed. An mHealth app that is evidence-based, theory-driven, and developed within a design framework, can bridge this gap in providing multidisciplinary care in the community setting. Health care providers in both tertiary and primary care often face significant time constraints during consultations. Engaging these health care providers in the app's development and evaluation process can enhance its usability and acceptability, enabling its incorporation into clinical care processes.

The proposed mHealth app will thus provide the foundation for accessible multidisciplinary care in the community, scaling up the KSMS program to provide evidence-based treatment to every family with overweight children. This approach aims to help reduce complications associated with obesity.

By evaluating the potential effectiveness of these multimodal complex interventions (Figure 1) in reducing childhood obesity, improving quality of life, and reducing health care visits, this study could provide cost-effectiveness data to support informed decisions for nationwide implementation.

Figure 1. Proposed mechanism of the mobile health (mHealth) app and its future integration into health care settings, health care provider training, and community programs.



Strengths and Limitations

The key strengths of this study include the co-design approach with a multidisciplinary team and parents, as well as the development of an evidence-based, theory-driven mHealth app. These elements are critical for ensuring effective digital interventions that promote behavior change in childhood obesity management.

However, this study has limitations. Nonresponder bias may arise, as responses from participants not identified as positive outliers are not captured. Additionally, the effectiveness of the mHealth app compared to standard care is being assessed in this study.

Conclusions

An evidence-based, theory-driven mHealth app developed within a structured design framework can bridge the gap in providing multidisciplinary care for families with overweight children in the community setting. This app will also empower families to improve self-management of childhood obesity. Future studies are required to examine the effectiveness of this mHealth app in managing childhood obesity and promoting better self-management compared to standard care.

Acknowledgments

This study received funding from the Agency for Science, Technology, and Research in Singapore through the FY 21 Prenatal/Early Childhood Grant Call (H22P0M0010). We thank Prof Hock Hai Teo for his role in critically reviewing and revising the manuscript.

Data Availability

Data sharing is not applicable to this article as no datasets have been generated or analyzed during this study.

Authors' Contributions

SHT drafted, critically reviewed, and revised the manuscript. KBK, CD, ZQO, and EJKL critically reviewed and revised the manuscript. CSEC conceptualized and designed the study and critically reviewed and revised the manuscript. All authors have approved the final manuscript as submitted and agree to be accountable for all aspects of the work.

Abstract

Background: The community-based, 4-level intervention of the European Alliance Against Depression (EAAD) is simultaneously addressing depression and suicidal behavior. Intervention activities target primary care health professionals (level 1), the general public (level 2), community facilitators (level 3), and patients and their relatives (level 4). Activities comprise the digital iFightDepression tool, a guided self-management tool based on cognitive behavioral therapy.

Objective: This study aimed to present the European Union–cofunded EAAD-Best study protocol, aiming at the implementation, dissemination, and evaluation of the 4-level intervention and the iFightDepression tool in several countries across Europe.

Methods: The 4-level intervention has been implemented for the first time in Bulgaria, Estonia, Greece, and Poland. In 3 countries that have already implemented the 4-level intervention (Hungary, Ireland, and Spain), activities have been extended to new regions. In addition, the nationwide uptake of the iFightDepression tool by patients with depression has been promoted in all mentioned countries and Italy.

Results: To evaluate the implementation of the 4-level intervention and the iFightDepression tool, data related to the process, output, and outcome were collected between 2022 and 2024. Data processing and analyses started in 2023. Analyses are expected to be completed in 2024. Results are expected to be published in 2025.

Conclusions: This paper informs researchers, practitioners, and stakeholders on how to implement best practices in mental health promotion and evaluate their effectiveness.

Introduction

Depression is one of the most prevalent, severe, and undertreated mental disorders [1]. Having a diagnosis of depression is associated with a reduction in life expectancy of around 10 years or more [2]. Contributing to this is the fact that depression increases the risk of another important mental health issue—suicidal behavior [3]. Approximately 703,000 people die by suicide every year [4] and the number of attempted suicides is considerably higher and rising [5]. The vast majority of completed suicides occur in the context of depressive disorders and other mental illnesses [2].

Due to the numerous factors contributing to suicidal acts, the best approach to address suicidal behavior is multifaceted interventions [6] that have been shown to be most effective [7]. Such multilevel intervention programs have been developed in different countries and either focus exclusively on suicidal behavior or simultaneously aim to improve care for people with depression [6]. A recent systematic review concluded that the most promising multifaceted intervention to prevent suicide is the 4-level intervention approach by the European Alliance Against Depression (EAAD) [8]. The authors reviewed 56 publications (describing 47 unique studies) in Linskens et al [8] on community-based or population-level suicide prevention strategies. EAAD's 4-level intervention offered the most evidence for its effectiveness, while evidence for other single- or multistrategy interventions was either unclear, inconsistent, or lacking. The authors, therefore, suggest that further randomized or observational studies are needed. The EAAD-Best project introduced in this paper will contribute to this identified research need.

The 4-level intervention has been implemented in local communities and simultaneously runs activities at 4 intervention levels (Figure 1).

- Level 1: Interventions aim to improve the capacity of general practitioners (GPs) and mental health care professionals (MHCPs) regarding the management of depression and suicidality. This is achieved by training sessions focusing on early detection, diagnosis, and treatment.
- Level 2: Interventions target the broader public and aim to raise awareness, increase knowledge on depression and suicide, reduce stigma, and improve help-seeking behavior. This is achieved through a public awareness campaign. It emphasizes the need for treatment, the availability of effective treatment options, and support services. Key messages are (1) depression is a real disease; (2) depression can affect anyone; (3) depression has many faces; and (4) depression can be treated.
- Level 3: Interventions aim to improve the capacity of community facilitators and gatekeepers concerning the recognition and handling of depression and suicide risk. Community facilitators and gatekeepers are nonmedical professionals who have a public and social function in society (geriatric caregivers, priests, pharmacists, police, journalists, counselors, midwives, teachers, social workers, managers, and company physicians). They frequently interact with people who are experiencing depression or suicidal ideation and are therefore well positioned to provide general preventive and supportive services. Journalists are informed about the risk of triggering the so-called Werther effect (copycat suicides) and are offered a media guide with recommendations on how to report and not to report about suicidal acts in order to reduce the risk of unwanted effects of media coverage. Capacity building is achieved through train-the-trainer sessions adapted to the specific needs of (subgroups of) community facilitators.
- Level 4: Interventions aim to support patients who are depressed and/or suicidal and their relatives by supporting self-help (eg, implementation of self-help groups and promoting the iFightDepression tool) and providing information about depression, suicidal behavior, and treatments. Identifying locations where people frequently take or attempt to take their lives in a certain region and starting activities to secure these places is also an element within the 4-level intervention.

Implementation of the 4-level intervention is supported by the EAAD coordination center that developed an implementation guide, a catalog of step-by-step recommendations (eg, how to organize a press conference and how to recruit GPs), and has accumulated a broad range of intervention and evaluation materials over the last years. Many materials have already been translated into various languages including the iFightDepression awareness website [9]. This website provides information about depression, its causes, symptoms, and treatments and is publicly accessible. The effectiveness of the 4-level intervention to reduce suicidal behavior was demonstrated by several studies in different countries, although not all evaluated community-based interventions showed the expected positive effects [10-13].

Within the 4-level intervention, the web-based iFightDepression tool is an important intervention component that can help reduce the treatment gap concerning psychotherapeutic interventions [14]. It is based on the principles of cognitive behavioral therapy and supports the self-management of people with mild-to-moderate forms of depression. Access and guidance to the tool are provided by health care professionals. The safety [15] of the tool and its efficacy [14,16] have been assessed for mild-to-moderate symptoms of depression in a randomized controlled trial with an active control group [14] and a study with a treatment-as-usual control group [16]. It is possible that patients with severe depression can benefit from digital interventions [17], but the risk of failing to use the intervention due to motivational problems that are often part of major depression also seems more likely and could cause further frustration and self-criticism. The recommended use of the iFightDepression tool is therefore currently limited to the patient

groups for which solid evidence is available, but as research progresses, this might be extended.

Figure 1. European Alliance Against Depression's community-based, 4-level intervention.

The 4-level intervention has been successfully adapted to different cultures and health care systems in more than 120 regions within and outside of Europe [18]. Important lessons that have been learned with growing experience are summarized as follows:

1. Targeting optimized care of depression and suicide prevention simultaneously is highly cost-effective and sensible for several reasons. Both are highly important mental health issues and depression is one of the key causal factors of suicidal behavior. Suicide-preventive measures unrelated to depression, such as access to lethal means, can easily be integrated in the 4-level intervention program. Given the high prevalence of depression, a public campaign on depression is likely to have a greater resonance than an exclusive suicide prevention campaign. The latter may further bear the risk of reducing the threshold for suicide due to the normalization of suicidal behavior or unfavorable secondary reporting, for example, in social media.
2. Being simultaneously active at all 4 intervention levels creates synergistic and catalytic effects [19]. An example of a synergistic effect is that the public health campaigns (level 2) not only increase awareness and knowledge in the general population but also increase the motivation of GPs and gatekeepers to participate in the training offered (levels 1 and 3). An example of a catalytic effect is the observed improvement of intersectoral cooperation between health professionals in communities participating in the 4-level intervention, an effect that has not directly been targeted by the activities [19].
3. Depending on the culture and health care system, intervention activities must find the right balance between bottom-up and top-down approaches. A bottom-up approach creates an ownership feeling in the community and is helpful to achieve sustainability. However, in countries with a less developed civil society and a more hierarchical political culture, more top-down support is required.
4. The pharmaceutical industry should not be involved in funding and implementation activities as this may reduce credibility and create conflicts of interest.
5. The implementation of the 4-level intervention in an initial model region raises interest in other regions, causing them to follow suit. The creation of a learning network of all implementing regions, which meet 2 or 3 times per year to exchange experiences and support each other, has proven useful.

Taking these and other lessons learned into account, the EAAD-Best project (full title: "Adapting and implementing EAAD's best practice model to improve depression care and prevent suicidal behavior in Europe") was set up and received funding from the Third Health Program (HP-PJ-2020) of the European Union (EU). As the title describes, the overall objective was the improvement of depression care and suicide

prevention in Europe given the strongly identified need for correct diagnoses of depression and suicidality as well as effective, evidence-based interventions. The project ran from April 2021 to March 2024 and allowed us to further adapt the 4-level intervention to new contexts and evaluate its effectiveness to add to the sparse database available for multifaceted suicide prevention interventions [8]. This paper aims to introduce the EAAD-Best project as a best practice model for the implementation of mental health interventions and their evaluation.

Methods

Goals of EAAD-Best

The central goals of EAAD-Best were the dissemination of the 4-level intervention to further regions in Europe and the nationwide uptake of the digital iFightDepression-guided self-management tool. These goals were achieved by:

1. The implementation of the 4-level intervention in model regions of EU countries in which the intervention had not yet been established (ie, implementation countries).
2. The dissemination of the 4-level intervention to new regions in EU countries in which this approach had already been implemented in a model region (ie, transfer countries).
3. The nationwide promotion the iFightDepression tool in participating countries and recruiting health professionals as guides who offer the tool to their patients.

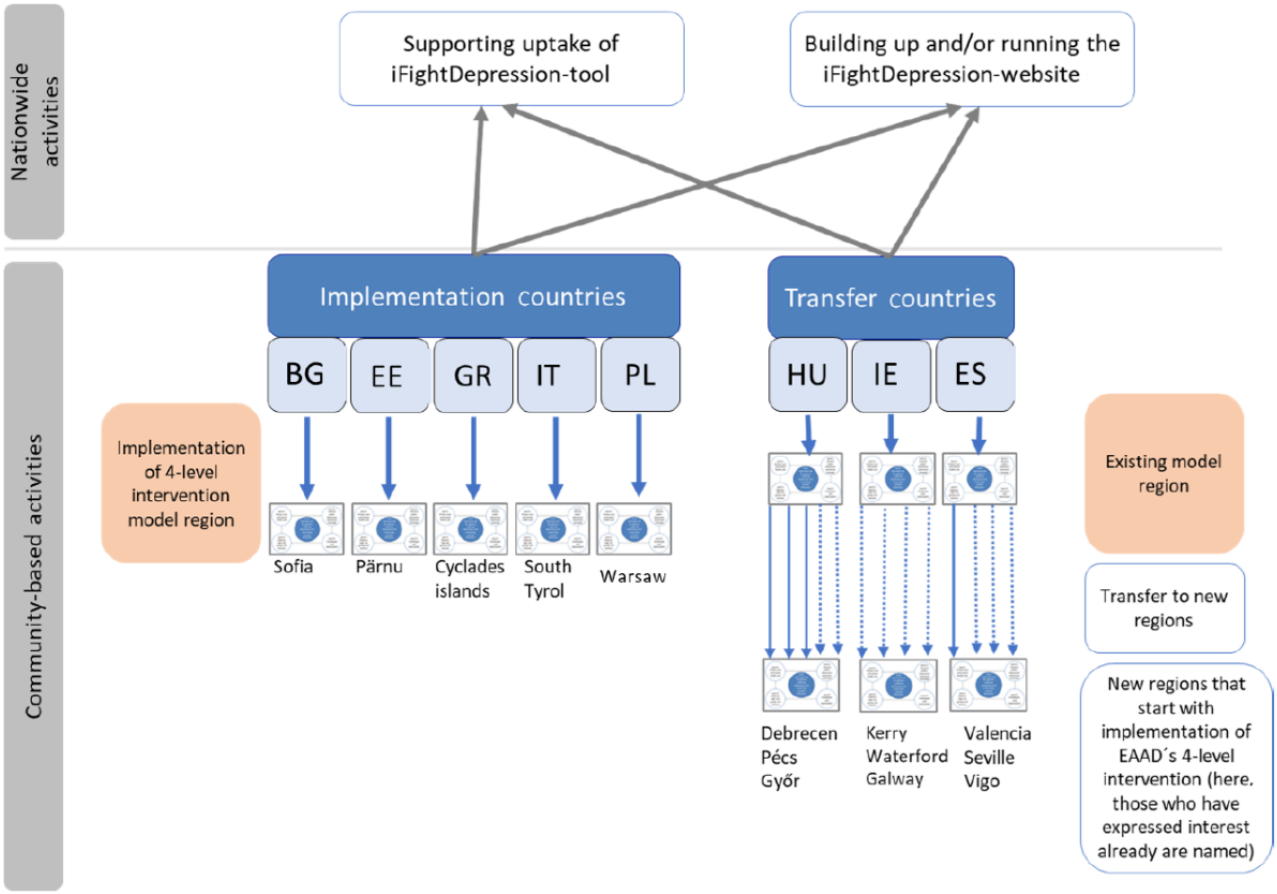
Overview of EAAD-Best Activities

Overview

The basic structure of EAAD-Best activities is illustrated in Figure 2.

The participating countries were chosen to represent the different regions of the EU. They differ not only in population and gross national income per inhabitant but also in their health care systems and national approaches to mental health, including the regional health care system facilities for patients with depression.

Figure 2. Basic structure of activities within EAAD-Best. *Due to the dropout of the Italian consortium member, Italy is no longer a full-fledged implementation country but focuses on the implementation of the iFightDepression tool and awareness website. BG: Bulgaria; EAAD: European Alliance Against Depression; EE: Estonia; ES: Spain; GR: Greece; HU: Hungary; IE: Ireland; IT: Italy; PL: Poland.



Implementation Countries

In 4 countries, the 4-level intervention was implemented for the first time: Bulgaria, Poland, Estonia, and Greece. Italy was named as another implementation country in the initial EAAD-Best proposal, but the Italian partner changed during the project duration and therefore could only participate in the implementation of the nationwide uptake of the iFightDepression tool.

Model regions were Sofia (Bulgaria), Warsaw central district (Poland), Pärnu (Estonia), and 2 regions in Greece (ie, North

Attica and Cyclades Islands). They were chosen based on accessibility for project partners and identified needs.

Transfer Countries

A total of 3 countries (Ireland, Spain, and Hungary) with previous experiences with the 4-level intervention and existing model regions offered the intervention to new regions. Ireland extended activities to Kerry and Cork. Spain targeted Valencia, Seville, Alcala la Real, and Vic, and Hungary focused on Szeged, Békéscsaba, Szentendre, and Baja. The regions were chosen based on accessibility for project partners, identified needs, and expressed interest.

The iFightDepression tool was promoted nationwide in all participating countries. It targets persons with mild-to-moderate forms of depression. Specific inclusion criteria are (1) age ≥15 years; (2) access to a computer, an internet connection, and an email account; and (3) mild-to-moderate forms of depression. Exclusion criteria are (1) age <15 years, (2) severe depression, (3) acute suicidality, and (4) current substance abuse.

Implementation Processes in EAAD-Best

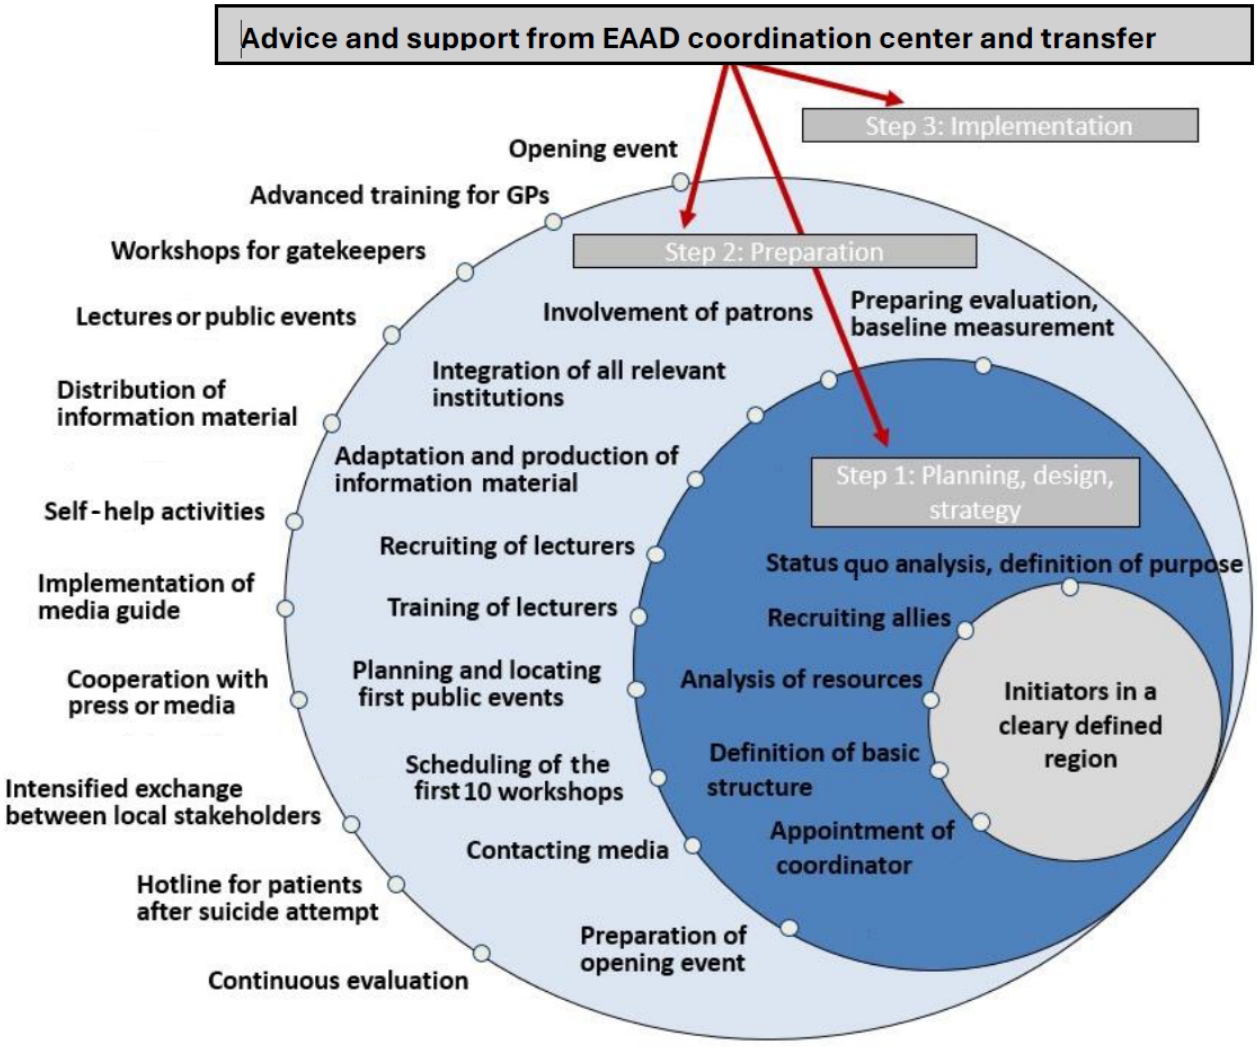
Initial Implementation of the 4-Level Concept in Implementation Countries

The process of implementing the 4-level intervention in implementation countries can be broken down into 3 steps:

- Step 1: Planning, design, and strategy
- Step 2: Preparation
- Step 3: Implementation

Within each step, there is a range of tasks and actions to consider (Figure 3).

Figure 3. Foreseen activities for planning, preparing, and implementing the European Alliance Against Depression's 4-level concept in the implementation countries. EAAD: European Alliance Against Depression; GP: general practitioner.



Step 1: Planning, Design, and Strategy

Status quo analyses in the model regions identify relevant stakeholders and institutions as well as potential gaps and limitations of the local care system (ie, "As Is" state). Next, the "To Be" state is defined (ie, what the local alliance seeks to achieve). Specific objectives can be derived by comparing the "As Is" state with the "To Be" state.

The identified network of stakeholders should be broad and include existing local health care initiatives and personal links

and partnerships. Stakeholders or potential sponsors should be involved in the preparation phase to increase their identification with the alliance.

Next, the alliance initiator is identified. It can be a person (eg, a psychiatrist), a small organization (eg, a self-help group), or an institution (eg, a psychiatric hospital). They should decide about the basic structure of the local alliance (eg, will it be part of an existing organization or will a nongovernmental organization be founded?). A small steering group (about 2-5 people) for leadership of the alliance should be formed and a local coordinator should be appointed.

Step 2: Preparation

In the preparation phase, the alliance is being formed and the interested institutions and stakeholders become integrated. Regular meetings are crucial, as most questions and fundamental decisions occur in this stage.

Materials required for activities on all 4 intervention levels must be translated and culturally adapted to regional needs (eg, public relation campaign materials, level-1 and -3 training materials, and iFightDepression awareness website). Templates are provided by the EAAD coordination center.

The professional groups that will receive training as part of intervention activities on levels 1 and 3 are defined and recruited as lecturers to run training sessions for other GPs, MHCPs, and community facilitators or gatekeepers. The first of these train-the-trainer training sessions take place and further ones are scheduled, so that respective dates can be announced at the opening ceremony and activities can start immediately afterward. A train-the-trainer information package including the referral of patients to the iFightDepression tool is provided by the EAAD.

A large public opening ceremony and further public events are prepared. Many types of public events are possible, such as public talks, podium discussions, theme nights, information booths, school projects, art exhibitions, or religious services. A range of events that are best suited to maximize contact with the target group is advisable.

A prominent and broadly respected person in the region should be involved as a patron. They do not need to have any connection with depression or suicide but should be willing to publicly support the alliance and its aims. A prominent patron will help gain support and cooperation from many partners, including the media.

The media are contacted actively, for example, by offering press releases on events or interviews on depression-related topics to journalists. The use of social media is also advised. It is recommended to appoint a person within the alliance responsible for all social media activities and "marketing" of the campaign.

Step 3: Implementation

During the implementation phase, different activities will be run simultaneously at the 4 levels. EAAD-Best partners focus on maintaining effective and frequent channels of communication with all alliance partners in this phase. Regular project meetings are essential to evaluate the status of all work, determine the next steps, and monitor the financial resources and compliance with an agreed timeline. Alliance partners receive feedback on their work to ensure high motivation and quality of work. If necessary, they are reminded of their responsibilities.

One key activity is the opening ceremony with all the stakeholders and patrons. Holding a press conference at the opening ceremony is advisable and is a good opportunity to provide local media with a press kit and media guidelines on reporting on suicides. A leaflet about the regional alliance against depression with basic information about depression and a map of contacts where to get help locally and ways to support the alliance (by donating, as a volunteer) should be distributed at the event. Setting up a public newsletter is a good way to promote the alliance and attendees at the opening ceremony can be invited to sign up for it. A range of material templates for the opening ceremony are provided by EAAD.

The main activities during the implementation phase are the recruitment and training of health professionals (level 1) and community facilitators or gatekeepers (level 3). The training can be delivered in person or through videoconferences.

Other activities concern an ongoing involvement with the media and the distribution of informative materials (especially flyers and posters) as a crucial aspect of the public awareness campaign (level 2). Talks and public events should take place continuously during the intervention period, as this not only benefits the dissemination of alliance activities but also indirectly raises awareness about depression as a health problem. Patients and relatives should be included as speakers at the events, as this will help fight stigma.

Dissemination of the 4-Level Concept to New Regions in Transfer Countries

In the 3 transfer countries, the goal was to expand the 4-level intervention activities from an existing model project to new regions. To achieve this goal, the following intervention steps were taken:

- Through press releases and other media activities, national and regional health politicians and stakeholders as well as nongovernmental organizations and self-help organizations were informed about the 4-level intervention concept. These activities should raise interest and motivation to start their own local alliances against depression and suicidal behavior in different communities.
- Those who were interested in starting a new regional alliance were supported in several ways: (1) financial support (ie, with a start-up budget of €3.800 [US $4.02]), (2) train-the-trainer sessions, (3) access to EAAD implementation materials and help with their local adaptation, and (4) continuous advice by the EAAD coordination center.
- The existing National Coordination Centre established a national learning and dissemination network of regional alliances by inviting all interested stakeholders (those implementing or interested in implementing regional 4-level interventions) to regular meetings. These allowed us to exchange experiences and best practices but also involved

workshops on topics such as fundraising, involving volunteers, or organizing press conferences.

Nationwide Uptake of the iFightDepression Tool in All Participating Countries

In order to make the iFightDepression tool available nationwide in all participating countries (ie, implementation and transfer countries), the following intervention steps have been implemented: (1) translation and cultural adaptation of the tool for all countries as needed; (2) in Greece, Italy, Hungary, and Spain, the iFightDepression tool was already implemented, and in all other intervention countries (Estonia, Bulgaria, Poland, and Ireland), a coordination site was appointed to manage the use of the iFightDepression tool; (3) advertised the tool to the general public and health professionals (GPs, MHCPs) through press releases, other media activities, and approaching professional organizations for GPs and MHCPs; and (4) trained health professionals to become guides and give patients access to the tool. The trainings were delivered in person or through videoconferences. e-Learning materials for GPs have been developed that allow them to complete the training at their convenience. It is followed by a test assessing correct understanding.

Evaluation of the Implementation of the 4-Level Concept in Implementation and Transfer Countries

Overview

Our evaluation approach considered monitoring and outcome measures. The monitoring evaluation involved process indicators addressing the extent to which planned activities took place in implementation and transfer countries. It also considered output indicators assessing the quantity and quality of the implemented activities. The outcome evaluation will test to what extent the 4-level intervention generated the expected positive effects in health professionals, community facilitators, and iFightDepression tool users.

Evaluation activities in implementation and transfer countries use the same materials and procedures described below.

Monitoring Evaluation

Process and output indicators were collected through a monitoring instrument twice per year. It presented a selection of core indicators of the 4-level intervention activities (eg, occurrence of the opening event and the number of attendees) to track whether planned activities took place and to assess their quantity and quality.

Outcome Evaluation

Given the limited time frame of this project, it was not feasible to evaluate whether the intended long-term outcomes of the 4-level concept (ie, reduction of suicidal behavior and improvements in the care of patients with depression) were achieved. Therefore, intermediate outcome indicators that are more directly linked to the operational goals of the 4-level intervention were selected. These are changes in self-judgment of the performance, importance, and competence of treating persons with depression and suicidal ideation. They were measured in health professionals and community facilitators participating in the level-1 and level-3 training sessions using self-developed questionnaires.

Data were collected at 2 measurement time points: before and immediately after the level-1 and -3 trainings. Informed consent was obtained before the first training session.

Evaluation of the iFightDepression Tool in All Participating Countries

To evaluate the iFightDepression tool and its effects, users were asked to complete 2 outcome measures. Their informed consent was obtained when registering for the iFightDepression tool, and all data were directly collected within the application. First, after their registration, users were asked to complete a self-developed survey measuring initial expectations regarding the tool. Then, over the following 8 weeks, mental well-being was assessed on a weekly basis with the Patient Health Questionnaire (PHQ-9) [20].

Ethical Considerations

Participating in any evaluation activity will require informed consent. Ethical approval has been obtained in all implementation and transfer countries before the start of data collection. The names of the ethics committees that approved the study are as follows: (1) Bulgaria: Central Ethics Committee of the Ministry of Health Republic of Bulgaria; (2) Estonia: Tervise Arengu Instituudi inimuuringute eetikakomitee, Research Ethics Committee of the National Institute for Health Development; (3) Greece: Department of Education, Research and Documentation Association of Regional Development and Mental Health; (4) Poland: ethics committee of the Maria Grzegorzewska University; (5) Hungary: Egészségügyi Tudományos Tanács, Tudományos és Kutatásetikai Bizottság; (6) Ireland: Clinical Research Ethics Committee of the Cork Teaching Hospitals; and (7) Spain: Comité Ético de Investigación Clínica de Galicia; Comité Ético de Investigación del Hospital Clínico de Valencia; and Comité de Ética de Investigación de los Hospitales Universitarios Virgen Macarena.

Results

Data collection was completed in March 2024. Data processing and analyses commenced in the autumn of 2023 and are expected to be completed by the end of 2024. Results are expected to be published in 2025.

Discussion

Principal Outcomes

EAAD-Best had three main objectives: (1) implementation of the 4-level intervention in model regions of EU countries in which the intervention had not yet been established, (2) dissemination of the 4-level intervention to new regions in EU countries in which it had already been implemented, and (3) nationwide promotion of the iFightDepression tool in participating countries. In general, all these objectives have been successfully achieved, as alliances against depression were established in all participating countries, iFightDepression guides were trained, and increasing numbers of people started using the tool. Analyses of the collected monitoring data

(currently ongoing, results expected to be published in 2025) will allow a more fine-grained conclusion regarding the quantity and quality of intervention activities. In line with previous studies (eg, [8,14]), we anticipate that the outcome evaluation (results expected to be published in 2025) will show that training of GPs, MHCPs, and gatekeepers will increase their subjective competence and their willingness to treat persons with depression and suicidal ideation in the future. Furthermore, iFightDepression tool users are expected to report a decrease in depressive symptoms. The anticipated results will add to the scarce literature on suicide prevention interventions [8] and, most importantly, will extend existing evidence on the effectiveness of the 4-level intervention and the iFightDepression tool to new regions and countries across Europe.

The following sections will discuss some practical issues involved in implementing and evaluating the 4-level concept and the iFightDepression tool and will highlight not only some of the challenges but also the strengths of the approach.

Participation of Professionals in EAAD Training

Participation in EAAD training sessions is completely voluntary. Professionals will not be remunerated for their participation. Recruiting GPs can be especially challenging due to time constraints and high workloads. Accordingly, trainings focus on practical materials for GPs and their patients, and are delivered in a convenient fashion (eg, in the evenings and online). The introduction of e-learning materials to allow GPs to complete the iFightDepression guide training has been very well received. It has also proven helpful to be able to award Continuing Medical Education points for training completion.

Training professionals will strengthen both their expertise in recognizing mental health issues and their ability to offer support. It is important to stress those benefits in communications. In particular, becoming a guide for the iFightDepression tool enables GPs to provide self-management support based on cognitive behavioral therapy to their patients.

Potential Risks and Benefits of Using the iFightDepression Tool

Previous studies have shown that the iFightDepression tool has beneficial effects on mental health without causing any adverse effects [14,15]. Therefore, the benefits of participation are expected to outweigh any potential risks (eg, suicidal crises can be overlooked) and unwanted effects (eg, an increase in rumination and somatization due to self-monitoring). In addition, all participants will remain within the usual care of their GPs or MHCPs while using the iFightDepression tool.

The expected benefits of the iFightDepression tool include increased uptake of treatment as online self-help tools are more accessible than traditional forms of psychological support. Hence, the iFightDepression tool has the potential to close the gap between people with depression seeking help and the limited immediate access to psychotherapy [1]. Furthermore, there will be a lower threshold to engage certain people who may be reluctant toward traditional mental health services. Given that the iFightDepression tool is used online and anonymously, users face no risk of stigmatization. The early detection of suicidal ideation and severe symptoms of depression through the inclusion of the PHQ-9 within the tool will help prevent attempted and completed suicides. In particular, the PHQ-9 contains 1 item that directly addresses suicidal ideation. If participants choose a response option indicating that they are experiencing suicidal thoughts or obtain a total score of 15 or above (indicating moderate-to-vigorous symptoms of depression), they will receive an automatic message suggesting contacting their health care professional, GP, or a quality-assured support service. Finally, the tool will strengthen the coping skills of participants, enabling them to manage current and future experiences of depression better.

Sustainability

The ultimate goal of EAAD-Best is that activities will continue to run and expand from model projects to national networks of alliances against depression upon project completion. In general, sustainability is a key aspect of the 4-level intervention. It has been considered in its development, for example, by making it as cost-effective as possible, flexible, and adaptive to various contexts and encouraging activities leading to an ownership feeling in the communities. Sustainability is further considered within implementation activities by asking partners after a defined intervention phase (2-3 years) to reflect on previous and ongoing activities, their main partners and stakeholders, experienced challenges, and facilitators so on. EAAD further recommends partners to create a national coordinator position that, on the basis of the experiences from the model project, can support and coordinate the dissemination of the approach in further cities and regions to make it efficient, cost-effective, and impactful.

Evaluation Challenges

Performing applied research like the presented implementation science project can pose challenges such as variability in implementation fidelity. This project tried to minimize such risks by implementing certain measures or processes. In general, questionnaires were always kept to a minimum to avoid overburdening project partners, professionals involved in trainings, and patients using the iFightDepression tool. The dedicated work package running evaluation activities in EAAD-Best provided templates for all assessments and reported completion rates at consortium meetings so that potential difficulties in certain countries could be identified and addressed right away. The training evaluations could be completed online or through paper and pencil to suit the local preferences and increase data completion. To match repeated assessments of training participants, a subject-generated identification code was used to allow correct matching while ensuring anonymity. Future publications on the results of the EAAD-Best project will discuss identified challenges and the chosen solutions in more depth.

Conclusion

The EAAD-Best project will contribute to improved depression care and prevention of suicidal behavior in Europe by extending the application of the 4-level intervention and the uptake of the iFightDepression tool. Besides supporting the implementation of best practices in mental health promotion and treatment,

EAAD-Best will also add to the implementation research evidence base in the area of mental health interventions. Implementing and evaluating a multilevel intervention, such as the 4-level intervention, bears certain risks and challenges, for example, convincing health professionals to join level-1 trainings, establishing wide and consistent networks of stakeholders, and finding funding opportunities to maintain and extend activities upon project completion, and so on. Lessons learned and identified pitfalls will be shared once the monitoring and outcome analyses have been completed (expected by the end of 2024 with resulting publications in 2025), to avoid costly mistakes and ensure an efficient implementation process with a wide and enduring impact beyond the EAAD-Best project in the future.

Acknowledgments

The authors acknowledge the EAAD-Best consortium. The present project received funding from the European Union's Third Health Program (HP-PJ-2020; grant 101018325). Although the described activities were cofunded by the European Union's Third Health Program, the views and opinions expressed are, however, those of the authors only and do not necessarily reflect those of the European Union or the European Health and Digital Executive Agency (HADEA). Abstract

Background: Bulimia nervosa and related syndromes (BN-S) characterized by binge eating vary considerably in illness severity and course. Using the Research Domain Criteria framework of the National Institute of Mental Health, we developed a model positing that the same set of physiological consequences of weight suppression (WS; defined as the difference between the highest and current adult body weight) contribute to binge-eating severity and maintenance by (1) increasing the drive or motivation to consume food (reward valuation effort [RVE]) and (2) decreasing the ability for food consumption to lead to a state of satiation or satisfaction (reward satiation).

Objective: Our funded project aimed to test concurrent associations among WS, physiological factors (leptin concentrations and postprandial glucagon-like peptide 1 [GLP-1] response), behavioral indicators of RVE (breakpoint on progressive ratio tasks) and reward satiation (ad-lib test meal intake), self-report of these core constructs, and binge-eating severity in BN-S (aim 1); test prospective associations to determine whether WS predicts BN-S maintenance in longitudinal models and whether posited mediators also predict BN-S maintenance (aim 2); and determine whether associations between WS and BN-S severity and maintenance are mediated by alterations in leptin levels, GLP-1 response, RVE, and reward satiation (aim 3).

Methods: We aimed to recruit a sample of 320 women with BN-S or noneating disorder controls, with BMI from 16 kg/m^2 to 35 kg/m^2, for our study. The study included diagnostic interviews; questionnaires; height, weight, and percentage of body fat measurements; weight history; fasting leptin level; postprandial GLP-1 and insulin responses to a fixed meal; and ad-lib meal and progressive ratio tasks to behaviorally measure reward satiation and RVE, respectively, at baseline, with at least 78.1% (250/320) of the participants providing data at 6- and 12-month follow-up visits. Data will be analyzed using structural equation models to test posited pathways.

Results: Data collection began in November 2016 and ended in April 2023, pausing in-person data collection from March 2020 to February 2021 due to the COVID-19 pandemic. Of 399 eligible women enrolled, 290 (72.7%) provided clinical, behavioral, and biological data at baseline, and 249 (62.4%) provided follow-up data. Measures demonstrated strong psychometric properties.

Conclusions: We seek to identify biobehavioral predictors to inform treatments that target key factors influencing the severity and course of binge eating. These data, supported solely through federal funding, can inform questions emerging from recent interest and controversy surrounding the use of GLP-1 agonists for binge eating.

Introduction

Background

On March 6, 2013, the National Institute of Mental Health (NIMH) released a request for applications titled "Advancing Eating Disorders Research through Dimensional Studies of Biology and Behavior (R01)" to stimulate research using the Research Domain Criteria (RDoC) framework to identify mechanisms underlying eating disorders. In response, our team submitted an application that addressed key requirements. Specifically, we proposed a model that (1) was transdiagnostic, bridging categories in the *Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition* (*DSM-5*) that involve recurrent binge eating; (2) was based on 2 RDoC positive valence domain constructs to explain the 2 defining features of binge eating in the *DSM-5*, including overconsumption of food and loss of control (LOC) over eating; (3) measured constructs and clinical features dimensionally, from a state of health to disease; and (4) used 3 units of analysis, including self-report via interview and questionnaire and biological and behavioral measurement. Our model translated work emerging from basic neuroscience studies of ingestive behavior in rodents to understand the severity and maintenance of bulimia nervosa (BN) and related syndromes (BN-S). This report provides an overview of our explanatory model, supporting literature informing our aims and hypotheses; our protocol for testing hypotheses and adjustments required by the onset of the COVID-19 pandemic; our data analytic plan; our timeline, including recruitment and retention over follow-up; a description of our sample; and psychometric properties of our measures. With data collection completed, this report addresses the feasibility of our approach to testing our model, and our discussion focuses on the implications of potential findings for the assessment, diagnosis, and treatment of eating disorders characterized by binge eating.

Explanatory Model

A comprehensive review of our explanatory model, including background literature and preliminary data, is available in an open-access article [1]. We proposed that weight suppression (WS), originally defined as the difference between the lifetime highest adult weight and current weight [2], represented a dimensional, transdiagnostic risk and maintenance factor for binge eating in eating disorders. Furthermore, we proposed that WS, independent of current adiposity, contributed to reduced circulating leptin levels, which contributed to a blunted glucagon-like peptide 1 (GLP-1) response to food intake, and that these reductions contributed to alternations in 2 RDoC constructs, reward valuation and reward satiation. Reward valuation represents "benefits of a prospective outcome [...] by reference to external information, social context (eg, group input), and prior experience" [3], and reward valuation effort (RVE) can be measured as the amount of work a reward is worth [4]. In contrast, reward satiation represents "the change in incentive value of a reinforcer over time as that reinforcer is consumed or experienced" [3], and reward satiation can be measured as the termination of reward consumption when it is freely available [4]. Disrupted RVE explains excessive appetitive drive to consume a reward, despite its costs, leading to LOC while eating. Perturbed reward satiation explains the diminished ability to reach a state of completion or satisfaction during consumption, leading to excessive food intake. LOC and excessive food intake represent the defining features of binge-eating episodes, and our model sought to explain both the severity and maintenance of BN-S defined by binge-eating episodes across *DSM-5* eating disorder diagnoses.

Supporting Literature

Women with BN often have a BMI within the range considered healthy [5], belying an average WS of 7.8 kg [6-14]. Cross-sectional and prospective studies support significant associations between greater WS and BN-S severity [9,14,15] and maintenance [6,8,9], controlling for age, BMI, body image disturbance, and dietary restraint [9,14]. In addition, robust evidence supports that greater WS predicts future weight gain [7,10,16-19]. This last point underscores how WS represents a state resulting from weight loss, which is difficult to maintain due to biological consequences known to influence ingestive behaviors. Our literature review focused on findings translated from basic neuroscience into clinical research that contribute to weight gain and may also impact the risk for binge-eating episodes.

Biological Consequences of Weight Loss

Weight loss includes loss of white adipose tissue, the primary source of the hormone leptin [20]. Leptin crosses the blood-brain barrier, providing a signal of stored energy to neural regions influencing ingestive behavior [20]. In addition to significant and large (r>0.90) positive associations between fat mass and circulating leptin levels [21], weight loss impacts leptin levels

independently of BMI [21,22]. Our previous work supported a significant association between greater WS and lower leptin levels, controlling for BMI [23,24] and body fat percentage [23].

Importantly, although WS and leptin levels represent states rather than traits, both demonstrate relative stability throughout the day and are unlikely to directly influence eating onset and termination. Instead, leptin modulates peripherally released meal-related signals that dynamically respond to changes in nutritional intake and impact ingestive behavior [25]. These signals include ghrelin, cholecystokinin, insulin, glucose-dependent insulinotropic polypeptide, secretin, peptide tyrosine tyrosine, insulin-like peptide 5, neurotensin, substance P, and GLP-1. The hormones relay information to the brain about acute changes in energy needs via stimulation of the vagus nerve, with some signals crossing the blood-brain barrier to bind to receptors in neural circuits that impact feeding [25]. Among these, our model focused on GLP-1 based on emerging research on its role in both reward valuation and reward satiation led by one of our investigators [26-30].

GLP-1 is released by L cells in the intestine, and research in rats suggested that leptin potently stimulated postprandial GLP-1 release via leptin receptors on intestinal L cells [31,32]. Thus, our model posits that lower leptin level is associated with blunted postprandial GLP-1 response. Supporting this prediction, individuals with higher leptin levels have demonstrated more robust GLP-1 responses to food intake [33]. These cross-sectional associations appear to reflect the influence of leptin on GLP-1 levels, rather than the reverse, as neither meal-induced increases in GLP-1 nor exogenous GLP-1 administration influence leptin levels in healthy volunteers [34,35]. Thus, our model predicts associations among greater WS, lower leptin levels, and blunted GLP-1 response to food intake, which then influence food intake via alternations in RVE and reward satiation.

Impact of Peripheral Leptin Levels and GLP-1 Response on Reward Valuation and Reward Satiation

Circulating leptin crosses the blood-brain barrier and binds to leptin receptors in many brain regions, including those involved in reward valuation (ventral tegmental area [VTA] and nucleus accumbens [NAc] [36] and reward satiation (several regions of the hypothalamus and the hindbrain) [37]. Peripherally administered leptin inhibits dopamine projections from the VTA to the NAc [36]. In the arcuate nucleus (Arc) of the hypothalamus, leptin inhibits neurons containing neuropeptide Y and agouti-related protein (NPY/AgRP) and activates neurons containing pro-opiomelanocortin and cocaine- and amphetamine-regulated transcript (CART) [37]. Mesolimbic dopamine signaling impacts many aspects of reward responsiveness [4,38], including RVE, measured as greater effort (breakpoint) in a progressive ratio (PR) task for reinforcers (eg, food, drugs of abuse, and intracranial self-stimulation) [39-42]. Manipulation of leptin receptor function in the VTA supports leptin's role in reward valuation. In a PR task for food reward, breakpoint was increased by knockdown of leptin receptor expression in the midbrain, including the VTA, but not the hypothalamus [43] and directly in the VTA, but not the substantia nigra [44].

Leptin activation of pro-opiomelanocortin/CART neurons decreases food intake in ad-lib meals across species, including humans [45]. In contrast, NPY/AgRP potently stimulate increased food intake [37]. Thus, when an organism loses adipose tissue (a state marked by WS), leptin levels decrease, activation of pro-opiomelanocortin/CART neurons decreases, and NPY/AgRP neurons remain active and increase ad-lib intake to return the organism to a state of energy balance [37]. Leptin infusions in the Arc [46] decrease ad-lib food intake in rats, and selective deletion of leptin receptors in pro-opiomelanocortin and AgRP neurons increased meal size in mice [47]. Thus, lower leptin levels contribute to diminished responsiveness to satiating signals during food intake. However, the clear causal effects of acute leptin administration in animal models may not reflect the physiological role of leptin in humans, given the noted within-day stability of both WS and circulating leptin levels. That is, an organism cannot lose and gain sufficient white adipose tissue from one meal to the next or within one meal to account for meal initiation or termination via physiological changes in leptin levels. Moreover, our previous work supported significant associations between greater WS and both lower leptin levels and a higher breakpoint on a PR task, and it also found a small negative association between leptin levels and breakpoint [23], further supporting a potential intermediary role for GLP-1.

Peripheral GLP-1 stimulates the vagus nerve, causing activation of the nucleus of the solitary tract (NTS), where central GLP-1 preproglucagon neurons are located [48]. Similar to the effect of leptin levels on GLP-1 release in the periphery, central leptin administration enhances GLP-1 release from preproglucagon neurons of the NTS [49,50]. GLP-1 neurons of the NTS project to multiple brain regions, including the VTA and NAc, where GLP-1 influences RVE [26,31,50-52], as well as to the Arc, paraventricular nucleus of the hypothalamus, and hindbrain, where it contributes to reward satiation [31,52]. In rats, 50% of VTA dopamine neurons express GLP-1 receptors [51], 30% of GLP-1 neurons in the NTS project to the VTA [53], and 40% project to the NAc [26,53]. This positions GLP-1 as a prime candidate for examining how *acute* changes in food intake influence reward pathways in the brain. Infusion of the potent GLP-1 agonist Exendin 4 in the VTA and NAc reduced breakpoint on a food PR task [54], and peripheral administration of a GLP-1 receptor antagonist blunted gastrointestinal nutrient-induced suppression of breakpoint on a food PR task [28]. Exendin 4 diminished conditioned place preference for cocaine [55], implicating GLP-1 signaling in reward responsiveness to a nonfood, noncaloric reinforcer. In healthy humans, meal-induced increases in GLP-1 levels reduced willingness to work for food rewards [56]. Thus, similar to leptin, GLP-1 appears to reduce RVE; however, work in humans has not clearly dissociated the effect of GLP-1 on reward valuation from its clear impact on reward satiation.

Similar to leptin, GLP-1 agonist treatment activates pro-opiomelanocortin and CART neurons [57], and peripheral or central GLP-1 administration suppresses ad-lib food intake and meal size in rodents [58-60]. In humans, peripheral GLP-1

infusion increased satiation and decreased food intake [61], and a meal pattern that increased GLP-1 response was associated with a 10% reduction in food intake during a subsequent ad-lib meal [56]. Moreover, since we initiated data collection to test our model, a plethora of research has emerged demonstrating the effects of GLP-1 agonists on weight via changes in food intake [25,62], and peripherally administered GLP-1 agonists cross the blood-brain barrier where they exert central effects on ingestive behaviors [63].

To summarize, animal-based studies show that leptin and GLP-1 reduce RVE through inhibitory effects in the mesolimbic dopamine pathway and increase reward satiation through a combination of inhibitory and excitatory actions in the Arc. We predicted that lower leptin levels would contribute to blunted postprandial GLP-1 release, which in turn would contribute to both increased RVE and decreased reward satiation. These behavioral consequences increase weight gain and increase the risk of experiencing large, out-of-control binge-eating episodes. We predicted that increased reward valuation would be associated with, and predict, increased frequency of LOC over eating, while decreased reward satiation would be associated with, and predict, consuming unusually large amounts of food.

Although no previous study has examined posited associations dimensionally and prospectively in humans, eating disorders characterized by binge-eating episodes are associated with lower leptin levels [23,64]; reduced GLP-1 response [65,66]; increased RVE, as measured by breakpoint on PR tasks [23,67-70]; and decreased satiation via greater food intake in ad-lib meals [71-77] compared to controls. Our laboratory was able to demonstrate hypothesized differences between women with BN and noneating disorder controls on each of these factors [23,66,78] and extended evidence of blunted GLP-1 response [66] and decreased satiation [78] in women with BN compared to those with purging disorder, which is a condition characterized by purging in the absence of binge-eating episodes [5]. This last finding addresses model specificity to eating disorders characterized by binge eating defined by LOC while eating an unusually large amount of food [5]. Finally, our cross-sectional analyses found that leptin levels statistically mediated the association between WS and reported duration of illness in BN-S [24].

Aims

Our funded project included the following aims. Aim 1 was to test concurrent associations among WS, physiological factors (leptin concentrations and postprandial GLP-1 response), behavioral indicators of RV-E (breakpoint on PR tasks) and reward satiation (ad-lib test meal intake), self-report of these core constructs, and binge-eating severity in BN-S. Aim 2 was to test prospective associations to determine whether WS predicts BN-S maintenance in longitudinal models and whether posited mediators also predict BN-S maintenance. Aim 3 was to determine whether associations between WS and BN-S severity and maintenance are mediated by alterations in leptin levels, GLP-1 response, RVE, and reward satiation.

Hypotheses

For examining BN-S severity using cross-sectional data, we hypothesized that greater WS would be associated with lower leptin levels, and lower leptin levels would be associated with lower postprandial GLP-1 response. We hypothesized that lower postprandial GLP-1 response would be associated with greater reward valuation and lower reward satiation. We predicted that greater reward valuation would be associated with a higher frequency of LOC over eating. We predicted that lower reward satiation would be associated with larger eating episode sizes, extending from eating episodes that were not large in control participants to objectively large binge-eating episodes in participants with BN-S across the full severity range (“eating/binge-eating episode size”). We also predicted a significant indirect pathway from WS to LOC frequency via leptin levels, GLP-1 response, and reward valuation. We predicted a significant indirect pathway from WS to eating/binge-eating episode size via leptin levels, GLP-1 response, and reward satiation. If supported, findings would demonstrate that biological concomitants of WS explain differences in the severity of binge eating via alterations in reward valuation and reward satiation.

For examining BN-S maintenance using longitudinal data, we hypothesized prospective associations in which greater WS would prospectively predict lower leptin levels, which would be associated with lower postprandial GLP-1 response. We hypothesized that lower postprandial GLP-1 response would be associated with greater reward valuation and lower reward satiation. We predicted that greater reward valuation would prospectively predict a higher frequency of LOC over eating. We also predicted that lower reward satiation would prospectively predict larger eating episode sizes.

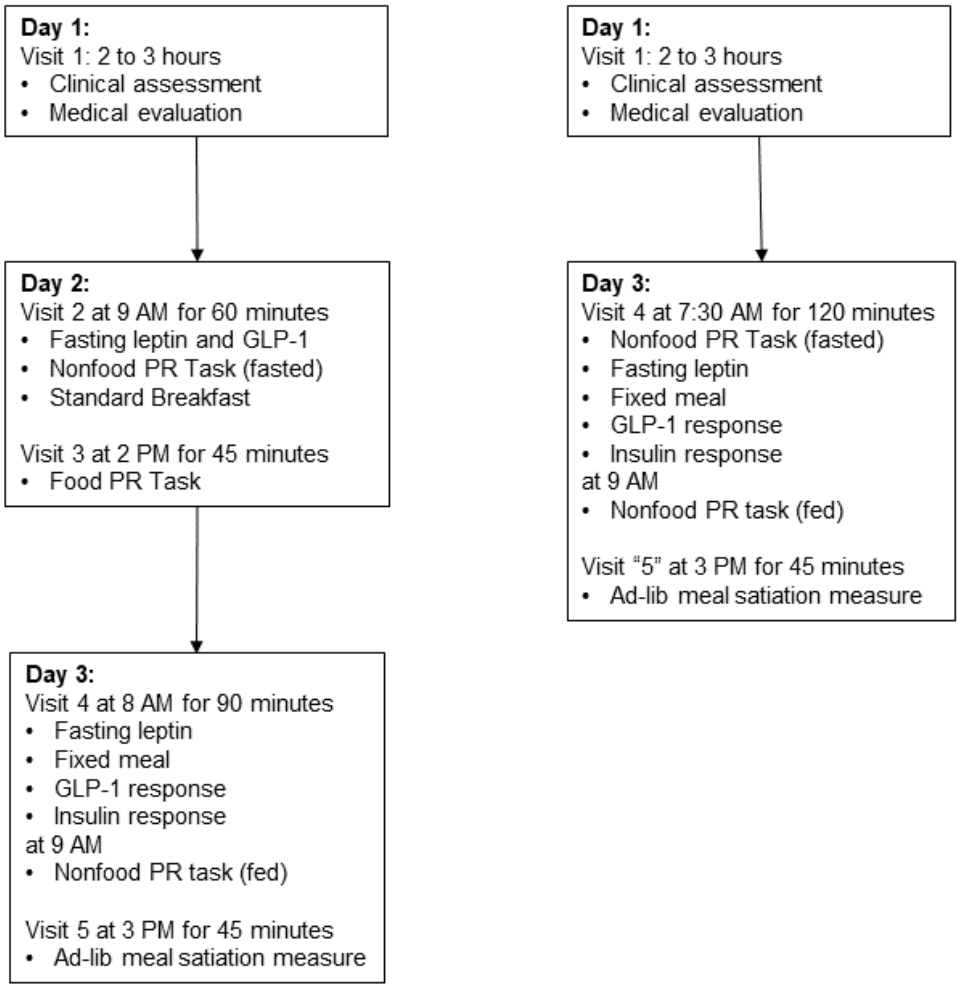
To examine the mediation of the association between WS and BN-S severity and maintenance via biobehavioral alterations, we predicted that reward valuation and reward satiation would mediate associations between WS and changes in LOC frequency and eating/binge-eating episode size. If supported, findings would translate findings from animal models in neuroscience to clinical outcomes in humans and identify GLP-1 as a potential target in future treatment studies of eating disorders characterized by binge eating, including BN-S.

Methods

Protocol

All data and sample collections, as well as assays, were conducted in a clinical research laboratory at Florida State University (FSU). Figure 1 presents an overview of study visits for participants enrolled before and after the onset of the COVID-19 pandemic.

Figure 1. Study protocol for participants enrolled before (left) and after (right) the onset of the COVID-19 pandemic. GLP-1: glucagon-like peptide 1; PR: progressive ratio.



Day 1 or Visit 1: Psychological and Medical Evaluation

At baseline, all participants completed in-person structured clinical interviews with clinical doctoral students and questionnaires on a laboratory computer (Measures section); a pregnancy test; an objective assessment of height, weight, percentage of body fat, and vital signs; and a medical screening. At baseline, participants also played Angry Birds (Rovio Entertainment) for 2 minutes, tasted M&M's (Mars, Inc) and frozen yogurt, and consumed the fixed meal used in visit 4 to ensure the ability to follow instructions in subsequent visits. After the onset of the COVID-19 pandemic, remote follow-up clinical assessments were offered via a Zoom (Zoom Communications) link, which complies with the Health Insurance Portability and Accountability Act (HIPAA), for interviews and a secure web-based link for questionnaires.

Days 2 and 3 Visits

The original protocol included 2 visits on day 2 at 9 AM (visit 2) and 2 PM (visit 3) and day 3 at 8 AM (visit 4) and 3 PM (visit 5). Start times were adjusted by up to 1 hour before or after indicated times, and any adjustment was held constant across a participant's visit. Participants were asked to abstain from eating or drinking anything except water and from purging or exercising after 11 PM before and between visits on both days. Participants were required to leave personal belongings, including mobile phones, books, and other items, in a bin outside the testing rooms. At the beginning of the morning visits, height, weight, body fat percentage, and vital signs were objectively measured, and a screening confirmed compliance with instructions and captured the past week's eating patterns and eating disorder symptoms. Task instructions were presented in print and via audio recording. We used digital video monitoring to detect technical problems and participant noncompliance during behavioral tasks. The revised protocol eliminated the day 2 visit but retained visit 2 tasks (Visit 2: Leptin, GLP-1, RVE for a Nonfood Reinforcer in Fasted State state).

Visit 2: Leptin, GLP-1, and RVE for a Nonfood Reinforcer in Fasted State

Participants had 5 ml of blood drawn by a registered nurse and completed momentary assessments before and after a PR task to play Angry Birds [79]. Briefly, participants were instructed that they could earn 1 minute of playtime in Angry Birds by pressing the space bar; the task consisted of up to 10 trials for up to 10 minutes of playtime, with the number of required presses increasing across trials (50 presses for trial 1, 250 presses for trial 2, 450 presses for trial 3, and so on up to 1850 presses

for trial 10). Participants were instructed that they should continue for as long as they wanted to play the game; they could stop at any time, and there were no right or wrong answers. When participants reached the criterion for a trial, a window opened, and they could play the game for 1 minute. After 1 minute, the screen automatically closed, and the participants were returned to the PR task, where they could work to gain access to continue the game. RVE was operationalized as a breakpoint, defined as the number of key presses in the last completed trial [80]. At 10 AM, participants consumed a standardized breakfast (300 kcal of yogurt parfait and juice) [23].

Visit 3: RVE for a Food Reinforcer

Participants completed momentary ratings before and after a PR task for M&M's [23], using the same design, instructions, and PR schedule as the nonfood task, to earn 10 M&M's per trial, with the potential to earn up to 100 M&M's over 10 trials. When participants reached the criterion for a trial, 10 M&M's dropped into a cup, and they were instructed to consume all M&M's before continuing to work for additional M&M's. The revised protocol eliminated the food PR task and associated momentary ratings.

Visit 4: GLP-1 Response to a Fixed Meal and RVE for a Nonfood Reinforcer in Fed State

A registered nurse placed an indwelling catheter into the participant's arm and allowed the participant to rest for 5 minutes. Participants completed momentary ratings before the nurse drew a fasting blood sample (5 ml) at –5 minutes for leptin, GLP-1, and insulin. Then, participants consumed a fixed liquid meal (Ensure Plus, Abbott Nutrition; 900 kcal in 660 g of fluid: 30% fat, 15% protein, and 55% carbohydrate) from –5 to 0 minutes. To capture GLP-1 and insulin responses to the fixed meal, 2 ml blood samples were drawn at +5, +15, and +30 minutes. Momentary ratings were completed immediately before each blood draw. After the last blood draw, participants had their intravenous catheter removed, rested for 5 minutes, and completed momentary ratings before and after the nonfood PR task (fed state). In the revised protocol, the fasted nonfood PR task and associated momentary ratings were completed before the first fasting blood draw, such that blood samples were drawn shortly after, rather than before, the fasted nonfood PR task.

Breakpoint on the nonfood PR task demonstrated excellent test-retest reliability (intraclass correlation [ICC]=0.91; 95% CI 0.80-0.96) over 2 weeks and convergent validity with the food PR task (r=0.51; P<.001) [79]. Consistent with animal models, breakpoint was lower in fed compared to fasted states across tasks (B=321.01, SE 552.40; P<.001). Finally, the nonfood task demonstrated discriminant validity from the measurement of satiation [79].

Visit 5: Ad-Lib Meal Assessment of Reward Satiation

Participants completed momentary ratings immediately before and after an ad-lib meal comprising 1.5 quarts (1420 g) of vanilla frozen yogurt (1.5 kcal/g) served at an individual place setting. Participants were presented with instructions in print and audio recorded to eat until they felt full or satisfied. Yogurt was weighed twice both before and after the meal using a top-loading, self-calibrated electronic balance, and the total intake was calculated in grams and kilocalories [81].

Training and Interrater Reliability

PKK provided all training and supervision for structured clinical interviewers and held biweekly assessment meetings. Interrater reliability (IRR) was examined via independent coding of audio recordings from 127 (16.5%) out of 769 interviews, randomly selected from each interviewer's assessments annually.

Participants

Textbox 1 presents the inclusion and exclusion criteria. Local recruitment was conducted via advertisements on social media platforms (eg, Instagram; Meta Platforms, Inc), billboards, pamphlets distributed to clinics, posters, outreach to college-based student organizations for ethnic or racial minority groups and churches, and emails to students at local universities with a link to a web-based eligibility screening. We received permission to send the mass email to female students aged 18 to 35 years once per academic term for all terms in which we recruited new participants at FSU and for one of the terms at a local Historically Black College and University. The mass email was the most effective recruitment tool, yielding the largest response. All prospective participants underwent telephone screenings to assess potential eligibility. Full eligibility was determined during the in-person assessment at baseline. The NIMH Data Archive (NDA) collection includes data from all eligible participants (N=399) and a small number of participants (n=6, 1.5%) who were later determined not to meet full eligibility criteria (details present in the Data Availability section).

Textbox 1. Eligibility criteria for participants.

Inclusion criteria

- Sex: female
- Age: 18 to 35 years
- BMI: 16 to 35 kg/m^2
- Free of psychotropic medications or stable dose of selective serotonin reuptake inhibitors for 8 weeks
- Free of alcohol, illicit drugs, and medications for 72 hours before reward valuation effort, reward satiation, and fixed meal tasks

Additional inclusion criteria for bulimia nervosa and related syndromes

- Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (*DSM-5*), binge episodes
  - ≥1,000 kcal within a 2-hour period and larger than what most people would eat in a similar context
  - Loss of control over eating during the episode
- More than 12 episodes of behavioral eating disorder symptoms (including binge, purging, and nonpurging behaviors) over the past 12 weeks
- Undue influence of weight or shape on self-evaluation, intense fear of gaining weight or becoming fat, or marked distress regarding binge eating
- *DSM-5* criteria for anorexia nervosa binge-purging, bulimia nervosa, binge eating disorder, or other specified feeding or eating disorder using the past 12 weeks as a measure of the past 3 months
- For current other specified feeding or eating disorder, score >16 on the Clinical Impairment Assessment; marked distress regarding binge eating; or impairment in one or more areas of life on the Structured Clinical Interview for DSM-5
- For atypical anorexia nervosa, BMI ≥18.5 to <19 kg/^{2} or >5% BMI reduction over a 1-month period

Exclusion criteria

- Medical condition or other treatment that could influence appetite, weight, or ability to participate
- Currently pregnant, nursing, or planning to become pregnant within the next year
- Planning to move >2 hours away from the laboratory within the next year
- Current blood, injection, or injury phobia

Additional exclusion criteria for noneating disorder controls

- Current eating disorder symptoms on the Eating Disorder Examination
- Current dietary restriction to lose weight on the Eating Disorder Examination (dietary restriction to prevent weight gain was permitted)
- History of any eating disorder symptoms on the Structured Clinical Interview for *DSM-5*
- Three-Factor Eating Questionnaire cognitive restraint subscale score ≥10
- Clinical Impairment Assessment score ≥16

To measure the severity of BN-S dimensionally from a state of health to disease, we included noneating disorder controls and participants with BN-S ranging from mild to severe. We deliberately recruited more participants with BN-S than controls to collect data appropriate for parametric analyses by minimizing variables with a modal value of 0. This strategy also prioritized the recruitment of participants with BN-S at baseline, as predictors of illness maintenance and the examination of GLP-1 dysfunction as a potential treatment target were most relevant for this group. Finally, this strategy reflected our previous research experience and the expectation that controls would demonstrate limited variance at baseline, when they were required to be free of eating pathology, and over the course of follow-up when the incidence of eating disorders would be rare. With reduced variability, a smaller number was expected to provide sufficiently narrow CIs on any secondary group-based analyses comparing controls to participants with BN-S.

Participants provided multiple and preferred methods of contact (phone calls, SMS text messages, and email). Participants also provided the name and contact information for at least 1 individual who would know how to reach them if the participant could not be contacted by their mobile number and gave permission for us to contact that individual if we lost contact. We used several strategies to enhance retention. First, we offered financial incentives to participants prorated by visit and a bonus for completing all visits as scheduled (details present in the Ethical Considerations section). Second, we provided written and verbal reminders and instructions for subsequent visits via calls, SMS text messages, and emails for 3 days and 1 day before visits and wake-up calls for morning visits. Third, we established clear participation policies: participants who missed 2 scheduled visits without prior notification were discontinued, and we limited rescheduled visits to 3 per sequence. Fourth, if ≥12 weeks passed between the day 1 interview and the final visit,

we required confirmation of continued eligibility via reassessment. Finally, a 6-month follow-up could begin 4 to 8 months after baseline, a 12-month follow-up could begin ≥10 months after baseline, and 6-month participation was not required to complete a 12-month follow-up. Assessment dates are included in the NDA collection.

Measures

BMI, WS, and Body Fat Percentage

Current weight and height were measured each day using a digital scale and stadiometer to calculate BMI (kg/m^2). We observed stability in BMI across days (r>0.95; P<.001), with no significant changes between days 1 and 2 (Cohen d=0.09), 2 and 3 (Cohen d=–0.07), and 1 and 3 (Cohen d=–0.007). WS was calculated as a percentage of BMI loss from the highest previous BMI, using self-reported highest adult weight at current height to calculate the highest BMI. At 6- and 12-month follow-up visits, we again asked about the highest adult weight to capture possible changes over time. Body fat percentage was measured using bioelectrical impedance analysis (Tanita Corporation of America), which demonstrates high correlations (r=0.88 to 0.94) with dual x-ray absorptiometry scans [82], supporting its feasibility (lower cost) and safety (no radiation exposure) in longitudinal studies with larger samples. We measured duration at current weight, time since highest weight, and duration of highest weight via self-report. WS represents our exposure variable, and BMI and body fat percentage represent covariates.

Interviews

The *Eating Disorder Examination* (EDE) *17.0D* [83] was selected due to previous evidence of good discriminant validity [84-87], IRR (0.83 to 0.99) [88,89], and good internal consistency of the restraint and body image subscales (Cronbach α>0.70) [90]. The EDE provided 3D outcome variables of eating disorder severity and maintenance, each with high IRR in the current project determined through ICC: LOC frequency (ICC>0.99), size of largest eating/binge-eating episode (in kcal; ICC=0.82), and the Global Scale score (ICC>0.99). LOC frequency represented the total number of eating episodes during the previous 12 weeks during which participants did not feel in control of their eating, regardless of the amount of food consumed. The size of the largest eating/binge-eating episode was captured by asking participants to report the largest amount of food they had eaten during the previous 12 weeks and recording the types and amounts of food consumed within 2 hours and converting these to kilocalories as described previously [78,91]. The EDE also provided scores with high IRR for restraint (ICC>0.99); eating concern (ICC=0.98); weight (ICC=0.99) and shape concerns (ICC>0.99); and symptoms for algorithms to diagnose current *DSM-5* anorexia nervosa (AN), BN, and binge-eating disorder (BED) in combination with objectively measured BMI. EDE symptom frequencies and durations permitted differential diagnoses of other specified feeding or eating disorder (OSFED) proposed by Keel [92]. IRR for symptom frequency or severity (ICC) and associated diagnostic thresholds over 3 months (κ) were good: objective binge episode size (κ=0.71), objective binge episode and inappropriate compensatory behavior frequency (ICC=0.97 and κ=0.93; ICC=0.96 and κ=0.91, respectively), fear of gaining weight or becoming fat (ICC=0.99 and κ=0.91), behavior to prevent weight gain (ICC=0.96 and κ=0.96), weight misperception (ICC=0.98 and κ=0.95), self-evaluation unduly influenced by weight (ICC=0.87) or shape (ICC=0.89 and κ=0.90), characteristics associated with binge episodes (ICC=0.78 and κ=0.73), and marked distress regarding binge eating (ICC=0.91 and κ=0.91). Marked distress regarding binge eating on the EDE was 1 of the 3 indicators of clinical significance for OSFED. The EDE was administered at baseline and 6- and 12-month follow-up assessments.

The Structured Clinical Interview for Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (SCID-5) [93] captured eating (lifetime) and related disorder diagnoses (lifetime and current). Previous work supported good IRR for SCID diagnoses, with κ=0.92 for major depressive disorder, κ=0.75 for dysthymic disorder, κ=0.81 for any substance use disorder, κ=0.85 for panic disorder, κ=0.91 for social phobia, κ=0.73 for specific phobia, κ=1.00 for obsessive-compulsive disorder, and κ=0.90 for posttraumatic stress disorder [94]. We confirmed the absence of lifetime eating disorder symptoms in noneating disorder controls by ignoring skip rules [95]. The OSFED addendum provided a second indicator of clinical significance. The overview covered current and past treatment, including medication use, to confirm eligibility. At follow-up, we evaluated but did not exclude based on the use, type, dose, and duration of medication, and information may be included as covariates. Follow-up assessments focused on the period since the previous interview (eg, the past 6 months) to reduce participant burden. Current depressive and substance use disorders are covariates.

Self-Reported Questionnaires

C*linical Impairment Assessment* [96] established impairment and distress specifically linked to eating disorder symptoms in the domains of personal, social, and cognitive function. Previous work supported high internal consistency (>0.90), test-retest reliability (0.86), and concurrent and discriminant validity [96,97]. A score ≥16 was a third indicator of clinical significance for OSFED [96].

The *Three-Factor Eating Questionnaire* [98] comprises scales for cognitive restraint, which has successfully differentiated dieters from nondieters for our study's threshold for determining eligibility of controls, and disinhibition and hunger, which distinguish between purging women based on binge episode size [89,91]. Previous work supported good 1-month test-retest reliabilities for cognitive restraint, disinhibition, and hunger subscales of >0.90, 0.80, and 0.83, and internal reliabilities of >0.90, 0.91, and 0.85, respectively [98].

The *Visual Analog Scales* (VAS) assessed momentary states by presenting a single item on each page of a booklet with a 100-mm horizontal line anchored from "none or not at all" to "extreme or extremely." These provided self-reported levels of reward valuation and reward satiation during behavioral tasks. Participants marked the line to record how they felt "Right Now," regarding hunger, fullness, satiation, how much they wanted M&M's and to play the game, how much they liked M&M's and the game, and how rewarding they found M&M's

and gameplay, urge to binge, urge to vomit, nausea, stomach discomfort, sadness, anxiety, tension, and preoccupation with weight and shape. VAS dimensional scores are sensitive to momentary changes associated with postprandial gut peptide responses to a fixed meal, and responses to an ad-lib and fixed meal differ significantly between controls and participants with eating disorders [78,99].

The following measures were included to supplement the clinical description of participants based on the measures described earlier for determining eligibility, exposure, and outcome variables; in response to comments provided during the grant review (Multimedia Appendix 1); and in anticipation of potential questions that may emerge during the review of manuscripts presenting tests of our model.

The *Body Shape Questionnaire* [84] measured feelings and attitudes about body shape and weight as a possible covariate, based on previous evidence of its high test-retest (0.88) [100], high internal reliability (>0.98) [100,101], and good discriminant and concurrent validity.

The *Positive and Negative Affect Scale* [102] assessed trait levels during visit 1 and state levels of positive and negative affect before and after biobehavioral assessments in visits 2 to 5 to examine these as possible covariates of RVE and reward satiation. The Positive and Negative Affect Scale is a widely used measure due to its high internal consistency, test-retest reliability, and construct validity [102,103].

The *Behavioral Inhibition and Behavioral Activation Scales* [104] and the *Sensitivity to Punishment and Sensitivity to Reward Questionnaire* [105] measure reward-related traits. The former measure has demonstrated high internal consistency (0.82) in previous work [104] and concurrent and discriminant validity with the latter measure in eating disorder samples [105].

Leptin, GLP-1, and Insulin Assessments

Enzyme-linked immunosorbent assays (MilliporeSigma) of plasma samples were used to measure leptin (EZHL-80SK) [106], active GLP-1 (EZGLPHS-35K [107], total GLP-1 [EZGLP1T-36K] [108]), and insulin (EZHI-14K) [109] levels. Insulin was added to the protocol in response to grant reviewers' (Multimedia Appendix 1) concerns about the narrow focus on GLP-1 and the evidence that insulin, similar to GLP-1, might influence reward valuation, in addition to its already defined role in satiation [63]. Blood samples were collected into prechilled K2 EDTA vacutainers, following protocol instructions, including the preparation of vacutainers with DPP-IV inhibitor (10 µl/ml of blood) for active GLP-1, before centrifuging at 2000 revolutions per minute for 15 minutes at 4 °C. Plasma was then pipetted into prechilled, aliquot tubes labeled by participant number, analyte, visit, date, and sample number, and immediately placed on ice and transferred to a –80 °C freezer. We extracted up to 4 aliquots, providing up to 3 backup samples for each analyte.

DLW supervised all assays and approved results without knowledge of the participant's clinical status. All participant samples were run in duplicate in 1 assay (eg, baseline leptin from visits 2 and 4) and batched to ensure a balanced representation of control and BN-S participants across assays. When results were outside the detection limits or the intra-assay coefficient of variation (CV) exceeded 10%, backup aliquots were run in subsequent assays to ensure reliable estimates. Preliminary analyses indicated low stability of fasting active GLP-1 levels from visit 2 to 4 (r_{191}=0.18, P=.01) at baseline, raising concerns about fasting active GLP-1 as a sole measure of individual differences in GLP-1 function across visits. We added assays of total GLP-1 in backup samples to the protocol, which had been proposed in our grant application in the section on potential pitfalls and solutions in response to grant reviewers' (Multimedia Appendix 1) concerns about measuring active GLP-1. Total GLP-1 demonstrated adequate stability for fasting concentrations from visit 2 to 4 (r_{193}=0.70; P<.001). The NDA collection includes both active and total GLP-1 values. For participants enrolled after the onset of the COVID-19 pandemic, all GLP-1 values represented total GLP-1 and came from visit 4. Importantly, multilevel model analyses demonstrate that visit 4 VAS fullness ratings were significantly predicted by changes in active GLP-1 (B=0.83, 95% CI 0.65-1.01; t_{734}=9.06; P<.001) and total GLP-1 (B=0.40, 95% CI 0.27-0.54; 2-tailed t_{708}=5.91; P<.001) values, with greater effect size for active GLP-1 level. Thus, both provide valid indicators of GLP-1 function, with total GLP-1 providing more stable, "trait"-like information and active GLP-1 value providing more sensitive, "state"-like information.

The kit user guides and information published on the MilliporeSigma (Merck Group) website and included in assay kits reported the following upper limits of interassay and intra-assay CVs, respectively: 6.2% and 4.6% for leptin [106], <15% and <10% for active GLP-1 [107], <12% and <5% for total GLP-1 [108], and 11.4% to 6.95% for insulin [109]. In our project, mean intraassay and interassay CVs, respectively, were 4.3% and 9% for leptin, 7.4% and 9.5% for active GLP-1, 2.9% and 10.3% for total GLP-1, and 3.9% and 8.9% for insulin. We observed comparable or better CVs compared to published estimates, except for the higher interassay CV for leptin. Date and assay (numbered consecutively) are included in the NDA collection so that future users can control for interassay variability.

Data Structure and Missing Data

NDA data are organized by measure and stored in long form. Variable names indicate visits via the "_#" naming convention. Regardless of when participants were enrolled, variable names retained their original designations. The "_2" suffix reflects variables collected before, during, and after the fasted nonfood RVE task. Similarly, data collected from the fixed meal assessment of GLP-1 and insulin responses are identified by the "_4" suffix, and data collected from the ad-lib meal assessment are identified by the "_5" suffix. Each visit has a "Notes" column to indicate protocol deviations that may impact data quality. In addition to attrition, participants skipping questions, experimenter error, and equipment failures contributed to missing values. Technical problems included M&M's jamming the dispenser and not dispensing the reward after participants reached the criterion (the apparatus was redesigned part way through the project to minimize this problem) and the computer program freezing. When a

participant's effort for reward exceeds the planned ratio, data from the session are included in the data collection but will not be included in planned analyses. Refer to the study by Keel et al [79] for an example of main analyses, which excluded values from sessions with noted problems and sensitivity analyses, including all available data. The NDA collection includes all available data; several variables must be calculated (eg, breakpoint).

Data Analytic Plan

For concurrent tests of severity, we plan to use structural equation models (SEM) in MPlus (version 8; Muthén & Muthén) to obtain estimates of overall model fit; account for shared variance; and provide path estimates within the model, including tests of indirect effects using bias-corrected bootstrapped CIs with 10,000 samples to include all available data in the model from the 399 eligible participants enrolled in the study. This strategy includes running correlations between all variables in the model as a first step, followed by SEM with WS as the sole exogenous variable and the remaining variables as endogenous variables. Both RVE and reward satiation will be modeled as latent variables, with pathways from both behavioral tasks and self-reported states from VAS ratings. For prospective associations and temporal mediation predicting illness maintenance, we proposed cross-lagged SEM with bootstrapping methods for testing indirect effects [110]. Model fit will be evaluated with common fit indices, with the following thresholds for interpreting good fit: root mean square error of approximation, comparative fit index, and Tucker-Lewis Index ≥0.90; root mean square error of approximation value ≤0.05, 95% CI >0.00 to ≤0.08; and standardized root mean square residual ≤0.08 [111-116]. Coefficients and their 95% CIs will be used to evaluate the significance of hypothesized direct and indirect pathways, and only direct pathways that are in the predicted direction, with 95% CIs that do not include 0, will be interpreted as supporting the a priori hypotheses generated by our model.

Sensitivity analyses will evaluate the impact of adding covariates with pathways to each endogenous variable in the model on overall model fit and parameter estimates. Covariates include age, BMI, body fat percentage, enrollment before and after the onset of the COVID-19 pandemic, hormonal contraceptive use, selective serotonin reuptake inhibitors use, current depressive disorder diagnosis, and current substance use disorder diagnosis. Because sensitivity analyses involve nonnested models, we will evaluate whether there is a qualitative change in the adequacy of model fit, from inadequate to adequate or from adequate to good. When there is no qualitative change in model fit, lower values on the Akaike information criterion and Bayesian information criterion will be interpreted as evidence of improved fit.

Power Analyses

We conducted power analyses in R (R Foundation for Statistical Computing) with PowMedR for mediation as our least-powered analyses. Across the posited indirect effects (eg, GLP-1 mediates the association between WS and reward satiation), a sample size of n=195 provides 80% power with path coefficients ≥0.22 from the initial variable to the mediator and from the mediator to the outcome variable, while controlling for the initial variable. Analyses on multiple imputed datasets indicated 80% power with path coefficients ≥0.20 to test indirect effects. We aimed for longitudinal data from 250 participants to permit exploratory moderation analyses for potentially weaker effects at higher BMIs, where leptin levels might be high despite high WS and high food consumption [1].

Ethical Considerations

The FSU Institutional Review Board Human Subjects Committee reviewed and approved the study protocol and materials (HSC 2016.15338/STUDY00000353). Written informed consent was obtained from all study participants before their participation. All data have been deidentified and only a study-generated ID number and a globally unique identifier number in the NDA have been retained. For the original protocol, participants were paid US $75 for day 1, US $50 for day 2, US $100 for day 3, and a US $35 bonus for a total potential compensation of US $780 for baseline and 6- and 12-month follow-up visits. For the revised protocol, participants were paid US $75 for day 1, US $110 for day 3, and a US $15 bonus for a total of US $400 for baseline and 6-month follow-up.

Results

Overview

The project was funded as an investigator-initiated R01 in August 2016, and data collection began in November 2016. Data collection from participants was completed in April 2023, and assays of analytes were completed in June 2023. Information presented on recruitment and retention addresses the feasibility of our design and provides context on information reported on the reliability of measures in the current sample.

Timeline and Recruitment

We aimed to recruit 320 women over a 5-year period to provide clinical, biological, and behavioral data. We estimated that 250 (78.1%) out of 320 women would complete 6- and 12-month follow-up visits, including approximately 78% (200/256) with BN-S and 78% (50/64) control participants. By March 2020, we had recruited 301 eligible participants. Due to the COVID-19 pandemic, the laboratory closed that month for in-person assessments. To retain participants with baseline data who had not completed 12-month follow-up, institutional review board (IRB)–approved, NIMH-approved, and HIPAA-compliant remote clinical assessments were added to our protocol.

On February 19, 2021, we reopened the laboratory for in-person follow-up visits for those who had completed all baseline visits before laboratory closure, implementing IRB-approved safety precautions. The precautions included (1) a screening checklist for symptoms, potential COVID-19 exposure, and a temperature check completed with the participant outside the laboratory before admitting them into the laboratory; (2) allowing only 1 participant into the laboratory at a time; (3) reducing study staff to the minimum required to complete a visit; (4) following masking and social distancing guidelines; (5) sanitizing all surfaces before and after running each participant; and (6) continuing to allow participants to complete follow-up clinical assessments via remote means. The final precaution reflected

evidence of minimal differences between in-person versus remote follow-up assessments conducted among those enrolled before the onset of the COVID-19 pandemic [117]. We adjusted pandemic-related precautions as needed, including periodically pausing in-person assessments in response to spikes in new variants and relaxing precautions with growing community immunity.

On October 8, 2021, we enrolled our first new participant since laboratory closure, supported by 2 no-cost extensions of our NIMH-funded grant and a US Department of Education Higher Education Emergency Relief Fund awarded to FSU. Before enrolling new participants, and with prior approval from the FSU IRB and the NIMH, we revised the protocol to reduce the number of in-person visits to conserve remaining funds and further minimize the risk of COVID-19 exposures. Changes were also informed by evidence of the reliability and the convergent and discriminant validity of our task for measuring RVE for a nonfood reward [79]. We completed data collection in April 2023. We experienced no known incidents of COVID-19 exposure in our laboratory during the project.

Retention

Figures 2 and 3 show retention across study visits and follow-up for participants enrolled before and after the onset of the COVID-19 pandemic, respectively. Among those 399 eligible, 321 (80.5%) had a current BN-S, 78 (19.5%) were noneating disorder controls. A total of 290 (72.7%) out of 399 women completed all baseline assessments, including 226 (70.4%) out of 321 with BN-S and 64 (82.1%) out of 78 controls (χ^2_1=4.3; P=.04; ϕ=0.10). Given the uncertainty surrounding the duration of the COVID-19 pandemic–related closures and concerns for participant safety, participants (91/399, 22.8%) without complete baseline assessments were considered ineligible to continue (n=83, 91% with BN-S and n=8, 9% controls). We estimate that the COVID-19 pandemic impacted 3.3% (13/399) participants' ability to complete baseline assessments, all of whom had BN-S. The mean time between days 1 and 2 was 17.7 (SD 15.1) days, between days 2 and 3 was 16.5 (SD 17.3) days, and between days 1 and 3 was 28.1 (SD 19.3) days. There was no significant difference between groups in days between study visits (P values ranged from .72 to .07, and effect sizes were small; Cohen d=–0.09 to 0.29).

Among the 290 women eligible for follow-up, 249 (85.9%) provided follow-up data, including 96 (33.1%) with 6-month, 123 (42.4%) with 6- and 12-month, and 30 (10.3%) with 12-month data. Groups did not differ in participation at 6-month (χ^2_1=3.5; P=.06; ϕ=0.11) or 12-month follow-up (χ^2_1=0.0; P=.95; ϕ==0.004). The mean time between baseline to 6-month follow-up was 6.0 (SD 2.2) months, 6- to 12-month follow-up was 8.5 (SD 7.8) months, and baseline to 12-month follow-up was 14.6 (SD 5.6) months and did not differ significantly between groups (P values ranged from .82 to .30, and effect sizes were small; Cohen d=–0.09 to 0.29).

Figure 2. Participant flow through the study for participants recruited before the onset of the COVID-19 pandemic. At the 6-month follow-up, 2 additional participants with BN-S completed questionnaire assessments but did not complete interviews for study visit 1. Participants who completed all visits at baseline were recruited to participate at the 12-month follow-up, whether or not they had completed 6-month follow-up. BN-S: bulimia nervosa and related syndromes.

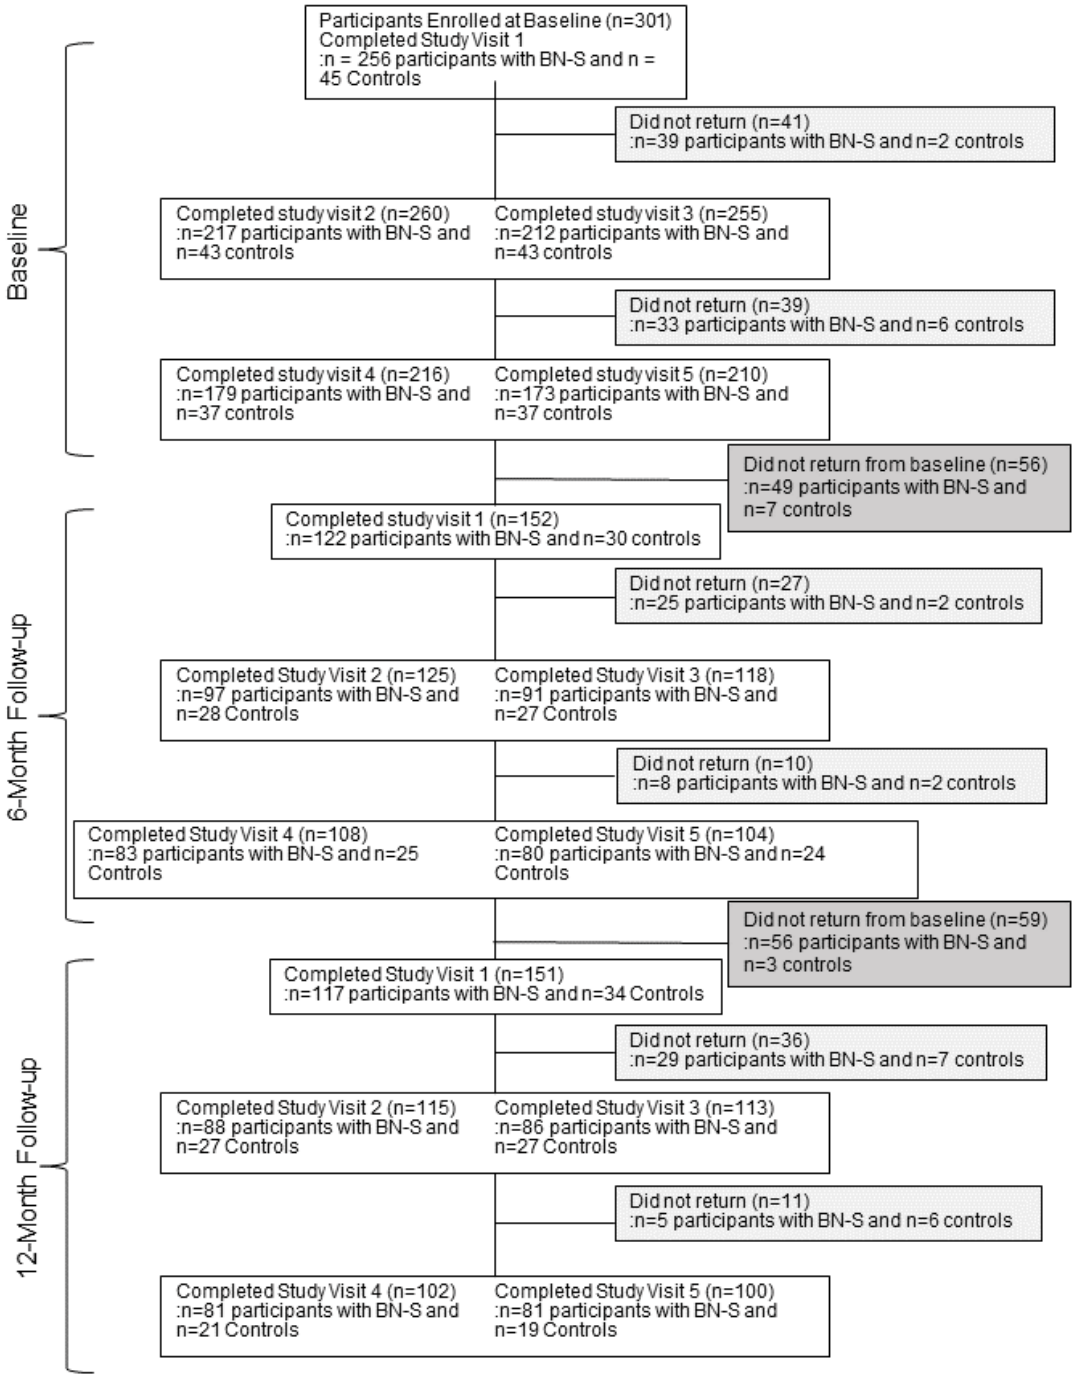


Figure 3. Participant flow through the study for participants recruited after the onset of the COVID-19 pandemic. BN-S: bulimia nervosa and related syndromes.

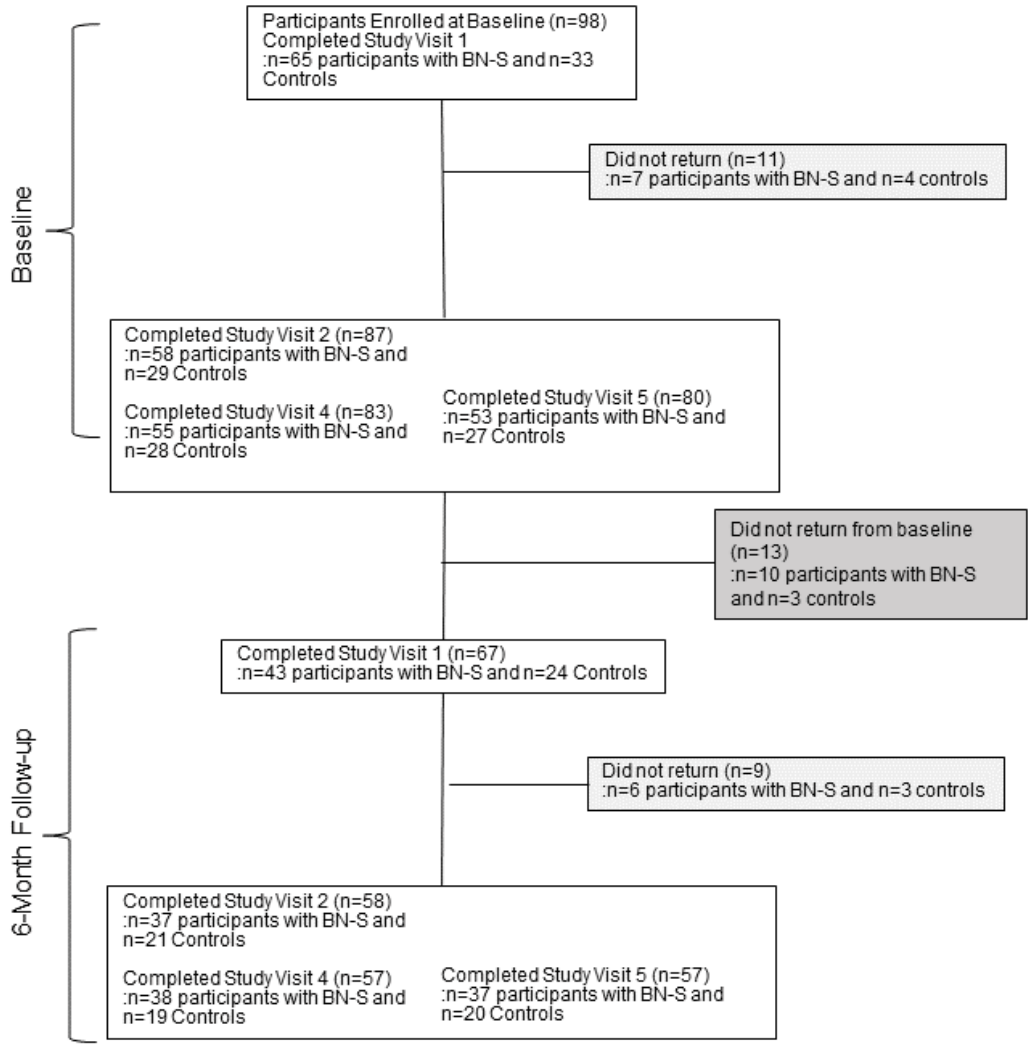

Sample Descriptors

Table 1 describes sample characteristics. Biological sex as female at birth was required for all participants (Textbox 1), and almost all endorsed being cisgender individuals. We did not assess sexual orientation. According to 2020 US Census data [118], the racial or ethnic composition of Leon County, Florida, was 0.4% American Indian or Alaska Native, 3.8% Asian, 32.1% Black or African American, 8.3% Hispanic or Latino, 0.1% Native Hawaiian or other Pacific Islander, 61% White (54.1% non-Hispanic and non-Latino), and 2.6% multiracial. Racial or ethnic composition of the sample differed from the county population (χ^2_5=91.9; P<.001; Cramer V=0.008), with lower participation among individuals identifying as Black or African American (χ^2_1=72.2; P<.001; ϕ=0.02) and greater participation among those identifying as Native Hawaiian or other Pacific Islander (χ^2_1=4.3; P=.04; ϕ=0.004) or multiracial (χ^2_1=6.7; P=.01; ϕ=0.005) relative to those identifying as White individuals. Furthermore, we observed greater participation among individuals identifying as Hispanic or Latinx compared to non-Hispanic or Latinx (χ^2_1=193.8; P<.001; ϕ=0.03).

There was no significant association between racial or ethnic identity and whether or not participants completed baseline visits (χ^2_5=2.1; P=.84 and χ^2_1=0.0; P=.99) and 6-month (χ^2_5=0.6; P=.99 and χ^2_1=1.3; P=.72) or 12-month (χ^2_5=1.6; P=.90 and χ^2_1=0.1; P=.79) follow-up (all effect sizes for all associations; η^2<0.01). Table 2 presents 6-month sample characteristics, and Table 3 presents 12-month sample characteristics.

Table 1. Characteristics of the sample at baseline for all eligible participants (N=399).

Characteristic	Total, n (%)	Bulimic syndrome group (n=321), n (%)	Control group (n=78), n (%)

Days since highest BMI, mean (SD; range)	460 (683; 0-4380)	513 (739; 0-4380)	294 (431; 0-1460)
Current BMI duration (d), mean (SD; range)	192 (298; 1-1825)	142 (190; 1-730)	351 (472; 7-1825)

Participants' mean age did not differ between groups, and BMI was significantly higher in BN-S than control participants ($t_{141.92}$=6.73; P<.001; Cohen d=0.85). Neither age nor BMI was associated with completing baseline or 6-month follow-up (P values ranged from .76 to .19, and Cohen d ranged from –0.13 to 0.03). However, older age (mean 20.6, SD 3.1 vs mean 20.0, SD 2.2 years; $t_{250.04}$=2.12; P=.04; Cohen d=0.24) and lower BMI (mean 23.9, SD 3.9 vs mean 25.0, SD 4.4; $t_{350.24}$=–2.53; P=.01; Cohen d=–0.25) at baseline predicted 12-month follow-up participation. WS was significantly greater in the BN-S group compared to control participants ($t_{157.57}$=4.08; P<.001; Cohen d=0.52) and was not significantly associated with completing baseline or 6- or 12-month follow-up (P values ranged from .31 to .93, and Cohen d ranged from –0.11 to 0.01).

Table 3. Characteristics of the sample at 12-month follow-up (n=153).

Eating Disorder and Psychiatric Diagnoses and Treatment

Table 4 presents *DSM-5* eating disorder and other psychiatric diagnoses and features at baseline. BN was the most common diagnosis, followed by OSFED-BN of low frequency or duration, with few participants meeting the criteria for current AN, BED, or their related OSFED. Diagnosis was significantly associated with completing baseline visits (χ^2_3=8.9; P=.03; ϕ=0.10), occurring in 7 (88%) out of 8 participants with AN binge-purging, 118 (77.1%) out of 153 participants with BN, 2 (50%) out of 4 participants with BED, and 99 (63.5%) out of 156 participants with OSFED diagnoses.

[a]EDE: Eating Disorder Examination.

[b]AN: anorexia nervosa.

[c]Not applicable.

[d]BN: bulimia nervosa.

[e]BED: binge-eating disorder.

[f]OSFED: other specified feeding or eating disorder.

[g]Guidelines presented by Keel [92] were followed for differential diagnosis of OSFED. There were no cases of current purging disorder due to the requirement of recurrent objectively large binge episodes as an inclusion criterion for participants with BN and related syndromes. In addition, 2 sets of criteria were used. Broad criteria were based on the key features that distinguish among the OSFEDs, such as significant weight loss of atypical AN, the presence of binge eating and inappropriate compensatory behaviors for BN of subthreshold duration or frequency, and the presence of binge eating and absence of recurrent inappropriate compensatory behavior for BED of subthreshold duration or frequency. Narrow criteria required the associated cognitive and affective features for each OSFED diagnosis so that narrow criteria for atypical AN indicated that all criteria for AN were met except for low weight, all criteria for BN were met except for duration or frequency of behavioral symptoms, and all criteria for BED were met except for duration or frequency of binge-eating episodes.

[h]Significant weight loss was defined as >5% reduction in BMI within 30 days or BMI <19 kg/m^2.

[i]SCID-5: Structured Clinical Interview for Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition.

[j]ED: eating disorder.

[k]Lifetime OSFED diagnoses were based on clinical interviewer assessments in the SCID-5. Given the possibility of meeting a lifetime diagnosis for >1 OSFED, no diagnostic hierarchy was used; however, parsimony was applied in making lifetime OSFED diagnoses to avoid diagnosing a prodromal phase or period of partial remission as a separate diagnosis.

[l]PD: purging disorder.

[m]NES: night eating syndrome.

[n]SSRI: selective serotonin reuptake inhibitor.

Most BN-S participants had a lifetime mood (256/321, 79.8%), substance use (183/321, 57%), or anxiety disorder (203/321, 63.2%), whereas most noneating disorder controls did not (14/78, 18%; 14/78, 18%; 10/78, 13%). All suicide indicators were more common in BN-S participants compared to controls (lifetime suicidal ideation: χ^2_1=39.1; P<.001; ϕ=0.32; past week suicidal ideation: χ^2_1=4.4; P=.04; ϕ=0.11; and lifetime suicide attempt: χ^2_1=9.1; P=.003; ϕ=0.15). No suicide attempts were reported in the week before the interview. Reflecting group differences, lifetime treatment for mental health was twice as likely in BN-S compared to control participants (χ^2_1=21.5; P<.001; ϕ=0.23).

Eating disorder diagnosis was not associated with participation at 6- or 12-month follow-up (Table 5 outlines 6-month follow-up data and Table 6 outlines 12-month follow-up data). Participants with current or lifetime obsessive-compulsive disorder at baseline were significantly less likely to participate at 12-month follow-up (χ^2_1=4.6; P=.03; ϕ=0.11 and χ^2_1=5.7; P=.01; ϕ=0.12, respectively). There were no other significant associations between completing baseline or follow-up visits and current or lifetime psychiatric diagnoses, suicide-related variables, or treatment.

Psychometric Properties of Measures

IRR was excellent for all lifetime and substantial for current SCID-5 diagnoses [119,120]. Table 4 includes κ statistics for lifetime and current SCID-5 diagnoses based on IRR assessment from an independent review of 127 interviews across the full project, including baseline and follow-up assessments. Estimates include in-person and remote interviews.

Table 7 presents internal consistency and Table 8 provides test-retest reliability for EDE interview and questionnaire scales. Cronbach α exceeded thresholds for acceptability across all assessments and compared favorably to published estimates for all measures. Test-retest reliability was good and generally higher over shorter intervals, likely reflecting true change in constructs over time.

Table 7. Internal consistency reliability of measures at baseline and follow-up.

Discussion

Principal Findings

The study protocol is designed to test an explanatory biobehavioral model for the association between WS and severity and maintenance of BN and related eating disorders characterized by binge eating. For BN-S severity, we expect significant cross-sectional associations between greater WS, lower leptin levels, lower GLP-1 response, greater reward valuation, and lower reward satiation. We also anticipate that greater reward valuation will be significantly associated with higher LOC frequency and a significant indirect pathway from greater WS to higher LOC frequency via lower leptin levels, lower GLP-1 response, and greater reward valuation. Furthermore, we expect that lower reward satiation will be significantly associated with larger eating/binge-eating episode size and a significant indirect pathway from greater WS to larger eating/binge-eating episode size via lower leptin levels, lower GLP-1 response, and lower reward satiation. If supported, findings would demonstrate that biological concomitants of WS explain variance in binge-eating severity via alterations in reward valuation and reward satiation. For BN-S maintenance (vs remission), we hypothesized significant prospective associations between these variables, with reward valuation and reward satiation temporally mediating associations between WS as the exposure and changes in LOC frequency and eating/binge-eating episode size, respectively, as the outcomes. If supported, findings would have implications for the assessment, diagnosis, and future clinical trials of eating disorders characterized by binge eating.

Current standardized eating disorder assessments, including the SCID-5 [93] and the EDE 17.0D [83], secure information about current body weight and lowest body weight in relation to height. However, neither includes a question about the highest lifetime adult weight. If findings support hypotheses, then future assessments would benefit from including this question to calculate WS as a prognostic indicator.

Results may inform diagnostic criteria for eating disorders. The *DSM-5* currently uses BMI as a severity indicator for AN, frequency of inappropriate compensatory behaviors for BN, and frequency of binge-eating episodes for BED [5]. If our model supports WS as a marker of severity transdiagnostically, then WS could provide a common metric across eating disorders and potentially explain differences in outcomes among them. Beyond broad, transdiagnostic implications, findings may also refine the discrepancies between the *DSM-5* and *International Classification of Diseases, 11th Revision* (*ICD-11*) in the definition of a binge-eating episode for diagnosis of BN and BED. Our model focuses on the *DSM-5* definition, which requires the consumption of an objectively large amount of food in addition to LOC. The *ICD-11* requires a subjective LOC combined with eating either "notably more or differently than usual" [121]. If findings support posited pathways from WS to episode size and LOC, this would support the validity of the *DSM-5* definition over the *ICD-11* definition.

Finally, given recent interest and controversy surrounding the use of GLP-1 agonists for binge eating (eg, semaglutide in Wegovy and Ozempic) [122,123], these longitudinal data, funded solely by the NIMH and the US Department of Education, can elucidate mixed findings from early clinical trials [124-126] and inform the design of future investigations. Specifically, our model contextualizes the impact of GLP-1 function for those who have lost weight, predicting greater disruptions associated with greater WS. Previous studies supporting the potential efficacy of GLP-1 agonists have relied on secondary analyses of data collected in open trials [125-127] or a randomized controlled treatment trial for obesity without placebo control [128]. In the sole double-blind, randomized controlled trial testing a GLP-1 agonist against a placebo for the treatment of BED [124], no significant differences emerged in remission of binge eating or BED. Similar to other studies of GLP-1 agonists, weight loss was significantly greater in the active compared to the control condition. However, participants on placebo lost only 0.9 (SD 0.7) kg over 17 weeks. Comparing improvements in binge eating on a placebo without weight loss may not provide a valid comparison against those treated with liraglutide, who lost 4.7 (0.8) kg of weight and experienced decreases in binge eating [124]. If our hypotheses are supported, future evaluations of GLP-1 efficacy will examine WS at intake and relative changes in weight over treatment as covariates in predicting changes in binge-eating severity.

Strengths of the project include the large, diverse sample; inclusion of multiple units of analysis; and longitudinal design, with high retention across multiple visits at baseline and high retention over follow-up. We retained 290 (72.7%) out of 399 women for all clinical, behavioral, and biological assessments at baseline, and 249 (85.8%) of these 290 women provided longitudinal data. This supports the feasibility of our approach even in the face of unanticipated challenges encountered with the onset of the COVID-19 pandemic. Studies using laboratory-based feeding paradigms [81] have included anywhere from 7 to 103 participants in PR tasks and fixed or ad-lib meals. Our combination of all methods in 290 participants far exceeds these benchmarks. Furthermore, most biobehavioral studies were constrained by their cross-sectional design, limiting conclusions regarding the role of observed disruptions as correlates, consequences, or contributors to pathology. Our measures had strong psychometric properties that minimized random error, and initial analyses indicate that effect sizes will exceed original estimates. Thus, we will have sufficient power for prospective analyses.

Project weaknesses include the absence of sexual orientation information and the exclusion of male participants. Eating disorders, including AN binge-purging, BN, BED, and their OSFED variants, predominantly affect female individuals [129,130]. Although restricting recruitment to women limits generalizability to men due to potential biologically based differences in the influence of ovarian hormones on GLP-1 function [65], it was not feasible to recruit enough men to directly examine sex as a biological variable. This limitation was due to the large sample size required for adequately powered analyses and the low prevalence of eating disorders in men. Despite this limitation, findings may impact the assessment, diagnosis, and treatment of a majority of those with eating disorders characterized by binge eating, given the preponderance of these disorders in women [129,130]. Furthermore, the sample demonstrated limited diversity in socioeconomic status. Participation requirements were likely too high for most individuals with limited resources or full-time commitments at work or home. These factors will impact the generalizability of findings. Attrition was related to age, BMI, and the presence of a BN-S at baseline. Greater attrition in BN-S may reflect a higher participant burden in this group, including longer interview duration due to greater pathology and behavioral task duration due to higher RVE and lower reward satiation. BN-S participants endorsed greater impairment, which may extend to impaired ability to follow through with study participation. Among participants who provided full baseline data and were eligible for longitudinal follow-up, we did not observe significant differences between BN-S and control groups. We advise using all available data with imputation for missing values to minimize the influence of biased attrition.

Finally, in using the RDoC approach to participant recruitment, we did not set a priori goals for the recruitment of participants who would fall into specific *DSM-5* diagnostic groups, and this may have limited the extent to which our sample has a transdiagnostic representation of all eating disorders characterized by binge eating. The requirement that participants be medically healthy and free of medications that could influence weight or appetite was necessitated by our interest in biological factors underlying RVE and satiation, consistent with the RDoC approach. This may have restricted the number of participants who presented with AN or BED, given the associations between extreme BMI and medical conditions. This, combined with our age range, may explain the large number of participants with *DSM-5* BN and OSFED characterized as BN with low duration or frequency. The latter group could lead to misinterpretation of the sample as including participants with "subthreshold" eating disorders. However, all participants had a full-threshold *DSM-5* eating disorder. Further, the minimum behavioral symptom frequency ensured that all participants met the minimum symptom frequency required for a *DSM-5* diagnosis of BED. Many of our OSFED participants

were engaging in binge eating frequently enough for a diagnosis of BN or BED, but the frequency of inappropriate compensatory behaviors was too high for a diagnosis of BED and too low for a diagnosis of BN.

Conclusions

Preliminary data from subsets of participants in this project have been included in other reports [1,79,131-133]; however, this is the first report presenting data from all participants and all waves. Future papers will focus on testing our model to predict the severity and maintenance of BN-S. Beyond testing our RDoC-informed model, biological and behavioral variables will be examined in novel combinations as predictors of changes in eating disorder expression and comorbidity. A careful review of this paper will help researchers accessing data through the NDA identify which data are most relevant (eg, active vs total GLP-1), their context (eg, pre– vs post–COVID-19 pandemic), and other factors that may influence interpretations. Grounding analyses with a full understanding of methods will facilitate rigorous and reproducible research.

Abstract

Background: HIV testing is the cornerstone of HIV prevention and a pivotal step in realizing the Joint United Nations Program on HIV/AIDS (UNAIDS) goal of ending AIDS by 2030. Despite the availability of relevant survey data, there exists a research gap in using machine learning (ML) to analyze and predict HIV testing among adults in South Africa. Further investigation is needed to bridge this knowledge gap and inform evidence-based interventions to improve HIV testing.

Objective: This study aims to determine consistent predictors of HIV testing by applying supervised ML algorithms in repeated adult population-based surveys in South Africa.

Methods: A retrospective analysis of multiwave cross-sectional survey data will be conducted to determine the predictors of HIV testing among South African adults aged 18 years and older. A supervised ML technique will be applied across the five cycles of the South African National HIV Prevalence, Incidence, Behavior, and Communication Survey (SABSSM) surveys. The Human Science Research Council (HSRC) conducted the SABSSM surveys in 2002, 2005, 2008, 2012, and 2017. The available SABSSM datasets will be imported to RStudio (version 4.3.2; Posit Software, PBC) to clean and remove outliers. A chi-square test will be conducted to select important predictors of HIV testing. Each dataset will be split into 80% training and 20% test samples. Logistic regression, support vector machines, random forests, and decision trees will be used. A cross-validation technique will be used to divide the training sample into k-folds, including a validation set, and models will be trained on each fold. The models' performance will be evaluated on the validation set using evaluation metrics such as accuracy, precision, recall, F_1-score, area under curve-receiver operating characteristics, and confusion matrix.

Results: The SABSSM datasets are open access datasets available on the HSRC database. Ethics approval for this study was obtained from the University of Johannesburg Research and Ethics Committee on April 23, 2024 (REC-2725-2024). The authors were given access to all five SABSSM datasets by the HSRC on August 20, 2024. The datasets were explored to identify the independent variables likely influencing HIV testing uptake. The findings of this study will determine consistent variables predicting HIV testing uptake among the South African adult population over the course of 20 years. Furthermore, this study will evaluate and compare the performance metrics of the 4 different ML algorithms, and the best model will be used to develop an HIV testing predictive model.

Conclusions: This study will contribute to existing knowledge and deepen understanding of factors linked to HIV testing beyond traditional methods. Consequently, the findings would inform evidence-based policy recommendations that can guide policy makers to formulate more effective and targeted public health approaches toward strengthening HIV testing.

Introduction

HIV/AIDS remains a public health threat, affecting 39 million people globally, of whom 25.6 million are within the Sub-Saharan African region [1]. More than half of the global HIV prevalence is concentrated in East and Southern Africa, according to the World Health Organization and the Joint United Nations Program on HIV/AIDS (UNAIDS) [1,2]. HIV testing is a crucial component of the HIV prevention and care continuum [3] and a pivotal step in realizing the UNAIDS's goal of ending AIDS by 2030 [4]. It aims to diagnose and minimize HIV transmission rates while enabling early and effective treatment. Rolling out HIV testing coverage and accessibility to populations with low HIV testing prevalence could assist in improving HIV epidemic control and elimination efforts [3-7].

South Africa has made significant progress toward the UNAIDS 2030 target, ensuring 90% of people living with HIV are aware of their status by the end of 2022 [8,9]. However, the country remains behind schedule as the 90% attainment was set for 2020. Furthermore, there still exist numerous barriers to the uptake of HIV testing [10]. According to Simbayi et al [10], lack of HIV testing is one of the key drivers of HIV infections among the South African adult population.

Previous studies have identified sociodemographic factors, sociobehavioral factors, socioeconomic factors, sexual behaviors, knowledge, attitudes, and perceptions about HIV that could influence an individual's decision to undergo HIV testing [6,7,11,12]. The uptake of HIV testing was found to be very low (34.9%) among Ethiopian youth due to regional variations [11]. The study revealed that being a male, following a protestant religion or orthodox religion negatively influenced the uptake of HIV testing [11]. The same study [11] noted that Ethiopian youth might undergo HIV testing if they have a good knowledge of HIV, engage in risky sexual behavior, are married, are rich, and have access to media. A retrospective analysis of the 2017 South African National HIV Prevalence, Incidence, Behavior, and Communication Survey (SABSSM) survey by Jooste et al [12] highlighted geographic variations by districts and sex in HIV testing among individuals aged 15 years and older. The districts with the lowest HIV testing were uMkhanyakude (54.7%) and Ugu (61.4%) in KwaZulu-Natal and Vhembe (61%) in Limpopo [12]. On the other hand, the uptake of HIV testing was higher among women than men in most of the districts [12]. Probably stemming from the common perception that women are at the highest risk of HIV, numerous studies substantiated a greater hesitancy in HIV testing uptake among men compared to women [11,12]. Socioeconomic factors such as rural residence, low education, household income, and high alcohol consumption have also been associated with low HIV testing uptake [13].

Traditional statistical and testing approaches have been widely used to scale up HIV testing interventions worldwide; while they are effective, they can be subject to certain limitations, such as accuracy, precision, and privacy issues [14]. In contrast, machine learning (ML) models are designed to address these limitations, as they can analyze complex datasets to uncover latent variables associated with HIV testing beyond the reach of conventional methodologies [15,16]. ML refers to the use and development of computer systems that learn and adapt without following explicit instructions, and algorithms are used to analyze and draw conclusions from data patterns [17,18]. The algorithms rely on domain knowledge of the data to develop features that make them work [18]. Various disciplines, including health care, use 3 major types of ML, namely, supervised machine learning (SML), unsupervised machine learning, and reinforcement learning [17-19].

A growing number of studies are developing predictive models to classify HIV high-risk populations for improved HIV testing in a resource-efficient manner [20-24]. Ovalle et al [25] applied support vector machines (SVM), random forest, and logistic regression within a Gay Social Networking Analysis Program, an intelligent web-based health-promotion intervention framework. This study explored the link between social media messages and participants' offline sexual health and substance use outcomes, deriving HIV risk scores for targeted HIV testing [25]. Various SML algorithms such as logistic regression, SVM, random forest, and XGBoost were used to accurately predict HIV risk in South Africa, in which age, being a female, and condom use were significantly associated with HIV positivity [26].

Evidently, ML techniques facilitate the development of economically viable HIV testing methods that offer optimal value for resources invested [16]. Importantly [16], asserts that HIV risk prediction with ML techniques could increase the HIV-diagnosed fraction to 96.5% by 2030, compared to the current traditional method projection of a diagnosed fraction of 93.8% by the same year in South Africa.

Although a significant amount of survey data is available on the factors associated with HIV testing in South Africa, there has been limited research on using ML approaches to analyze

and forecast these factors. Thus, it is against this backdrop that this study is pioneering in using four SML algorithms (logistic regression, random forest, SVM, and decision trees) across all five cycles of the SABSSM surveys to provide new insights into the determinants of HIV-testing behavior in South Africa. The primary aim of this study is to determine consistent predictors of HIV testing and to compare the performance of the four SML models using repeated adult population-based surveys in South Africa to develop an evidence-based predictive model to enhance HIV testing.

Methods

Study Design

A retrospective analysis of data from multiple cross-sectional surveys will be used to predict factors associated with HIV testing across the five cycles of the SABSSM survey using SML algorithms. The analysis will involve four SML algorithms in developing an HIV testing predictive model for the South African adult population. This protocol followed several guidelines and checklists, such as the STROBE (Strengthening the Reporting of Observational Study in Epidemiology) checklist [27] (this can be found in Multimedia Appendix 1), the updated guidance for reporting clinical prediction models that use regression or ML [28] (this can be found in Multimedia Appendix 2), and the development and validation of observational and qualitative study protocol reporting checklists for novice researchers (ObsQual checklist) [29].

Data Source and Population

This secondary data analysis will make use of the 5 cycles of the SABSSM surveys conducted by the South African Human Science Research Council (HSRC). The SABSSM surveys are a series of nationally representative surveys conducted periodically in South Africa to assess the prevalence, incidence, behaviors, and communication related to HIV/AIDS [10]. The first SABSSM survey was conducted in 2002 with 9963 individuals interviewed, followed by SABSSM 2005 (n=23,275), SABSSM 2008 (n=20,826), SABSSM 2012 (n=38,431), and SABSSM 2017 (n=36,609) being the fifth survey [10,30-33]. All five cycles of the SABSSM datasets were made available to the research team on August 20, 2024, after filling and submitting the digital request form via the HSRC website [34]. This study's analysis will focus on adults aged 18 years and older, using data from the five cycles of the SABSSM survey—2002, 2005, 2008, 2012, and 2017. The final sample size for this study will be determined after cleaning and removing outliers from the datasets.

Inclusion and Exclusion Criteria

The SABSSM dataset is a combination of children's, adolescents', and adults' data. This analysis will only include male and female individuals aged 18 years and older from the SABSSM survey. Data outside the defined age bracket from the SABSSM survey data will be excluded from this analysis.

Study Variables

The outcome variable for this study will be HIV testing. The exposure variables are sociodemographic (age, sex, ethnicity or race, education level, marital status, employment, and rural and urban residence), socioeconomic (household income, financial status, and access and usage of health care facilities), sexual behaviors (history of sexually transmitted infections, knowledge of HIV transmission, number of sexual partners, and condom use), HIV knowledge and awareness (knowledge toward HIV prevention, testing and treatment services, and knowledge of HIV status), and perceptions and attitudes (attitudes toward HIV testing, perceived risk of infection, stigma, and discrimination related to HIV). Table 1 describes a few selected variables that are consistent across all the five SABSSM survey datasets. The complete list of the dependent and independent variables extracted from 2002, 2005, 2008, 2012, and 2017 SABSSM survey datasets can be found in Multimedia Appendix 3 (SABSSM 2002 variables), Multimedia Appendix 4 (SABSSM 2005 variables), Multimedia Appendix 5 (SABSSM 2008 variables), Multimedia Appendix 6 (SABSSM 2012 variables), and Multimedia Appendix 7 (SABSSM 2017 variables).

Table 1. Summary of variable and variable definitions from the SABSSM[a] dataset[b].

Variable name and variables	Variable descriptions	Variable recode
Outcome variable (HIV testing)		
HIV testing		
Ever had an HIV test	• Yes • No • No response	• Yes • No
Exposure variables		
Sociodemographic		
Age		
Respondent's age in years	Integer	• <20 • 20-24 • 25-29 • 30-34 • 35-39 • 40-44 • 45-49 • ≥50
Sex		
Sex of the respondent	• Male • Female	• Male • Female
Geotype		
Geographical location	• Urban formal • Urban informal • Rural formal • Rural informal	• Urban • Rural
Race		
Race	• African • White • Colored • Indian or Asian • Other	• African • Colored • Indian • White
Highest level of education		
Respondent's highest level of education obtained	• No schooling • Up to Std[c] 1/Gr[d] 3/ABET[e] 1 • Std 2-Std 3/Gr 4-Gr 5/ABET 2 • Std 4-Std 5/ Gr 6-Gr 7/ABET 3 • Std 6-Std 7/Gr 8-Gr 9/ABET 4 • Std 8/Gr 10/NTC[f] 1 • Std 9/Gr 11/NTC 2 • Std 10/Gr 12/Matric/NTC 3 • Certificate or diploma with Gr 12 • Bachelors degree • Postgraduate degree (HDE/Hons/Masters/PhD)	• No schooling • Primary • Secondary • Tertiary
Sociocultural		
Age at first marriage		
How old was the respondent when married for the first time	Integer	• <18 • 18-23 • 24-29 • 30-35 • >35
Male circumcision status		

Variable name and variables	Variable descriptions	Variable recode
Whether the male respondent is circumcised	• Yes • No	• Yes • No
Independent variable (socioeconomic)		
Employment status		
Employment status	• Unemployed • Sick or disabled and unable to work • Student or pupil or learner • Employed or self-employed • Other	• Unemployed • Sick or disabled and unable to work • Student or pupil or learner • Employed or self-employed • Other
Independent variable (sexual history, sexual behavior, and lifestyle)		
Ever had sexual intercourse		
Whether the respondent ever had sexual intercourse	• Yes • No • No Response	• Yes • No
Number of sexual partners in a lifetime		
Number of people the respondent had sexual intercourse within a lifetime	Integers	• 1 person • 2-5 • >5
Condom use decision		
Who suggested using a condom? The second most recent person	• Yourself • Your partner • Mutual agreement	• Yourself • Your partner • Mutual agreement
Independent variable (health status or pre-existing medical conditions or disabilities or stigma or violence)		
General well-being		
In general, would you say that your health is excellent, good, fair, or poor?	• Excellent • Good • Fair • Poor	• Excellent • Good • Fair • Poor
Independent variable (knowledge, awareness, and perception of HIV/AIDS)		
Knowledge of HIV/AIDS		
Can AIDS be cured?	• Yes • No • I don’t know	• Yes • No • I don’t know

[a]SABSSM: South African National HIV Prevalence, Incidence, Behavior, and Communication Survey.

[b]Only a few selected variables that are common across the five SABSSM surveys were included in Table 1. Please see Multimedia Appendices 1-5 for the complete list of dependent and independent variables.

[c]Std: standard.

[d]Gr: grade.

[e]ABET: adult basic education training.

[f]NTC: National Technical Certificate.

Data Extraction

A data extraction tool (Table 2) with headings such as study year, sample size, study population, age group study settings, and main variables was used to describe the characteristics of the available datasets of the SABSSM surveys. Each dataset was examined, and key variables that could influence HIV testing were identified using additional tools (Table 1, Multimedia Appendix 3 [SABSSM 2002 variables], Multimedia Appendix 4 [SABSSM 2005 variables], Multimedia Appendix 5 [SABSSM 2008 variables], Multimedia Appendix 6 [SABSSM 2012 variables], and Multimedia Appendix 7 [SABSSM 2017 variables]).

Table 2. Characteristics of the five SABSSM[a] survey datasets[b,c].

Study name and year	Sample size, n		Prevalence of HIV testing (reported), %
	Calculated	Individual Interview Response	
SABSSM 2002 [30]	14,450	9963	21.4
SABSSM 2005 [31]	24,236	23,275	30.5
SABSSM 2008 [32]	23,369	20,826	50.8
SABSSM 2012 [33]	42,950	38,431	65.5
SABSSM 2017 [10]	39,132	36,609	75.2

[a]SABSSM: South African National HIV Prevalence, Incidence, Behavior, and Communication Survey.

[b]The study is focused on the general population of South African adults aged 18 years and older.

[c]Study variables were extracted and redefined to guide the data cleaning and preprocessing, as detailed in the data preprocessing section.

Data Preprocessing and Feature Selection

The SABSSM survey datasets are open access data available upon request through the HSRC website [34]. All five cycles of the SABSSM datasets were accessed on August 20, 2024. We have explored them to understand the patterns and the nature of all the variables needed to develop an HIV testing predictive model. For this analysis, RStudio (version 4.3.2; Posit Software, PBC) will be used. The research team will first clean and process the available data to handle outliers and missing values and identify relevant dependent and independent variables in the five cycles of the SABSSM survey to be included in the predictive modeling. This will be followed by feature selection to eliminate redundant and irrelevant variables. Numerical features will be standardized to ensure consistency scaling, and the features will be analyzed to categorize those that will most likely influence HIV testing. We will conduct a chi-square test between the dependent variable (reported HIV testing status) and the independent variables (Table 1). Variables (features) with $P<.05$ will be considered important predictors and will be retained in the final model for predicting HIV testing status. Potential confounders and redundant variables will also be addressed during the feature selection, as detailed in the risk for bias assessment section. One-hot encoding will be used to encode the important HIV testing predictors based on the information available on the SABSSM surveys. One-hot encoding is the process of transforming categorical variables into binary variables, represented by values of 0 and 1, enabling their usage by ML algorithms [35]. This procedure will be accomplished by an R package known as “dplyr” [36].

Algorithms

This study will use four SML algorithms that are widely used in the field of health care, namely, logistic regression, decision trees, random forests, and SVM [37]. Logistic regression is a statistical method commonly used in ML for classification and predictive analytics tasks [38]. It solves classification problems by assigning multiple observations to a discrete set of categories or cases [38]. Another classifier that will be used in this analysis is SVM, a group of SML algorithms that can be applied to classification or regression [39]. The SVM can act as nonprobabilistic binary linear classifiers, depending on their configuration. For instance, a linear kernel function would make an SVM perform as a binary linear classifier. Moreover, SVM can also handle nonlinear classification tasks [39]. Similarly, a decision tree is also an SML classifier that categorizes or predicts depending on prior sets of questions [40]. According to Jo [19], a decision tree resembles a tree that classifies based on the branches of its root nodes. Random forest is also a very popular SML algorithm [22]. It is a robust SML algorithm well-suited for classification tasks involving complicated relationships between different features.

Training and Model Validation

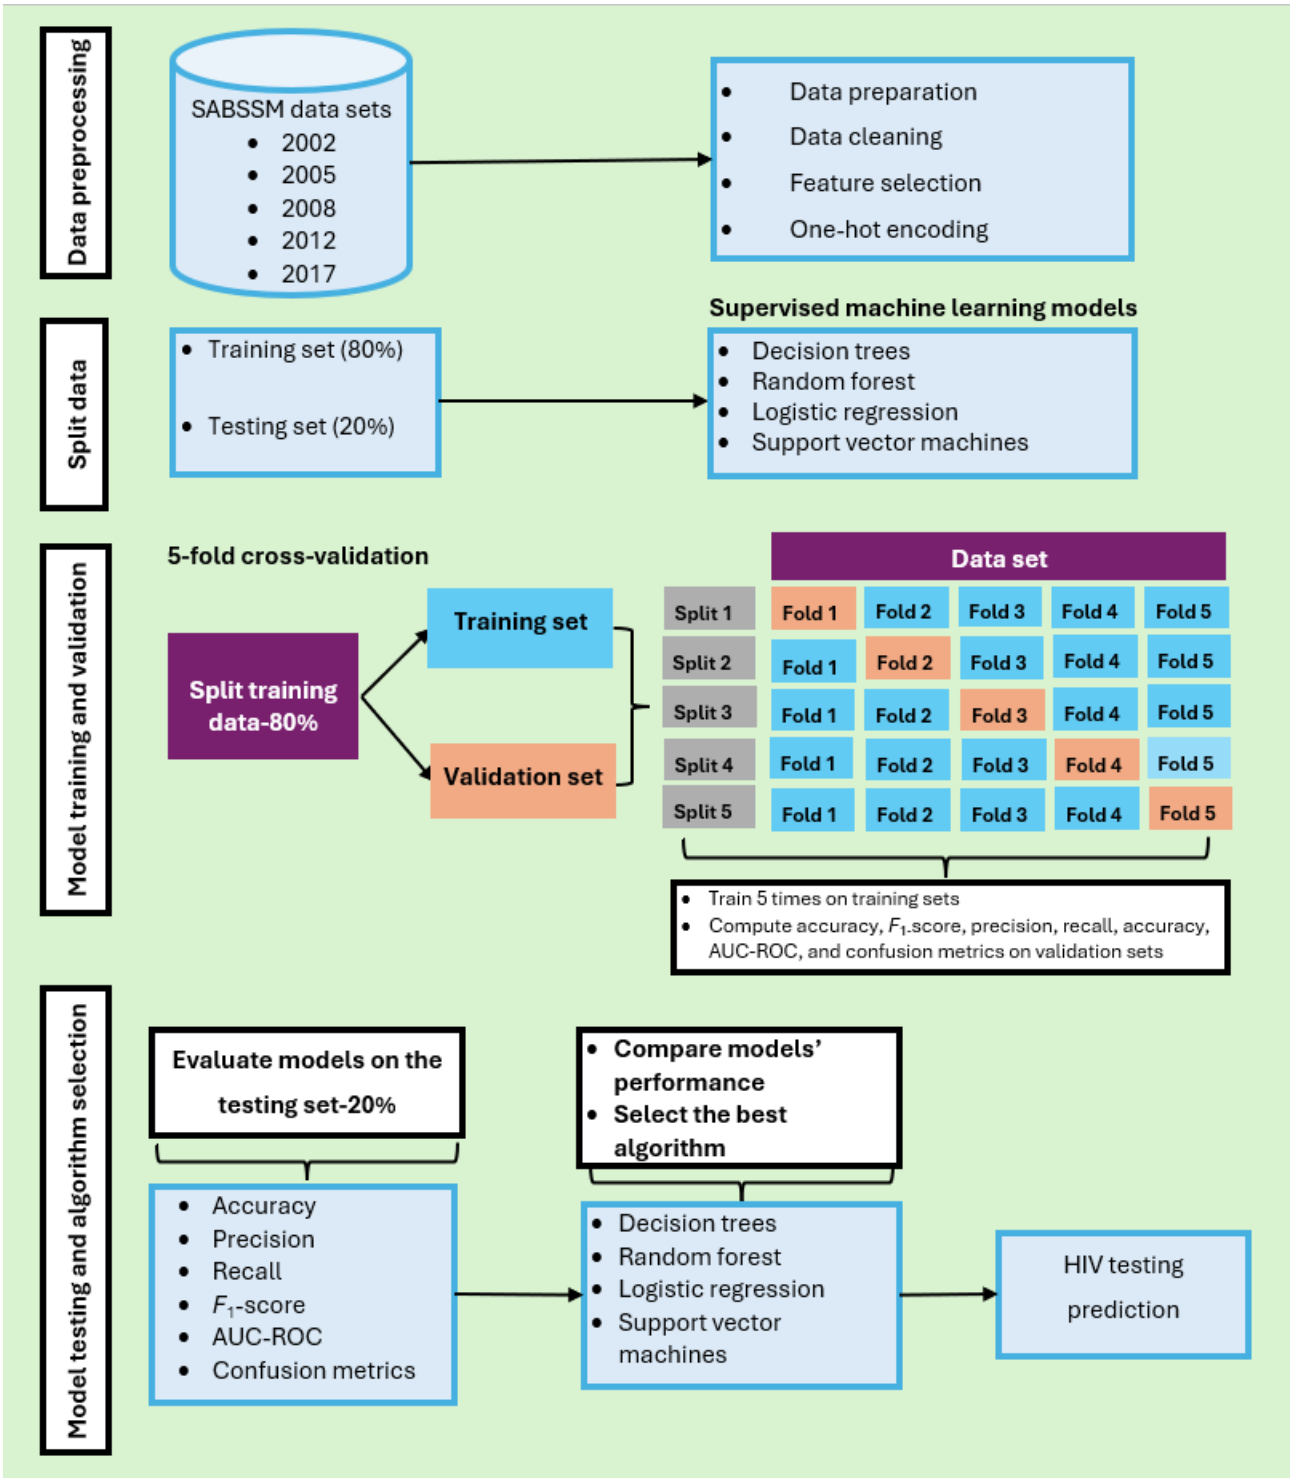
After the preprocessing and feature selection, each cleaned dataset will be split into 80% training and 20% testing samples. The 80/20 rule is the most used splitting ratio, and anecdotal evidence has supported it as being an effectively valid rule [41]. Training and validation will be done to set a probability threshold to predict those factors associated with HIV testing. Four standard SML algorithms will be applied to the training sample, such as logistic regression, decision trees, random forests, and SVM [37]. A cross-validation technique will be used, in which the training sample will be divided into k-folds, including a validation set, and models will be trained on each fold. Usually, k is taken to be 5 or 10, but may differ depending on the dataset size [42]. This study will use either a 5-fold or 10-fold cross-validation technique, depending on the compatibility with the available datasets. The models’ performance will be evaluated on the validation set using the following evaluation metrics: accuracy, precision, recall, F_1-score, area under curve-receiver operating characteristics, and confusion matrix.

Evaluation and Algorithms Selection for Predicting HIV Testing

Model evaluation involves selecting the best-performing model by providing an unbiased estimate of how well the models generalize on new or unseen data [18]. Upon completing the model development, the performance of the four SML models will be assessed on the testing sample using standardized performance evaluation metrics, including accuracy, precision, recall, F_1-score, area under curve-receiver operating characteristics, and confusion matrix [43]. This procedure will assess the performance of logistic regression, SMV, random forest, and decision trees in order to select the best-performing models in predicting HIV testing status using the five cycles of the SABSSM datasets. Figure 1 [21,43] depicts the data

processing stages, HIV testing predictive models to be used, and performance evaluation criteria.

Figure 1. Data preprocessing and HIV testing prediction modeling (created using PowerPoint [version 16.0.1; Microsoft Corp] diagram flow and concept guided by Mutai et al [21], Chingombe et al [38] and Chingombe et al [43]. AUC-ROC: area under curve-receiver operating characteristics; SABSSM: South African National HIV Prevalence, Incidence, Behavior, and Communication Survey.



Risk for Bias Assessment

Since the proposed study will analyze secondary data from multiple cross-sectional data, it is pertinent to assess and mitigate potential bias to ensure the validity and reliability of the results. The Joanna Briggs Institute Critical Appraisal Checklist for Analytical Cross-Sectional Studies (this can be found in the Multimedia Appendix 8) will be used to mitigate the risk of bias in this study. At first, the researchers reviewed published reports of the five SABSSM surveys to understand the study designs, study population, sample biases, study variables, and the data collection methods used in each survey by the HSRC. This process guided the development of the study design, eligibility criteria, and variable selection for this study. As of August 20, 2024, the authors have started exploring the SABSSM datasets to clean the data and treat missing values.

Imbalanced data occurs when one class has significantly more observations than the other, leading algorithms to be biased toward the majority class. In such cases, the researchers will use various techniques to address this and ensure fair model performance. Potential confounders of HIV testing will be identified based on consultations with the literature, as well as the use of statistical measures. Additionally, a variance inflation factor will be used to detect multicollinearity and remove redundant variables associated with HIV testing. This process will also inform the selection of features to be used for the HIV testing predictive modeling.

Data Management

This predictive modeling will use the SABSSM datasets sourced from the HSRC, with no personal information collected from the study participants. Following the data preprocessing and analysis, the preliminary results will be maintained securely using a memory stick that requires an access code. Only the researcher and the research team will be able to review these findings. The results to be published will not contain any identifying information. The electronic data will be stored in the Boloka data repository, password-protected with username access. The Boloka project aims to harness big heterogeneous data to evaluate the impact of HIV responses among key populations in generalized epidemic settings in Sub-Saharan Africa. All the data used in this study will be managed in compliance with the Protection of Public Information Act. The data generated from this study will be securely stored in the Boloka data repository for five years following the study's completion. It is important to note that the SABSSM datasets are governed by an End User License. As per the data-sharing conditions stipulated by the HSRC, the study's data cannot be duplicated, reshared, or sold without prior approval from the rights holder [34].

Ethical Considerations

This study protocol forms part of a doctoral study at the University of Johannesburg (UJ) by the first author (MJ), titled, "Integration of machine learning algorithms to predict HIV testing associations using repeated cross-sectional survey data in an adult South African population: an HIV testing predictive model." The study protocol was approved by the UJ Research and Ethics Committee on April 23, 2024; ethics approval REC-2725-2024 (this can be found in Multimedia Appendix 9). Further, the doctoral study falls under an umbrella project funded by the South African Medical Research Council under the South African Medical Research Council/UJ Pan African Centre for Epidemics Research Extramural Unit, titled: "Harnessing big heterogeneous data to evaluate the potential impact on HIV responses among the key populations in generalized epidemic settings in Sub-Saharan Africa" (ethics approval: REC-1504-2022). Since this study will analyze secondary data, a waiver of informed consent for secondary data use was obtained from the UJ Research and Ethics Committee (this can be found in Multimedia Appendix 9). According to Shisana and Simbayi [30], Shisana et al [31-33], and Simbayi et al [10], all the SABSSM surveys have been approved by the HSRC REC, and studies were conducted in accordance with international ethical standards, as well as the South African Children ACT 2007. Additionally, the SABSSM research team ensured that participants obtained voluntary informed consent. The authors of this study received the SABSSM datasets without any identifying information, and no further efforts will be made to reidentify the study participants during the analysis. The SABSSM datasets are open access data governed by an End User License that cannot be duplicated, reshared, or sold without prior approval from the rights holder (HSRC) [34]. This study will adhere to these data-sharing conditions and all the ethical standards governing the use of secondary data of human participants.

Results

The authors were given access to the SABSSM datasets for this retrospective analysis by the HSRC on August 20, 2024. All 5 datasets were downloaded from the HSCRC database and explored to identify the independent variables likely to influence HIV testing uptake as of September 30, 2024. The selected dependent (HIV testing status) and dependent variables (age, sex, province, marital status, knowing a place to test for HIV, male circumcision, condom use, sex debut, knowledge and perception of HIV, STI symptoms, visit a doctor, and contraceptive use) were recorded for each SABSSM dataset as similar to Table 1 (complete list of variables can be found in Multimedia Appendix 3 [SABSSM 2002 variables], Multimedia Appendix 4 [SABSSM 2005 variables], Multimedia Appendix 5 [SABSSM 2008 variables], Multimedia Appendix 6 [SABSSM 2012 variables], and Multimedia Appendix 7 [SABSSM 2017 variables]). The preprocessing and feature selection phase described in the methods section will determine which variables are to be used for the HIV testing predictive modeling. This process is expected to be completed by November 30, 2024.

The results of this study will be available by January 31, 2025, and each step of the analysis will be visualized and presented in tables and graphs. The anticipated date of publication for the proposed study is June 2025.

Discussion

Principal Findings

The proposed study seeks to identify intricate patterns and relationships among various sociodemographic, behavioral, and contextual variables that contribute to individuals' decisions to undergo HIV testing in South Africa. Since the first SABSSM survey in 2002, varying rates of HIV testing among South Africans have been reported by the HSRC, showing increased trends in each cycle until 2017 (Table 2). By applying SML learning techniques across the five cycles of the SABSSM survey datasets, the findings of this study will ascertain consistent variables predicting HIV testing uptake among the South African adult population over the 20-year period. Furthermore, the study will evaluate and compare the performance metrics of the four different SML algorithms, and the best model will be used to develop an evidence-based predictive model to enhance HIV testing among the South African adult population.

The emergence of ML applications in health care has demonstrated significant progress. However, predictive modeling in the context of HIV testing is relatively low in developing countries due to challenges such as usability issues, lack of expertise, and insufficient health care data [44]. Steadily, research institutions within specific African countries are increasingly expressing interest in this field.

A study conducted in Tanzania applied SML algorithms, including XGBost and random forest, to develop a model aimed at enhancing HIV index testing, with the recommendation that other health facilities use their model to simplify their work [18]. The study found that knowledge of HIV, age, sex, and marital were significantly associated with HIV index testing [18]. Likewise, a South African study by Majam et al [26] confirms that SML models can be built using digital surveys from low- and middle-income countries to predict high HIV groups for enhanced HIV testing. The models predicted, with over 80% accuracy, that female individuals hesitant to report condom use, and those who had not undergone HIV tests within the past year were at the highest risk of HIV [26]. In addition, an SML technique was used to assess the sociobehavioral predictors of HIV from Demographic and Health Survey data in 10 East and Southern African countries. According to the study, seven male and five female individuals would need to be tested to find one HIV-positive individual [37]. It is also important to consider HIV testing preferences for individuals undergoing HIV testing. Confidentiality, distance from the testing center, and method of data collection were identified as factors determining individual HIV testing preferences in South Africa [45].

The proposed study will expand on the existing knowledge of HIV testing predictors through the application of SML algorithms. Our choice of using SML is based on their heightened predictive accuracy, interpretability, efficiency, and adaptability. The proposed study aims to develop a predictive model to forecast HIV testing associations using repeated cross-sectional survey data in an adult South African population. The developed evidence-based model would assist relevant stakeholders in devising targeting HIV testing interventions in striving toward the UNAIDS 2030 goal of eradicating AIDS in South Africa.

Strengths and Limitations

To the best of our knowledge, this will be the first study to conduct HIV testing predictive modeling using all 5 cycles of the SABSSM surveys by applying SML algorithms. The large volume of data will be crucial for the generalizability of the developed models, as well as the major findings. It is also important to mention that the research involves a multidisciplinary team of experts across public health, epidemiology, biostatistics, and data science. The well-equipped team will devise a comprehensive methodological approach to developing an adaptable HIV testing predictive model.

However, this study is expected to face some limitations as the SABSSM surveys may contain missing values; proper imputation techniques will be used to address this issue. Since some ML models are not well developed, causing spatial and temporal variations, this could also be a limitation in our proposed study. Furthermore, because the analysis focuses on secondary datasets gathered using cross-sectional designs, the researchers are aware of potential limitations such as biases and lack of control over the variables included. The Joanna Briggs Institute Critical Appraisal Checklist will be used to mitigate the risk of bias in this study.

Conclusions

This study will contribute to knowledge and deepen understanding of factors linked to HIV testing beyond traditional methods. Consequently, the findings would inform evidence-based policy recommendations that can guide policy makers to formulate more effective and targeted public health approaches toward strengthening HIV testing in South Africa.

Acknowledgments

The study presented in this publication is within the scope of the Boloka Project and forms an essential part of a doctoral study by MJ conducted within the South African Medical Research Council/University of Johannesburg (SAMRC/UJ) Pan African Centre for Epidemics Research (PACER) Extramural Unit. The research outlined here was made possible through funding from SAMRC under its Division of Research Capacity Development, supported by the South African National Treasury (Project Code: 57035, SAMRC File ref: HDID8528/KR/202). The content of this paper remains the sole responsibility of the authors and does not necessarily represent the official views of SAMRC or UJ. Additionally, this paper forms an integral part of MJ's PhD study and is generously funded by the Global Excellence Stature (GES) 4.0 Scholarship at UJ. The authors express their gratitude to the SAMRC/UJ PACER and the UJ GES 4.0 for providing financial support for this study. We also extend our sincere appreciation to the Human Science Research Council and all the participants of the SABSSM surveys for providing the data used in this study.

Data Availability

The datasets to be analyzed in the proposed study are not publicly available due to the data-sharing conditions of the Human Science Research Council (HSRC; prohibition of the duplication, resharing, or selling of data without prior approval from the rights holder) but are available from the HSRC on reasonable request [32].

Authors' Contributions

MJ, RNP-M, EP, and YAS conceived and designed the study. MJ, RNP-M, and EP reviewed the literature. MJ wrote the first draft of the paper. MJ and YAS developed the methodology and identified machine learning models that will be used for predictive modeling of HIV testing. RNP-M, EP, and YAS reviewed and supervised the work. MJ, RNP-M, EP, and YAS edited the manuscript. All the authors contributed to this paper.

Abstract

Background: Mental illness is one of the top causes of preventable pregnancy-related deaths in the United States. There are many barriers that interfere with the ability of perinatal individuals to access traditional mental health care. Digital health interventions, including app-based programs, have the potential to increase access to useful tools for these individuals. Although numerous mental health apps exist, there is little research on developing programs to address the unique needs of perinatal individuals. In an effort to fill this gap, a multidisciplinary team of experts in psychology, psychiatry, obstetrics, and pediatric primary care collaborated to develop the novel Perinatal Skills Program within Maya, a flexible and customizable cognitive-behavioral skills app. Maya-Perinatal Skills Program (M-PSP) uses evidence-based strategies to help individuals manage their mood and anxiety symptoms during pregnancy and post partum.

Objective: This pilot study aims to assess the feasibility, acceptability, and usability of M-PSP and explore links between program use and symptoms of anxiety and low mood.

Methods: This single-arm trial will recruit 50 pregnant or postpartum individuals with mild-to-moderate anxiety or mood symptoms. Participants will be recruited from a variety of public and private insurance-based psychiatry, obstetrics, and primary care clinics at a large academic medical center located in New York City. Participants will complete all sessions of M-PSP and provide feedback. Outcome measures will include qualitative and quantitative assessments of feasibility, acceptability, and usability, passively collected program usage data, and symptom measures assessing mood, anxiety, and trauma. Planned data analysis includes the use of the grounded theory approach to identify common themes in qualitative feedback, as well as an exploration of possible associations between quantitative data regarding program use and symptoms.

Results: The recruitment began on August 2023. As of October 2024, a total of 32 participants have been enrolled. The recruitment will continue until 50 participants have been enrolled.

Conclusions: Digital health interventions, like M-PSP, have the potential to create new pathways to reach individuals struggling with their mental health. The results of this study will be the groundwork for future iterations of M-PSP in the hopes of providing an accessible and helpful tool for pregnant and postpartum individuals.

Introduction

Maternal mental health plays a pivotal role in influencing the health and well-being of both mothers and their children. In the United States, there is a growing maternal health crisis, in which mental health conditions rank among the top causes of preventable pregnancy-related deaths for mothers [1,2]. During pregnancy and the postpartum period, perinatal mood and anxiety disorders (PMADs) significantly influence a mother's ability to function, care for, and bond with their newborn, which can have an impact on the child's subsequent socioemotional developmental trajectory [3-5].

Though PMADs remain prevalent, with global perinatal depression rates at 26.3%, there is a serious lack of effective, accessible, and affordable mental health care for individuals in the perinatal period [6]. This is particularly true in low- and middle-income communities and countries. In these areas, a general scarcity of maternal mental health services is further exacerbated by stigma, fewer financial resources, and logistical barriers that interfere with connecting to care [7]. As such, many struggling individuals suffer in silence, without appropriate recognition or intervention for their pressing maternal mental health needs [8].

Fortunately, the digital age offers a beacon of hope in bridging the divide between growing community needs and barriers to care, and digital health interventions have the potential to improve maternal mental health outcomes [9]. Specifically, smartphone apps may be able to offer accessible and user-friendly platforms that teach useful coping strategies, which may be especially beneficial for mothers who have difficulty accessing traditional mental health services [10]. However, the landscape of mobile health apps using evidence-based information or psychological interventions is relatively sparse, and efforts to tailor these tools to meet the unique needs of the perinatal population are in the early stages of the field [11,12]. There are numerous mobile health apps targeting this population, with a range of tools for prevention, screening, and treatment, and varying content that includes psychoeducation, symptom monitoring, cognitive behavioral therapy (CBT), mindfulness, and attention bias modification training. Thus far, evidence regarding the effectiveness of existing mobile health interventions is mixed. Recent meta-analyses and systematic reviews demonstrate that app-based interventions are effective for individuals with mild-to-moderate symptoms of perinatal depression and anxiety and may be effective at preventing and treating postpartum depression compared to control groups [12,13]. Few of the existing apps use both evidence-based strategies and provide psychoeducation, as well as target both pregnant and postpartum individuals and both depression and anxiety. More research is needed to aid in the development of technology that is feasible, acceptable, and effective for pregnant and postpartum individuals who need tools to support their mental health.

To help address the critical gap in care needs, this study will present a protocol to assess the feasibility and acceptability of the novel Perinatal Skills Program within Maya, a cognitive-behavioral skills app. Maya-Perinatal Skills Program (M-PSP) is a 12-session mobile app–based program teaching evidence-based strategies to manage mood and anxiety symptoms for perinatal individuals. Following a community-based participatory research model, the study team is seeking feedback from users throughout the early stages of program development. User input will help inform future iterations of the app-based program in hopes of creating a tool that can effectively meet the needs of this population. This protocol represents the first step in the development of a tool designed to increase access to evidence-based skills for individuals with PMADs.

Methods

Aims

The primary aim of this study is to assess the feasibility and acceptability of M-PSP. Specifically, the team will evaluate the mobile app–based program in terms of user satisfaction, perceived use of the program, and engagement with the program. A secondary aim of the study is to look for any associations between program completion and engagement with mental health symptoms.

Design

This study is a mixed methods open pilot trial assessing the feasibility, usability, and acceptability of M-PSP in a perinatal population. There are no comparison arms in the trial. Outcomes will include a combination of quantitative and qualitative data gathered via self-report questionnaires, interviews, and data passively collected through the app. This methodology will allow for the collection of symptom data, participant perceptions and feedback on their experience using the app, and information on app use and engagement. Results will provide information on the potential use of this program in helping pregnant and postpartum individuals manage mood and anxiety symptoms, as well as future directions for program development.

Setting

The study is being conducted through a large academic medical center in New York City. Participants will be recruited through various departments within the medical center, including a psychiatry specialty center, primary care and pediatric settings, and obstetrics and gynecology clinics. These sites range in providing services through private pay, private insurance, or public insurance.

Participants

The study is currently open to recruitment, with the aim to recruit 50 pregnant or postpartum individuals across all sites. In prior studies, feasibility studies often include a sample size of approximately 50 participants, which is deemed appropriate to ensure robust findings and comprehensive insights into app usability and effectiveness, balancing the need for inclusivity and accurate representation while accounting for potential participant attrition in digital mediums [14,15]. The inclusion criteria for study participation include (1) aged 18 years or older; (2) pregnant or up to 12 months post partum; (3) scoring 8-16 on the Edinburgh Postnatal Depression Scale (EPDS) [16] or 5-14 on the Generalized Anxiety Disorder-7 Scale (GAD-7) [17]; (4) able to read and speak English; (5) have access to a smartphone or mobile device capable of receiving SMS pushes and supporting Qualtrics Surveys and App (Weill Cornell Medicine); and (6) available to speak by phone or secure videoconference. The exclusion criteria include (2) safety concerns at the time of enrollment; (2) current substance use disorder; (3) current symptoms of psychosis or mania; and (4) history of bipolar or psychotic disorder.

M-PSP is designed to address mild-to-moderate anxiety and depression symptoms and may not be appropriate for more severely impaired individuals. In order to secure feedback from participants matching the app's target population, the inclusion criteria include those scoring in the mild-to-moderate range on anxiety and depression ratings. Participants with safety concerns at the time of intake, including recent suicidal ideation or self-harm, are excluded as they are at higher risk for heightened symptoms and risk in the perinatal period. Eligibility is not impacted by receipt of clinical care outside of the study, and participants are not excluded if they are receiving concurrent treatment for depression or anxiety.

Study participants may be disenrolled from the study if they are nonresponsive to 16 outreach attempts across 4 consecutive weeks or if their pregnancy ends.

Outcome Measures

Primary Outcome Measures

Feedback Interviews

Feedback interviews, led by staff via phone or video calls, include open-ended questions aimed to elicit qualitative feedback on program content, structure, and functionality, as well as user engagement and satisfaction. Questions such as "What ways could the app have been better tailored to help expectant or postpartum individuals?" will be asked to have a better gauge of acceptability, while questions like "What suggestions or comments do you have about the total number of sessions?" help address the feasibility of an intervention during and after pregnancy.

In-App Surveys

Weekly in-app feedback surveys are self-report measures that include Likert-scale questions regarding participant experience with specific session-by-session app-based content and structure (eg, "How helpful was Cognitive Practice [TINTED or Thinking Like a Lawyer]?"; "How likely are you to review any part of Session 3 again [eg, video, exercises, or quiz]?"). In particular, questions such as "How helpful was the content for you as an individual who is pregnant or postpartum?" and "How easy was it to fit using the app into your day-to-day life?" inform us of the acceptability and feasibility of the app, respectively, throughout the study.

User Version of the Mobile Application Rating Scale

Whereas the in-app surveys elicit session-by-session feedback, the user version of the Mobile Application Rating Scale (uMARS) elicits more global feedback on the overall app experience. The uMARS [18] is a validated 27-item self-report questionnaire evaluating engagement, functionality, aesthetics, information, subjective quality, and perceived impact of the app-based program. In particular, engagement, aesthetics, and information subscores will be used to measure acceptability and the functionality subscale will reflect the app's usability.

Mean scores are derived for each of these subsections, which can then be averaged to determine an overall App Quality Score. Responses are rated between 1 and 5, with 5 indicating higher levels of satisfaction. Stoyanov et al [18] found that uMARS exhibited satisfactory internal consistency (α=.90).

Passive Data Collection

M-PSP passively collects data, encompassing information captured without active user input, such as when sessions were completed, frequency of program usage, and program completion. These data points will serve as measures of program feasibility and user engagement.

Secondary Outcome Measures

Intake Survey

Participants will complete an intake questionnaire comprising questions related to demographics, health, mental health, and pregnancy history.

Edinburgh Postnatal Depression Scale

The EPDS [16,19] is a 10-item self-report measure of mood symptoms in perinatal individuals. Responses are coded on a scale of 0=lowest severity to 3=highest severity, with 30 being the highest score possible. Cutoffs are as follows: scores 7 and below indicate depression is unlikely, scores 8-13 indicate mild depression, 14-18 indicate moderate depression, and 19 and higher indicate severe depression [20]. Cox et al [21] found that the EPDS is a valid screening scale for depression and has satisfactory sensitivity (79%) and specificity (85%).

The Edinburgh Anxiety Subscale

The Edinburgh Anxiety Subscale [22] uses items 3, 4, and 5 from the EPDS to assess levels of anxiety among perinatal individuals. A score of 5 and above indicates the presence of anxiety [23].

Pregnancy Symptom Tracker

The daily Pregnancy Symptom Tracker (PST) is an ecological momentary assessment tool that aims to merge and consolidate gold-standard symptom measures into a format that is friendly and efficient for users, while also tracking information related to sleep, exercise, and daily behaviors. Developed by a group

of psychiatrists and reproductive psychiatrists, the measure takes 30-60 seconds to complete. Users use a sliding scale to indicate the degree of each symptom or behavior present within the last 24 hours.

GAD-7

The GAD-7 [17] is a 7-item self-report measure assessing symptoms of anxiety. Responders indicate the frequency of symptoms on a scale of 0=not at all to 3=nearly every day, with total scores running from 0 to 21. A score of 0-4 indicates minimal anxiety, 5-9 indicates mild anxiety, 10-14 indicates moderate anxiety, and 15-21 indicates severe anxiety. Spitzer et al [17] found that the GAD-7 exhibited reliable sensitivity (89%) and specificity (82%), validating its effectiveness as a screening tool for generalized anxiety disorder.

Patient Health Questionnaire-9

The Patient Health Questionnaire-9 (PHQ-9) [24] is a validated 9-item self-report measure assessing symptoms of depression. Responders indicate the frequency of symptoms on a scale of 0=not at all to 3=nearly every day. Scores can range from 0 to 27, with an additional qualitative question regarding the level of difficulty caused by symptoms ranging from no difficulty at all to extreme difficulty. Scoring interpretation is as follows: 1-4 (minimal depression), 5-9 (mild depression), 10-14 (moderate depression), 15-19 (moderately severe depression), and 20 and greater (severe depression). Kroenke et al [24] found that a PHQ-9 score ≥10 exhibited a satisfactory sensitivity of 88% and a specificity of 88% for major depressive disorder.

Perinatal-Post Traumatic Stress Disorder Questionnaire-II

The Perinatal-Post Traumatic Stress Disorder Questionnaire-II (PPQ-II) [25] is a validated 14-item self-report measure assessing symptoms of trauma among postpartum individuals. Frequency and duration of symptoms are rated on a 5-point Likert scale from 0=not at all to 4=often for more than a month, with total scores ranging from 0 to 56. Scores of 19 above indicate a clinical range of symptoms that would benefit from additional support. Komurcu Akik and Durak Batigun [25] found that the PPQ-II demonstrates validity and reliability as a scale for assessing the perinatal post-traumatic stress symptoms experienced by mothers.

The M-PSP Intervention

The Perinatal Skills Program was developed within Maya, a CBT skills app that is customizable and allows for the creation of individualized programs for multiple populations. M-PSP was adapted from one such program, Maya-Cognitive Behavioral Skills Program (M-CBT), which was a 12-session program that provided gold-standard, evidence-based strategies to help young adult users learn tools to manage anxiety and low mood. Preliminary data from a feasibility and acceptability trial of M-CBT suggest that the app is feasible and acceptable, and results showed a substantial decrease in both depression and anxiety from pre- to post-intervention [26]. In response to rising maternal mental health needs, an expert team of clinical psychologists specializing in CBT and reproductive psychiatrists with expertise in perinatal mental health adapted M-CBT into M-PSP. The team also consulted with physicians within pediatric primary care and obstetrics departments to better understand the needs of expectant and new parents. Changes to the original program included tailoring language and examples to address concerns that are common during and after pregnancy, as well as modifying skills as appropriate for the perinatal population. Several new skills were added, such as tools for managing communication and relationships as an expectant or new parent (Multimedia Appendix 1).

Users can work through each M-PSP session on their own schedule and are able to unlock up to 2 sessions per week. This pacing mirrors typical CBT session structure, allowing time for homework and practice between sessions, which is crucial for skill development and mastery [27,28], and acknowledges research showing that most people engage with apps for a limited duration, necessitating a structured yet flexible format to maximize engagement and effectiveness [29,30]. Each session in the program includes 3 main sections: learn (where new information and skills are shared), practice (where users can try out the skills they learned), and review (wrap-up of key lessons and takeaways). Users are introduced to a range of evidence-based tools throughout the 12 sessions (Table 1). There are also homework assignments for each session allowing users to practice what they have learned throughout the week. Users can individualize their experience by entering and tracking mood and anxiety ratings, planning for real-world skills use, personalizing examples, choosing preferred exercises to try, and reflecting on skill practice. The app has been programmed to help users see their progress through the app and track change toward self-identified goals. Users are also able to make use of tabs within the app for quick access to specific information, such as videos, skill practice, and favorite tools. Study staff have weekly meetings to ensure protocol is adhered to.

Table 1. M-PSP[a] session content.

Session	Session objectives and content
Session 1: Understanding symptoms and treatment	• Psychoeducation on perinatal anxiety and mood symptoms • Sleep tips for pregnancy and post partum. • Identifying common perinatal patterns of thoughts, feelings, and behaviors
Session 2: Facing challenges	• Identifying how emotions impact behavior during the perinatal period • Learning to gradually approach and overcome challenging tasks • "Face It!" exercise to craft an individualized goal ladder for daily practice
Session 3: Shifting thoughts	• Cognitive restructuring techniques to reframe unhelpful thinking • Guidance on effective communication and managing evolving relationships • Introduction of "TINTED Thoughts" exercises to recognize and correct cognitive distortions
Session 4: Relaxing your body and mind	• Introduction to relaxation exercises and audio-guided muscle relaxation meditation session. • Distress tolerance tips to manage stressful moments • "Face It!" exercise to craft an individualized goal ladder for daily practice
Sessions 5-10: Practice and use skills	• Revisiting the list of challenging situations and tracking progress • Continued practice of helpful thoughts and "Face It!" exercises • Introduction to problem-solving skills and additional distress tolerance exercises
Sessions 11-12: Maintenance and relapse prevention	• Guided selection of an exercise for ongoing skill practice • Skill review and reflection exercise • Guidance on next steps to support sustained mental health

[a]M-PSP: Maya-Perinatal Skills Program.

Procedure

As of October 2024, the study is open to recruitment. Recruitment strategies involve advertisements through listservs, clinician information sessions, and flyers within inpatient and outpatient departments. Interested individuals can complete a digital contact information form via a Health Insurance Portability and Accountability Act–compliant survey platform or have their providers complete the contact forms on their behalf.

Study staff reach out to individuals who have completed the form to screen for eligibility. Eligible participants are given further details about study involvement and complete informed consent. Study staff help participants download the app and provide an orientation, with recommendations to use the program for 10 minutes a day, 4 days a week. While it is recommended to complete the program within 6 weeks, sessions can be completed at the participant's convenience. All participants will be allowed up to 18 weeks for completion in order to account for delays or interruptions that may have occurred during pregnancy or after labor and delivery. Within 1 week of the study orientation, the research assistant will conduct a brief 5-minute phone check-in using a scripted protocol to ensure participants have been able to access and start the app, check on potential technical issues, and answer any questions related to app navigation.

Throughout participation, participants will be able to complete up to 2 sessions per week and will complete the in-app feedback surveys after each session. They will also be sent a text to their phone with a link to complete the daily PST. Additional assessments occur at midpoint (following completion of session 6), post (completion of session 12), and follow-up (6 weeks after post). These assessments include the staff-led feedback interviews via phone or videoconference, as well as the uMARS and all symptom measures. When risk items are endorsed on the daily PST, symptom measures, or during the assessments, study staff are notified and the participant is contacted by a licensed provider to conduct a formal risk assessment and safety plan as necessary.

To aid in retention and study completion, study staff monitor app completion progress and maintain contact with participants to schedule feedback interviews (Table 2). Through these methods, staff are able to problem-solve technical difficulties and other barriers to session completion as needed. Participants are encouraged to reach out via email or phone with any questions or concerns. Study staff follow institutional review board (IRB) guidelines to report any adverse events within the required timeline.

Data Analysis Plan

To analyze qualitative data from the feedback interviews, the grounded theory approach [31] will be used to review all responses and develop a consensus on existing themes. The data will then be systematically coded using these themes in order to identify core concepts and response patterns to derive meaningful interpretations of the feedback.

Data passively collected from the app will be transformed into practical means and ranges that will be used to understand user engagement and program feasibility. Means and SDs will be computed for demographic information and relevant symptom and acceptability questionnaires. Continuous scores from symptom scales and acceptability questionnaires will be analyzed in relation to app use and engagement. Correlations between these variables with be assessed using either Pearson or Spearman correlation depending on data distribution. For example, we will examine the correlation between EPDS symptom scores and app completion rates to explore whether postpartum depression symptoms are related to program feasibility. Hypothesis testing will be conducted with a *P* value=.05 as the threshold for statistical significance, and clinical significance will be considered for correlations that meet a meaningful cutoff (eg, 0.6 or 0.8). This analysis will help identify any demographic characteristics or symptoms that may require greater attention in future iterations of the program to ensure its effectiveness for a broad range of perinatal individuals. For participants who dropped out before study completion, all available data will be included, and any missing data will be handled using simple imputation. A correlation matrix will be generated to explore the relationships between symptom scales (eg, EPDS and GAD-7) and app engagement variables (eg, frequency of use, duration of use), allowing us to investigate possible associations without the need to correct for multiple testing in this exploratory pilot study.

Ethical Considerations

The study was granted approval through the Biomedical Research Alliance of New York IRB (BRANY #23-02-134-380) and the internal IRB within the academic medical center at which the trial is being conducted. The study has been registered at ClinicalTrials.gov (protocol number NCT05897619). This protocol was written in accordance with the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) guidelines (Multimedia Appendix 2) [32]. All participants provided informed consent and were made aware that they could withdraw from the study at any time without penalty. Participants are not compensated for their participation. All participants may continue to use the MAYA app following study completion if they so choose and will be given a list of resources, including referrals for clinical care.

While no individual data will be reported, the study team will report results via publication following trial completion. Health care providers within the Weill Cornell Medicine or NewYork-Presbyterian network may be given access to a summary of qualitative and quantitative outcomes. Every participant is given a unique study identifier. All data collected were confidential and safely stored per protocol approved by the IRB. As a small, unblinded study that does not involve invasive procedures or greater than minimal risk, there is no data monitoring committee. The study is internally sponsored, with no external funding organization involved in study design, management, monitoring, or analysis. The study is fully monitored by internal co-investigators, with IRB oversight through BRANY.

Results

The pilot trial received internal funding in August 2023 and data collection started in September 2023. As of October 2024, 32 participants have been enrolled in the study. It is anticipated that enrollment will continue throughout 2024, with projected

recruitment completion in December 2024. Data analysis will be completed upon study completion of the last participant.

Discussion

This study aims to assess the feasibility, usability, and acceptability of the M-PSP, a 12-session program teaching skills derived from CBT and adapted to suit the unique needs of a perinatal population. Regarding feasibility, it is anticipated that outcomes will indicate the program is able to be worked through by users, but that pacing and session length may need more flexibility in future versions of the app to account for the particular demands of this population. It is hypothesized that users will find the skills to be acceptable, but that some of the sample videos need revision to more directly reflect mood and anxiety concerns during and after pregnancy. Further, the study team anticipates that users will have input on specific content that could be added to improve their satisfaction with the app. Regarding usability, it is anticipated that the app will be user-friendly and easy to work through. As the secondary aims are exploratory, there are no specific hypotheses related to symptom measures as they are related to engagement. These outcomes will inform future iterations of the program in hopes of developing a widely accessible and useful tool for pregnant and postpartum individuals.

While the findings from this pilot study will provide valuable insights, several limitations must be acknowledged. This study relies on self-report data, which may introduce biases such as social desirability or recall errors. In future studies, clinician assessment of symptoms could help to mitigate these concerns. In this and future studies, the use of passively collected app usage data should provide some objective metrics regarding engagement and feasibility. A further limitation is the small sample size. As a pilot trial, this study is not powered to detect statistical significance, as the primary aim is to assess feasibility and acceptability rather than efficacy. Therefore, these findings should be interpreted as preliminary, and further research with larger samples will be necessary to assess the program's effectiveness in improving mental health outcomes.

Despite these limitations, this study is an important step in helping to fill the gap between an increasing maternal mental health crisis and barriers to appropriate support. By using a community-based-participatory research model, the development team has been able to consider input from researchers and clinicians across different specialties and will be able to incorporate feedback from end users through each stage of program development. Once feedback has been considered and incorporated into the program, the team will look to conduct future studies to assess the effectiveness of the tool in helping perinatal individuals manage anxiety and mood symptoms. Per guidelines on progressing from a pilot trial to a fully powered randomized controlled trial (RCT) [33], the research team has outlined a number of criteria that will influence the next steps. To ensure adequate participant numbers for an RCT, the pilot trial will need to demonstrate a 50% retention rate between screening and enrollment. The team will also move forward if 75% of participants complete primary outcome measures, which consist of feasibility, acceptability, and usability feedback interviews and surveys. While the study team will track adherence to the intervention (ie, completing M-PSP sessions), this will not be used as a criterion for progressing to a full RCT as nonadherence may be attributable to feasibility or acceptability concerns that the pilot study intends to illuminate so that future versions of the app can be modified prior to an RCT.

Acknowledgments

The study receives funding from the Weill Cornell Medicine Ritu Banga Healthcare Disparity Research Award and the Weill Cornell Medicine Children's Health Council. Dr Lara Baez receives funding through the National Institute of Mental Health training grant (T32 MH115882).

Data Availability

The datasets generated during this study will be available from the corresponding author on reasonable request.

Authors' Contributions

ATY led study conception and design, development of the intervention, and manuscript drafting. AH, SG, and SB made substantial contributions to study conception and design. LB, LO, and CG have contributed significantly to the study design. AA and EB have led data acquisition and drafted portions of this manuscript. AD, AO, ML, MS, and IS have drafted portions of this manuscript. MS and SZ contributed to the development of the intervention and design for data acquisition. AF led the development of the original intervention and conception of the overall app-based programming.

Conflicts of Interest

None declared.

Abstract

Background: Current autism assessment procedures are costly and resource-intensive. The COVID-19 pandemic accelerated the adoption of telemedicine, highlighting the benefits of innovative diagnostic tools. Telemedicine-based pathways could enhance accessibility and equity in autism diagnostics.

Objective: The Children with Autism Technology Enabled Assessment (CHATA) project aims to develop and pilot an open-source autism diagnostic pathway for children up to 5 years old, delivered through telemedicine. The pathway is designed to be culturally and linguistically adaptable, increasing its applicability to diverse populations and integrating with existing National Health Service digital systems.

Methods: Initial pathway development was informed by systematic evidence reviews, coproduction, and mixed methods usability. CHATA comprises 2 key elements: online self-completed standardized autism questionnaires and a structured online interview and observation by a trained clinician. Out of 60 families near the top of the local waiting list will be invited to participate in the pilot evaluation, assessed using both the CHATA and usual assessment pathways. Sensitivity and specificity will be calculated by comparing the diagnosis of autism through CHATA with usual care. Quantitative usability assessment will be gathered from all families using the System Usability Scale (where a mean above 68 indicates above-average usability). A subset of CHATA assessments will be reviewed for interrater reliability (measured by the Cohen κ for categorical data [diagnosis present or absent], with values indicating the level of agreement; eg, <0 indicating no agreement, 0.61-0.80 indicating substantial agreement). Qualitative data on acceptability, feasibility, and usability will be gathered from semistructured interviews with a subset of families and health care providers. We will recruit 60 families for the main pilot study (including the usability testing) and 10-15 participants for the qualitative substudy. Data will estimate CHATA's diagnostic accuracy, validity, reliability, usability, and acceptability. Patient and public involvement will be integral throughout. The study will take place in a socio-economically deprived, ethnically diverse inner-London Borough within a community-based child health National health service responsible for the Autism assessment of children and young people up to the age of 13 years.

Results: Ethics approval was received in June 2023 (Research Ethics Committee reference 22/LO/0751; IRAS project ID 320499). Data collection commenced in April 2023 and completed in October 2024. Project end date is March 2025. As of November 2024, we had enrolled 57 participants to the pilot study and 12 to the qualitative substudy.

Conclusions: The CHATA project aims to establish a novel, culturally sensitive, equitable, and accurate online autism assessment pathway. By addressing geographical and linguistic barriers, this pathway seeks to reduce service costs, shorten waiting times, and promote equity in autism diagnosis. The procedures developed are expected to be generalized to other populations nationwide.

Introduction

Autism spectrum disorder (ASD) is a complex neurodevelopmental condition marked by difficulties in social communication, restricted and repetitive behaviors, and sensory sensitivities [1]. Despite a significant increase in autism prevalence in the United Kingdom among children aged 10-14 years, only about 1 in 190 children are diagnosed during the preschool years [2]. Consequently, many children are not identified or assessed until they have been in school for several years, leading to educational disadvantages. As of December 2023, over 170,000 people in England were awaiting an autism assessment, with 85% waiting beyond the recommended 13 weeks [3]. While data on waiting lists for older children in child and adolescent mental health services are available, equivalent data for preschool assessments is less reliable [4]. However, anecdotal evidence suggests lengthy waiting times of 36-42 months for preschool appointments, with some regions having no availability at all. Autism can be reliably identified by 24 months [5], but the average diagnosis age is >5 years in Europe and North America [6,7].

Structural inequity exists in autism assessment. Girls, and people from ethnic minorities or lower socioeconomic groups, receive support later than their peers, if at all. The 2024 Child of the North (UK) report found that ethnicity and associated language barriers play an important role in determining who gets assessed; overall, children of white heritage are substantially more likely to receive an autism diagnosis than children of Asian heritage [8,9].

Traditional autism evaluations involve developmental history, current behavior descriptions, and direct observation of social interaction skills. The COVID-19 pandemic has increased interest in using telehealth for preschool autism assessments. Various tools and methods are used in telehealth, including video-based observations, digital questionnaires, and online behavioral checklists. These tools can be used for both live (synchronous) and recorded (asynchronous) assessments, providing flexibility in how evaluations are conducted. Telehealth offers benefits like flexible scheduling, increased accessibility, fewer no-shows, optional audio and video recording, reduced travel and costs, fewer room bookings, and lower environmental impact [10]. Families in rural or underserved areas can now access diagnostic services more easily through remote assessments [11]. In addition, telehealth can significantly reduce wait times by enabling quicker initial screenings and follow-ups, which is especially beneficial given the high demand for autism assessments and the limited number of specialists available [11]. Our recent systematic review found that Telehealth assessments are as accurate as in-person assessments, with over 80% diagnostic agreement [12]. Online asynchronous parental reports and behavioral observation tools also show high validity and reliability, with agreement rates of 82%-88% compared with in-person assessments.

However, telehealth also faces several limitations. Technological barriers are a significant issue, as not all families have access to the necessary technology or reliable internet connections [13]. This can create disparities in who can benefit from telehealth services. In addition, there is a need for more training for clinicians to effectively use telehealth tools and ensure consistent and accurate assessments [14]. The standardization of telehealth procedures is still evolving, which can affect the reliability of these assessments. Equity issues are another concern. Telehealth may not be equally effective for all populations, as cultural and language differences can impact the accuracy of assessments. Moreover, telehealth tools may not be validated for diverse populations, potentially leading to biased outcomes.

We have developed a telemedicine assessment pathway - Children with Autism Technology Enabled Assessment (CHATA) that combines both asynchronous (parent online questionnaires) and synchronous (online clinical assessment) elements. Designed currently for children up to 5 years old, it has been developed to optimize linguistic and cultural accessibility. Given the potential limitations of the telemedicine approach, refining approaches such as CHATA and conducting pilot trials are crucial. These efforts can help improve the efficiency of autism screening and diagnosis by developing more reliable and user-friendly telehealth tools. They can also address disparities in telehealth access and effectiveness, ensuring that all children, regardless of their background, receive accurate, and timely diagnoses. Furthermore, refining CHATA can contribute to the standardization of telehealth procedures, making them more consistent and reliable across different settings. Ultimately, this study aims to enhance the efficiency and equity of autism assessments for children. Our objectives are to refine the pilot version of the CHATA diagnostic assessment for preschool children with suspected autism,

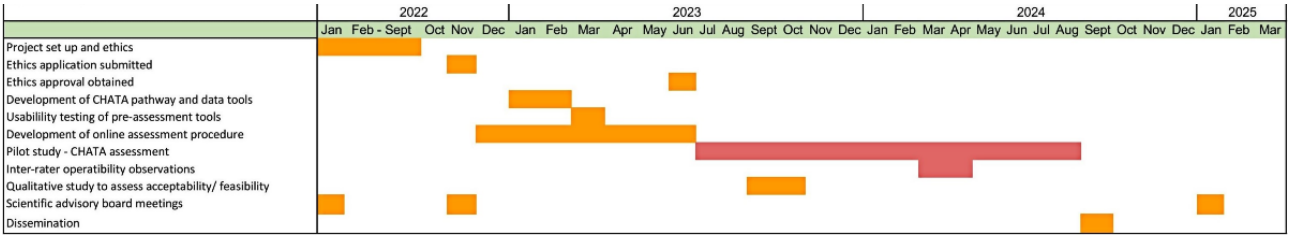
evaluate its usability, acceptability, feasibility, and interrater reliability, and estimate its sensitivity and specificity.

Methods

Study Design

This mixed methods study integrates pathway refinement, pilot evaluation, and implementation, using both qualitative and quantitative approaches. It focuses on usability, acceptability, feasibility, clinical validity, and reliability. The research framework is grounded in Behavioral Science and Participatory Action Research [15]. This approach captures diverse challenges and resilience factors among families, addressing the limitations of solely using survey questionnaires. Qualitative data will enrich quantitative findings, providing a comprehensive understanding of individual experiences. The study timeline is provided in Figure 1.

Figure 1. Study timeline. CHATA: Children with Autism Technology Enabled Assessment.



Study Setting

The study will take place in the London Borough of Newham (LBN), UK, known for its high ethnic and linguistic diversity, with approximately 78% of the population from ethnic minority groups and over 140 spoken languages. LBN is also among the most deprived areas in England, with over 50% child poverty. The East London National Health Service (NHS) Foundation Trust provides community child health services, including the Children with Autism in Newham–Diagnosis Service (CHAND) for children up to 13 years old. Due to underfunding and increased demand during the COVID-19 pandemic, over 1200 children are currently awaiting assessment by CHAND (personal communication as of June 14, 2024).

Patient and Public Involvement

To inform the initial development of CHATA and this pilot study protocol, 2 patient and public involvement (PPI) workshops were held with 8 parents of children who had online autism assessments during the COVID-19 pandemic. The group included 5 Asian or Asian British parents and 3 Black or Black British parents, 1 requiring an interpreter. While most preferred face-to-face appointments, they accepted online assessments for reduced waiting times. A “Parent Voice” representative, an Asian parent of children with autism is a named co-investigator, who will participate in regular meetings, assist with study design, and analysis, and provide ongoing feedback.

Stakeholder Engagement

A Scientific Advisory Board will guide the development of the online autism assessment pathway, meeting biannually with regular email updates. Additional engagement with the National Institute for Health and Care Excellence guideline stakeholders will explore novel provisions. Study outcomes will be disseminated through an event with local clinical service stakeholders, and key findings will be shared through the NHS Trust website. In addition to scientific manuscripts and presentations, a pamphlet will publicize the study’s outcomes and policy implications.

Usual Autism Pathway Procedures in Study Setting

The usual care pathway in LBN, referred to as the “CHAND reference pathway,” currently includes the following steps:

1. Referral: made to CHAND.
2. Triage: conducted by a multidisciplinary team (MDT) based on referral information, resulting in 1 of 3 outcomes: acceptance, request for additional information (eg, school report), or rejection.
3. Assessment decision: if accepted, the triage team determines whether the case is straightforward or complex based on demographics (eg, age) and clinical factors.
4. Assessment: straightforward cases are booked to see a pediatrician or senior speech and language therapist alone. Complex cases are booked for a multidisciplinary assessment involving at least 2 clinicians (eg, pediatricians, speech, and language therapists, psychologists, and occupational therapists). One clinician conducts an Autism Diagnostic Observation Schedule, Second Edition (ADOS-2) assessment [16], and the other takes a case history. If a diagnostic outcome is not reached, the case is discussed at a wider MDT meeting, including representatives from pediatrics, speech and language therapy, occupational therapy, and psychology. Additional assessments may include a school visit, a Diagnostic Interview for Social and Communication Disorders with parents [17], or an informal observational assessment to evaluate mental health difficulties or masking in girls.
5. Feedback and follow-up: diagnostic feedback and psychoeducation about autism and autism-specific supports are provided. Local signposting and invitations to postdiagnosis group workshops or one-to-one sessions with a parent connector are offered.

The service is diagnostic only and does not provide postdiagnosis support or interventions. Onward referrals for occupational or speech and language therapy are made with the family’s consent. All children under 5 undergo a face-to-face physical examination with a pediatrician, where blood and genetic testing may be considered.

CHATA Index Assessment Procedures

The CHATA index pathway, designed to be compatible with National Institute for Health and Care Excellence guidelines for autism assessment [18] and to replace, where appropriate, usual care CHAND assessment step 4 above, involves 2 steps:

1. Digital questionnaires: participants complete a series of self-administered questionnaires within 45 minutes on an NHS-compatible digital platform.
2. Online clinical observation: this is followed by a real-time, semistructured parent-child interaction through video conferencing, taking between 30 and 60 minutes depending on the need for interpreting.

Both the questionnaire and observational data are hosted on Drupal, a secure, open-source web application, locally hosted on an NHS server.

Digital Questionnaires

The questionnaire was developed by integrating items that effectively identified autistic behaviors in preschool children from the following sources:

1. 3di interview, a computerized diagnostic tool used by UK Autism assessment teams [19]. The full 3di comprises nearly 200 questions, applicable across the full range of children and adolescent ages. We developed a preschool version using data from 1,437 children referred to the Great Ormond Street Hospital Social Communication Disorder Clinic (2005-2023). Using a discriminant function analysis, we identified 41 questions that best discriminated preschool children (n=356) assigned an autism diagnosis by the multidisciplinary clinic. From nearly 200 questions, 41 were selected for their effectiveness in distinguishing autism in preschool children. These interview questions were reconfigured into questionnaire format for CHATA.
2. The Modified Checklist for Autism in Toddlers, a screening tool for children under 30 months, consisting of 20 questions for parents [20].
3. The Developmental Check-In, a brief ASD screening tool validated for Hispanic children aged 24-60 months, includes 26 questions with accompanying photographs to aid parents with limited literacy [21,22].

An audit of the CHAND waiting list identified Urdu and Bengali (Sylheti and Dakar dialects) as the most frequently spoken languages after English. Questionnaires were professionally translated and back-translated, with parent focus groups assessing their accuracy and acceptability. Audio descriptions were created for participants with low literacy and uploaded alongside the written questionnaires.

Five parents/carers of children under 5 years of age who had undergone autism assessment participated in usability testing using the “think aloud approach” and the quantitative System Usability Scale (SUS; Multimedia Appendix 1), standard usability assessments [23,24]. Usability feedback was broadly positive, with critical feedback focused on the need to ensure clear instructions for accessing the questionnaires.

Online Observations

The online observations will be conducted by an experienced clinician in preschool autism assessment, trained in the ADOS-2 autism assessment. Parents will use a broadband phone camera for the session, guided by the clinician through semistructured interactions with their child. This online observation was developed informed by the TELE-ASD-PEDS model, where the clinician remotely observes and instructs the caregiver in real-time tasks [25]. Scoring will align with the ADOS-2 methodology [16]. For the purposes of this pilot study sessions will be recorded for independent analysis to assess inter-rater reliability.

The assessment includes a 10- to 20-minute clinical interview, followed by a structured real-time observation. The clinician will review preassessment results to tailor the interview, focusing on specific concerns. During the observation, the child will perform activities with common household items and toys, guided by detailed instructions provided in advance. This will assess social communication, interaction, and restricted or repetitive behaviors. Interpreters will assist families who do not speak English as their first language, translating instructions and responses.

Recruitment to Pilot Study

Families receiving health services at an inner London clinic, specifically those on the autism assessment waiting list, will be recruited. Potential participants will be contacted through telephone or email and provided with detailed study information. Participants can discuss any questions with the research assistant through various communication methods. Cultural advocates will ensure cultural sensitivity during recruitment (see inclusion and exclusion criteria in Textbox 1).

Cultural advocates and trained research team members will ensure a supportive environment.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Parents and caregivers of children aged 5 or younger on the autism assessment waiting list in Newham, East London.
- Residents of Newham.
- Parents and caregivers aged 18 or older.

Exclusion criteria

- Inability to give consent.
- Known safeguarding concerns.
- Nonspeakers of English, Urdu, or Bengali.

Sample Size and Sample Size Justification

We will recruit 60 families for the main pilot study (including the usability testing) and 10-15 participants for the qualitative sub-study.

For clinical validation with approximately 80% power and an estimated 90% prevalence, a minimum sample size of 34 is needed to detect high sensitivity [26]. To detect high specificity with similar power, a minimum of 310 is required. A prestudy audit of the CHAND service showed a 90% autism diagnosis rate, like the 86% conversion rate in Bradford Autism Services [9]. Given the pilot nature of this study, we chose a pragmatic sample size of 50-60, prioritizing sensitivity assessment over specificity.

The sample size for quantitative usability testing is driven by the overall pilot sample size.

Approximately 15 participants are anticipated for the qualitative study, sufficient to reach thematic saturation and thoroughly explore core themes and patterns.

Estimated Diagnostic Accuracy

Families will complete both parts of the CHATA assessment, the online questionnaire and a structured videoconferencing clinical assessment, before their usual face-to-face CHAND clinical assessment. Following the CHATA assessment, children will proceed with the standard clinical assessment, including an in-person physical examination by a pediatrician and review at the MDT meeting for complex cases. This process (from the first CHATA assessment to the initial CHAND assessment) is expected to be finished within 6 weeks and will not affect their position on the clinical service waiting list.

Families will receive general autism information but no diagnosis from the CHATA assessment. The CHATA assessment results will be classified as autistic, nonautistic, or unsure by the research clinician but will not be shared with families or the clinical team to maintain blinding. The CHAND clinical team will record their own assessment outcomes and disclose them to the family as per usual processes. An independent researcher will compare the CHATA diagnostic outcome with the CHAND diagnostic outcomes from electronic health records to determine sensitivity and specificity.

Quantitative Usability

All families enrolled in the pilot will complete the SUS after completing the online questionnaires [24]. The SUS is a validated, widely used tool for measuring the usability of systems, with scores ranging from 0 to 100. The SUS consists of 10 items, with responses recorded on a 5-point Likert scale ranging from “Strongly Disagree” to “Strongly Agree.” Participants’ responses will be anonymized and collected into a database for analysis.

Qualitative Acceptability, Feasibility, and Usability Substudy

A qualitative study will include 10-15 families from the main study, chosen to represent diverse languages and experiences. This subset will help assess the acceptability and feasibility of the CHATA process, focusing on both positive aspects and areas for improvement. Recruitment will end when thematic saturation is reached, meaning no new themes emerge from the data. Data analysis will continue until no new codes appear, only recurring themes. In addition, 2-5 health care providers involved in autism assessments will be interviewed to gather their perspectives on the CHATA assessment, including its strengths and challenges. All interviews will be recorded with the participants’ consent.

Time Taken for Assessment

Informed by a recent study estimating the cost taken to undertake autism assessments in UK NHS services [27], we will estimate the time taken for each child to be seen under the usual care pathway, recording the grade of health care providers undertaking the assessments and compare that to the time taken to be seen under CHATA. We will then estimate costs associated with these using standard NHS outpatient costings.

Quantitative Data Analysis

Usability Data

The SUS score for each participant will be calculated using the standard method: for each of the 10 items, scores range from 0 to 4. Positive items (1,3,5,7,9) will have 1 subtracted from the response, while negative items (2,4,6,8,10) will have the response subtracted from 5. The total score will be multiplied by 2.5, resulting in a final SUS score ranging from 0 to 100.

To summarize the CHATA online questionnaire usability, we will compute the mean, median, and SD of SUS scores. Scores will be interpreted as follows: above 68 is considered above average, 50 to 68 is marginally acceptable, and below 50 may indicate usability issues. We will perform subgroup analyses to compare SUS scores across different demographics (eg, age, language, and education) using *t* tests or ANOVA, as appropriate. The mean SUS score, with a 95% CI, will provide a precise estimate of usability, and significant differences between groups will be reported. If the mean SUS score falls below the acceptable threshold of 68, we will conduct qualitative follow-up interviews to explore specific usability issues. The findings will inform any necessary revisions to improve the CHATA pathway’s usability.

Diagnostic Accuracy

To evaluate the diagnostic accuracy of the CHATA pathway, we will calculate sensitivity, specificity, and positive predictive value (PPV; Multimedia Appendix 2). Sensitivity measures the pathway’s ability to correctly identify autism, calculated as the number of true positives divided by the sum of true positives and false negatives. Specificity, reflecting the pathway’s ability to correctly identify nonautistic cases, is calculated as the number of true negatives divided by the sum of true negatives and false positives; however, we may not have sufficient power to calculate this. PPV, which indicates the likelihood that a positive result truly indicates autism, is determined by dividing the number of true positives by the total number of positive results. These metrics will be assessed using data from the pilot cohort to evaluate the CHATA pathway’s accuracy in diagnosing autism in young children from diverse backgrounds.

Interrater Reliability

A second clinician will review about 10% of the online pilot assessment recordings and compare their diagnostic decisions with those of the original clinician. For inter-rater reliability, we will analyze the consistency of ratings across independent reviewers who are blinded to the initial results. Out of 13 observations, randomly selected from 60, will be reviewed independently by a second clinician and supervised by a third senior clinician. All reviewers will be trained to ensure consistent understanding of the assessment criteria. The primary measure of inter-rater reliability will be Cohen κ for categorical data (diagnosis present or absent), with values indicating the level of agreement (eg, <0 as no agreement, 0.61-0.80 as substantial agreement). The analysis will determine the consistency of the CHATA pathway across different clinicians, with high reliability indicating reliable use of the pathway and lower reliability suggesting areas for improvement. Results will be reported with CIs, and significant discrepancies will prompt a follow-up review to address potential issues in training, criteria, or guidance.

Qualitative Analysis

We will transcribe and, if necessary, translate the interview data for analysis using reflexive thematic analysis with an inductive approach. This analysis will evaluate the acceptability, feasibility, usability, and barriers or enablers of the assessment tools. A feasibility study will gather insights from parents, caregivers, and clinicians on both online and in-person assessments to identify effective aspects and challenges.

Interviews will be conducted within 2 weeks of the online assessment, either in-person at Child Development Clinics or online based on participants' preferences. The interviews will be broad to capture diverse experiences, with topic guides (Multimedia Appendix 3) adjusted as new themes emerge. Qualitative data will be analyzed using NVivo [Lumivero] software, guided by the Theoretical Framework of Acceptability and the Theoretical Domains Framework [28,29]. The Theoretical Framework of Acceptability examines acceptability across 7 domains, including affective attitude and perceived effectiveness. The Theoretical Domains Framework integrates 33 behavior change theories and 14 domains to explore factors influencing behavior change, helping to identify barriers and enablers to implementation. We will use thematic analysis as outlined by Braun and Clarke [30], a widely used method for identifying, analyzing, and interpreting patterns of meaning within data. This approach is flexible and provides a detailed, nuanced understanding of the data, making it well-suited for the exploratory nature of this study. Since the study is qualitative and does not start with a pre-existing hypothesis, thematic analysis is particularly appropriate for uncovering insights.

The analysis will be reflexive, meaning it will involve continuous reflection and iteration by the research team. Out of 2 team members will independently familiarize themselves with the data, then regularly meet to discuss themes, resolve discrepancies, and finalize the themes and subthemes. The findings from this analysis will inform further iterations and refinements of the assessment tools to ensure they are as acceptable and effective as possible for both providers and recipients of the assessments.

Ethical Considerations

This study has been approved by the London Bloomsbury Research Ethics Committee (reference 22/LO/0751).

Measures to support participants include clear communication, confidentiality assurance, flexible scheduling, addressing recruitment barriers, providing interpreters, offering supporting letters for nursery absences, and incentives like vouchers.

Children flagged for concerns related to Adverse Childhood Experiences or safeguarding will be assessed using the standard pathway, following all ELFT safeguarding protocols.

Before participation, each participant will review the information sheet (Multimedia Appendix 4) and consent form with a research team member, who will address any questions. Consent can be provided in various formats: face-to-face, by post, email, video call, or telephone. Participants will indicate their preferred communication method and availability. Materials and consent forms will be translated into participants' preferred languages if needed. Non-English speakers will have the option to discuss the study with an interpreter through phone. Before the observation assessment, participants will receive detailed instructions and consent to record the session if desired. Researchers will be trained in consent processes, including assessing mental capacity. Parents will assess their child's willingness to participate; if a child shows discomfort or resistance, they will not be enrolled in the study.

Data will be anonymized once data collection is completed and before any analysis. Digital recordings from qualitative interviews will be securely transferred to a dedicated NHS server drive and permanently deleted from recording devices and video conferencing platforms once verified. Pseudonymized transcripts will be stored on this secure drive, separate from the original recordings, which will be kept in a password-protected folder. Participants' contact details will be stored in a separate, password-protected database on NHS servers. Hard copies of pseudonymized transcripts and research notes may be printed and kept in locked filing cabinets. Anonymized data will be retained on secure servers for 10 years before permanent deletion. All data handling will comply with the Data Protection Act 2018, with the participating NHS Trust as the Data Controller and Chief Investigators as data custodians.

Results

Chata project funding commenced in April 2021, ethics approval obtained in June 2022 pilot study data collection commenced in April 2023, and completed in Oct 2024. Pilot study end date is March 2025. As of Nov 2024, we had enrolled 57 participants in the pilot study and 12 in the qualitative substudy.

Discussion

Overview

This paper outlines our protocol for refining and evaluating a novel online autism assessment system tailored for children

under 5 within East London's culturally and linguistically diverse population. The primary goal is to address the limitations of traditional autism assessments, which include high costs, lengthy procedures, and extensive waiting lists that often exceed 2 years, as well as reduced applicability to non-White and non–English-speaking groups. By the end of this study, we anticipate being able to describe the sensitivity, specificity, quantitative and qualitative usability, interrater reliability, acceptability, and feasibility of the CHATA pathway.

Feasibility and Strategies

Conducting this trial presents inherent challenges due to the complexity of autism assessments in young children and the diverse needs of our target population. We are focusing on developing tools that are effective across diverse cultural and linguistic backgrounds. By integrating feedback from PPI and using non–English languagebased methods, we aim to ensure that the tools are culturally and linguistically appropriate. This approach is supported by previous research emphasizing the importance of cultural sensitivity in diagnostic tools [31,32]. To maximize the use of available clinical time, we are collecting parental information online before the assessment and ensuring that direct observations are concise. Literature supports this approach, noting that preassessment data collection and streamlined observations can significantly improve diagnostic efficiency [33].

We recognize the potential risks associated with implementing a novel assessment tool, including issues with engagement and the accuracy of online assessments. To mitigate these risks, we have designed a comprehensive evaluation process that includes both quantitative and qualitative assessments. This involves calculating sensitivity, specificity, and PPV to ensure diagnostic accuracy and conducting interrater reliability checks to maintain consistency [16,25].

We are taking several steps to minimize risks. All clinicians involved in the assessment process will undergo thorough training to ensure consistent application of the assessment criteria. This is critical for maintaining the reliability and validity of the assessments, as highlighted in previous research [33]. We have established robust protocols for data handling to ensure confidentiality and compliance with the Data Protection Act 2018. This includes secure storage of digital recordings and pseudonymized transcripts, as well as safeguarding participants' contact details. Adherence to these protocols is essential for protecting participant privacy and maintaining trust [34]. The study will incorporate iterative feedback from participants and clinicians to continuously refine the assessment tools. This iterative approach, supported by research on diagnostic tool development, emphasizes the importance of ongoing evaluation, and adjustment to effectively meet user needs [35].

Conclusion

Our study aims to develop a novel online autism assessment tool that addresses the limitations of traditional methods while being adaptable to diverse populations. By incorporating a range of assessment methods, ensuring rigorous training, and adhering to data protection standards, we strive to overcome the inherent challenges of this trial. Although the study is not designed to assess the cost-effectiveness of the assessment, it will focus on refining the tools and evaluation methods. Next steps include optimizing the efficiency of the questionnaire by reducing the redundancy of items and including visual content that has been created with ethnically diverse populations. Future research will need to assess sensitivity and specificity in a larger sample, address the long-term impact and cost-effectiveness of the online assessment system, and evaluate its applicability to a broader population, including those with lower digital literacy. The findings from this study will contribute valuable insights into autism diagnostics and provide a foundation for future trials aimed at improving assessment practices and reducing waiting times for autism services nationwide.

Acknowledgments

The authors thank the public and patient involvement participants involved in the development of the assessment tool and the study protocol and documents. This study is supported by the Patrick Paul Foundation (REC reference 22/LO/0751). PK was affiliated with the Great Ormond Street Institute of Child Health at University College London and East London NHS Foundation Trust at the time of the study and is currently affiliated with the School of Health and Well Being at the University of Glasgow and NHS Highland.

Abstract

Background: The neonatal mortality rate in Pakistan is the third highest in Asia, with 8.6 million preterm babies. These newborns require warmth, nutrition, and infection protection, typically provided by incubators. However, the high maintenance and repair costs of incubators pose a barrier to accessibility for many premature and low birth weight neonates in low- and middle-income countries. This study aims to implement a context-specific kangaroo mother care (KMC) model in Sanghar within secondary health care facilities and catchment communities.

Objective: This study aims to achieve at least 80% KMC coverage for premature and low birth weight neonates.

Methods: This research uses a mixed methods design grounded in implementation science principles, with the goal of developing adaptive strategies tailored to district and facility managers, as well as health care workers, leveraging previous evidence on the benefits of KMC. The research is conducted in the district of Sanghar, Sindh with an emphasis on promoting KMC for infants weighing between 1200 and 2500 g in three facilities. It includes preimplementation data collection, training of health care providers and lady health workers, and intervention involving mother-baby skin-to-skin contact, breastfeeding initiation, and postdischarge follow-ups. Ethical considerations and data management are prioritized, to improve KMC coverage and neonatal health outcomes.

Results: This research will be implemented over a period of 18 months. The primary objective of this research is to achieve an 80% improvement in KMC coverage, with the secondary objective to promote optimal breastfeeding practices among postpartum mothers. Key indicators include the proportion of eligible infants enrolled in KMC, the percentage of mother-baby pairs receiving skin-to-skin care postdischarge, and the duration of KMC during the neonatal period. Additionally, the study will assess exclusive breastfeeding rates, neonatal weight gain, and neonatal deaths within the cohort. The data management team will evaluate the effectiveness of the model in achieving the targeted KMC coverage.

Conclusions: The integration of KMC into the health care system will provide valuable insights for policy makers regarding effective implementation and scaling strategies. The study's findings will highlight facilitators and barriers to KMC adoption, benefiting regions across Pakistan and globally. Additionally, these findings will offer valuable insights for the development of future newborn care programs.

KEYWORDS

kangaroo mother care; scale up intervention; health facility; community; preterm infants

Introduction

Neonatal mortality continues to be a significant challenge for public health systems in low- and middle-income countries (LMICs), despite the global reduction in newborn deaths from 5 million in 1990 to 2.4 million in 2019. The majority of neonatal deaths occurred in India, Nigeria, and Pakistan [1]. Of these, 75% occurred during the first week of life, due to factors like preterm birth, intrapartum-related complications, low birth weight (LBW), birth asphyxia or lack of breathing at birth, infections, and congenital disabilities [2]. The leading cause of neonatal death is the preterm complication, defined as the live birth of a newborn before 37 weeks of gestation. An estimated 15 million babies are born prematurely every year, and approximately 1 million children die each year due to preterm birth complications. Additionally, many survivors face lifelong disabilities, including learning disabilities and visual and hearing impairments [3].

In Asia, Pakistan ranks third in neonatal mortality, with 8.6 million preterm babies. Premature and LBW neonates require warmth, adequate nutrition, and protection from infection [4]. Typically, these newborns are cared for using incubators, which are ventilated, sterile, moist, and oxygenated devices that provide life support by maintaining body temperature and ensuring a safe environment [5]. However, the maintenance and repair of incubators have significant financial implications, making this care modality challenging and inaccessible for most premature and LBW neonates in low- and middle-income countries, including Pakistan.

In Pakistan, 32% of neonates are born with LBW, representing one-third of all births in the country. In November 2015, the World Health Organization (WHO) identified kangaroo mother care (KMC) as the primary method of managing LBW and premature births [6]. The WHO has defined KMC as a practice of early, continuous, and prolonged skin-to-skin contact between mother and babies, in addition to exclusive breastfeeding or breastfeeding, early discharge after the onset of KMC in the hospital with continuation at home, and adequate support and follow-up for mothers at home [7].

The KMC strategy comprises three main components: thermal care by continuous skin-to-skin contact, support for exclusive breastfeeding or provision of other appropriate nutrition, and early detection and response to any complications that may arise. A systematic review has indicated that KMC is an effective and safe alternative to conventional neonatal care for LBW infants, especially in resource-limited settings [8]. For clinically stable LBW infants <2500 g, implementation of KMC has shown potential to reduce mortality, and if widely applied, could reduce premature deaths [9,10]. Globally, KMC has been recognized as an integral component of the newborn health initiative following the Every Newborn Action Plan [11]. WHO and the United Nations Children's Fund have advocated for facility-based KMC as a routine method of care for clinically stable LBW newborns [12]. However, recent data from the Pakistan Demographic and Health Survey 2017-2018 revealed that only 6.3% and 6.5% of skilled birth attendants (SBAs) in rural Sindh and Balochistan, respectively, conducted newborn care practices that involved placing the newborn in skin-to-skin contact with the mother during childbirth [13].

In a recent study conducted by the Saving Newborn Lives program and Maternal and Child Health Integration Program, a situational analysis of 5 Asian countries, including Pakistan, was carried out to evaluate facility-based KMC [14]. Findings from the Maternal and Child Health Integration Program project implementation in Pakistan suggested that ensuring facility readiness, improved capacity of service providers at facility and community, and focused community mobilization effectively help program planners implement KMC at both levels of care [9,10]. India, on the one hand, has demonstrated substantial improvement in newborn and infant survival using a community-based KMC implementation and interpreted that community-initiated KMC substantially improves newborn baby and infant survival [7]. In Pakistan, researchers in newborn health have recently highlighted KMC as a top preterm intervention as part of the Every Newborn Action Plan [9,11]. Despite KMC being recognized as a cost-effective intervention, its adoption in Pakistan, both at the community and facility level, has been minimal.

The primary objective of this scaleup project is to introduce a context-specific KMC model in Sanghar focusing on secondary health care facilities and catchment communities, with the aim of attaining a minimum of 80% KMC coverage for premature and LBW neonates. Following the implementation of the KMC model in the targeted facilities and communities, the study also aims to assess the impact of this low-cost intervention on reducing neonatal morbidity and mortality among premature and LBW newborns within the rural health system of Sindh, Pakistan. This project will involve and encourage the adoption of the low-cost KMC model by public health facility leadership and community. Additionally, an implementation model tailored to the local context will be developed and assessed to achieve enhanced coverage. The findings of this study will hold significant implications for the government and other stakeholders in implementing and scaling up KMC at the district, provincial, or national level.

Methods

Study Design

A mixed methods design will be used with the principles of implementation science to develop an adaptive strategy to help district managers, facility managers, and health workers both at the facility and the community to identify ways to improve implementation. Considering the evidence from prior studies in Sindh and Pakistan proven to reduce the risk of hypothermia,

improve the rate and duration of breastfeeding, improve early initiation of breastfeeding practices, improve mother-infant attachment and bonding, and reduce parental distress related to their infant's well-being due to constant attachment [15-18], we aim to scale up the current practices for reaching over 80% coverage of KMC from the baseline. In the preimplementation phase of formative research, we will gather data on components of the health system and the organization of services, knowledge and skills of health care providers, and the community perceptions, acceptance, and challenges. Findings will be used to inform the development of an initial implementation model, addressing facility and community challenges, improving provider's skills, and community acceptance, and improving service delivery to strengthen the health system services. This will be followed by regular assessments at different levels of KMC coverage.

We will implement the research in three facilities in District Sanghar. Our intervention promotes KMC for babies born weighing >1200 and <2500 g, both within the facility and its catchment area.

Setting

The study will be conducted in Sanghar, which is in central Sindh; the total population of the district is 47.9 million, with 71% of the population residing in rural areas and 29% residing in urban areas. The district has a strong primary care setup with 60 basic health units and 6 rural health centers. Sanghar has 6 Mother and Child Health Centers and 2 maternity homes. The district is comprised of 38.3% public health facilities and 32.4% private health facilities, which translates into 70.7% institutional deliveries. Regarding assistance during delivery, District Sanghar has 72.2% of deliveries with SBAs compared to 82.7% of deliveries with SBAs in Sindh. The district reports poor maternal and child health indicators and a high neonatal mortality rate at 33 per 1000 live births, followed by infant and under-5 mortality rates at 47 and 56 per 1000 live births, respectively.

The intervention period for the study will be 18 months (from January 2022 to June 2023). Three public health facilities will be selected to adopt the KMC model. The selection of these facilities will be based on the availability of Maternal, Newborn, and Child Health services, as well as logistical considerations, such as availability of Basic Emergency Obstetric and Neonatal Care services, immediate referral capabilities, availability of human resources, and the monthly turnover of women seeking outpatient care for maternal health services, including the average number of deliveries (approximately 80-120) during the finalization of study sites.

Study Population

Inclusion Exclusion Criteria

All stable newborns provided relevant consent of birth weight >1200 and <2500 g delivered at a targeted health facility or home in the catchment area of the correspondent health facility within District Sanghar will be considered for study. Newborns who are sick according to predefined criteria (ie, do not tolerate oral feeds, severe respiratory distress including respiratory rate of <20 breaths per minute, grunting, central cyanosis, very severe chest in-drawing, convulsions, unconsciousness, and severe hypothermia of <32 °C) will not be included. They will first be stabilized and referred to advanced care facilities. Newborns delivered outside the catchment area and those whose families did not provide consent will not be included.

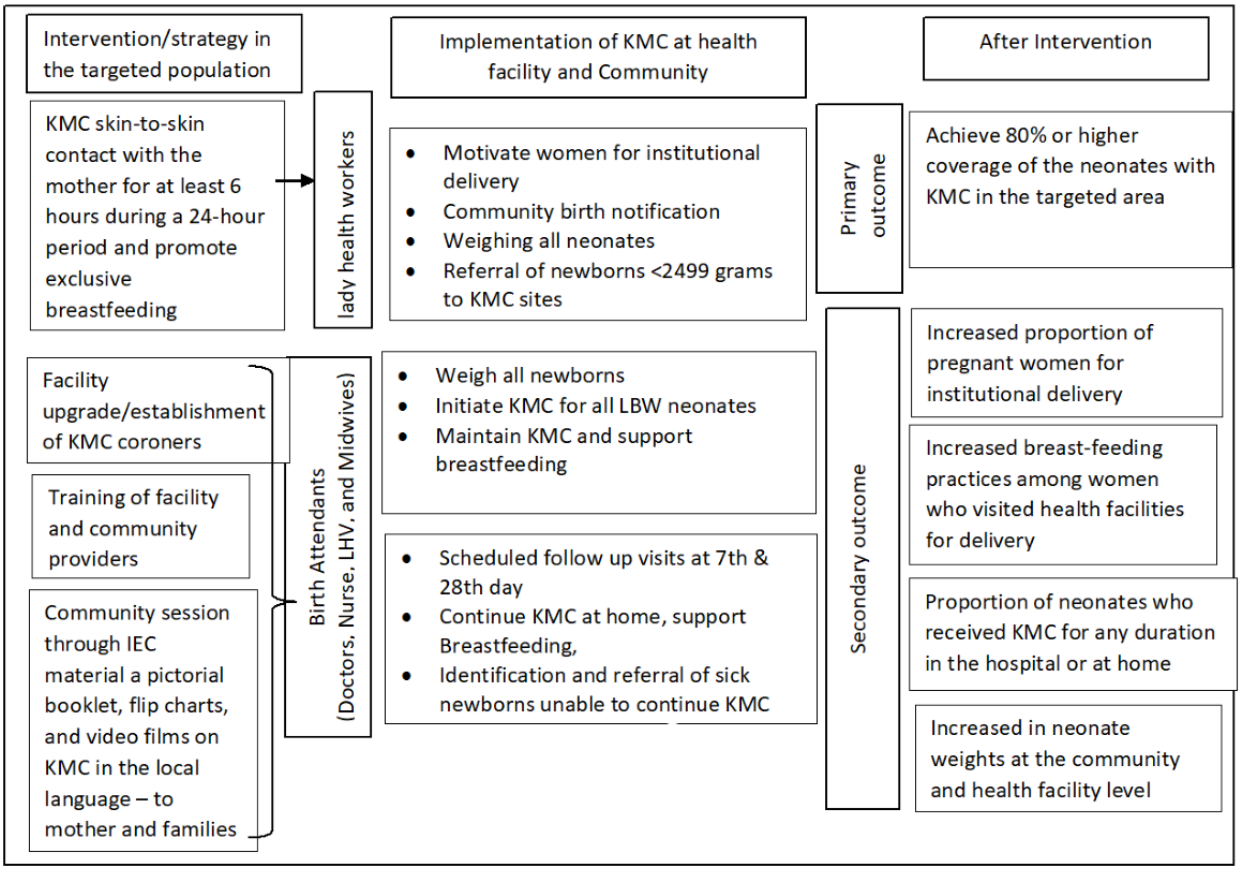
Sample Size

We will include all newborns delivered in the selected facilities according to the inclusion and exclusion criteria over the 18-month implementation period.

Intervention and Study Implementation Strategy

The study will implement the KMC model in District Sanghar which involves skin-to-skin contact between the mother and the infant for a minimum of 6-8 hours within a 24-hour period, along with exclusive breastfeeding. Implementing the KMC delivery model (Figure 1) will take place in 3 stages: prefacility, facility, and postfacility. At each of these stages, various activities will be conducted, which include, enhancing the capacity of both the facility and community health care providers, establishing effective referrals from the community to health care facilities for institutional deliveries and KMC interventions, providing education on KMC to mothers, families, and the community to improve newborn health outcomes, and reinforcing follow-up procedures for both the community and health care facility.

Figure 1. KMC implementation model. IEC: information, education, and communication; KMC: kangaroo mother care; LBW: low birth weight; LHV: lady health visitor.



All stable enrolled newborns (with relevant consent obtained) will be placed with skin-to-skin contact and breastfeeding will be initiated within the first hour of life. Mothers will be given tutorials on administering KMC by a trained physician or nurse or lady health visitor at the facility within 6 hours after delivery. At discharge, mothers and family members will be provided with counseling and encouraged to continue KMC practice at home.

Formative Research Phase

We will use our (Umeed-e-Nau project) [10] project baseline data to assess KMC in the community, to review the current health care system, infrastructure, and resources available in the district. The available information will also help assess the existing newborn care practices, health care staff capacity, and community awareness about KMC. For successful KMC implementation, the study will identify key stakeholders involved in newborn care, including health care providers, administrators, policy makers, community leaders, and parents, and engage them in the planning process, ensuring their perspectives are considered and addressing any potential barriers to successful implementation. As part of our research planning, we will conduct interviews (focused group discussion and in-depth interviews with them to gain insights into the local context and factors influencing newborn care practices). In addition, we will also conduct observations to understand health system barriers, bottlenecks, community beliefs, knowledge, and attitudes toward KMC and further identify any cultural or social barriers that may need to be addressed. For this assessment, we will use the COM-B (Capability, Opportunity, Motivation, and Behavior) [18] to understand better the factors influencing behavior change within the community.

We will adopt a multipronged approach that involves active participation from both mothers and health care staff. This approach will address the various components required for behavior change: capability (knowledge or skill needed to perform a behavior), opportunity (a social environment that enables a behavior), and motivation (effective counseling and follow-ups to encourage and activate behavior change). Based on the findings from the formative phase, we will develop a plan for scaling up KMC across the targeted health facilities within District Sanghar.

Intervention Phase

Prefacility Level

The prefacility-level activities will include training of health care providers, and promoting facility birth by involving lady health workers (LHWs) to refer pregnant women for institutional delivery. This has already been implemented by LHWs, who provide immediate referrals for LBW babies delivered at home or in other facilities through KMC counseling.

Counseling during antenatal care visits by LHWs will help increase institutional deliveries and facilitate intrafacility referrals of LBWs to KMC sites. Each month, LHWs will prepare a list of pregnant women as part of their routine activities, submitting this list with their monthly reports to their

respective lady health supervisors. Data collectors will validate this information during their monthly visits to the LHWs.

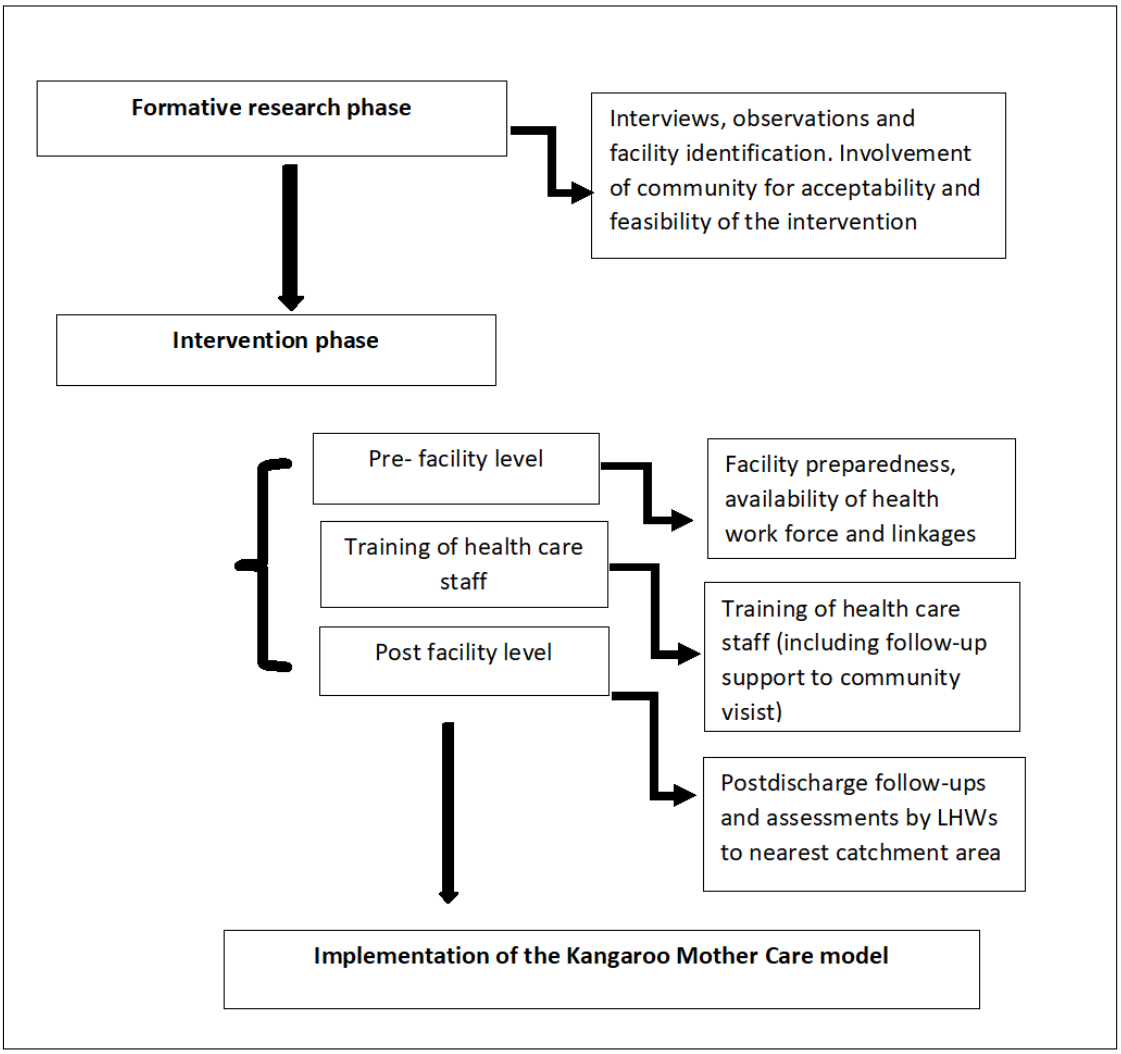
Pregnant women in the community will be encouraged to visit health facilities for antenatal care and institutional delivery through the LHWs, as this is part of their mandate. This antenatal visit and counseling will also include information about KMC. This activity aims to identify the total number of pregnant women who can be referred to the facility for delivery and KMC if their neonates meet the inclusion criteria of weighing >1200 and <2500 g.

All neonates will be screened at birth, and those with a birth weight of >1200 and <2500 g will be referred to the KMC functional site in their respective tehsils or districts. The KMC intervention will be initiated with all LBW babies meeting the inclusion criteria who are delivered within the study catchment area, either at the KMC site or by referral to the KMC sites.

Training of Health Care Staff

KMC experts from Aga Khan University (AKU) will serve as master trainers for the training, based on educational material on KMC in the local language for mothers, families, health facility providers (physicians, nursing staff, and lady health visitor staff), LHWs, and study staff at the district level. The training routine will consist of a 1-day classroom and 2-day real-life field scenario for facility providers. Similarly, the LHWs of the selected facility catchment area will also be trained for institutional delivery referral, KMC case notification, and follow-ups. They will be trained to deliver information, education, and support for the KMC practices at the household level in a 2-day training workshop by respective health facility providers. At discharge, mothers and family members will be counseled so that KMC can be continued at home. Facility staff will notify the data collector of discharges and schedule follow-up visits on the 7th and 28th day (Figure 2).

Figure 2. Flow diagram for study implementation. LHW: lady health worker.



Postfacility Level

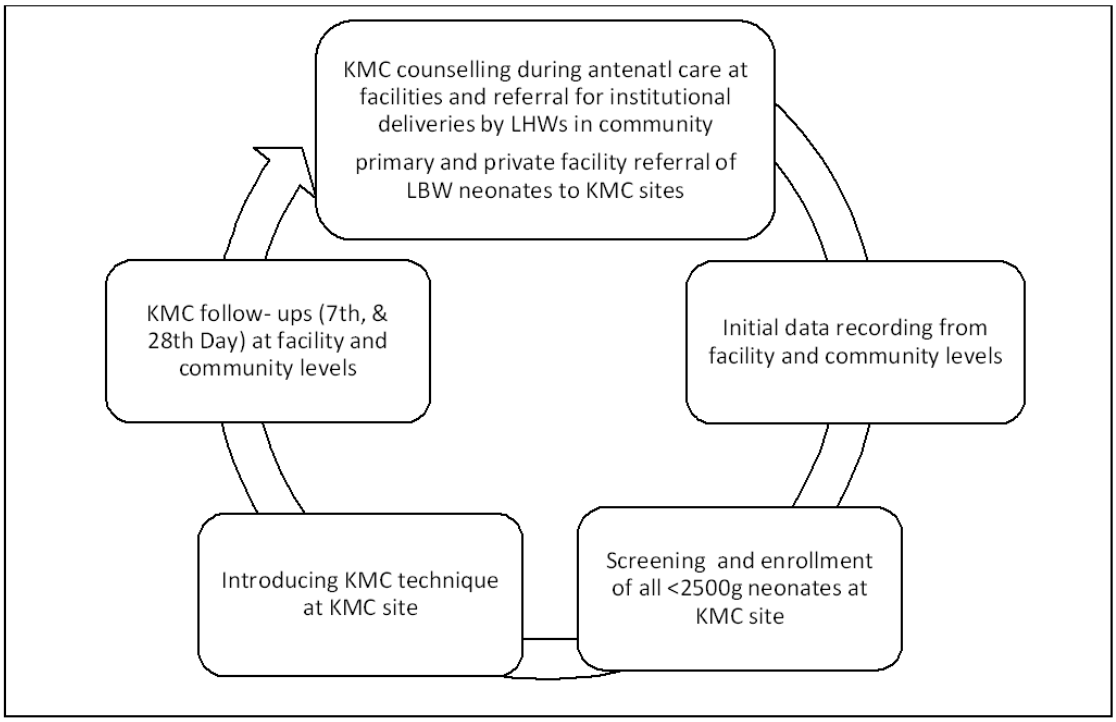
Community-based KMC will be administered at home by LHWs exclusively to enrolled neonates discharged from facilities and those born at home within the catchment population of a designated KMC facility. Postdischarge, follow-up will be conducted by respective LHWs. They will visit the home on the 7th and 28th days to assess the implementation of the postfacility KMC protocol. The follow-up team will continue to monitor the newborn at each visit, using a checklist to assess KMC practices, including skin-to-skin contact duration (hours per day) and breastfeeding status, and recording the newborn's

weight. Additionally, the team will identify and refer sick newborns to the facility and assist with the referral process. This approach, aligned with the health systems strengthening component (continuum of care), aims to create a linkage between facility and community, encouraging the continuation of KMC at home.

Implementation of KMC (The Delivery Model)

The most effective KMC delivery strategy will be determined based on program findings. Data will be gathered from all established KMC sites to assess coverage and adherence to KMC guidelines, including the utilization of communication and training materials and the effectiveness of implementation tools. The results on progress and compliance with process indicators will be shared at the District Health Program Management Team meeting. This meeting will convene key stakeholders, such as health facility managers, LHW program focal persons responsible for managing outreach components, and other individuals involved in the design, implementation, and rollout of the KMC delivery model. Continuous collaboration with these provincial-level stakeholders will enable the integration of best practices and adjustments at the facility level to promote effective KMC and its sustained benefits for vulnerable populations (Figure 3).

Figure 3. Continuous scale-up model of KMC, Umeed-e-Nau, at the facility level. ANC: antenatal care; KMC: kangaroo mother care; LBW: low birth weight; LHW: lady health worker.



Data Collection Teams

The KMC intervention will be carried out by health workers, including facility staff and LHWs, employed by the district or provincial government at both health facility and community levels. The role of the AKU research team in implementation will primarily be supportive, initially focusing on the formulation of the study design and ongoing process assessment for monitoring and evaluating the intervention's outcomes in the target population. The AKU team will also facilitate data collection by conducting interviews with various stakeholders, such as health care providers, administrators, policy makers, community leaders, and parents, to evaluate the feasibility and acceptability of the intervention. Additionally, the team will provide quality assurance and guidance to health facility staff and community-based health care providers to ensure the effective execution of the KMC intervention within a supportive environment.

Data Management

The collected dataset will be linked to participant identification numbers, separate for mothers and newborns. The cleaned dataset will be presented in monthly review meetings with the principal investigator for review and feedback. Data quality assurance methods would include digital real-time checks for missing values and inconsistency, random spot checks, and data validation coupled with independent monthly audits. The collected data will be stored in a password-protected file and only the data manager from the data management unit will be allowed to access the data and will share the analysis elsewhere needed.

Ethical Considerations

The study was approved by the ethical review committee of the AKU, Karachi-Pakistan (2021-6444-19970). Before enrollment into the study, a verbal explanation of the research will be provided, and written consent will be obtained from the mother or an adult family member. In cases where the participant cannot read the informed consent form, a research team member will read it out to them before recruitment. The participants will be

fully informed that they have the right to withdraw from the study at any time, without any negative consequences or compensation, and their decision to withdraw will not impact their access to any services provided by the facility. The study will be scaled up within the existing health system so monetary compensation will be provided. However, all the LBW neonates enrolled in the study will be provided with standardized KMC kit which includes, a shirt for mother and baby suites 3 zero size, diapers, woolen cap, socks, soap bar for neonates.

We will also maintain the participant's confidentiality during our research, all identified information of the study participants will be kept confidential and can only be accessed by the principal investigators or supervisors. The findings will be conveyed to the communities through the health system's channels, as well as district, provincial, and national health authorities will be informed through project dissemination and publication in peer-reviewed journals.

Results

Expected Results

Through the implementation of this research, our results include achieving an 80% improvement in KMC coverage and promoting optimal breastfeeding practices among postpartum mothers. The data collection of our research is completed and so far, 12499 live births have been reported and we enrolled 3046 LBWs for KMC and we successfully followed up all registered neonates. We are currently cleaning and refining our data sets for analysis and the actual results of our research will be available in the original research article. The key indicators to be measured include the proportion of eligible infants enrolled in KMC, the percentage receiving skin-to-skin care within specified timeframes post discharge, and the duration of KMC during the neonatal period. Additionally, the study will assess the proportion of eligible infants exclusively breastfed at various intervals, along with monitoring neonatal weight gain and tracking neonatal deaths within the enrolled cohort. The data management team will evaluate the model's effectiveness in achieving the targeted KMC coverage among the entire study population, as outlined in the outcome measurement section.

Evaluation

Effective KMC coverage is defined as the number of newborns receiving KMC divided by the total number of newborns eligible for KMC (>1200 and <2500 g) at the facility and communities during the evaluation period. To measure the denominator for effective KMC coverage, it is preferred that all facility births be identified during facility visits by reviewing birth registers from all facilities. In addition, the data collector will liaise with LHWs to obtain the number of home births and their birth weights. To calculate the numerator for effective KMC coverage, the data management team will quantify the number of newborns weighing >1200 and <2500 g who received KMC in the study population. All enrolled newborns will be followed by the data collector in the facility or at home to collect data at two points: the 7th and 28th day of initiation of KMC. At each time point, the team will record the data through the KMC checklist. We will disseminate the scaling-up findings of KMC across facilities in Sanghar districts with further dissemination of this scale-up at the provincial and national levels to encourage its implementation within other provinces.

Discussion

Increasing Coverage for Premature and LBW Neonates

This will be the first implementation research project to develop and evaluate scale-up models for achieving high population coverage with KMC in Pakistan. Implementation of a context-specific KMC model in Sanghar within secondary health care facilities and surrounding communities will help to achieve at least 80% KMC coverage for premature and LBW neonates. The model in the targeted facilities and communities will also assess the impact of this low-cost intervention on reducing neonatal morbidity and mortality among premature and LBW newborns within the rural health system of Sindh, Pakistan.

This project is a collaborative initiative between AKU and the provincial government, aiming to evaluate the effectiveness of scaling up KMC coverage. Preliminary data indicates that KMC is currently practiced for <5% of LBW infants in these settings, with no competing interventions promoting KMC at the study sites [6]. There is existing literature on the barriers and facilitators of KMC within health facilities [19-21]. This project presents a timely opportunity to integrate KMC into the existing health care system in partnership with the government. The goal is to identify effective scale-up models for implementation in large, countrywide settings. While the study focuses on KMC coverage as a key outcome, we aim to develop a model that integrates KMC as an essential component of newborn care, rather than projecting it as a standalone vertical program.

The study will exclude community-based follow-ups to evaluate improvements in newborn weight for families that do not provide consent for such follow-ups. Further, the accuracy and reliability of outcome measurements, such as growth parameters and developmental milestones, were not used.

Conclusions

The outcomes of this implementation research will extend beyond the study area to benefit other regions within Pakistan and globally. The findings will inform strategies to enhance essential newborn care provision at health care facilities, seamlessly integrating KMC without the need for a separate vertical program. Insights gained from this research will not only illuminate the challenges associated with scaling up KMC but also offer effective solutions to address them. Furthermore, these experiences hold promise for shaping the design and implementation of future infant and childcare programs, facilitating their swift adoption by both health systems and communities. The findings of this study will provide robust evidence to inform the development of policies and programs aimed at preventing neonatal mortality and improving maternal and child health and growth outcomes in resource-limited settings.

Acknowledgments

This study is funded by the Bill & Melinda Gates Foundation as part of the Umeed o Nau project. We also acknowledge the Directorate General of Health Services, Department of Health, Government of Sindh, along with the District Health Officer's Office in Sanghar, health care facility staff, and the community at large for their invaluable support and collaboration in implementing this project.

Authors' Contributions

ZAB led the funding acquisition of the main kangaroo mother care scaleup intervention project. SM conceptualized the study design with guidance from ZAB. SA, SS, and ZM provided inputs on public sector service delivery platforms. HN, AAS, and SK drafted theoretical framework. SM drafted the first version of the manuscript and HN incorporated feedback from all the coauthors. All authors reviewed subsequent manuscript drafts. All authors have read and approved the final version of the manuscript.

Abstract

Background: Telehomecare monitoring (TM) in patients with cancer is a complex intervention. Research shows variations in the benefits and challenges TM brings to equitable access to care, the therapeutic relationship, self-management, and practice transformation. Further investigation into these variations factors will improve implementation processes and produce effective outcomes.

Objective: This study aims to concurrently analyze implementation and evaluate the effectiveness of TM for patients receiving anticancer oral therapy. The objectives are to (1) contextualize how and why TM is implemented according to (a) site characteristics, (b) team characteristics, and (c) characteristics of patients receiving anticancer oral therapy; (2) assess TM effectiveness for recording electronic patient-reported outcome measures (ePROMs) and patient-reported experience measures (ePREMs) according to the site, implementation process, and patient characteristics; (3) describe the acceptability and feasibility of TM from the perspectives of the people directly or indirectly involved and provide evidence-based actionable guidance in anticipation of provincewide implementation.

Methods: This type II hybrid effectiveness-implementation study uses a concurrent mixed methods design. Evaluability assessment is integrated into an emerging practice in 3 participating sites to enable the evaluation of implementation strategies on TM clinical outcomes. Quantitative data for ePROMs and ePREMs will be collected using validated oncology questionnaire. Descriptive statistics and repeated measures using multiple linear mixed models and generalized estimating equations analyses

will be undertaken alongside interpretive descriptive coding of qualitative data. Qualitative data will be gathered from key informants guided by the RE-AIM (reach, efficacy, adoption, implementation, maintenance) framework and its extension, PRISM (practical robust implementation and sustainability model). The concurrent approach allows results at multiple stages of this study to be integrated iteratively. The methodological choice aims to provide real-world data that are rigorous, rapidly usable in practice, and transferable to other settings.

Results: Questionnaires were pretested and the technological platform was codeveloped with members of the cancer care team and patients. Preparatory work was carried out to configure the TM platform and activate coordinating mechanisms between members of the cancer care team, patients, information technology experts, and the research team. A steering committee with 3 working groups was established to oversee the technological, clinical, and evaluation aspects of this study. Recruitment of patients for ePROMs started in February 2024, and data collection is expected to continue until March 2025. Interviews with members of the cancer care team began in November 2024. Full analysis should be completed by September 2025.

Conclusions: This study will clarify how, why, for whom, and under what conditions TM can complement current care models. Our evaluability assessment will help to address implementation complexities and better understand intervention-to-practice operationalization so that implementation might be adapted to contextual factors without potentially harmful or inequitable impacts on patients.

Introduction

Background

Use of anticancer oral therapy, administered alone or in combination, is increasing rapidly in patients with cancer [1,2]. Anticancer oral therapy offers patients the convenience of taking medication at home, which has considerable benefits (eg, reduced hospital visits, time spent in waiting rooms and transport, transportation costs, as well as increased autonomy) [3,4]. However, there are important concerns around nonadherence to treatment [5] and the transfer of responsibility for drug administration, management of side effects, and monitoring of warning signs from the members of the cancer care team to the patients and primary care professionals, who are not always comfortable with these roles. Interdisciplinary cancer care teams (oncologists, nurses, pharmacists, psychologists, social workers, and others) are part of multiteam systems [6] that include primary care professionals (family physicians, nurses, social workers, and community pharmacists), patients, lay caregivers, nonprofit community organization workers, managers, and policy makers. Not everyone is necessarily prepared for the role and practice changes required by telehomecare monitoring (TM) [4,7,8]. Several conditions must be met to assure the safety of patients receiving anticancer oral therapy. For example, patients require capacities for self-management and adherence to treatment, the support of a family member or lay caregiver, and timely access to members of the cancer care team when needed. These team members need to establish regular and proactive monitoring, as well as effective communication and coordination, to ensure prompt response in case of need [3,7,9]. The proposed study aligns with priorities for research on TM [10] by looking specifically at its use among patients receiving anticancer oral therapy. This study focuses on the importance of structuring the increasing use of TM in such a way as to maintain the therapeutic relationship and optimal communication between patients and members of the cancer care team. The proposed structure involves a digital platform that is easy for patients to use and is regularly monitored by members of the cancer care team and alerts them when follow-up is required. This study addresses the integration into clinical processes and the effectiveness of TM on patient-reported outcomes and experience of receiving anticancer oral therapy treatments [11] based on differences in setting, team, and patient characteristics.

There are multiple terms (eg, telecare, virtual care, and eHealth) and definitions of telehealth that frequently overlap [12]. In this study, the term TM is used to describe interactions between patients in their own homes and members of the cancer care team. Telehealth generally refers to a health or social service provided at a distance using synchronous or asynchronous videoconferencing, digital applications, or telephone to improve health [11,13]. Telehealth is not new, but before the COVID-19 pandemic, its use was uncommon in cancer care and limited in most health systems [14]. For example, a 2019 study reported that only 0.6% (3/464) of family physicians in Québec, a province in Canada, had ever used telehealth, compared to 4.2% (108/2569) of the respondents in the rest of Canada [15]. Little data are available on the postpandemic use of telehealth in Canada. A national survey of 1038 participants in the United States found that the proportion of professionals in cancer care teams (oncologists, nurses, and residents) using telehealth increased from 19% to 84% during the COVID-19 pandemic [16].

In the oncology context, a systematic review (2017-2020; where, it should be noted, only 3 of 37 studies were conducted in Canada) concluded that telehealth is appropriate for symptom evaluation in adult patients during active treatment and survivorship [17]. Studies report several telehealth benefits for patients [17-20], namely improved accessibility, satisfaction,

effectiveness, and comfort (especially in people with moderate symptoms or physical limitations); better adherence and treatment persistence; reductions in transportation costs and absences from work for medical follow-up; less decline in quality of life; and fewer emergency department visits. Benefits for members of cancer care teams include the potential to work remotely and thus contribute to maintaining service accessibility [21], real-time monitoring of patients-reported outcomes, and maintenance of communication among the teams involved along the care trajectory [19]. At the health system level, one study finds that telehealth can reduce missed appointments and has the potential to positively impact the efficiency of human resources [22].

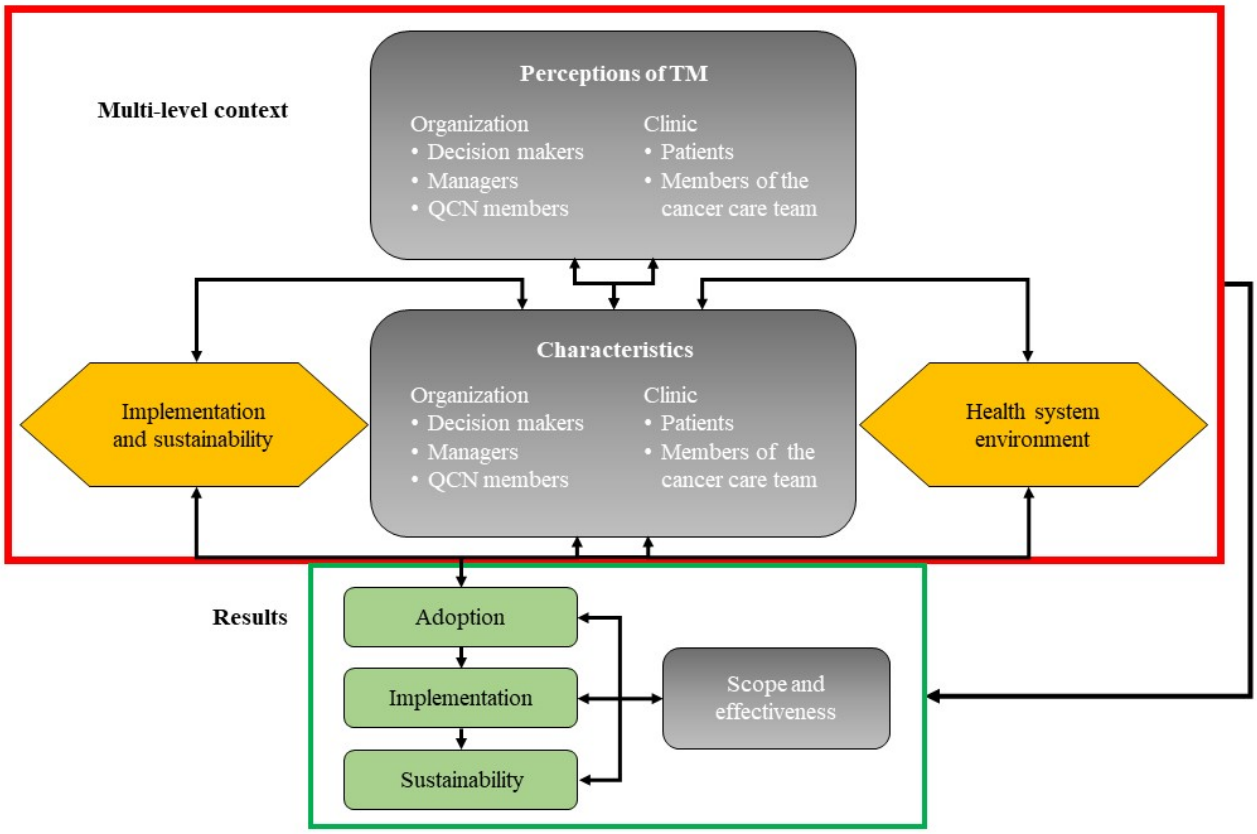
However, the limitations of telehealth must also be recognized. Recent studies find that some patients prefer in-person consultations and do not wish to continue with TM after the pandemic [17], while others prefer a hybrid approach that considers their needs and preferences [21]. Some studies [20,23] warn against a model that replaces in-person visits with telehealth to reduce health care costs or deal with shortages of human resources. Other limitations include poor internet access, the cost of computers and tablets, and difficulties with remote communication, especially for people with low technological or health literacy [24]. It is crucial that recourse to telehealth does not create disparities in access to care, notably for people who may have problems using technology [17,25] and people in situations of vulnerability who require in-person psychosocial support [26]; the risk of disparities is heightened when telehealth is hastily planned, as was the case during the pandemic [24]. For members of the cancer care team, the use of TM depends on new practices, supported by legitimate leaders and dedicated resources, and a context that includes a history of successful transformation [27]. Structures must be in place to identify implementation barriers and find means of overcoming them to prevent undesirable organizational effects (eg, interpersonal conflict, lack of organizational support, burnout, intention to quit, and absenteeism) [28,29] or jeopardize the quality of care (eg, depersonalization of care, diminished partnership in care, and threats to the therapeutic relationship and relational continuity) [30]. The compatibility between TM and established practices, and perception of its usefulness, have a strong impact on TM use and on team members' satisfaction [31]. At an institutional level, major changes require attention to organizational, legal, and ethical challenges (patient records, protection of personal information, professional responsibility, and technological evolution) [32]. To summarize, the scientific literature identifies the benefits and limitations of telehealth in cancer care. However, the diversity of participants and clinical conditions in available studies, the various research methods used, and the plurality of contexts make it difficult to grasp the nature and extent of challenges around TM implementation and effectiveness in a given context [20]. Our study aims to improve understanding of these challenges by producing evidence specific to the local context on predictors of real-world adherence to TM and its potential effects.

TM can be conceptualized as a multifaceted telehealth intervention that involves a network of heterogeneous groups (eg, patients, managers, members of the cancer care team, primary care professionals, decision makers, nonprofit community organization workers, information technology experts, and professional orders or associations), with different and even competing goals and interests and acting at different system levels. The novelty of TM differs between users. Our previous work shows that multifaceted interventions produce anticipated results when the network of people involved rally around a common objective [27], with shared leadership [33], and in partnership with patients [30].

Theoretical and Operational Model

From the perspective of actor-network theory (ANT) [34,35], translating TM into practice occurs through nonlinear processes: common definition of the problem and rationale for TM (problematization), expectations and strategies to engage team and patients (interest generation), role attribution and engagement of the people involved (enrollment), coordination of network action (mobilization), and sustainability (irreversibility). These building blocks, also considered as management tools [36], are consistent with an evaluability assessment [37]. They guide our participatory approach to providing evidence-based and actionable guidance on the use of TM that will benefit patients, their caregivers, and members of the cancer care team. At the operational level, this study is based on the RE-AIM (reach, efficacy, adoption, implementation, and maintenance) framework [38], and its PRISM (practical robust implementation and sustainability model) extension [39]. The RE-AIM/PRISM framework encourages consideration of the characteristics of patients, members of the cancer care team, and their practice setting (Figure 1).

Figure 1. TM study framework adapted from RE-AIM/PRISM. QCN: Québec Cancer Network; PRISM: practical robust implementation and sustainability model; RE-AIM: reach, efficacy, adoption, implementation, maintenance; TM: telehomecare monitoring.



Preparatory Work

The national telehomecare platform is supported by the Québec Ministry of Health and Social Services. The telehealth coordination office, housed in one integrated health and social services center [13], has a mandate to manage the platform's deployment in several hospital centers. TM is based on evidence and adaptation achieved through experimentation in clinical settings. The platform was co-developed with the formal participation of stakeholders (eg, patients, managers, information technology expert collaborators, clinical leaders, and researchers). Preliminary work allowed the TM platform to be configured for use with patients [40]. Locally, its configuration was conceived and undertaken collectively by pharmacists, pivot nurses in oncology, and patients. Various strategies were implemented to support TM use to report symptoms and support self-management (eg, demonstration video, support resources, educational modules, symptom management messages, warning signs or "red flags" with decision supports, and accompaniment by survivors of cancer). Preimplementation indicators were the frequency of evaluations by patients, warning sign thresholds for clinical tools, specific alert management algorithms to guide cancer care team members' interventions, range of monitoring (percentage of potential patients, percentage who accepted, percentage who refused, and percentage of red flags addressed), and teaching and training needs. This preliminary work was financially supported (salaries, equipment, and expertise) and closely accompanied by members of the cancer program of the Québec Ministry of Health and Social Services. The preparatory work revealed challenges in implementation (eg, identifying members of the cancer care team to assign to TM, redistributing work, leadership style, and pace of patient recruitment). Facilitating and impeding factors need to be systematically assessed to achieve expected effectiveness and guide scale-up across the province.

Aim and Objectives

This study aims to concurrently examine the implementation process and evaluate the effectiveness of TM for patients receiving anticancer oral therapy. In line with the conceptual framework, the specific objectives are as follows:

1. To contextualize how and why TM is implemented according to (a) site characteristics (location, mandate, resources, and supports), (b) team characteristics (members of the cancer care team, managers, and coordination with primary care and nonprofit community organizations), and (c) characteristics of the patients receiving anticancer oral therapy.
2. To assess TM effectiveness for digitally recording electronic patient-reported outcome measures (ePROMs) and electronic patient-reported experience measures (ePREMs) according to the site, implementation differences, and patient characteristics.
3. To explore the acceptability and feasibility of TM from the perspective of the people directly or indirectly involved and provide evidence-based actionable guidance in anticipation of provincewide implementation.

Methods

Study Design

This mixed methods evaluability study uses a type II hybrid effectiveness-implementation design. An evaluability assessment is appropriate for all stages of a novel intervention [37,41,42]. It enables (1) formative assessment of clinical, organizational, and technological components through reflection "on and in practice" and rapid feedback on findings; (2) better planning; (3) accelerated integration of research findings through constant interaction between researchers and stakeholders; and (4) identification of new ways of doing things to achieve scale-up objectives [37,41,42]. A type II hybrid effectiveness-implementation design enables in-depth analysis of TM integration in a natural setting (objective 1) and effectiveness for patients receiving anticancer oral therapy (objective 2) [43,44]. Type II refers to the concurrent study of implementation and effectiveness, an approach that is recognized in cancer care interventions [45] and is consistent with the RE-AIM/PRISM framework [43] (objective 3). A mixed concurrent approach, suited to participatory evaluability assessment [37], integrates quantitative and qualitative data [46]. The voluntary participation methodology allows for the inclusion of multiple perspectives, and equity, diversity, and inclusion considerations [47]. Our study adheres to ethical research standards [48] and responsible research conduct [49]. Researchers will endeavor to maintain relationships based on trust and mutual respect by being attentive to issues around the social acceptability of health research, by protecting the identity of participants, and by involving patient partners from the very start of our study [50].

Our study comprises the following interdependent phases:

1. Preparing the ground (objective 1; duration 4 months) includes presentation of the TM study to the actors involved, development of reciprocal engagement between the research team and TM leaders including patient partners and community actors, and an environmental scan [51] to understand local dynamics (potential participants; rate of inclusion in TM; technical, professional, and personal challenges; and workforce or resource challenges). This process of collecting, interpreting, and using information from the internal and external TM environment informs strategic decision-making, guides accompaniment efforts, and ensures the progress of this study by resolving difficulties that may arise.
2. Analysis of implementation and clinical effectiveness based on RE-AIM/PRISM (objectives 1 and 2; duration 12 months) assesses achievement of TM goals and evaluates expected benefits and absence of unexpected negative effects related to its use, ePROMs and ePREMs, and resource use. Markers of TM use will be defined according to patients' perspectives, cancer care team reorganization of work and collaboration with primary care and nonprofit community organization partners, use of human and financial resources in local arrangements, and levers and means used to overcome obstacles to safe implementation while upholding equitable access to care for patients.
3. Integrated planning for sustainability and spread (objective 3; duration 4 months) extracts lessons for eventual changes to be brought to TM to improve sustainability and future scale-up to other groups of patients (eg, intravenous therapy, immunotherapy, postsurgical cancer follow-up, palliative non–end-of-life care, and survivorship follow-up) [4]. This stage will identify the clinical, organizational, and equity challenges of TM as a complex highly context-dependent intervention. The transferability of this real-world study must also be optimized [43], especially where geographic and local dynamics differ.
4. Dissemination of results (duration 4 months) relates to the plan described in the later section of the protocol on integrated knowledge translation, for presenting findings to various groups of end users.

Study Sites

This study will be conducted in 3 cancer centers in the province of Québec, Canada, that have introduced TM over various periods (1 year or 1 month) and dedicated varying levels of human and financial resources. These cancer centers are located in hospitals that are part of the Québec Cancer Network. These centers have distinguishing characteristics (Table 1): geographic location (mega-urban, semiurban, or urban) [52], population served, mandate (academic or community), size of the cancer care team, team caseload (number of visits or number of treatments), primary care centers (number of community service centers or number of family medicine groups), TM work redistribution between members of the cancer care team (designated leadership or shared leadership), and formal partnership with survivors of cancer trained for TM support and research.

Differences between study sites will help understand perceptions of TM in real-world contexts and the influence of various factors on adoption, implementation, effectiveness, and potential sustainability, as illustrated in Figure 1.

Table 1. Characteristics of participating cancer centers[a].

	Site 1	Site 2	Site 3

[b]Coordination model apparent in early implementation.

Participants and Sampling

This study involves key informants knowledgeable of TM. The sampling strategy for patients is nonprobabilistic, based on eligibility criteria preestablished by the cancer care team. Inclusion criteria are receiving anticancer oral therapy, being interested in TM for a minimum duration of 6 months, having internet access and experience using it, being able to report symptoms with existing tools, being open to educational material, and being able to recognize warning signs. For key informants (patients, members of the cancer care team, managers, institutional decision makers, and nonprofit community organization workers), purposive sampling [53] aims to obtain a cross-section of views from people at different decision-making levels around TM (clinical, organizational, or system). These strategies are appropriate given the exploratory nature of an evaluability study.

We estimate from hospital administrative records that between 100 and 200 patients receive anticancer oral therapy each year (N=400 in 3 participating centers). Preparatory work since March 2022 shows that about 160 of these patients would meet our inclusion criteria and about half would continue completion of the ePROMs questionnaires over 6 months (80 patients × 26 weeks × 3 times a week=6240 results) and the ePREMs experience of care questionnaire at 3 months (ePREMs: n=80). A sample of 40 participants is considered sufficient for an exploratory study of a health services intervention [54]. We estimate that about 12 individual interviews per site with patients, members of the cancer care team, and managers (n=36) would allow for theoretical saturation of qualitative data [55]. This will be supplemented by interviews with decision makers (eg, policy level, professional orders, and national organizations; n=9), for a total of 45 interviews of about 60 minutes. Participants will be offered CAD $60 (US $41.90) compensation.

Quantitative Data Collection

Clinical data collection tools for ePROMs are based on those used in the Patient Reported Outcomes to Enhance Cancer Treatment study [56]. Ten questions, with French versions available for Canada [57], are taken from the PRO-CTCAE (Patient-Reported Outcomes Version of the Common Terminology Criteria for Adverse Events) library of the National Cancer Institute (eg, nausea or vomiting, diarrhea, constipation, dyspnea, stomatitis, skin problems, acne, hand-foot syndrome, edema, pyrexia, and more). The items are reported on a 5-point scale. Six questions on symptoms from the Edmonton Symptom Assessment System-revised are included (pain, depression, anxiety, insomnia, and fatigue) [58]. Subquestions on self-management support were created by the interdisciplinary team at the integrated health and social services center overseeing implementation to direct patients to educational modules on the TM platform. The ePROMs responses are collected 1 to 3 times per week according to patients preference. In preparatory work, 90% (144/160) preferred 3 times a week. The ePREMs questionnaire includes dimensions on health system responsiveness adapted for patients [27], satisfaction [56], and health-related quality of life [59], all measured with validated tools. Along with these dependent variables, self-reported clinical data (tumor site, time since diagnosis, treatment type, and comorbidities) and sociodemographic data (sex, gender, age, education, perceived health status, and

economic situation) are collected (control variables) to enable comparison with other studies [56]. The ePREMs questionnaire will be administered 3 months after the start of TM [56]. The time for completing the questionnaire is estimated at 20 minutes, and compensation of CAD $20 (US $13.97) is anticipated. We will monitor the indicators to associate contextual factors with clinical and implementation data and promptly identify unanticipated undesirable effects of TM. These are the dependent variables of this study.

Qualitative Data Collection

Semidirected individual interviews conducted at the mid-point in this study aim to describe enabling and impeding factors for each of the dimensions of the RE-AIM/PRISM framework, which include multilevel aspects (eg, perceptions of TM and characteristics of organizational and clinical stakeholders, the context of implementation and sustainability, and the impact of the wider health system environment) and mechanisms that support adoption, implementation, and sustainability to achieve the scope and effectiveness of TM (Figure 1). For example, questions inspired by other studies [17,56] and adapted to respondent type address the following: ease of understanding and using TM, usefulness and relevance of self-reported items, quality of communication and accessibility, clinical utility, and sense of self-efficacy for patients. Specific questions for members of the cancer care team to focus on the following: effects on their work, time management, ability to adapt their practice, adjustment of follow-up algorithms, and ways that data influence (or not) their discussions with patients. All participants will be questioned about their satisfaction and proposed improvements for scale-up and their perception of added value to the quality and safety of care.

Data Analysis Procedure

Standard descriptive statistics will enable data to be summarized (ePROMs, ePREMs, sociodemographic, symptom severity, and percentage of indicators of the scope of TM). For ePROMs, the number of questionnaires completed will be calculated for each patient, and the number of completed weekly ePROMs questionnaires will be divided by the number of expected questionnaires. Intrasite comparisons between measures will detect differences in exposure to TM and establish key periods on the patients trajectory. Relationships between the ePROMs items and patient characteristics will be described using Spearman correlations and chi-square tests. Multiple linear mixed models and generalized estimating equations for repeated measurements on the ePROMs [60] will be used to assess relationships between patient characteristics, ePROMs items, and ePREMs dimensions. Statistical significance will be $P<.05$. These analyses will identify the most important determinants of health status, relevant indicators, and appropriate moments for measurement.

Recorded and transcribed interviews will be analyzed using a descriptive interpretive approach [61] with 2 coders independently coding meaning units. A first coding cycle will focus on themes of the RE-AIM/PRISM framework, and a second interpretive cycle will identify links between context, implementation, and effects [61]. Finally, a synthesis of this qualitative process integrating quantitative results [62] will be codeveloped with volunteers from patients, people involved in care, and the research team.

The integration (qualitative data+quantitative data) will occur at several stages: (1) methodology, with linking sampling strategies, where participants for interviews are selected from among patients receiving anticancer oral therapy; (2) data collection, by adopting a simultaneous interactive approach [63] in which emerging results will iteratively lead to adjustments to future interview questions; and (3) interpretation, in partnership with spokespersons from the various groups involved (eg, professionals, patients, lay caregivers, nonprofit community organization workers, managers, and policy makers). Attention will be paid to quality criteria for qualitative [61] and mixed methods [62] studies to mitigate study limitations.

Ethical Considerations

This project was approved by the Research Ethics Board of the Research Centre of the Montérégie-Centre Integrated Health and Social Services Centre, which serves as the review board for all sites in this multicenter project (MP-04-2024-825, initial approval: August 29, 2023; renewed approval: June 7, 2024). This study will be conducted according to the Helsinki Declaration, and informed consent will be obtained from all individual participants [48]. Study results will be presented at the group level and will ensure that no individual, whether patients or staff, will be identifiable. Participation is voluntary and participants can withdraw from this study at any time.

Integrated Knowledge Translation

The integrated knowledge translation plan (Textbox 1) includes approaches suited to use during and at the end of the project [64]. The research team considers it important to establish bidirectional exchanges between knowledge producers and users and involves knowledge users at all stages of this study. This approach is chosen strategically for its positive impact on the adoption of new evidence-based practices, as well as for its potential contribution to managing problems that may arise during this study. ANT provides the basis for considering the heterogeneity of people involved in TM. ANT has been widely used in applied research to study the production and use of research evidence [64]. It contributes to a better understanding of why research results do not translate easily and are not integrated rapidly into settings for which the research was produced. This is consistent with the idea that people (professionals, patients, lay caregivers, nonprofit community organization workers, managers, and policy makers) as well as context (technology platform, computers, equipment used, and funding) act on the implementation and effectiveness of TM. The plan is inscribed in a project where sustainability and scale-up are anticipated right from preliminary work. It also aims to amplify the impacts of the research at provincial, national, and international levels. As a result, the activities, format, timing of, and vehicle for dissemination will be adapted to each target audience.

Textbox 1. Integrated knowledge translation plan of audience and activities.

Actors in the field

- Early detection of barriers, facilitators, controversies, and potential solutions
- Accessibility of the research team to actors in the field
- Discussion of interim findings in each setting
- Debriefing meetings to triage adjustments during implementation
- Newsletter published every 4 months on our website, distributed to partner networks of coresearchers and collaborators
- Support for team members for cancer and local managers
- End-of-project presentation of results in each site

Academic and research communities and trainees

- Generation of interest among the next generation of researchers in the renewal of cancer care: graduate students, oncologists, physicians, and health care professionals
- Dissemination of this study and its results in courses offered by research team members in their universities
- Mobilization of the coauthors' networks
- Sharing of tools developed and found useful for consolidating patients-reported outcomes and for team resilience in facing the challenges of telehealth
- Development of evaluative, interventional, and theoretical application of actor-network theory studies and conceptual studies based on the RE-AIM (reach, efficacy, adoption, implementation, maintenance) framework and its extension, PRISM (practical robust implementation and sustainability model)

Institutional stakeholders and knowledge brokers

- Mobilization of partner networks at multiple decision-making levels
- Presentations at collaborator and stakeholder events
- International peer-reviewed scientific conferences
- Websites to reach a wider audience
- Publication in open-access peer-reviewed journals

General public

- Tailored appropriate messages to share knowledge with different interest groups and the general public as part of an open science approach to broad dissemination

Results

An interdisciplinary steering committee including various stakeholders such as researchers, managers, members of the cancer care team, decision makers, and community actors, has been implemented to oversee the TM implementation. Its members are involved in 3 working groups that report to the steering committee; these groups will support the technological, clinical, and evaluation aspects of this study and address and assist in the resolution of controversies. At the onset of the project, our discussions with patients raised awareness that "imposing substitution on everyone could jeopardize the trust that is essential to our relationship with the cancer care team and increase the stress on us and our families; we don't want that."

An expert committee comprising the TM leader, a pharmacist, a pivot nurse, an information technology expert, and the principal investigator supports organizational readiness, ensuring that local needs for implementation are met and that the TM platform is operational at all sites. This committee developed a PowerPoint (Microsoft Corp) presentation aiming to (1) inform members of the cancer care team and managers of the state of science about TM content, structure, and patient-professional communication mechanisms; (2) describe the potential benefits and limitations of TM for patients, members of the cancer care team, and organizations; (3) present the objectives of the evaluability assessment and effectiveness-implementation study design; and (4) describe the ePROMs monitoring platform and ePREMs questionnaire. Between November 2023 and February 2024, a total of 72 members of cancer care teams from the participating settings took part in the 90-minute session and received continuing education credits. Meanwhile, the codebook for ePROMs was developed and questionnaires for ePREMs were pretested in two cycles by a team of patient partners, researchers, and knowledge users.

Access to the TM platform by the research coordinator and principal investigator required institutional authorization and engagement to ensure adherence to strict measures to protect personal data and confidentiality. This authorization process

was initiated in December 2023, with permission granted in March 2024.

Between February and July 2024, a total of 35 patients were enrolled and had completed ePROMs on the TM platform 1 to 3 times a week; 6 interviews of patients had been conducted. As of November 2024, a total of 1831 ePROMs and 41 interviews had been completed. Further, data collection with team members and other people concerned with the implementation had been initiated. The collection of quantitative and qualitative data is expected to be completed by March 2025, and the full analysis is expected to be completed by September 2025.

Preliminary interpretive coding of interviews suggested that the TM platform was easy to use and that members of the cancer care team provided prompt feedback when symptoms persisted despite self-management and educational material. Patients expressed they would like access to the TM platform on small devices that was not yet available and questioned how their oncologist was informed about the ePROMs. Clarification around the roles of nurses and pharmacists was desired to avoid confusion. The most important positive impact was the implication of a patient partner who explained the platform, how to fill in information, and could be reached for further support in using the platform.

Discussion

Expected Findings

This study will produce new data on the deployment of TM to support ambitions to modernize services available to patients [65]. The results will help inform decisions by integrating clinical, organizational, and health system considerations. This multilevel study will contribute to efforts to satisfy the growing appetite for telehealth, as well as its acceptability and feasibility [66]. Expected impacts are (1) a clinical contribution by informing the use of patient-reported outcomes, achievement of self-management objectives, and prompt team response to needs; (2) an organizational contribution by producing information on contextualized best practices, centered on the needs and preferences of patients, that improve access to care and appropriate use of resources and serve as a complement to and not substitution for clinical contact; and (3) a social win-win type contribution by reducing inequalities of access related to geographic or social distance, while providing essential data on opportunities and risks perceived by some groups of patients.

A recent review on telehealth reports that TM is promoted as a promising future direction for the management of anxiety and depression in patients with cancer [67]. Our study will contribute to efforts to identify types of symptoms that can be managed with TM and asynchronous interventions along with others that require in-person encounters. As patients cautioned us during the preimplementation phase, TM should not be a substitute for face-to-face interventions or be used for workforce rationalization. Additionally, our integrated knowledge translation strategy will activate the dissemination of best practices that recommend establishing the patient-professional relationship before integrating telehealth into care [68]. In the context of health human resources, TM promoters should be aware of the temptation to limit the face-to-face component of care, which may be harmful to the quality of care. Although proximity can be established through in-person or online encounters [69], patients participation [30] and collaborative governance [70] appear essential to prevent the expedient use of TM.

This study may also contribute to reducing disparities arising from the uneven use of telehealth technologies. However, other organizational priorities can increase the risk of TM program failure and increase disparities in access according to the capacities of individual patients and the availability of family caregivers to accompany them in using TM.

Strengths and Limitations

The inclusion of 3 settings chosen for their different characteristics increases the originality of this study's contribution. Multisite studies offer a wider perspective and will add to findings from single-institution studies on teleconsultation [17]. Our evaluability assessment will provide new empirical data on models of care that integrate TM services in advancing the quintuple aim of better health, improved care experience, well-being of members of the cancer care team, and health equity throughout the cancer journey. Our focus on how complementarity is achieved between TM and traditional face-to-face encounters aligns with calls for practical evidence in most recent reviews [17,67].

Some limitations are also anticipated in this study. The methodologies have potential biases. These include selection bias arising from convenience sampling and the fairly small sample size of participants, and observation bias due to real-world data collection that may compromise the application of results to wide-scale implementation [71]. These limitations could be compounded by the use of mixed methods [46] and by linking the implementation process to effectiveness in the specific participating sites. However, the production of such evidence provides detailed information that supports knowledge users in their decision-making and helps save time and avoid TM implementation failure.

Conclusions

TM is a complex intervention at the interface of clinical and organizational domains. Telehealth services for patients with cancer emerged as a key theme during the COVID-19 pandemic and will only become more important in the future. Our evaluability assessment will provide new empirical data on how to design TM services that prioritize a patients-centered approach aligned with patient needs, preferences, and realistic expectations. The focus on how complementarity between TM and traditional face-to-face encounters takes shape will answer the call for practical evidence to inform implementation. Our knowledge translation plan will create opportunities to share the successes that emerge and inspire other settings. Findings may also help to improve follow-up care for patients receiving other types of anticancer treatment that require close monitoring and management. In the event of implementation failure in this study, information on contributors to failure will help prevent

TM promotors from falling into some of the potential traps of implementing complex interventions.

Acknowledgments

We are grateful to all members of the cancer care teams and patients who were involved in the preparatory work and will be participating in this study for their time and contributions. We thank the Fonds de recherche du Québec–Santé for their financial support. The funding source has had no role in this study's design and will have no role in the collection, analysis, or interpretation of data, in writing this paper, or in the decision to submit for publication. This study has received funding from the provincial research funder Fonds de recherche du Québec–Santé (Oncopole ACCES-Onco, grant 326483-2023).

Data Availability

The datasets generated or analyzed during this study will not be publicly available due to ethical considerations (ie, conditions of consent received from participants) but will be available from the corresponding author on reasonable request.

Authors' Contributions

DT, TJ-M, AD, MCB, DB, JC, MD, CF, BG, M Larivière, FL, M Lemonde, ÉM, NM, MP, SS, and CW handled the conceptualization, funding acquisition, methodology, and review and editing of the writing of this study. DT, TJ-M, and AD administered the project. DT did the supervision, visualization, and writing of the original draft. DT and DB worked on the validation of this study.

Conflicts of Interest

None declared.

Abstract

Background: The consequences of preterm birth extend beyond the clinical conditions of the newborn, profoundly impacting the functioning and well-being of families. Parents of preterm infants often describe the experience of preterm birth and subsequent admission to the neonatal intensive care unit (NICU) as a disruptive event in their lives, triggering feelings of guilt, helplessness, and fear. Although various research examines changes in parents' well-being and perception of self-efficacy during the stay in the NICU, there is a lack of research analyzing what happens in the transition phase at home after the baby's discharge. Recently, scholars have advocated for the use of web-based support programs to monitor and prevent preterm family maladjustment and assist parents.

Objective: This interdisciplinary research will develop a sociopsychological model focused on assessing the well-being of parents of premature infants during and after their stay in a NICU. Specifically, the study aims to (1) monitor the mental health of parents of premature infants both at the time of the child's discharge from the NICU and in the first 6 months after discharge to prevent family maladjustment, (2) deepen our understanding of the role of digital tools in monitoring and supporting preterm parents' well-being, and (3) study the potential impact of the relationship with health care professionals on the overall well-being of parents.

Methods: This project combines mixed methods of social research and psychological support with an eHealth approach. The well-being of parents of premature infants will be assessed using validated scales administered through a questionnaire to parents of preterm infants within 6 NICUs at the time of the child's discharge. Subsequently, a follow-up assessment of parental well-being will be implemented through the administration of the validated scales in a web application. In addition, an ethnographic phase will be conducted in the NICUs involving observation of the interaction between health care professionals and parents as well as narrative interviews with health care staff. Finally, interactions within the digital environment of the web application will be analyzed using a netnographic approach. We expect to shed light on the determinants of well-being among parents of premature infants in relation to varying levels of prematurity severity; sociodemographic characteristics such as gender, age, and socioeconomic status; and parental involvement in NICU care practices. With the follow-up phase via web application, this project also aims to prevent family maladjustment by providing psychological support and using an eHealth tool.

Results: The results are expected by October 2025, the expiration date of the Project of Relevant National Interest.

Conclusions: The eHealth Study on Preterm Parents' Well-Being aims to improve preterm parents' well-being and, indirectly, children's health by reducing social costs. Furthermore, it promotes standardized neonatal care protocols, reducing regional disparities and strengthening collaboration between parents and health care staff.

Introduction

Background

The World Health Organization defines as preterm a birth that occurs before 37 weeks of gestation [1]—in Italy, approximately 6% of newborns are born before term [2]. Preterm birth is a multiproblematic event with 3 main consequences. First, it poses a medical risk to the newborns as many of these infants are in critical condition and can experience a range of substantially and potentially life-threatening medical complications. The second consequence concerns the economic and medical cost of caring for these babies given the advances in perinatal and neonatal care that have contributed to a substantial increase in the survival rate of these infants, particularly for extremely premature ones who, until a few decades ago, had no chance of surviving [3]. The third consequence is that the premature birth of a child and the subsequent admission to the neonatal intensive care unit (NICU) are distressing experiences for parents. Parental stress and parenting difficulties in the first years of the child's life are well-known consequences [4]. Moreover, many longitudinal studies have described how prematurity negatively affects infants' development [5,6], and evidence has been gathered supporting that parent well-being and infants' long-term developmental outcomes are closely related [7]. Parents often describe premature birth and the subsequent hospitalization in a NICU as an emotional roller coaster and a disruptive life event [8]. An unexpected birth can trigger feelings such as guilt for not completing the pregnancy, helplessness, and fear of not being able to protect one's child [6]. Moreover, parent-infant separation once admitted to the NICU represents a major source of stress for both parents and their infants [9]. Prematurity affects not just the child and parents as individuals (eg, by delaying the exploration of the parental role) but also the family triad (and potential siblings) as it hinders the initiation of mutual understanding and the consolidation of affectionate and meaningful relationships. Indeed, the hospital environment limits the parent-child relationship, which primarily develops through the incubator's windows [10]. These restrictions, while serving to protect infants from pathogens, complicate the interaction between parents and newborn, making it even more challenging to activate caregiving modes necessary for the infant's psychological development, a task primarily undertaken by medical staff for clinical reasons [11]. Another important factor to consider, highlighted by Russo et al [12], is that the sociodemographic characteristics of parents act as independent stress predictors, with gender, occupational status, and age particularly playing a role in the levels of stress and depression among parents of hospitalized children. Furthermore, few studies have investigated fathers' experiences in these particular circumstances [6]. In Italy, especially during the COVID-19 pandemic, many NICUs applied restrictions regarding the frequency and time of parents' access, and fathers are usually less involved than mothers in practices such as skin-to-skin contact and kangaroo care, managing to start building a relationship with their babies only after discharge. As researchers have pointed out [13], it is important to consider the characteristics and points of view of both mothers and fathers as both parents are at risk after preterm births. Research suggests how parents' negative feelings can be reduced by giving them value as actors who can make decisions for the newborn [14]. The Family Integrated Care (FICare) model represents an example of a way to address the need for humanization and parent participation in health care for high-risk newborns admitted to the NICUs. Through this approach, parents have the opportunity to become increasingly engaged in their responsibilities, and their active involvement in care is a prerequisite for the consolidation of parenting skills, which are essential to cope with the separation through the NICU [15]. However, a recent study has pointed out that, although most units in different European countries report a neonatal care policy that encourages parents to take part in the care of their infants, parental involvement is still generally limited in Italy [6].

In addition, there is some evidence suggesting that the feasibility of implementing FICare with families of infants who are severely premature or critically ill remains a concern [16]. These cases often involve significant medical complexity, requiring intensive care, which may limit opportunities for parental involvement. Furthermore, the emotional and psychological toll of caring for an infant who is critically ill can hinder parents' ability to participate actively in caregiving activities, highlighting the need for tailored support to address these challenges. Although various research examines changes in parents' well-being and perception of self-efficacy during the stay in the NICU, there is a lack of research analyzing what happens in the delicate transition phase at home after the baby's discharge [17]. Moreover, to the best of our knowledge, no studies have specifically examined how socioeconomic factors such as parental income or geographic distance from the NICU influence participation in FICare. This represents a gap in the literature as these factors may pose challenges for certain families. To fill this gap, the intervention and participatory project aim to give voice to preterm parents and their experiences. An interdisciplinary study to set neonatal practices and enhance families' well-being (the Study on Preterm Parents' Well-Being [ParWelB]) was designed by the Department of Sociology and Social Research of the University of Milano-Bicocca (principal investigator: AD) and funded by the Cariplo Foundation. Starting in May 2021, ParWelB has been promoting constructive communication and collaboration among and between caregivers and parents in the NICU.

Recent studies highlight the importance of fostering the parent-newborn bond, showing that strengthening this interaction benefits both parents—through reduced anxiety and depression—and children, who experience improved neurological outcomes [6]. Longitudinal research further suggests that parental stress and anxiety can impair bonding and family adjustment, with potential consequences for the development of preterm infants [5]. Parental self-efficacy and social support play a crucial role in adapting after an adverse

situation such as preterm birth [18]. Scannel [19] recently suggested how interventions that target the development of parental self-efficacy and social support can strongly impact the sense of competence, satisfaction in the parenting role, and resilience of all members of the family. Furthermore, Ionio et al [20] highlight in their work that having more information on how parents perceive neonatal care and an understanding of their needs also after the discharge of their newborn may allow health care staff to identify parents at risk, plan early interventions to meet their needs, and promote family functioning. Given the importance of building parents' self-efficacy, new neonatal practices (for upcoming preterm infants and parents) should be shaped based not only on the biomedical knowledge perspective but also on preterm parents' values, lived experiences, and perspectives.

The transition from the NICU to the home is a pivotal and challenging period for parents of preterm infants. It involves adjusting from the highly structured and professionally supported NICU environment to taking on full caregiving responsibilities at home. This shift can heighten feelings of uncertainty and stress, particularly as parents face reduced access to health care professionals and must navigate complex medical or developmental needs independently.

Our study is an interdisciplinary research project that, building on the premises of the ParWelB project, strives to assess preterm parents' well-being during and after the hospitalization in the NICU by combining mixed methods (using research strategies such as standardized questionnaires with internationally validated scales and ethnography) and psychological support through an innovative and technology-driven approach. Recently, scholars have championed the use of web- and app-based support programs to both monitor and prevent preterm family maladjustment and assist parents who struggle with transitioning to the home [21,22]. Furthermore, the work of Garfield et al [23] with infants with very low birth weight showed that parents who received an app-based support program improved parental self-efficacy and discharge preparedness compared with the control group. Therefore, the Bicocca research unit decided to team up with the Department of Psychology of the Catholic University of the Sacred Heart of Milan to design an eHealth (information and communications technology use to the advantage of human health) research project that assesses parents' well-being, particularly at the crucial time of discharge and the first 6 months at home, offering support to parents who are more fragile. Parenting self-efficacy has been understood as the way in which parents perceive their ability to care for their child [24] and has been associated with positive parental outcomes [25]. The well-being of parents refers to the fact that, given that preterm birth is a highly stressful event for parents [26], considering the difficulties and uncertainties they experience during this acute phase is of significant importance to prevent family maladjustment [27]. Families' involvement in the care of their high-risk neonates at NICUs represents the main axis of parent-partnered care initiatives. Each preterm parent develops a personal way to evaluate the situation based on the NICU lived experience. Specific characteristics may also influence the response to the hospitalization of one's child. Significant effects have been identified in relation to gender (mothers and fathers seem to differ in responses and relation to certain measures) and to the degree of social support that parents have access to. The latter has been found to impact positively the resiliency factor associated with coping strategies of families who have a child with a chronic illness [28], and there is a great need for studies investigating its impact on preterm parents.

Thus, the main focus of this research project is to develop a sociopsychological model focusing on the assessment of preterm parents' well-being during and after admission to a NICU with the use of eHealth.

Objectives

Stemming from these premises, our research's main aims could be synthesized as follows: (1) to monitor the mental health of parents of premature infants, with a plan for early intervention and a 6-month follow-up to prevent family maladjustment; (2) to stimulate eHealth growth by advancing knowledge on the role of digital-based tools in monitoring and supporting the well-being of parents whose infants have been hospitalized in the NICU for critical health situations (prematurity but also a wide spectrum of disabling or fatal diseases); and (3) to study the potential impact of the relationship with health care staff on the overall well-being of parents. In addition, our research aims to investigate potential differences in psychological well-being between parturients and nonparturients by also studying the impact of certain social characteristics (eg, nationality, educational level, employment status, and cultural enjoyment).

Methods

Ethical Considerations

Participation in the study will be on a strictly voluntary basis. According to the Declaration of Helsinki, respondents will receive written and oral information about the study and provide signed consent. They could withdraw consent at any time with no consequences for the future treatment of themselves or their infants. The eHealth ParWelB (e-ParWelB) project is financed by the Italian Ministry of University and Research with Next Generation EU and was approved in 2022 as a Project of Relevant National Interest (protocol 20225R7XB3). The project was submitted for approval to the ethics committees of the involved universities (University of Milano-Bicocca and Catholic University of the Sacred Heart of Milan) and, subsequently, to the 6 different territorial ethics committees to which the hospitals involved in the study are affiliated. The data are pseudoanonymized, meaning that each questionnaire is linked to a unique alphanumeric code that can be traced back to the user's web application code. Protective measures include compliance with legal and ethical standards; restricted access; and security protocols to prevent unauthorized access, disclosure, modification, or destruction. Finally, the project will not provide specific compensation to participants.

Recruitment

This study will be conducted simultaneously in 6 different Italian NICUs. Focusing on several units simultaneously has several advantages. First, it enables us to build a sample of satisfactory size within a reasonable time frame. Italy has a low birth rate,

and therefore, concentrating on only 1 unit would pose a significant risk of obtaining an inadequate sample for any complex statistical analysis. In addition, the presence of various NICUs introduces a comparative dimension to the study. Previous research on neonatal intensive care [29] has shown that each unit has its own unique identity with different routines, idiosyncrasies, and decision-making processes. This identity is strongly influenced not only by the cultural context in which the unit is embedded but also by the administrative structure of the hospital and the legislative framework foreseen for neonatal care practice. This is particularly relevant in the Italian case, where the management of the public health system happens mainly at the regional level, with relevant differences between regions. Moreover, this study includes 5 NICUs from the public sector and 1 belonging to a private hospital, adding another possible layer of differences in the work culture of the units.

This research focuses mainly on the population of preterm parents—more specifically, parents of children born before 36+6 weeks of gestational age (GA) and hospitalized in intensive or subintensive care units for at least 10 days (critical threshold of hospitalization length). Considering the research objectives, it is crucial to distinguish infants according to the severity of prematurity because of the strong impact that the latter has on the health of the child and the duration of the hospitalization period. Therefore, there will be 3 groups: children born before 28 weeks of GA, infants born between 28+1 and 32 weeks of GA, and children born between 32+1 and 36+6 weeks of GA.

To be included, parents of preterm infants must meet the following criteria: (1) they must speak fluent Italian or English, (2) they must be aged ≥18 years, and (3) their children must not have other genetic pathologies or other pathologies not linked to the preterm birth.

These 3 limitations help us in creating a more consistent sample and, therefore, in obtaining more focused results. Situations such as teenage pregnancies or genetic pathologies further complicate a family's life and, therefore, the task of assessing its well-being. While we acknowledge that they are both worthwhile topics of research, they are beyond the scope of what could reasonably be studied within the framework of our research.

To determine a satisfactory sample size for this research, we calculated using G*Power (Heinrich-Heine-Universität Düsseldorf) that the minimum sample size required, considering a probability of α error of .05, power ($1 - \beta$ error probability) of 0.95, and an effect size of 0.345, will be 175 preterm infants (350 parents).

We want to stress the fact that, due to the very peculiar nature of the studied population, this will not be a probabilistic sample but rather a *convenience* sample. As explained previously, the decline in Italy's birth rate does not allow us to use the yearly average estimation of preterm babies born in each of the partner hospitals as a reliable predictor for constructing our sample.

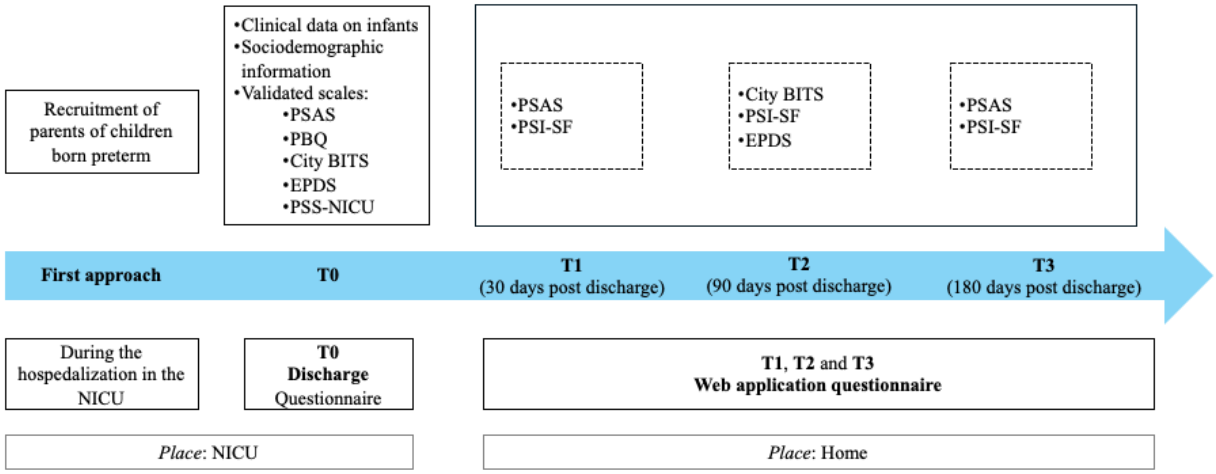
Research Design

To achieve the research objectives, this study will use a mixed methods approach that combines ethnographic observations with standardized questionnaires. The goal of this approach is to enhance the results by complementing the strengths of different methodologies [30]. The quantitative aspect of this research aims to investigate the potential impact of preterm birth on the psychological well-being of parents during the early months of their child's life. Recent literature emphasizes that preterm birth can have a significant impact on parental well-being, exposing them to a high likelihood of developing anxious, depressive, and sometimes even posttraumatic stress symptoms [31]. The questionnaires with validated scales used in this research will be used to create composite statistical indexes that measure, for each responding parent, levels of stress, depression, anxiety, perception of parental self-efficacy, quality of the bond established with their child, and the perception of the social support received. The reasons that prompted us to consider such tools stem from the literature highlighting the necessity of using specific instruments in investigating parental distress in the postpartum period, to adequately capture the specific reasons leading to the experience of such unique feelings [32]. Moreover, questionnaires with validated scales are a valuable tool in psychological research. They allow data to be collected from a large number of participants in an inexpensive and standardized manner. The ease of administration and access to personal information encourage the disclosure of candid data, reducing the social reaction effect as well as allowing people to respond more freely. The qualitative aspect of this research involves the use of the range of methods provided by ethnography, considered particularly suitable for studying the dynamics of critical health practice in action [29,33] as the ethnographic approach allows for an understanding of how medical discourse (eg, protocols, standards, and knowledge) forms within everyday medical practices (eg, informal actions, skills, behaviors, and the physician-patient relationship) that are involved in care trajectories [34]. The e-ParWelB project will use a focused ethnographic research approach with different methods. During the NICU stay, we will combine research strategies, including focused ethnography, which entails observing the relational dynamics between different staff members and between staff and parents; discussing with neonatologists their notes and accounts regarding the neonate's care pathway; observing the habits and procedures of health care staff to reveal how prognostic knowledge is shaped; and, finally, conducting narrative interviews with the staff to capture narratives about family needs and perceptions of care practices.

Parents will be approached and recruited by a psychologist within the NICU or sub-NICU when the medical staff announce their child's discharge. At this stage, the project will be thoroughly explained to them, and they will be requested to provide written informed consent. Parents of premature infants will be invited to participate in this study a few days before the discharge. The timing of recruitment will be individually determined based on the assessment conducted by the neonatologist considering the infant's prognosis. When the health care staff informs the parents that their baby will be discharged, allowing them to envision their return home, an interview will be conducted within the NICU wards (T0). During this session, a structured interview will be administered along with specially designed questionnaires combining internationally validated scales with standardized questions related to

socioeconomic status (Figure 1). The administration of the self-report questionnaires will be carried out via the Qualtrics XM platform (Qualtrics International Inc; managed by the scientific coordinators of the e-ParWelB) accessible through the Qualtrics offline app using tablets.

Figure 1. Study model. BiTS: Birth Trauma Scale; EPDS: Edinburgh Postnatal Depression Scale; NICU: neonatal intensive care unit; NPST: Nurse-Parent Support Tool; PBQ: Postpartum Bonding Questionnaire; PSAS: Postpartum Specific Anxiety Scale; PSI-SF: Parenting Stress Index–Short Form; PSS:NICU: Parental Stressor Scale: Neonatal Intensive Care Unit.



Subsequently, the study includes a follow-up phase to monitor the psychological well-being of parents of premature infants after discharge. The follow-up will be conducted through the use of a specially designed web application accessible only to participants that will allow for the monitoring of parents' adaptation and psychological well-being for up to 6 months after the newborn's discharge from the NICU. Parents will be asked to complete validated scales at 3 specific time points: 30 days (T1), 90 days (T2), and 180 days (T3) after discharge from the NICU (Figure 1). The presentation order of the validated scales will vary during the 3 follow-up time points. This choice will ensure that no mechanisms of response automation based on memory are created. The responses provided by parents to the validated scales used within the web application will trigger automated alerts signaling difficult or potentially risky situations. Parents whose responses have triggered an alert will be contacted by a psychologist to offer them psychological support and possible referral to dedicated services. In addition, during this monitoring period, a series of support forums will be implemented within the e-ParWelB web application—in fact, the web application will incorporate a space for peer discussion where issues related to, for example, daily care practices or family well-being can be discussed; a private messaging channel for psychological support where each user will be able to turn to an experienced psychologist for support in case of need; and, finally, a technical forum where each user can report malfunctions or request technical support regarding the web application's functionality.

A brief overview of the validated scales used in the surveys (in the discharge questionnaire and the follow-up questionnaires) and the topics covered by the standardized questions, which are more sociologically oriented, present in the discharge questionnaire is outlined in the following sections. Finally, a brief description of the netnography and of the focused ethnography that will take place in the NICUs and the related data collection techniques is presented.

Measures and Instruments

Measures at T0 (Discharge Questionnaire)

At the time of the child's discharge from the NICU, the investigation will focus on assessing anxiety, depressive, and posttraumatic symptomatology while also investigating parents' perceptions of their self-efficacy in bonding with their child within the chaotic and stressful environment of the NICU.

For this purpose, several validated scales will be used. Most of the literature on postpartum anxiety [35-37] refers to measures of generalized anxiety, which can often prove problematic from a psychometric perspective [38]. To date, the only available questionnaire specifically measuring postpartum anxiety is the Postpartum Specific Anxiety Scale (PSAS) [39,40]. Furthermore, the instrument has demonstrated excellent psychometric properties (ω ranging from 0.72 to 0.90 across the 4 scales and λ4 ranging from 0.71 to 0.92 across the 4 scales). For these reasons, the research team deemed it the most sensitive and appropriate tool for capturing the construct under investigation in the target population.

Postnatal depression is the most widely measured disorder in the postpartum population, which today, in Italy, is mostly subject to routine screenings for this condition. Following a careful analysis of the most recent literature [41,42], the Edinburgh Postnatal Depression Scale (EPDS) [43,44] emerged as the most widely used self-report questionnaire for measuring postpartum depression due to its ease of administration, cultural adaptability, and excellent psychometric properties. The validated Italian version has demonstrated good validity and reliability (Cronbach α=0.7894), confirming the validity of the EPDS in identifying postnatal depression. For these reasons, the research team deemed it the most sensitive and appropriate tool for capturing the construct under investigation in the target population.

Research on posttraumatic stress disorder (PTSD) during the postpartum period has typically adapted questionnaires developed for other populations, such as war veterans, which often prove poorly suited for capturing the specificities of childbirth trauma. Perinatal research comparing general PTSD measures with specific postpartum PTSD measures has found that, although highly correlated, the agreement between these scales in identifying PTSD diagnoses is low [45]. Therefore, the choice of measurement type is crucial for identifying cases of postpartum PTSD. In addition, the criteria of the American Psychiatric Association for PTSD measurement have significantly changed in the transition from the Diagnostic and Statistical Manual of Mental Disorders, Fourth Edition, to the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition. Therefore, it is essential to adhere to these new measurement criteria. The City Birth Trauma Scale [46] is a tool specifically developed to measure childbirth-related PTSD according to the recent Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition, criteria and is, to the authors' knowledge, the only instrument with these specificities. This instrument has previously demonstrated excellent reliability (Cronbach α=0.92). For these reasons, the research team deemed it the most sensitive and appropriate tool for capturing the construct under investigation in the target population.

The Parental Stressor Scale: Neonatal Intensive Care Unit [47,48] aims to capture parents' perception of distress experienced during their children's stay in the NICU. To reconstruct parental distress, the underlying model of the scale considers the interaction between various psychological and physical stress factors, such as stress related to sounds, lights, noises, and other sensory experiences typical of a highly technologized health care setting [47]. The Parental Stressor Scale: Neonatal Intensive Care Unit provides the opportunity to obtain various types of information: levels of stress related to specific situations experienced by parents with preterm infants, overall stress levels, individual stressful elements, and overall tension levels. The translation and validation study in Italian has found good psychometric properties of this tool [48].

Scientific research on the complex experience of preterm birth increasingly emphasizes that such an experience can pose significant challenges for parents, particularly in the development of bonding, which is the early relationship that develops post partum between mother and child [49]. A careful analysis of the literature [50,51] allowed us to select a questionnaire widely used in investigating bonding in the postpartum period: the Postpartum Bonding Questionnaire (PBQ) [52,53], a tool designed to measure the quality of the bond between parents and children and identify whether there are disturbances in the relationship. The Italian adaptation of the PBQ was developed using the back translation procedure [54]. Studies demonstrate that the Italian version of the PBQ has good psychometric properties and can be implemented in the Italian cultural context to assess early mother-child relational difficulties [53].

Moreover, the assessment at discharge will also take into account further aspects in light of the fact that several studies have shown that some minor stress factors such as the distance from one's home to where the child is hospitalized may contribute to a higher level of maternal discomfort [55]. The socioeconomic characteristics of family units, such as educational level, social class, job insecurity, employment status, and migration background, have also been examined as risk factors for preterm birth [56,57]. In addition, the study by Miles et al [58] revealed that the marital status of the mother is also a significant factor in predisposing to or preventing the development of a mood disorder. Specifically, married women who perceived a high level of support from their partners reported lower levels of postpartum depression than unmarried women. Conversely, among women with preterm infants, maternal age or level of education do not appear to be correlated with the onset of mood disorders [59]. Another factor that seems to mitigate the onset of mood disorders in parents of preterm infants is a high level of social support [60]. For these reasons, the discharge questionnaire will gather basic sociodemographic information from parents, such as gender, age, nationality, geographic origin, family composition, and educational level. A series of self-assessment questions will be used to evaluate the perceived social support of parents of premature infants. In particular, we have designed 6 items that inquire about perceived social support from partners, family members, friends, and health care personnel. Furthermore, respondents will be presented with a series of questions regarding the frequency of cultural activities, which will serve as indicators of their level of cultural capital, along with a series of questions aimed at capturing their occupational situation.

Finally, a validated scale will be used to gather information regarding parents' perception of nursing support during the infant's hospitalization, the Nurse-Parent Support Tool (NPST) [61]. Scientific research has highlighted the crucial role of parents' perceptions of the actual support provided by nursing staff in mitigating the stressful effects of the NICU stay [62]. In light of this evidence, Miles et al [61] devised the NPST, a scale specifically addressing the educational and informational aspects of staff support as perceived by parents that is widely used in NICUs today [63]. The NPST is a 5-point Likert-scale questionnaire consisting of 21 items divided into 4 groups: informational support, emotional support, appraisal and parental esteem support, and caregiving support. Each item is rated on a scale from 1 (*Almost never*) to 5 (*Almost always*), with higher scores indicating a higher perceived level of support provided by the nursing staff. The validity and reliability of the Italian version of the NPST were assessed by Montirosso et al [48].

Follow-Up Measures at T1, T2, and T3 (Web Application Questionnaire)

At the time of discharge, the involved parents will be invited to register on the web application specially designed for this research. Through the web application, participants will independently complete 3 short questionnaires at the 3 different times designed for follow-up (T1 at 30 days after discharge of the newborn, T2 at 90 days after discharge of the newborn, and T3 at 180 days after discharge of the newborn) to monitor their mental health status. In the web application, some validated scales already proposed at the time of discharge will be implemented. The scales are presented to participants in different moments to minimize potential bias due to response based on learning or recollection. Specifically, (1) *during T1*, participants

will be invited to independently complete the PSAS and the Parenting Stress Index–Short Form (PSI-SF); (2) *during T2*, participants will be invited to independently complete the City Birth Trauma Scale, the EPDS, and the PSI-SF; and (3) *during T3*, participants will be invited to independently complete the PSAS and the PSI-SF.

The only validated scale for which completion will be required at every follow-up time point is the PSI-SF [64,65]. The existing literature has highlighted the possibility of early identification of stressful parent-child systems to develop interventions aimed at reducing stress that could decrease the frequency and intensity of emotional and behavioral disorders in children in our society [65,66]. The characteristics of the child, those of the parent, the family context, and particularly stressful life events are some of the elements of the parent-child system that have been identified as important [64,67]. The Parenting Stress Index was developed in response to the need for an assessment measure of these characteristics. For the purposes of this scientific research, the PSI-SF was adopted, which is an abbreviated version of the Parenting Stress Index that investigates parental distress, dysfunctional parent-child interactions, and difficult child behaviors. The brevity of the PSI-SF allows primary health care providers to identify families most in need of follow-up services [68]. Furthermore, the PSI-SF represents an extremely interesting, agile, easy-to-administer, and interpretable tool. The Italian version of the PSI-SF has been translated and validated by Guarino et al [69] and investigates stressful systems through 3 subscales: parental distress, dysfunctional parent-child interaction, and difficult child behaviors.

Our intention is to use the PSI-SF as a potential *risk screening tool*, namely, a technique that can identify parent-child systems under excessive stress and, thus, serve as an important component within prevention programs aimed at reducing the frequency and intensity of emotional and behavioral disorders [69]. The responses provided by parents to all validated scales used within the web application, in cases in which they exceed the threshold values established for each scale, will indeed allow for the automated activation of alert signals for situations of difficulty or potential risk. Finally, as mentioned previously, all psychological scales used in this study are internationally validated, ensuring their reliability across diverse populations, including those with preterm infants. The sociodemographic section of the questionnaire was tested in a pilot study involving 104 parents [12], which preceded this project and allowed for refinement of the questions to better suit the target population. While these tools provide a strong foundation for data collection, future research could explore additional validations to further tailor the measures to this specific group.

Netnography

As mentioned previously, the web application will feature three specific communication channels through which users can interact: (1) a public forum for peer discussion only where users will be able to post messages, share opinions and ideas, or ask questions on issues related to the daily childcare at home; (2) a private communication channel through which users can contact the psychologist to ask for support in case of discomfort, uneasiness, or other states of distress; and (3) a forum dedicated to the technological tools available to participants in which it is possible to both report technical malfunctions to IT staff and discuss among parents and researchers the impacts of the eHealth tool on its users and their well-being.

The textual corpora produced by users will be downloaded and will form the empirical basis for data analysis through an approach of digital ethnography.

For many years now, computer-mediated communication has been fully integrated into people's daily lives, blurring the distinction between offline and web-based social worlds as they both coexist and fully overlap [70]. Therefore, it has become increasingly important and relevant for social researchers to study society in and through the internet. Although methodological reflections around digital research have been manifold and have also given rise to different terminologies and definitions, in this contribution, we use the term *netnography*, coined by Kozinets [71], to illustrate our digital ethnography approach that adapts the typical techniques and tools of ethnography to the study of web-based communities, which interact through a computer-mediated communication. The presence of the researchers, as well as the fact that messages written in the forums will be subject to analysis, is clear to the participants from the outset, so our netnography will use an overt observation technique.

In our project, the web-based community is closed, meaning that the web application and its tools can only be accessed through a username and password if one participates in the study and has agreed to take part in the follow-up phase. Some methodological perspectives on web-based research place great importance on the medium [72] and, by consequence, on the specific digital environment and its characteristics that shape the spaces, times, opportunities, and constraints under which web-based interactions take place. In our case, one of the main constraints is that messages in the public forums (*n. 1*, a public forum for peer discussion, and *n. 3*, a forum dedicated to the technological tools) will be published subject to approval by the members of the research team to avoid the use of inappropriate language or extremely off-topic communications. If some messages are rejected, they will also end up in the analysis, but they will obviously not affect the overall interaction as they will not be visible to other users. Time is another important feature that will have consequences for the flow and volume of communications as the web application will see the asynchronous access of participants, who are gradually recruited over time. Although the messages in the public forums will remain fixed and always visible, participants who complete the 180-day follow-up period may have less incentive to access the web application, resulting in no further discussion with other newly recruited participants. On the other hand, the accumulation of messages over time could stimulate other interactions, also providing an incentive for participants to use the web application not only as a tool for filling out periodic questionnaires. From a research point of view, we are particularly interested in the volume, modalities, and content of the digital interactions between participants, aware of the constraints to which such communications are subjected. It will be useful to understand the representations, perceptions, and perspectives of premature parents and the impact of prematurity

and of the care practices in daily life. Moreover, we will pay attention to the adaptation processes carried out to cope with the transition period after discharge from the NICU and how parents deal with their new domestic life. In the analysis, even though the participants are pseudoanonymized through a unique alphanumeric code, we can trace and use as a segmentation variable the one that discriminates between the partner who gave birth and the one who did not, for example, to account for differences in the prevalence and occurrence of the messages and topics reported. Furthermore, the *n. 3* forum has the goal to explore how digital-driven changes affect families. It is dedicated to specifically discussing the tools in the web application through a process of facilitation by a member of the research team stimulating dialogue on dedicated questions. As previously stated, this section of discussion about the web application is intended not only as technical support but also as a space for group reflection on the impact of the digital tools introduced by e-ParWelB to support families' well-being. The material created by users in this section will then be analyzed with the aim to explore whether web-assisted alerts and expert and peer support on the web were beneficial to families' well-being and, eventually, how these tools might be improved in the future. This phase of research will also allow us to reflect upon the implications of introducing a digital medium in the relationship between the health care staff and families [73], as in the tradition of sociology and science and technology studies working together on health care issues [74].

Ethnography

The qualitative part of this research aims to study the NICU environment through the use of focused ethnography [75,76]. This term indicates a research method based on brief and intensive observations with the aim of analyzing well-defined phenomena within a specific context. While the classic form of ethnography is centered on the study of broad topics, such as the holistic observation of social groups or institutions, focused ethnographies narrow down their perspective to the analysis of specific actions, interactions, and social situations. This implies a few changes in the position of the observer compared to the situation of traditional ethnography. First, the researcher cannot face the fieldwork unprepared but must be at least theoretically confident with the context of the actions that are to be studied. Second, traditional ethnography provides a range of observer positions, from participant as observer to observer as participant [77], whereas focused ethnography does not involve the same opportunity for observing as a participant because of the nature of the object of study. It would be both highly inappropriate and technically impossible for the focused ethnographer to participate actively in, for example, a medical examination or an operation. Instead, a more distant observer position is possible. In this way, the focused ethnography researcher may be excluded from contextual factors of importance. While traditional ethnography affords the chance to actually participate in the life of the studied social milieu, focused ethnography does not offer the same opportunities of active participation. This usually happens due to the inherent characteristics of the participants under investigation. Active participation in skill-intensive activities would be both highly unrespectful and unfeasible for the focused ethnographer. Consequently, it is said that, in focused ethnography, researchers are not doing observant participation but that they are participating as observers.

A brief recap of the main traits of focused ethnography and its difference from traditional ethnography is shown in Table 1.

Table 1. Comparison between focused ethnography and traditional ethnography derived from the study by Andreassen et al [78].

Characteristic	Focused ethnography	Traditional ethnography
Subject matter	• Episodes in social fields • Clear research focus • Familiar cultures • Background knowledge before data collection • Applied research	• Entire social fields • Broad research purpose • Foreign cultures • Gaining knowledge from engagement in the field • Basic research
Data collection	• Relatively long planning phase • Intermittent visits with particular time frames • Focused exploration • Video or audio recordings or detailed, focused field notes • Often multi-sited • Time intensity	• Relatively short planning phase • Full-time participant observation over a longer period • Open exploration • Extensive and in-depth written field notes • Often single sited • Time extensity
Researcher role	• Alterity • Observer as participant • Selected informants who hold a specific knowledge serve as key participants	• Strangeness • Participant as observer • Participants are often those with whom the researcher develops close relationships
Data analysis	• Analysis intensity • Collective data analysis sessions	• Experiential intensity • Solitary data analysis

Focused ethnography is a particularly appropriate technique for our research due to the traits of medical practice, which comprise bounded and clearly delineated social occurrences or scripted exchanges. This statement has been proved true by an increasing number of studies using this technique within the hospital setting in recent years [79-82]. This technique affords the means to

investigate particular episodes or interactions within social milieux such as NICUs, facilitating nuanced and comprehensive insights into the influence of sociocultural factors on the interaction between the NICU staff and preterm parents. This specific effort of focused ethnography will be divided into 2 steps, each involving the staff members of NICUs in hospitals collaborating with the project. First, the researcher will observe the routine practices that constitute what is defined as *ward life*, trying to create as little interference as possible with the staff's activities. At this stage, the researcher's focus will not be on individuals but rather on the overall context of neonatal intensive care and the social interactions occurring within it. Second, the researcher will use narrative interviews to gather additional information from the NICU staff. The use of interviews is quite common in focused ethnography, as explained by the relevant literature on the topic: "The focused ethnography researcher may be precluded from contextual factors of importance. Applying method triangulation as a cornerstone in ethnography is a way of overcoming this dilemma. For example, combining short observations with interviews will give opportunities to ask about the context in which the observations take place, as well as to explore how the participants experience being observed" [78]. In these narrative interviews, the researcher will aim to involve staff members with profiles as diverse as possible regarding their roles, length of service, gender, and age. The objective is to achieve what the literature calls a "maximum variation sample" [78], maximizing sample diversity (while acknowledging that this is a nonprobabilistic convenience sample) across certain characteristics to capture the complexity of the studied reality.

Throughout both of the aforementioned steps, this research will try to analyze the meaning and effects of the NICU staff decisions and practices on the parents' well-being. This focus on the analysis of existing procedures in skill-intensive contexts, especially medical-related ones, has been referred to in previous research as *exnovation*. *Exnovation* refers to the attempt to foreground what is already present—though hidden—in specific practices to render explicit what is implicit in them [83]. A focus on exnovation allows us to bring to light implicit matters of actual practice and develop a fresh perspective on the ingenuity of the professionals and the specific structure of their practices. It offers insights into their specific modes of ordering day-to-day practices [84]. Exnovation, in other words, elucidates competencies of coordination and alignment of these modes of ordering of which those involved are not always aware [29]. In other words, this research aims to reflect on existing practices of care aimed at preterm parents and their children and deepen our understanding regarding their effects with the aim of preventing family maladjustment after a traumatic event such as preterm childbirth.

Regarding the organization of the qualitative tools for the research, the access to the field will be negotiated separately in each NICU to take measures to avoid disrupting staff work and minimize impact on organizational routines. To conduct an ethical and respectful data-gathering process, NICU staff will be informed about the research in advance by the department heads, with whom a partnership has been established for the project, thus ensuring that they are aware of the research procedures. Once access is granted, the researcher present in the department will autonomously organize interviews with the staff.

Expected Outcomes

The e-ParWelB central impact will be developing and piloting a model of sociopsychological assessment tailored for parents whose infants have been hospitalized in the NICU for critical health situations connected to prematurity. The model, by increasing preterm parents' perception of self-efficacy and well-being, will allow for the prevention of family maladjustment [5,6] and, therefore, the indirect improvement of preterm child health outcomes [7]. The mixed methods social research that we designed is expected to achieve the following results: (1) to reduce the discomfort and maladjustment caused by prematurity on preterm parents and assess their perceptions of social support (from family, friends, potential employers, and colleagues), perceptions of preparedness, and parental self-efficacy from the time of discharge and for the following 6 months; (2) to analyze the difference between mothers' and partners' responses to preterm birth in terms of stress, negative feelings, and perceptions of parental self-efficacy and social support; (3) to determine which neonatal care practices, forms of communication, and environmental settings of the NICU are more likely to reduce negative feelings and foster the well-being of preterm parents; and (4) to advance the knowledge on the role of a digital-based tool in monitoring and supporting families' well-being during the follow-up.

On the latter point, e-ParWelB intends to engage in the relationships among science, technology, and society by addressing how the hospitalization experience of preterm families may inform technology and science development. At the same time, we aim to identify the effect of the introduction of a digital technology–driven assessment and support model on families' well-being and on care practices in the neonatal intensive care wards. In particular, the e-ParWelB project directly connects with the objectives of (1) developing a public health system enhancing investments in terms of human, digital, structural, instrumental, and technological resources; and (2) improving scientific research in the biomedical and health field.

Indeed, the interdisciplinary approach to promote eHealth in premature families enhances the dialogue between science (health care and medical knowledge) and society (families' perspectives) on the topic of preterm birth through the aid of digital technology. This will be possible with the implementation of the e-ParWelB web application, which will follow processes of responsiveness and adaptation as well as considering criteria of accessibility following responsible research and innovation principles. As the web application constitutes both a tool to periodically monitor parents' well-being and a digital space for sharing and discussion, both with a psychologist and among peers, the project has a multi-side technological and scientific impact.

At the same time, we aim to identify the effect of the introduction of digital technology on families' well-being and on care practices. For instance, through the netnographic exploration of the web-based space of discussion within the e-ParWelB web application, we aim to address the eventual

health care web-based community of practice forming in the forum [85]. Drawing on the idea by Timmermans and Berg [86], an orientation of *technology in practice* allows for a critique by scholars in the social sciences regarding the complicated modalities in which the *social* and the *material* intertwine in technologies for health care, as well as possibly influencing their creation and implementation. Thus, referring to what in science and technology studies literature is known as the *sociotechnical approach*, we are interested in how the social and health care aspects influence the development of the digital technology and, at the same time, in modalities through which the digital medium affects families and the care process, especially after discharge [87,88]. Therefore, we also aim to understand the impact of the web application on families' well-being.

Results

We expect to observe these results by the end of October 2025, the date set as the conclusion of the Project of Relevant National Interest funded by the Ministry of University and Research.

Discussion

Impact

This research project aims to identify the social determinants of preterm parents' well-being. It will monitor their feelings and perceptions of well-being during the baby's hospitalization and after discharge, with the goal of reducing their distress and discomfort. Unlike previous studies, this project places a significant emphasis on both mothers and fathers, analyzing how gender differences and parental roles influence their experiences and affect outcomes related to perceived well-being and social support. Furthermore, using ethnographic methods, this study delves into the everyday life of NICU wards. It examines these environments both as sites of high-skill professional practice and as arenas of social interaction between staff and parents. The aim is to understand the social arrangements and practices that facilitate staff work and parental participation and involvement during the sensitive period of their baby's hospitalization. Finally, the use of technology in this study serves a dual purpose. Instrumentally, it enables the monitoring of parental well-being after discharge, but it also prompts deeper sociological inquiries into its role at the intersection of medical science and society. In addition, technology acts as a medium for mutual aid, fostering specific web-based peer discussions and shaping new forms of social support and community among parents of preterm infants.

The e-ParWelB project not only contributes to scientific and technological development, but its impact on the social and economic dimensions also stems from the premise that, by increasing the well-being of preterm parents it is possible to indirectly improve their infants' health outcomes. As scholars have argued, the abrupt disruption of the establishment and development of parental mental representations, combined with the possibility that both the baby and the mother are in critical condition, can make preterm birth a traumatic event for parents [89]. Therefore, reducing the family's maladjustment enhances future health—including mental health—in premature children [7]. Moreover, parents' mental health is supported, as well as their self-efficiency, preventing a large set of repercussions. For society at large, this also means introducing factors of prevention in terms of social and economic costs that unhealthy individuals and families might incur. Furthermore, the situation of premature birth care in Italy sees scattered NICUs applying different protocols for what concerns the role played by the parents of hospitalized newborns. As the latest report of the Italian Society of Neonatology shows, for instance, just 63% of the NICUs allow free-time access for parents [90]. When looking at the regional location, we observe an unequal distribution of the free-time access wards. Indeed, in the northern regions, 88% of NICUs do grant free-time access, whereas in the south, just 34% percent do [90]. Thus, by developing a piloted model for preterm parents' sociopsychological assessment, e-ParWelB will produce knowledge about the best practices to be implemented in NICUs, enhancing the opportunity for stakeholders and policy makers to make neonatal care protocols less regionally uneven and more efficient when concerning the collaboration between parents and health care staff.

Strengths and Limitations

The e-ParWelB project was preceded by the ParWelB project (principal investigator: AD), and although with a different institutional setup and collaborations with different NICUs, the 2 projects stand in a relationship of continuity, building on the same theoretical and methodological premises. Therefore, practical experiences and careful analyses regarding actual strengths and limitations have already been carried out for the previous project [10].

In general, the greatest strength of the entire research project lies in listening to and empowering the parents of premature children who participate in the study, making them more aware of and helping them deal with the challenging situation of prematurity, advancing deep reflections that do not stop at purely medical practices but also promote a person-centered approach to stimulate new neonatal practices and foster the well-being of families.

In this context, it is essential to reconnect the social dimension with the medical experience, also owing to the support of technology, and this is one of the main objectives of the project.

Indeed, we aim to study a model for monitoring and assessing parental well-being and look at the relationship between the medical-nursing staff and the parents of premature babies from a sociological and psychological perspective with the aim of promoting public awareness and participation, also by involving the medical-nursing staff with respect to the values, personal experiences, and point of view of the parents.

These strengths are accompanied by deep reflection in mapping out the potential limitations of the project and strategies to mitigate them.

Among these, access to the study is worthy of consideration. An actual constraint on access for preterm parents is language—the lack of cultural mediators and translators in the project allows only for participation of people fluent in Italian and English. As Italian and English were also the only languages in the previous ParWelB project, we have already ascertained

that a nonnegligible proportion of parents, often with migration backgrounds, were unable to participate in the study, and we expect this situation to be repeated. This is uncomfortable for mainly 2 reasons. First, it does not allow a specific population of parents, who often are more likely to be in situations of marginality or social isolation, to access the direct and indirect benefits of the project, such as stimulating self-reflections on their parental role and gaining access to psychological support after discharge. Furthermore, from a purely scientific point of view, there is less opportunity to investigate how certain cultural differences and social support (which is often lacking or expressed in different ways among people with a migratory background) impact the well-being of preterm parents and their experiences in the NICU.

One of the main aspects to consider when reflecting upon the pros and cons of this project is the possible bias introduced by the implementation of the web application, which is a digital technology not necessarily available to all social groups. Digital literacy, availability of connection to the internet, and access to digital devices are all necessary conditions to participate in the study, and the lack of one of these aspects may act as an additional exclusion factor, possibly affecting marginalized social groups or groups with specific needs [91,92]. Nonetheless, parents excluded from the digital space are necessarily excluded from tools of expert and peer support.

In addition to access barriers to the study, this project faces other possible limitations regarding engagement and participation during the research activity that can be reversed. In the previous ParWelB project, due to the COVID-19 pandemic, researcher access to the NICU was restricted, so parent recruitment, discharge survey administration, and web application registration were performed entirely by NICU staff, usually by psychologists or neonatologists. Overall, in this way, NICU staff were more involved, but some methodological forms of control by the researchers were lacking regarding modalities of both study presentation and survey administration to parents [93]. In the new e-ParWelB project, while we no longer have the limitations of the pandemic, a blended approach was chosen as we will maintain a deep involvement by NICU staff, especially psychologists, in recruitment, survey administration, and web application enrollment at discharge. Above all, previous experience has shown that the relationship of trust built between the NICU staff and parents is central to engaging the latter in the project. Therefore, it is in the project's interest to maintain these relationships both to provide parents with referents whom they consider reliable and with whom they have already become familiar during their stay in the NICU and to engage the medical-nursing staff further, stimulating an even closer relationship between these 2 social actors beyond purely medical practice. On the other hand, in the previous project, the participation rate dropped by 10% for parents recruited in the second half of the project timeline, an indicator that the motivation and consequent convincing power of the NICU staff toward parents slightly declined over time [93]. Therefore, the presence of a researcher can also be decisive in rekindling motivation and emphasizing the importance of parental participation throughout the recruitment phase. In the e-ParWelB project, in some NICUs, there will be a constant presence of a project researcher, who will take part in recruitment together with the staff and will personally take care of survey administration at discharge and invite participants to register on the web application. In NICUs where the constant presence of the researcher is not expected, it will be arranged if no one in the NICU can recruit parents or the research team notices a decline in the participation rate. Therefore, this flexible choice allows us to maintain and strengthen the bond between the parents and the NICU staff and, at the same time, provide help and support to the participants or NICU staff and ensure the correct conduct of the research from a methodological and ethical point of view.

In conclusion, one of the critical aspects of the ParWelB project was the high dropout rate during the follow-up surveys using the web application. To address this issue, the new project, e-ParWelB, proposes a lighter monitoring approach, with a shorter total period and lower frequency (6 months of monitoring instead of 1 year and 3 surveys instead of 12), thus impacting participants to a lesser extent. A less intrusive follow-up, both in terms of frequency and volume of questionnaire completion, will not affect the capacity of researchers to monitor the well-being of the participants, whereas it will lower the commitment required from users, allowing them to allocate their time and energy to other activities related to the web application, such as forums.

Acknowledgments

This research project would not have been possible without the funding of the Italian Ministry of University and Research as a Project of Relevant National Interest—2022 call for submissions (protocol 20225R7XB3; European Research Council, Social Science and Humanities field; Unique Project Code: H53D23005630006). This project is not sponsored by any entity, organization, or company.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to the inclusion of sensitive information, such as respondents' psychological distress, diagnosis of psychopathology, and clinical data on infants admitted to the neonatal intensive care unit. However, deidentified data may be made available from the corresponding author on reasonable request in accordance with ethical and legal considerations.

Authors' Contributions

AD, FP, GL, MFF, CR, MN, BF, GC, and CI were responsible for conceptualization and investigation. AD, FP, GL, MFF, and CI conducted the methodology and formal analysis. AD and CI managed resources and project administration. The original draft was written by FP, GL, and MFF. AD, FP, GL, MFF, CR, MN, and CI contributed to the review and editing process. Supervision was provided by AD and CI. All authors have read and agreed to the published version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Functional abdominal pain disorders (FAPDs) are common in young people and are characterized by persistent or recurrent abdominal symptoms without apparent structural or biochemical abnormalities. FAPDs are associated with diminished quality of life, school absence, increased health care use, and comorbid anxiety and depression. Exposure-based internet-delivered cognitive behavioral therapy (ICBT) has demonstrated efficacy in alleviating abdominal symptoms and improving quality of life. However, a deeper understanding of effect mechanisms and identification of possible additional treatment targets could refine treatment.

Objective: This protocol paper aims to describe a study focusing on children and adolescents undergoing ICBT for FAPDs, aiming to further investigate the underlying mechanisms of effect.

Methods: Children (8-12 years), adolescents (13-17 years) with FAPDs, and their respective parents will be included for 10 weeks for ICBT. First, detailed trajectories of effect are examined through a randomized single-case design study involving 6 children and 6 adolescents (substudy 1). Following this, an open-ended explorative pilot study with 30 children and 30 adolescents explores potential illness-related cognitive biases and interoceptive accuracy before and after treatment (substudy 2). Finally, spanning across these 2 substudies, including all parents from substudies 1 and 2, we will assess parental distress and illness worries before and after treatment, and how these factors impact the treatment adherence and outcomes of the child or adolescent (substudy 3).

Results: Recruitment of participants began in June 2022 and is finalized for substudy 1 and ongoing for substudies 2 and 3. Recruitment is expected to be completed by January 2025, with final data collection during April 2025.

Conclusions: The findings have the potential to contribute to the ongoing improvement of specialized psychological treatment for FAPDs in young people.

Introduction

Functional abdominal pain disorders (FAPDs) affect up to 15% of children and adolescents and are characterized by recurrent or persistent abdominal pain and other debilitating gastrointestinal symptoms such as changes in defecation patterns and nausea [1,2]. The disorders are associated with reduced quality of life, high absence from school, and increased health care use [3]. Psychiatric comorbidities, especially anxiety and depression, are prevalent [4] and up to 40% persist in reporting abdominal symptoms into adulthood [5].

The pathophysiology of FAPDs is not fully understood but recent research suggests a biopsychosocial perspective where the complex interactions of physiological processes such as visceral hypersensitivity, psychological factors like emotional distress and anxiety, and social factors including family dynamics and environmental influences can contribute to the development and maintenance of gastrointestinal symptoms [6]. These factors combined are related to altered processing of sensory stimuli along the brain-gut axis with persistent or recurrent experience of abdominal pain and other gastrointestinal symptoms [7-10]. This altered processing can be understood within the framework of predictive processing, a theory suggesting that the brain consistently evaluates predictions regarding sensory inputs and discrepancies from these predictions [11]. Crucial factors contributing to the development of maladaptive predictive processes encompass cognitive biases marked by symptom-related fear and catastrophizing with an attentional bias toward pain or gastrointestinal stimuli [12-15]. This may be accompanied by the avoidance of situations expected to trigger symptoms [4,16-18] and changes in the interoceptive ability to sense, process, and interpret body signals [19]. Parental behaviors, such as solicitous responses, fearful communication about symptoms, and encouraging avoidance of situations that may provoke symptoms, can further influence the child's perception of bodily stimuli [20-23].

In summary, understanding the pathophysiology of FAPDs involves navigating a complex system of various factors and processes. Consequently, treatment may encompass different targets, including both child-specific and contextual, that is, typically parental-specific factors.

In line with this, cognitive behavioral therapy (CBT) is the treatment supported by the strongest evidence of effect [24-26], with its main focus on restructuring potential child symptom-related maladaptive cognitions, emotions, and behaviors, and often with parental involvement. Swedish studies have documented the efficacy of internet-delivered cognitive behavioral therapy (ICBT) aimed at children and adolescents with FAPDs and their parents [27-29]. The ICBT focuses especially on exposure exercises and parental management of their child or adolescent's symptoms. By enabling the child or adolescent to manage symptoms in previously avoided situations and thereby minimizing the gastrointestinal-specific fear, the treatment reduces the proposed visceral hypersensitivity, which over time leads to fewer abdominal symptoms.

Still, a proportion of the young patients do not improve from ICBT as the number needed to treat has been reported to be around 4, meaning approximately 4 patients must receive the treatment for 1 additional patient to experience adequate symptom relief [27,29]. Therefore, a deeper understanding of the mechanisms of change and the potential influence of additional modifiable factors on the treatment effect is required to improve treatment effects even more.

In the current study, we will evaluate translated versions of the Swedish ICBT for children and adolescents with FAPDs in a Danish context. The treatments target both children (aged 8-12 years) and adolescents (aged 13-17 years) and their parents, which provides a unique possibility to examine both child or adolescent and parental factors before and after treatment. The aims of the study are to (1) investigate the detailed trajectory of the effect of ICBT in children and adolescents with FAPDs, (2) explore potential illness-related cognitive biases and interoceptive accuracy in children and adolescents with FAPDs compared with healthy controls, and if these factors are changed after ICBT, and (3) explore if parental distress, illness worries, and behaviors may impact the child or adolescent's treatment adherence and outcome.

This protocol article is reported following the SPIRIT (Standard Protocol Items Recommendations for Interventional Trials) guidelines [30].

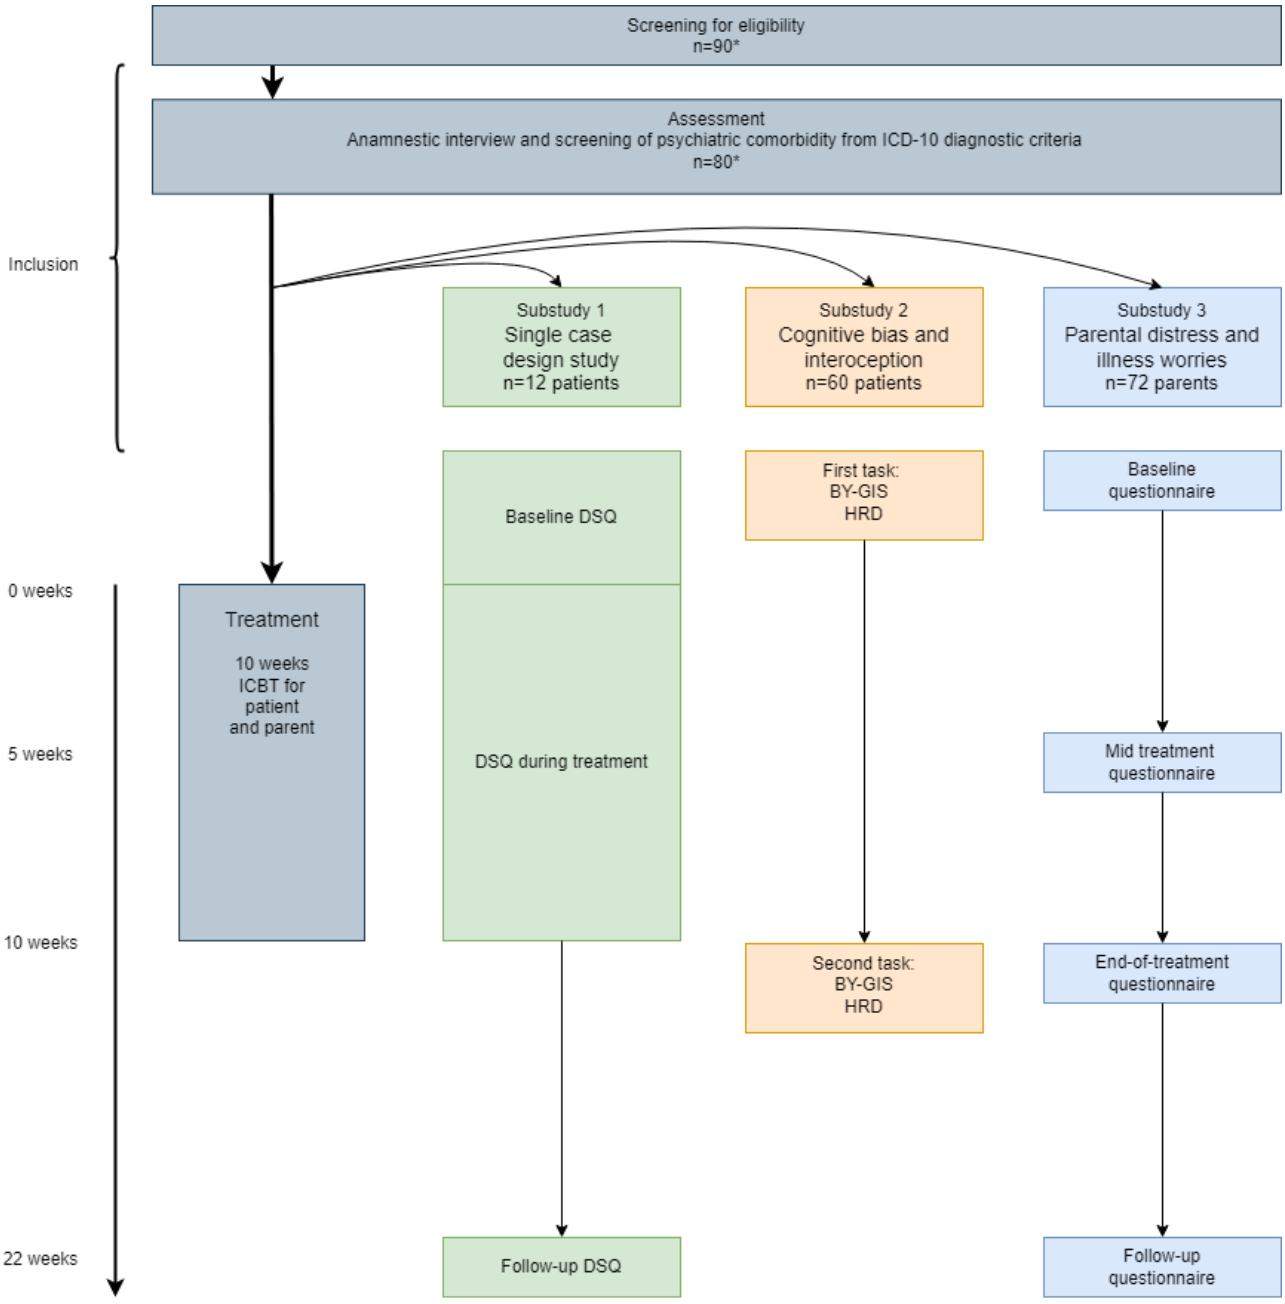
Methods

Study Design

The study includes 2 recruitment phases. The first phase concerns a single case experimental design (SCED) study (substudy 1) with a total of 12 patients (6 children and 6 adolescents, respectively). The second phase concerns an open pilot study on cognitive biases and interoceptive accuracy (substudy 2) with a total of 60 patients (30 children and 30 adolescents, respectively).

Consequently, a total of 72 children and adolescents, along with a corresponding number of parents, will undergo ICBT for FAPDs throughout the entire study. Parental distress and illness worries will be assessed before, during, and after the treatment in all included parents (substudy 3; Figure 1).

Figure 1. Overall study design. BY-GIS: biases in youth toward gastrointestinal-related stimuli; DSQ: daily short questionnaire; HRD: heart rate discrimination; ICBT: internet-delivered cognitive behavioral therapy; ICD-10: International Statistical Classification of Diseases, Tenth Revision.



Study Setting and Recruitment

Children and adolescents diagnosed with FAPD will be referred to the project from pediatric departments located at 4 hospitals (1 university hospital and 3 regional hospitals, respectively) as well as from private pediatric practitioners in the Central Denmark Region. Due to a slow referral rate of adolescents, we have been granted permission from The Central Denmark Region Committees on Health Research Ethics to expand the inclusion area to include additional regions (the North Denmark Region and the Region of Southern Denmark). We will maintain continuous communication with referring pediatricians to ensure sufficient participant enrollment. This will include in-person meetings, emails, and newsletters.

Eligibility Criteria

Eligible participants will be invited for an assessment interview at the Department of Child and Adolescent Psychiatry, Aarhus University Hospital Psychiatry. The assessment will include psychiatric comorbidities, such as neurodevelopmental disorders, mood disorders, and suicidal risk, systematically evaluated according to the *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision*) diagnostic criteria. Assessments

will be performed by medical doctors who are either trainees or specialists in child and adolescent psychiatry.

Inclusion Criteria

First, age 8-17 years. Second, a primary diagnosis according to the ROME-IV criteria of one of the FAPD subtypes—irritable bowel syndrome (IBS) or functional abdominal pain not otherwise specified (FAP-NOS) documented by the child's regular pediatric physician [31]. The somatic evaluation includes recommended routine medical investigations, that is, growth, fecal calprotectin, and blood samples (TSH [thyroid stimulating hormone], total IgA [immunoglobulin A], IgA-tissue transglutaminase, complete blood count, C-reactive protein analysis, and liver enzymes). Third, stable dosage of regular FAPD-related medication such as laxatives, antidiarrheal medicines, or psychopharmacological medication during the past month.

Exclusion Criteria

First, another medical or psychiatric disorder that better explains the symptoms. Second, severe child psychiatric or social problems (eg, high level of suicidal ideation, school absence of more than 40% during the past month, or ongoing substance abuse). Third, ongoing psychological treatment. Fourth, insufficient language or computer skills (patients and parents). Fifth, severe family problems (eg, child maltreatment, parental substance abuse or severe psychiatric illness, and custody fight).

Intervention

Translation Procedure

For this study, the Swedish ICBT programs were translated into Danish. The translation procedure was stepwise; first, a direct translation was performed by native Danish speakers familiar with the Swedish language; second, a mutual discussion of the Danish translation took place within the research group, including a discussion of problematic sentences or wordings; third, remaining issues were discussed with the Swedish authors, and a final consensus on the Danish translation was reached. This translation was reviewed by both a Danish language expert and a clinician with experience with the patient group to make further refinements. Finally, in the last step, the revised translation was reviewed again by the Danish research group for final adjustments.

Design and Content of Treatment

The 4 distinct ICBT programs used in this study are targeted children (8-12 years), adolescents (13-17 years), and the parents of each group, respectively. The treatment lasts for 10 weeks and consists of 10 modules for children, adolescents, and parents of children (with a new module every week) and 5 modules for parents of adolescents (with a new module every other week). An overview of treatment content can be seen in Table 1. The programs include sections with videos, exercises, and quizzes designed to actively engage the child or adolescent in the treatment. Psychoeducation regarding FAPDs, detection of avoidance behavior, a brief mindfulness exercise called "SOL (Stop, observe, let go)" and graded repeated exposure exercises comprise some of the central components covered in the programs for both children and adolescents. The first modules of treatment introduce the above-mentioned concepts whereas later modules focus on repeated exposures. The purpose of "SOL" is Stopping, Observing how the stomach feels, and Letting go of the focus on the stomach and continuing with the activity. The parental programs emphasize supporting their child or adolescent's exposure, decreasing attention to their child or adolescent's abdominal symptoms, and prioritizing shared positive activities. Each module ends with planning of the homework assignments which are evaluated first thing in the next module.

Table 1. Overview of the content of treatment for each module.

Module	Children (8-12 years)	Parents	Adolescents (13-17 years)	Parents
1	• Introduction to the treatment format • Psychoeducation on FAPDs[a] (video) • Mapping "stomach behaviors" (control, avoidance, safety) • Setting treatment goals • Homework: Self-monitoring	• Introduction to the treatment format • Positive attention • Focus shift • Mapping common parental behaviors • Handling personal frustrations • Homework: Focus shift, breaks, involving peers	• Introduction to the treatment format • Psychoeducation on FAPDs (video) • Setting treatment goals • Homework: self-monitoring	• Introduction to the treatment format • Focus on positive attention and shared moments • Mapping common parental behaviors • Homework: Shared positive moments
2	• Psychoeducation on impact of thoughts and "SOL"[b] (video) • Constructing an exposure hierarchy. • Homework: Utilize "SOL" in everyday situations.	• Golden moments • Board game with rewards for exposure exercises. • Homework: Golden moments, focus shift, planning rewards"	• Mapping "stomach behaviors" (control, avoidance, safety) • Behavior analysis • Homework: Behavioral experiment (avoiding "stomach behaviors")	
3	• Behavior analysis • Psychoeducation on exposure exercises (video) • Homework: Exposure exercises.	• Supporting child's exposure exercises • Managing school absences • Homework: board game rewards, golden moments, focus shift	• Psychoeducation on impact of thoughts and "SOL" (video) • Toilet habits (frequent visits, urgency) • Homework: "SOL" and new toilet habits	• Psychoeducation on FAPDs (video) • Acknowledging and shifting focus to reduce symptom focus • Homework: Shared positive moments, letting go of parental behaviors, focusing on alternative adolescent behaviors
4	• Toilet Habits (frequent visits, urgency) • Behavior analysis • Homework: Exposure exercises, new toilet habits, "SOL"	• Parental stress and recreational activities • Homework: recreation, golden moments, board game rewards, focus shift	• Psychoeducation on exposure exercises (video) • Behavior analyses • Construct exposure hierarchy • Homework: "SOL," toilet habits, finish exposure hierarchy	
5	• Repetition • Behavior Analysis • Homework: Exposure exercises, toilet habits, eliminating safety behaviors, "SOL"	• Repetition • Mapping challenges • Homework: recreation, golden moments, board game rewards, focus shift	• Exposure exercises • Anticipatory anxiety • Emotional versus behavioral goals • Homework: Exposure exercises, "SOL," toilet habits.	• Encourage and support the adolescent's exposure • Psychoeducation on exposure exercises (video) • Homework: Shared positive moments, support and encouragement, support adolescent's exposure
6	• Positive analysis of new behaviors • Advancing exposure difficulty • Homework: Advancing exposure exercises, toilet habits, "SOL"	• Problem-solving with child • Homework: recreation, golden moments, board game rewards, focus shift, problem-solving	• Further details on exposure and rewards • Homework: Exposure exercises, "SOL," and toilet habits	

Module	Children (8-12 years)	Parents	Adolescents (13-17 years)	Parents
7	• Positive behavior analyses • Evaluation of Treatment Goals (from Module 1) • Homework: Exposure exercises, toilet habits, "SOL"	• Parental behavior analyses in child interaction • Homework: recreational, golden moments, board game rewards, focus shift	• Level up exposure exercises • Homework: Exposures exercises, "SOL," toilet habits	• Managing personal frustrations • Engaging in recreational activities • Listening effectively • Homework: Shared positive moments, support and encouragement, support adolescent's exposure, active listening, parental recreation
8	• Positive behavior analyses • Advancing exposures to a "Super Hard Day" • Homework: Exposure exercises, the "Super Hard Day," toilet habits, "SOL"	• Review of progress • Reward for efforts • Homework: recreation, golden moments, board game rewards, focus shift, parental reward	• Emphasis on more challenging exposures • Homework: Challenging exposure exercises, "SOL," toilet habits	
9	• Treatment repetition using quizzes • Progress evaluation • Homework: Final exposure exercises, toilet habits, "SOL"	• Progress evaluation • Challenge evaluation • Homework: recreation, golden moments, board game rewards, focus shift.	• Focus on how to further challenge oneself. • Homework: Exposure exercises	• Review of treatment • Parental behavior evaluation (comparison with module 1) • Future training and relapse prevention plan
10	• Treatment goal and exposure hierarchy evaluation • "Stomach behavior" evaluation (comparison with module 1) • Future training and relapse prevention plan	• Parental behavior evaluation (comparison with module 1) • Future training and relapse prevention plan	• Treatment goal and exposure hierarchy evaluation • "Stomach behavior" evaluation (comparison with module 1) • Future training and relapse prevention plan	

[a]FAPDs: Functional abdominal pain disorders.

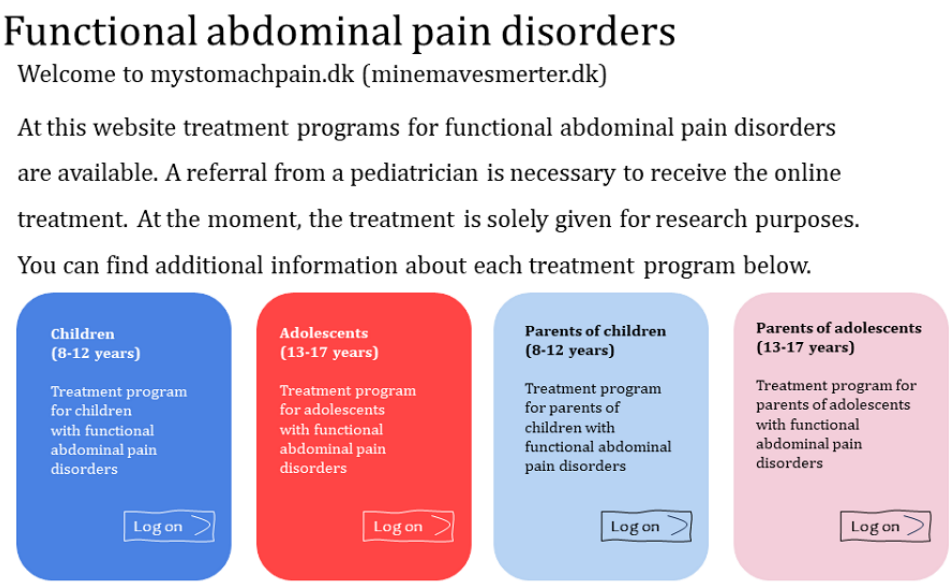
[b]SOL: Stop, observe, let go.

Modifications and Web Page

The Danish versions of the ICBT programs were pretested in 2 children and 2 adolescents with biweekly feedback from the patients and parents on overall experience and content (telephone interviews performed by a research assistant). Minor modifications were performed, mainly in the adolescent program where the IBS treatment was adjusted to include IBS and FAP-NOS. Furthermore, the mindfulness exercise "SOL" was integrated in the adolescent program to further support the process of labeling thoughts and sensations.

All treatment elements are delivered through a web page specifically designed for this study (Figure 2). Each family will choose 1 primary parent to participate in the treatment at the assessment. All 4 treatment programs are supported by a therapist who provides written feedback after each module. The affiliated therapists will be psychologists and medical doctors with knowledge of CBT. They will receive weekly supervision from Danish specialists in CBT and further supervision from the Swedish research team, who developed and tested the original programs.

Figure 2. Screenshot of the start page for the Danish treatment programs (all text is translated from Danish to English).



Measures

Measures in the Single Case Design Study (Substudy 1)

Children and adolescents will answer a daily short questionnaire (DSQ) throughout a pretreatment baseline period, randomized to last between 5 and 15 days, throughout the 10 weeks of treatment, and for a final 7-day follow-up period 3 months after treatment. The DSQ is an 8-item questionnaire, designed in line with the SCRIBE (Single-Case Reporting guideline In BEhavioural interventions) guidelines [32], addressing specific targets of the intervention, with items from different validated questionnaires for children and adolescents [32,33]. The full DSQ questionnaire is shown in Textbox 1. The primary outcome in the SCED study is the level of gastrointestinal symptoms assessed using 2 items from the Pediatric Quality of Life Inventory (PedsQL) Gastrointestinal Symptoms Questionnaire [34]. Secondary outcomes include illness worries, avoidance behavior, and level of pain acceptance as measured by the Visceral Sensitivity Index (VSI), irritable bowel syndrome behavioral response questionnaire (IBS-BRQ), and the Chronic Pain Acceptance Questionnaire – Adolescent Short Form (CPAQ-A8), respectively [35-37]. The items have been modified into questions concerning the last 24 hours and are rated on a 0-10 scale (“not at all” 0, “all the time” 10).

Textbox 1. Daily short questionnaire (DSQ).

During the last 24 hours, on a scale from 0 (not at all) to 10 (all the time)

1) Did your stomach hurt?

2) Did you feel discomfort in your stomach?

3) Did you worry about the problems in your belly?

4) Were you frightened when you felt discomfort in your belly?

5) Did you avoid going out in case you had belly problems?

6) Did you spent more time on the toilet than you ideally would like?

7) Did you do things that are important and things that are fun even though you have problems in your belly?

8) Has the most important thing been to keep your symptoms under control whenever you did something?

Measures on Cognitive Bias and Interoception (Substudy 2)

Cognitive biases will be assessed before and after treatment using a newly developed experimental design with a computerized web-based task: biases in youth toward gastrointestinal-related stimuli (BY-GIS) [38]. The BY-GIS task consists of a combination of a word task, which is a modified version of the Health Norms Sorting Task [39-41] and a picture task inspired by Gehrt et al [42]. The BY-GIS task is adapted to be appropriate for children and adolescents, featuring gastrointestinal-related stimuli (ie, words related to abdominal symptoms and pictures of food, leisure, and school situations). The BY-GIS task has 3 phases—encoding, free recall, and recognition. In the encoding phase, participants are asked to rate words and pictures presented to them. In the free recall phase, participants are instructed to recall as many words and pictures from the encoding phase as possible, and in the recognition phase, they are presented with words and pictures from the encoding phase along with new words and mirror images of the original pictures. They are then asked to mark which items have been presented to them before. The

development, test, and full procedure of the BY-GIS task are described by Bjerre-Nielsen et al [38].

Interoception will be investigated before and after treatment using a psychophysical measure of cardiac interoception, that is, the heart rate discrimination (HRD) task, developed by Legrand et al [43]. During the HRD task, participants have their heart rate monitored using a pulse oximeter while they are presented with auditory and visual stimuli from a computer and answer questions about their sensations of heart rate and subjective confidence in their answers. Thereby, the interoceptive performance (psychometric threshold, slope, and reaction time) and the metacognitive performance (confidence) can be measured. In collaboration with researchers from the Center of Functionally Integrative Neuroscience at Aarhus University, the task was adapted for a younger age group and pretested in 3 children and adolescents. Adaptations consisted of shortening the test by reducing the number of repetitions of trials, as well as replacing written instructions about the conduction of the test with direct oral guidance from a research assistant.

For both studies in substudy 2, we will perform parallel studies on healthy controls. The BY-GIS task was already tested in 96 healthy controls [38], and the interoception test setup will be performed in 60 healthy controls (all aged 8-17 years).

Measures of Parental Factors and Child Treatment Effects (Substudy 3)

To assess how parental distress, illness worry, and behavior impact the child's overall treatment effects in various domains and treatment adherence, all participating parents and children or adolescents in the ICBT programs will answer extensive questionnaires before assessment (T1: baseline), halfway through treatment (T2: mid-treatment), at end of treatment (T3: end of treatment), and 3 months after the end of treatment (T4: follow-up; Figure 1). Furthermore, the number of completed treatment modules will be obtained from the treatment web page after the end of treatment. The specific measures to be used are shown in Table 2 and described subsequently.

Table 2. Overview of questionnaires in substudy 3.

Outcome	Instrument	Time points and respondents[a]			
		T1	T2	T3	T4
Parental factors					
Parental distress	SCL-8[b] [44,45]	P	P	P	P

Parental Factors

Parental distress will be assessed by the Symptom Checklist-8, an 8-item subscale from the Symptom Checklist Revised-90, screening for emotional symptoms. Items are rated on a 5-point scale from 0 “not at all” to 4 “a whole lot,” with a total range from 0 to 32. Higher scores indicate more emotional distress [44,45].

Parental illness worries will be assessed by the Health Anxiety by Proxy Scale (HAPYS), a newly developed questionnaire assessing parents’ worries about their child’s health [46]. The questionnaire covers 26 items about health anxiety by proxy, rated on a 5-point scale (from 0 “not at all” or “never” to 4 “a whole lot” or “most of the time”), with a sum score range from 0 to 104. In addition, there are 6 items about the impact of the worries rated on a 4-point scale (from 0 “no” to 3 “yes, severely”), with a sum score range from 0 to 18. Higher scores indicate a high level of health anxiety by proxy and the impact of the anxiety, respectively. HAPYS is a valid measure of health anxiety by proxy with good psychometric properties, including high internal reliability and known-groups validity [47].

Parental illness behavior will be measured by the Adult Responses to Children’s Symptoms, which is originally a 29-item questionnaire [48]. In this study, 2 subscales (monitor and protect subscales) comprising 15 items will be used. Items are rated on a 5-point scale from 0 “never” to 4 “always” with a score range from 0 to 60. Higher scores indicate a higher degree of monitoring and protective responses [49,50].

Child or Adolescent Treatment Effects—Main Measures

Gastrointestinal symptoms will be assessed by PedsQL gastrointestinal symptoms [34]. This is a 9-item questionnaire assessing gastrointestinal symptoms related to functional or organic gastrointestinal diseases, during the past month, on a 5-point scale from 0 “never” to 4 “almost always.” Scores are reversed and transformed into a 0-100 scale, with high scores indicating greater quality of life. Pain intensity will be assessed by the Faces Pain Rating Scale – revised (FPS-R) [51]. The FPS-R score includes 6 pictures of faces, each showing an increasing amount of pain and scored on a 2-step scale between “no pain” (0) and “worst pain” (10). The scale is validated in children and adolescents and found to be sensitive to change [52].

Child or Adolescent Treatment Effects—Additional Measures

Quality of life will be measured by the 23-item PedsQL [53], which is a widely used questionnaire to assess quality of life during the past month in children and adolescents. Items are scored on a 5-point scale from 0 “never” to 4 “almost always.” Scores are reversed and transformed into sum scores between 0 and 100, with high scores indicating higher quality of life.

Overall symptom load will be assessed by the Children’s Somatic Symptom Inventory. It measures somatic symptoms during the last 2 weeks using 24 items, rated on a 5-point scale from 0 “not at all” to 4 “a whole lot,” with a range in scores from 0 to 96. High scores indicate a high symptom load. The questionnaire is found to be reliable and psychometrically sound for children and adolescents with abdominal pain disorders [54].

Depressive symptoms will be measured using the Mood and Feelings Questionnaire Short. It comprises 13 items rated on a 3-point scale from 0 “not true” to 2 “true,” with a range from 0 to 26, where higher scores indicate more depressive symptoms. The questionnaire is found reliable for evaluating depressive symptoms in both clinical and community populations of children and adolescents [55,56].

Anxiety levels will be assessed with 2 different questionnaires—the Spence Children Anxiety Scale Short (SCAS-S) [57,58] for general anxiety, and the Visceral Sensitivity Index-Children (VSI-C) [35,59] for gastrointestinal-specific anxiety. SCAS-S contains 19 items which are answered on a 4-point scale from 0 “never” to 3 “always,” with a total range from 0 to 57, where higher scores indicate higher anxiety levels. The questionnaire is designed for use in children and adolescents, and the short version is validated for screening of anxiety levels in children and adolescents [58]. The VSI-C is a shortened child-adapted version of the VSI for adults [35], with 7 items answered on a 6-point scale from 0 “strongly disagree” to 5 “strongly agree,” with a range from 0 to 42, where higher scores indicate more GI-anxiety. It has been found reliable and valid in children and adolescents with FAPDs [60].

Avoidance and control behavior will be assessed by the IBS-BRQ–Child-adapted short version with 11 items, which is an adapted version of the IBS-BRQ for adults [36]. Items are rated on a 7-point scale from 0 “never” to 6 “always,” with scores ranging from 0 to 66, where higher scores indicate more avoidance. It has been validated for children and adolescents with FAPDs [60].

Illness perception will be assessed by the Brief Illness Perception Questionnaire [61,62], which is a 9-item questionnaire where 8 items are answered on an 11-point scale, and 1 item is an open-ended question. The total score range is 0-80, with higher scores indicating more severe illness perception.

Illness worries will be assessed by the Childhood Illness Attitude Scale with 11 items from the fear factor [63]. The questionnaire is developed and validated for children and adolescents. Items are answered on a 3-point scale from 0 “never” to 2 “most of the time,” with a total score range from 0 to 22, and higher scores indicate more illness worries.

Pain acceptance will be assessed by 2 items from the CPAQ-A8 [37]. One regarding pain willingness and one regarding activity engagement. They are both answered on a 5-point scale from 0 “never true” to 4 “always true,” the item on pain willingness is reversed scored, and higher scores then indicate higher pain acceptance.

Other Measures

Parents will provide information about school absence (hours last month) for children (aged 8-12 years) and about their work absence (days past month). Adolescents will provide information about their own school absence (hours last month).

Adverse events will be assessed by adolescents and parents of children using a binary (yes or no) question and an open-ended question to describe the potential event in detail.

Treatment satisfaction will be assessed by the Modified Experience of Service Questionnaire [64], which is a 13-item questionnaire with 10 items scored from "not true" to "certainly true" and 3 free-text items. The total score range is 0-20 with higher scores indicating a better experience with the treatment.

Sample Sizes

According to research design standards [65], a minimum of 3 replications are recommended in a SCED study (substudy 1). However, to achieve sufficient power for randomization tests, a higher number of potential randomizations is recommended [66]. The number of randomizations is influenced by both the number of participants and the number of possible starting points; hence, guided by Levin et al [67], we chose 6 participants in each group.

For substudy 2, we based our power analysis on potential differences in cognitive bias and interoception between cases and healthy controls on a previous similar study on cognitive bias in children and adolescents [40] and studies on interoceptive accuracy in adults with functional disorders [68-69]. Based on these study findings, calculations show that in order to detect a minimum effect size of 0.5 (Cohen *d*), 60 patients and 100 healthy controls are required for the cognitive bias outcome, and a minimum of 51 patients and 51 healthy controls for the interoception outcome to achieve 80% power at an α level of .05. The subsequent analysis of the possible impact of treatment on these 2 factors is more explorative and therefore no a priori power calculation is provided. The same concerns the last study on parental factors (substudy 3) as possible effect moderators. However, here the sample size is the largest possible, comprised of parents from substudies 1 and 2.

Data Collection and Management

The DSQ, the BY-GIS task, and questionnaires are set up in REDCap (Research Electronic data capture; Vanderbilt University) [70], hosted by Aarhus University, and distributed through SMS text message or email. REDCap is a secure, web-based software platform designed to facilitate data capture for research studies.

For the DSQ (substudy 1), a text message reminder will automatically be sent through REDCap 2 hours after the initial SMS text message. If the DSQ is not completed 2 days in a row, a research assistant will contact the family by phone. For the BY-GIS task (substudy 2) and the extensive questionnaire (substudy 3), REDCap will generate automatic email reminders 24, 48, and 72 hours after the initial email if they are not completed. If there is no response after 7 days, a research assistant will contact the family by phone.

The interoception task in substudy 2 will take place at the Center of Functionally Integrative Neuroscience at Aarhus University Hospital in a behavioral testing room, and data will be stored in REDCap.

Data Analyses

In substudy 1, visual inspection analyses will be applied to demonstrate the effect of the intervention on all outcomes [71]. In addition, within-case effect size measurements will be calculated using Tau-U [72] and between-case effect sizes will be determined using hierarchical linear regression models to account for the serial dependency of data [73]. A randomization test will be applied to test differences in means for the baseline versus treatment, and baseline versus follow-up periods, respectively [74].

In substudy 2, participants' descriptions reported in the recall phase of the BY-GIS task will be coded to their corresponding word or picture and category presented in the encoding phase (eg, picture-description "children and cake" coded as the birthday picture within the fun category). Coding for the first 20% of participants will be conducted by 2 independent raters (ESN and EB-N). If the consensus rating exceeds 90%, 1 rater will code the remaining cases independently. A third and experienced rater (TBG) may be consulted to resolve potential disagreements. Baseline data will be analyzed descriptively and compared with (1) data from a healthy control group who performed the same experimental test [38], and (2) end-of-treatment data, exploring potential differences in the outcomes from the encoding, recall, and recognition phases using *t* tests or nonparametric tests, depending on data variability in the samples.

Baseline measures of interoceptive performance and metacognitive measures will be analyzed descriptively and compared with (1) measures from a healthy control group and (2) end-of-treatment measures, using *t* tests or nonparametric tests, depending on data variability in the samples.

In substudy 3, the potential moderation of parental factors on treatment adherence (number of completed modules) and main measure (gastrointestinal symptoms) for children or adolescents will be investigated using negative binomial regression and linear mixed models, respectively, adjusting for baseline parental distress, illness worries, and illness behavior, respectively.

In addition, the potential effect of treatment on these parental factors and all other child or adolescent measures will be analyzed using linear mixed regression models.

An experienced statistician will provide statistical support for all analyses.

Ethical Considerations

The study will be conducted according to the guidelines of the Declaration of Helsinki. The study was approved by The Central Denmark Region Committees on Health Research Ethics (record 1-10-72-277-21, 1-10-72-80-22, and 1-10-72-142-22).

Written informed consent will be obtained from parents and adolescents (≥15 years) whereas children and adolescents (<15 years) will only give oral consent.

Children and adolescents will be compensated with a gift card (value 150 DKK [US $21.13]) for the first time participating in the interoception study. No other compensation will be provided.

Results

Recruitment of participants began in June 2022. Substudy 1 is finalized and expected to be published in 2025. Recruitment for substudies 2 and 3 is ongoing. By November 2024, 45 children and 24 adolescents have been included. Due to a skewed distribution in referrals, with a predominance of referrals on children, we continue to include children and adolescents until we have reached 30 adolescents. Inclusion is expected to be completed by January 2025 and data collection in March 2025.

Discussion

Principal Findings

With this study, we aim to explore previously sparsely investigated areas of ICBT for children and adolescents with FAPDs related to both child or adolescent and parental factors. This includes examining the detailed trajectory of effect, the presence of and potential changes in cognitive biases, and interoceptive inaccuracy after treatment, as well as investigating the potential role of parental distress, illness worries, and behavior as effect moderators.

Previous studies have demonstrated the effectiveness of Swedish ICBT programs in reducing abdominal symptoms and improving the quality of life in children and adolescents with FAPDs. Mediation analyses have shown that positive changes in symptom-specific avoidance behavior and fear mediate the treatment effects [17,18,27,29]. However, the detailed trajectory of treatment effects—specifically when and how possible changes occur during treatment for individual patients—remains unknown, and this will be investigated in substudy 1. This research could provide new insights into the mechanisms of change underlying treatment effects and could be clinically valuable for both therapists and patients.

To the best of our knowledge, this study is one of the first to assess cognitive biases and the ability to sense and interpret signals from the body (ie, interoception) in this patient group in comparison with healthy controls as well as to explore potential changes in these factors after treatment with CBT. Both factors are suggested to play a vital role in the predictive processing model, explaining the pathophysiology of FAPDs [11]. However, so far, they have mainly been studied in adults with various functional disorders [40,68-69,75-78]. By uncovering more knowledge about these factors, the results can potentially be used to further refine already established treatments. For example, this could involve adding biofeedback to train interoceptive accuracy or enhancing exposure exercises addressing specific cognitive biases that lead to fearful responses to gastro-related sensations and avoidance behavior.

Parental worries and anxious behaviors toward the child or adolescent's symptoms can impact the overall well-being of the child or adolescent. These factors are suggested to be part of the complex pathophysiology of FAPDs [9,20,21,48] and are therefore important to investigate further. Parental emotional distress has been found to negatively moderate the effect of ICBT for adolescents with chronic pain [79,80], whereby high levels of parental emotional distress lead to less improvement in disability for the adolescent. However, it is currently unknown how the level of parental distress impacts the effects of the ICBT programs for young patients with FAPDs [29,81]. A specific type of parental emotional distress is health anxiety by proxy, which is a recently described clinical phenomenon characterized by parents' excessive and distressing worries and rumination about their child's health, often involving fears of serious diseases being overlooked by medical professionals [82,83]. This fear may lead to frequent medical visits and investigations of the child [84]. In this study, we will use the newly developed HAPYS questionnaire [46,47] to assess parental health anxiety by proxy. To our knowledge, this is the first systematic examination of this specific type of parental emotional distress in parents of children and adolescents with FAPDs. Such type of parental anxiety may especially lead to symptom-related protective and monitoring behaviors, which are suggested to play a crucial role in the development, maintenance, and even aggravation of the child's FAPD and related health care visits [48-50]. The Swedish ICBT has been shown to effectively reduce such maladaptive parental behavior in both children and adolescents [28,29]. Still, the impact of parental emotional distress, particularly illness worries and related behavioral responses, on the effect of ICBT in children is less well-investigated [85] and no studies have yet been conducted specifically in relation to adolescents. This is why, in this study, we will explore parental distress, illness worries, and behaviors before and after ICBT and examine how these factors impact treatment adherence and treatment effects in both children and adolescents. By uncovering more knowledge about these parental factors, we aim to gain a better understanding of family dynamics and identify potentially important parental characteristics to focus on during treatment, thereby further improving its effectiveness.

The study has some limitations. In substudy 1, the generalizability of SCED study results has traditionally been questioned due to the low number of participants. However, our study adheres to guidelines that include multiple data points across different phases, randomization of the length of the baseline phase, and replication across several participants, thereby optimizing generalizability. Furthermore, participants are expected to answer daily questions for an extended period, which could induce some fatigue in responding and potentially affect reliability. Still, the inclusion of several close data points increases precision in analyses and helps buffer against occasional data loss. In addition, the setup was tested on 4 prestudy patients, who reported that the daily questionnaire was easy and quick to answer.

In substudy 2, we use the BY-GIS task, which is newly developed and has not been previously tested in patients. However, the task is developed based on well-known paradigms and previous tests, and it has already been tested in a sample of 96 healthy age-matched controls with good usability [38]. The interoception HRD measures participants' ability to sense their pulse, which is not directly related to gut sensations but falls within the broader perspective of interoception. However, studies in adults suggest altered interoceptive accuracy across different diagnoses of functional disorders and chronic pain,

which indicates that there may be a general hypersensitivity to inner sensations in this patient group as well [86]. Since this study is one of the first to investigate interoceptive accuracy in children and adolescents with FAPDs, we believe it is still valuable to use this well-known and widely used interoception measure.

Substudy 3 is an open pilot trial without a control group for comparison which means conclusions regarding the clinical effect of the treatment should be interpreted with caution. However, the substudy is explorative and primarily aims to investigate new and additional modifiable treatment targets on a parental level.

Conclusion

In conclusion, this study is expected to provide new and important information about the process of the effect of ICBT, increase our understanding of modifiable treatment targets within the framework of predictive processing in children and adolescents with FAPDs, and shed light on parental factors that are important for the child's treatment adherence and effect. Overall, this research can guide the further development of even more effective psychological treatments for one of the most prevalent chronic pain disorders in children and adolescents.

Acknowledgments

We are thankful to Professor Micah Allen for the development and support on the interoception test method and use of laboratory facilities, statistician Anders Helles Carlsen for statistical support, pediatric departments, and private pediatric practitioners for referral of patients for our study, and Helle Veller Mortensen for language editing.

Abstract

Background: Adverse medicine events (AMEs) are unintended effects that occur following administration of medicines. Up to 70% of AMEs are not reported to, and hence remain undetected by, health care professionals and only 6% of AMEs are reported to regulators. Increased reporting by consumers, health care professionals, and pharmaceutical companies to medicine regulatory authorities is needed to increase the safety of medicines.

Objective: We describe a project that aims to co-design a digital reporting platform to improve detection and management of AMEs by consumers and health care professionals and improve reporting to regulators.

Methods: The project will be conducted in 3 phases and uses a co-design methodology that prioritizes equity in designing with stakeholders. Our project is guided by the Consolidated Framework for Implementation Research. In phase 1, we will engage with 3 stakeholder groups—consumers, health care professionals, and regulators—to define digital platform development standards. We will conduct a series of individual interviews, focus group discussions, and co-design workshops with the stakeholder groups. In phase 2, we will work with a software developer and user interaction design experts to prototype, test, and develop the digital reporting platform based on findings from phase 1. In phase 3, we will implement and trial the digital reporting platform in South

Australia through general practices and pharmacies. Consumers who have recently started using medicines new to them will be recruited to use the digital reporting platform to report any apparent, suspected, or possible AMEs since starting the new medicine. Process and outcome evaluations will be conducted to assess the implementation process and to determine whether the new platform has increased AME detection and reporting.

Results: This project, initiated in 2023, will run until 2026. Phase 1 will result in persona profiles and user journey maps that define the standards for the user-friendly platform and interactive data visualization tool or dashboard that will be developed and further improved in phase 2. Finally, phase 3 will provide insights of the implemented platform regarding its impact on AME detection, management, and reporting. Findings will be published progressively as we complete the different phases of the project.

Conclusions: This project adopts a co-design methodology to develop a new digital reporting platform for AME detection and reporting, considering the perspectives and lived experience of stakeholders and addressing their requirements throughout the entire process. The overarching goal of the project is to leverage the potential of both consumers and technology to address the existing challenges of underdetection and underreporting of AMEs to health care professionals and regulators. The project potentially will improve individual patient safety and generate new data for regulatory purposes related to medicine safety and effectiveness.

Introduction

Adverse medicine events (AMEs), also known as adverse drug events, are unintended effects that occur following administration of a medicine and include adverse reactions and harm from medication errors [1]. AMEs are common and result in patient harm. In Australia, an estimated 1.2 million people reportedly experienced an AME within a 6-month period [2]. While AMEs can occur in anyone, people with chronic conditions and older people are particularly vulnerable to and are most affected by AMEs. For example, 1 in 5 hospital admissions of older adults in Australia is due to AME [2-4]. According to a 2022 estimate, medicine-related hospital admissions, including instances of noncompliance, overdose, and AME, incur an estimated annual cost of Aus $1.4 billion (US $870 million) in Australia, with AME being the most prevalent contributing factor [2,5]. Early detection and management of AMEs are crucial to preventing avoidable harms such as medicine-related falls, hospitalizations, and deaths. However, findings from surveys and reviews of consumer medical records conducted internationally suggest that many consumers do not disclose their AMEs unless prompted to do so. Consequently, up to 70% of AMEs are undetected by health care professionals [6,7], emphasizing the need for proactive interventions to identify and resolve AMEs.

AMEs are also underreported to medicine regulatory authorities (“regulators”), making it difficult to understand how medicines affect consumers. Spontaneous reporting of AMEs is the most common mechanism of safety surveillance worldwide after a medicine has been introduced to the market [8]. Spontaneous reporting of AMEs by consumers, health care professionals, and pharmaceutical companies is vital for regulators to identify potential medicine safety signals [9] and—when relevant—mandate necessary changes, such as updating product labels or withdrawing medicines from the market. A major challenge, however, is the very low AME reporting rate; as evidenced by a systematic review of 37 studies from 12 countries, only an estimated 6% of AMEs experienced by patients were reported [10].

Consumers often detect AMEs before their health care professionals notice them [11], and, where patient engagement is implemented, consumer self-report of AMEs alerts regulators to new and previously unknown reactions prior to health professional reports [12,13]. In Australia, however, the number of reports to regulators from consumers is disproportionately low compared with those made by health care professionals and pharmaceutical manufacturers [14], partly because of consumers’ limited awareness of the reporting system and perceived absence of benefits of reporting [15]. The AME reporting system, developed by the medicine regulatory body, the therapeutic goods administration (TGA) [14], has seen limited consumer uptake in Australia. Furthermore, there is currently no Australian-specific AME reporting platform co-designed with consumers. To address this gap, we developed a prototype system in a small pilot project comprising both Android and iOS apps and a public-facing website for consumers to report any AMEs they experienced [16]. The system was shown to be user-friendly. However, the development involved limited stakeholder engagement and participation (3 consumers) due to the inherent nature of a small pilot project.

Building on this pilot project, the current project aims to co-design with stakeholders (consumers, health care professionals, and regulators) a digital reporting platform to improve AME detection, management, and reporting. The ultimate goal of this project is to empower consumers to actively detect, manage, and report AMEs, fostering a collaborative approach with their health care professionals, and at the same time improve AME reporting to the TGA.

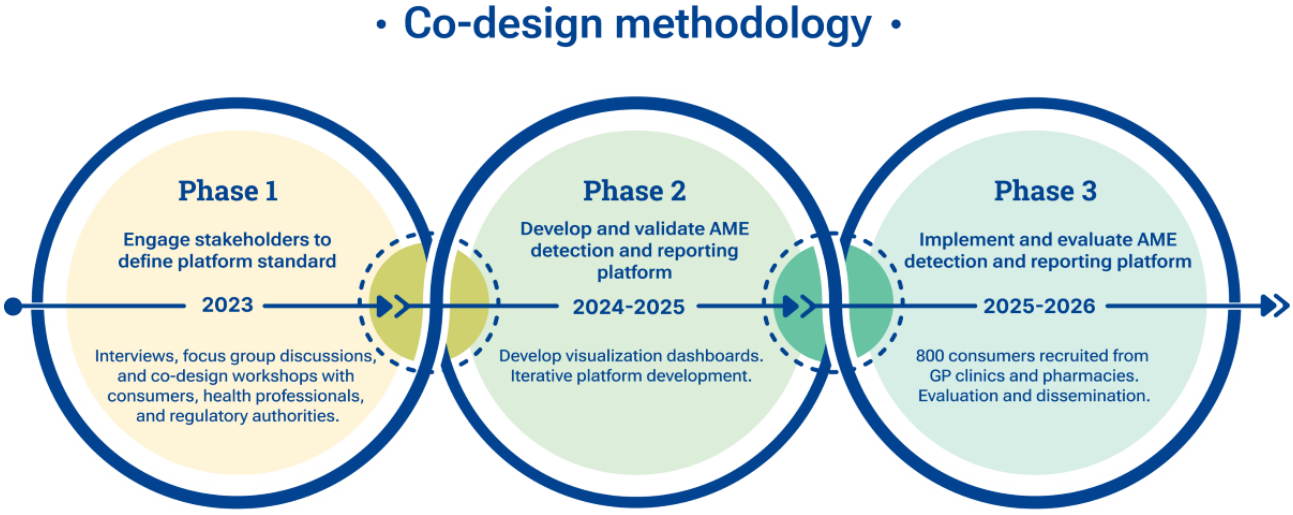
Methods

Study Design

The project is being conducted in 3 phases (Figure 1) from 2023 to 2026 and uses a co-design methodology that prioritizes designing equitably with all stakeholders [17]. Co-design methodology focuses on generating and reflecting on data related to people's lived experiences and engaging participants in action to enhance the quality of their lives. Co-design facilitates collaboration among stakeholders to address challenges within sociotechnical systems and daily services [18,19]. It uses design-based strategies to collect qualitative data around users' experience and the interests of the stakeholders providing services to those users to foster dialogue for mutual insights. Using a range of research methods including stakeholder workshops, focus group discussions, and interviews, co-design aims to describe, categorize, question, and evaluate the needs, experiences, opinions, interests, decisions, and behaviors of stakeholders, ensuring equity through structured reflection. This project builds on the findings of our pilot project [16], using the pilot's prototype as the foundation for developing the co-design activities.

This project builds on the findings of our pilot project [16], engaging stakeholders in phase 1 and advancing to the development and validation of the platform in phase 2. The pilot's prototype serves as a foundation for developing the co-design activities. Our project is guided by the Consolidated Framework for Implementation Research, which considers 5 domains for effective intervention development and implementation: innovation, outer setting, inner setting, individuals, and implementation process [20]. The innovation domain includes the construct's trialability and evidence base, which we addressed in our pilot work [16] and systematic review [21]. We will consider constructs in each domain that influence use of our platform by consumers including innovation, complexity and usability, consumer needs and preferences, feedback, design, and engagement [20,22-24].

Figure 1. Key activities in each phase of the project. AME: adverse medicine event; GP: general practitioner.



Phase 1: Engage With Stakeholders to Define Platform Development Standards

Phase 1 involves interviews, focus groups discussions, and co-design workshops with 3 specific stakeholder groups: consumers, health care professionals, and regulators (Table 1). Consumers eligible for inclusion must be 18 years of age or older, take regular medications or have previously experienced an adverse event from any medication, and own a smartphone or tablet. Health care professionals must be practicing as medical doctors, pharmacists, or nurses in Australia, and regulators will be eligible if they are involved in the postmarketing assessment of safety information for human medicinal products within Australia. Individuals will be excluded if they cannot speak, read, or write in English, or do not provide informed consent.

We will use purposeful sampling to recruit consumers with broad demographic variation to ensure that they represent consumers across different ages and social groups, levels of education and experience, and who have a range of health conditions and use a range of medications to ensure that our platform meets the needs of diverse groups of people. In addition, health care professionals and personnel who work for the medicine regulators will be recruited. All participants will be asked to participate in all 3 activities: semistructured interviews, focus group discussions, and co-design workshops. Attrition is natural in longitudinal projects such as this, and we will mitigate this by recruiting additional participants.

The interviews, focus group discussions, and co-design workshops will be conducted face-to-face where possible and audio- or video-recorded where participants agree. If participants are located interstate from the researchers or prefer to engage remotely for convenience, interviews, focus group discussions, and co-design workshops will be conducted on the web. When preferences differ, separate face-to-face and web-based workshops will be organized to accommodate participants' preferred formats. All recordings will be transcribed verbatim, manually coded inductively, and analyzed thematically in ATLAS.ti software (ATLAS.ti Scientific Software Development GmbH) [25]. Using the Capability, Opportunity, Motivation, Behavior (COM-B) model [26], a well-established model for analyzing and modifying behaviors, the themes identified will inform the recognition of barriers and facilitators to adopting a

digital platform for reporting AMEs. The themes will also be used to highlight key design features essential to meeting the needs and preferences of each of the stakeholder group. Based on these analyses, persona profiles (which will be used to summarize the identified needs, priorities, motivations, goals, and challenges of each user archetype) and user journey maps [27] (which will be used to visualize and document participants' discussions of the likely experience personas might have during the process of reporting or reviewing AMEs as they move through the system) will be developed which will be used to guide subsequent phases of the project.

Table 1. Description of the different activities in phase 1 of the project.

Activity	Number	Aim	Duration	Outcome
Individual semistructured interviews	Ten to fifteen consumers; 10 health care professionals and regulators.	• To understand their experience with, or perspectives toward medicine use and the current AME[a]-reporting process in Australia. • To enable participants to offer their ideas and insights in confidence without the possible influence of bias from other participants.	Approximately 60 minutes per interview.	Findings will be used to develop personas that will then be discussed in focus group discussions to determine their accuracy and thoroughness as exemplar of user groups.
Focus groups discussions	Two focus-group discussions with each of the 3 stakeholder groups.	• To consider and define the respective needs, priorities, and motivations the personas—developed based on the findings from the interviews—might have for reporting an AME and to define the reporting goals for the platform.	Each stakeholder focus group discussion will run for 2 hours.	Outcomes from the discussions will inform the development and delivery of the co-design workshops.
Co-design workshops	Three co-design workshops held for the same stakeholders collectively.	• To employ the co-designed user personas to build a user journey map as a means to evaluate the processes of AME detection, management, and reporting, generate and agree on notional platform content and feature set to guide its subsequent development.	Each co-design workshop will last 3-4 hours and will contain multiple activities, each varying in duration but capped at 60 minutes. Regular breaks will be incorporated between activities to maintain engagement and focus.	The workshops will result in user journey maps which will be used to visualize and document participants' discussions of the likely experience personas might have during the process of reporting or reviewing AMEs as they move through the system.

[a]AME: adverse medicine event.

Phase 2: Develop the Platform and Interactive Data Visualization Tool

The second phase of the project focuses on the development of the platform. First, we will work with a software developer and user interaction designers to develop the underlying relational structure that received data from users might have, how the data function in terms of reporting, and what principle features a front-end user experience might have for gathering them (phase 2a—platform development). At a minimum, the project aims to achieve a fully functioning web-based reporting platform, a mobile app, or both, based on findings from phase 1. It will include a fully refined user interface and database integration and search function to operate with the TGA's Database of Adverse Event Notifications [28]. To ensure equity across stakeholder interests, we will continue to adhere to co-design principles throughout this phase by inviting consumers, health care professionals, and regulators to participate in this process. The platform development will undergo cycles of iteration and review where stakeholders will test, compare, and contribute to decision-making on the content, form, and function of the platform through each iteration. We will perform the iterative cycles with stakeholders until no new issues are identified with the platform. We anticipate that the process will require up to 5 cycles before saturation and a deployable outcome is achieved. Stakeholders recruited in phase 1 will be invited to participate in this process, and additional participants will be invited to compensate for any attrition.

Next, as part of our communication and engagement strategy, we will develop an interactive data visualization tool or dashboard to translate and disseminate the data collected to the public, health care professionals, and regulators (phase 2b—development of interactive data visualization tool). The visualization tool will be implemented with back-end integration in the digital reporting platform and developed collaboratively through 2 co-design workshops with 8 stakeholders. The visualization tool will be configured to allow both consumers and their health care professionals to access the data they provided, obtain information on the medicines they are taking,

and compare their experience with those reported by other consumers taking the same medicines. A separate visualization tool will be developed for use by regulators and will include further levels of configuration necessary for them to examine data relative to their decision-making. All consumer reports will be reviewed by study investigators (clinicians) for causality assessment (ie, likelihood that the medicine caused the observed AME) using the Naranjo probability scale [29]. The causality assessment will be done to determine whether the platform has collected all the information needed for a causality assessment.

Phase 3: Digital Platform Implementation and Evaluation

In the third phase of the project, we will implement the new platform in general practices and pharmacies in South Australia and assess its impact for (1) increasing AME detection, (2) improving AME management, and (3) increasing AME reporting and enhancing existing TGA workflows.

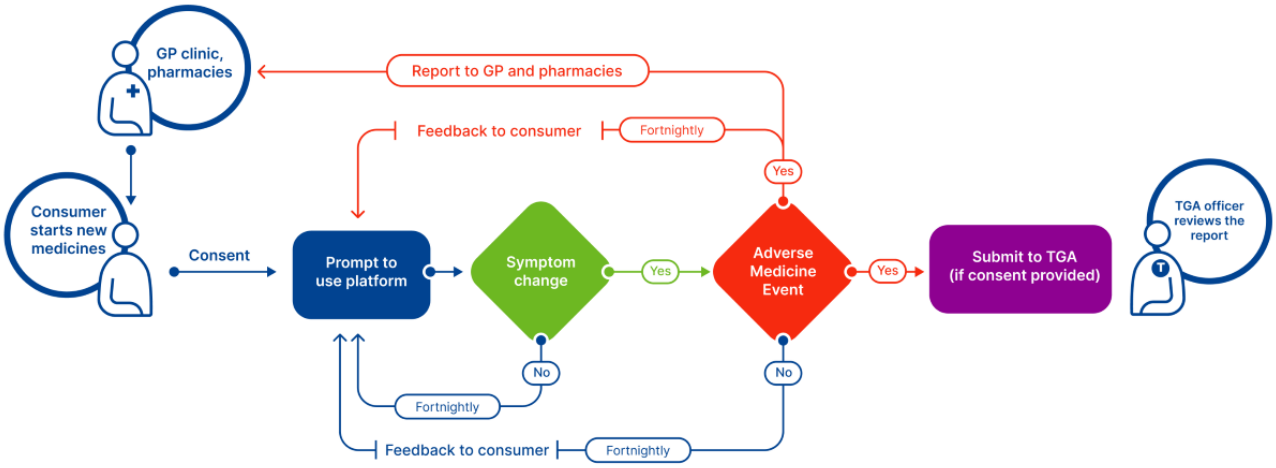
A quasi-experimental study will be conducted to involve consumers who have recently begun taking new medicines. This is because most AMEs tend to occur within 4 weeks of patients commencing new medications [30]. Depending on results from phases 1 and 2, criteria for further inclusion may be specified (eg, consumers initiating medicines with a black triangle warning). Eligible consumers will be identified initially by general practices and pharmacies applying the inclusion or exclusion criteria to their software (eg, Doctors Control Panel software [Doctors Control Panel Software Pty Ltd] [31] and dispensing software used in the pharmacies). Eligible consumers will then be approached by a dedicated research assistant via phone, text message, or email to assess their eligibility, discuss the details of the project, answer any questions, and facilitate the process of obtaining informed consent from interested individuals. We will seek consent to send information reported by consumers to their health care professionals and regulators (ie, the TGA). Consumers will then be prompted to use the platform to report whether they have experienced any suspected or possible AME. Consumers will access the platform either by downloading the mobile app or by visiting the website. Where the consumer has consented, a report will be sent electronically to their general practitioner and pharmacist to enable targeted assessment for managing the AMEs. For those who provided consent, consumer reports will also be submitted to the TGA. Subsequent prompts to use the platform will be sent to the consumers via automated text messages. The frequency of sending the text messages will be determined based on co-design workshops with stakeholder groups. Consumers will be given a summary report of their data and access to the interactive data visualization tool (Figure 2).

Based on interventions to improve AME reporting [32], which report a relative risk of 2.04 (57% in intervention group vs 28% in controls), α value (significance level: rejecting the null hypothesis when it is actually true) of .05, and power of 80%, a total of 80 consumers experiencing and reporting AME is needed. Assuming that 20% of consumers starting medicines experience an AME [33] and half of the consumers will report their AMEs with targeted prompts from the research team [34], we aim to recruit 800 people for phase 3. The sample size was calculated based on Statistical Power Analysis using R [R Foundation for Statistical Computing] [35]. Initial database analysis in one of our participating clinics with 8 full-time equivalent general practitioners indicated that each general practitioner prescribes a medicine that is new to the patient for about 40 people per month (320 per month for the practice), supporting the feasibility of recruitment of 800 participants within 6 months.

To assess whether the platform improved AME detection, interrupted time series analysis will be used to determine the proportion of AME detected before and post platform implementation in the general practices. A random sample of up to 1000 patient records in the participating general practices will be manually reviewed by nurses at the practices to determine the number of AMEs detected up to 3 months prior to platform implementation. Furthermore, we will describe the number of AME reports submitted to the TGA by our study participants post platform implementation.

Finally, we will conduct 2 focus group discussions with the project team and stakeholders to evaluate the implementation process (what works, where, and why) [20], the acceptability of, and satisfaction with the platform. Questions related to the implementation process will be adopted from the Consolidated Framework for Implementation Research interview guide tool [20]. The focus group discussions will be audio-recorded, transcribed, and analyzed using thematic analysis [25].

Figure 2. Flowchart for platform implementation in Australia. GP: general practitioner; TGA: therapeutic goods administration.



Ethical Considerations

Ethics approval for phases 1 and 2 has been received from the University of South Australia human research ethics committee (application ID 204984). Ethics approval will be sought from the same committee prior to starting phase 3. Informed consent will be sought from all participants. All data obtained during the project will be deidentified. Participants in any phase of the project will receive compensation at an hourly rate, provided as either a gift voucher or a direct bank transfer in Australian dollars (Aus $). Compensation rates, approved by the human research ethics committee, are set at Aus $35 (US $21.85) per hour for consumers, Aus $200 (US $124.88) per hour for medical doctors, and Aus $100 (US $62.44) per hour for pharmacists and nurses. Furthermore, participants attending in person will receive a transportation allowance of Aus $30 (US $18.73). No compensation will be provided to regulators, as they are prohibited from accepting it.

Results

This project is initiated in 2023 and will run until 2026. Phase 1 will result in persona profiles and user journey maps that define the standards for the user-friendly web-based communication platform and interactive data visualization tool or dashboard. This platform will be further developed and improved in phase 2. The platform will contain fully refined user interface features, an icon system for nonverbal communication, and integration with TGA's Database of Adverse Event Notifications to support the reporting of AMEs by consumers and health care professionals. The final phase—phase 3—will provide insights of the implemented platform regarding its impact on AME detection, management, and reporting. Altogether, the efforts will result in a platform through which consumers can report AMEs to their general practitioners and pharmacists and TGA. We will publish findings progressively as we complete our analyses. In addition to the traditional research outputs (journal articles and conference papers), the designers on our project team will develop a series of nontraditional research outcomes including the dissemination of visual outcomes in the form of a public exhibition, either on the web or in person. We will organize public displays of the visual works at multiple venues in Australia to increase awareness and discussions about the importance of detecting, managing, and reporting AMEs. We will promote the exhibitions and project findings through our teams' respective institutions' media platforms.

Discussion

Expected Findings and Implications

Medicine safety is complex and requires well-developed systems, strategies, and processes to keep consumers safe. Effective systems and strategies for AME detection, management, and reporting are crucial to ensure that medicines are used safely and effectively. However, AME reporting by consumers remains low [14]. Instead, consumers were generally more likely to report AMEs to doctors or pharmacists [36], potentially stemming from inadequate or lacking systems that enable the proactive detection and management of AMEs. Our project will bring these 2 aspects together to build what we hypothesize to be a single, readily available solution that integrates AME detection and management by consumers in consultation with their general practitioners and pharmacists and which also potentially benefits AME reporting to regulators. As such, our project aims to serve both patient-level clinical needs and population-level regulatory needs on medication safety issues.

The level of end user involvement during the development phase of digital interventions that are implemented in practice is unclear. Despite the development of numerous digital interventions to improve medicine management and safety, the minimal engagement of end users in this process and a failure to meet their needs adequately result in the low adoption of these interventions in practice [37]. For instance, the implementation of GuildCare (GuildLink), an AME surveillance system designed for Australian community pharmacists, was introduced in 2014. While the initial year saw a notable increase in AME reporting rates to the TGA, the subsequent year saw a decline, hinting at challenges in maintaining sustained adoption [38]. Factors influencing the adoption and ongoing use of digital health technologies include cost, simplicity of language, ease of use, design, scientific evidence base, motivation, and perceived value by end users [22-24]. To effectively tackle the challenges related to fulfilling the requirements of stakeholders

and overcoming low adoption rates, our project takes a unique approach by grounding it in a multidisciplinary ideology from its outset. This includes collaborating with experts from various disciplines including medicine safety, co-design, user-experience design, communication design, psychology, engagement, and cybersecurity to address fundamental issues that predict successful implementation of the system in practice. This partnership, grounded in a co-design methodology, also represents one of the first instances where a digital intervention for AMEs is coproduced with consumers, health care professionals, and the regulators. The approach seeks to ensure that the digital intervention directly addresses the needs of the 3 stakeholder groups, thereby increasing the likelihood of adoption in practice and ensuring its long-term sustainability.

AME reporting by consumers has the potential to improve the safety of medicines. In a previous study conducted in Australia, despite acknowledging limited awareness, consumers expressed a positive attitude toward AME reporting [15]. The perceived lack of benefits for the reporting consumer, however, was recognized as a barrier to the reporting process [15]. The significance of our proposed platform lies in its potential to incorporate consumers' voices into their medicine and health care journey, enabling consumers to report AMEs to their health care professionals and to the regulators. If successfully implemented, the proposed platform has the potential to result in an increase in the proportion of consumer AME reports submitted to the TGA, which currently accounts for only 3.4% of the total reports submitted to the TGA [39].

There has been a decline in the percentage of AME reports from doctors in Australia, decreasing from 28% in 2003 to 4% in 2016 [36]. The potential increase in participation by consumers through use of our proposed platform may contribute to increased identification of safety signals. By streamlining the AME reporting process to the TGA, our platform has the potential to contribute to more timely detection and verification of potential medicine safety signals. This initiative addresses a national [40] and global health priority [41] and addresses 2 components of the Australia's National Strategy for Quality Use of Medicines: monitoring outcomes and improving people's ability to solve problems related to medicines, such as negative effects.

The introduction of a visualization tool as part of the platform has the potential to enhance end user interaction and participation in research and may facilitate early and effective communication of safety issues to relevant stakeholders. The development of interactive data visualization tools marks a creative initiative to enhance communication and transparency between consumers and regulators. While visualization tools for conveying important public health issues have become common, especially during the Covid-19 pandemic, they frequently lack transparency in describing the development process, fail to engage end users in design and development, and leave uncertainty about whether they adequately meet the needs of those end users [42]. Our user-centric co-design methodology for this project has the potential to ensure that the visualization tools effectively meet the diverse needs of consumers, health care professionals, and regulators alike.

Limitations

First, the success of our digital reporting platform will ultimately rely on the level of user engagement and participation. Robust stakeholder engagement strategies, including co-design workshops and ongoing collaboration, do not guarantee user uptake and continued use. Factors beyond our control, such as accessibility to devices, individual motivation and preferences, and previous negative experiences with reporting, may influence the level to which consumers actively engage in this new digital platform. The introduction of any new system, service, or technology is frequently considered an additional burden or challenge when implemented in practice. However, our early engagement strategy with stakeholders, from phase 1, is designed to potentially mitigate some of this resistance and to increase the chances of adoption. Second, the reliance on interrupted time series analysis for outcome evaluation introduces potential confounding factors that may not be fully accounted. Third, the small number of consumers recruited in phase 3 means that we will not be able to determine whether the platform had an overall effect on the number of consumer reports to the TGA, or whether the reports from our platform helped generate new or different medicine safety signals. Another potential limitation is that phase 3 will be conducted in South Australia, which may restrict the generalizability of findings to the broader Australian population or internationally. However, this limitation will be mitigated by incorporating insights from participants across multiple states in Australia during phases 1 and 2. Finally, certain processes in our project rely on interim review or support from members of the research team. These workflows and processes will require revision and adaptation when implemented in clinical practice.

Conclusions

This paper describes our co-design project that will actively involve key stakeholders in the development and evaluation of a new digital platform for AME detection, management, and reporting, with a central focus on consumers. The use of a co-design methodology ensures the incorporation of the perspectives and requirements from consumers, health care professionals, and regulators—a crucial element for fostering the adoption and sustainability of the intervention. The project harnesses the potential of both consumers and technology to address the existing challenges in underdetection and reporting of AMEs to health care professionals and regulators. The overarching goal is to enable consumers to actively participate in medication safety-related matters, thus enhancing the quality of their lives, influencing clinical decisions related to their health, and contributing to overall medicine safety.

Abstract

Background: Alzheimer disease and related dementias (ADRDs) are increasingly common progressive conditions that have a substantial impact on individuals and their primary care partners—together described as a *dyad*. The stressors experienced by dyad members at around the time of ADRD diagnosis commonly produce clinically elevated emotional distress (ie, depression and anxiety symptoms), which can become chronic and negatively impact health, relationships, and the overall quality of life. Dyads commonly report unmet needs for early support to address these challenges early after diagnosis.

Objective: This study is part of a larger study that has the primary objective to develop, adapt, and establish the feasibility of Resilient Together for Dementia (RT-ADRD), a novel dyadic skills-based intervention aimed at preventing chronic emotional distress early after diagnosis. The present study protocol describes an open pilot of the RT-ADRD intervention. This study will allow the study team to gather feedback on intervention components, administration of study measures, issues within general protocol, and perceptions about live video interventions prior to a larger feasibility trial.

Methods: All study procedures will be conducted on the web (via phone and health care system–supported videoconferencing) to optimize accessibility, inclusion, and representativeness. Eligible dyads will include couples (up to N=10) referred from Mount Sinai Hospital (MSH) clinics within 3 months of an ADRD diagnosis. Dyads will be referred by their diagnosing clinicians (eg, neurologists, geriatricians, and neuropsychologists) and screened for eligibility. Eligible dyads will have at least one member who exhibits clinically elevated emotional distress and will demonstrate capacity to consent to research participation on a standardized assessment. Consenting dyads will complete baseline assessments of emotional distress, quality of life, relationship

functioning, and resiliency skills. Dyads will then participate in 6 weekly RT-ADRD sessions together (30-60 minutes each). After the conclusion of the intervention, dyad members will complete posttest assessments with similar measures as the pretest. Finally, dyads will participate together in a single 60-minute exit interview to gather information on intervention content and procedures to refine the intervention before a pilot feasibility trial.

Results: This study has been approved by the MSH institutional review board and is registered on ClinicalTrials.gov (NCT06421545). We anticipate that the study will be completed by late 2024.

Conclusions: We will use these results to administer changes and develop procedures for a pilot feasibility trial of RT-ADRD relative to a minimally enhanced control condition. Our study will allow us to gather comprehensive information on proposed RT-ADRD procedures and content and the best ways of delivering prevention-focused interventions to reduce the potential for chronic emotional distress stemming from ADRDs.

Introduction

Background

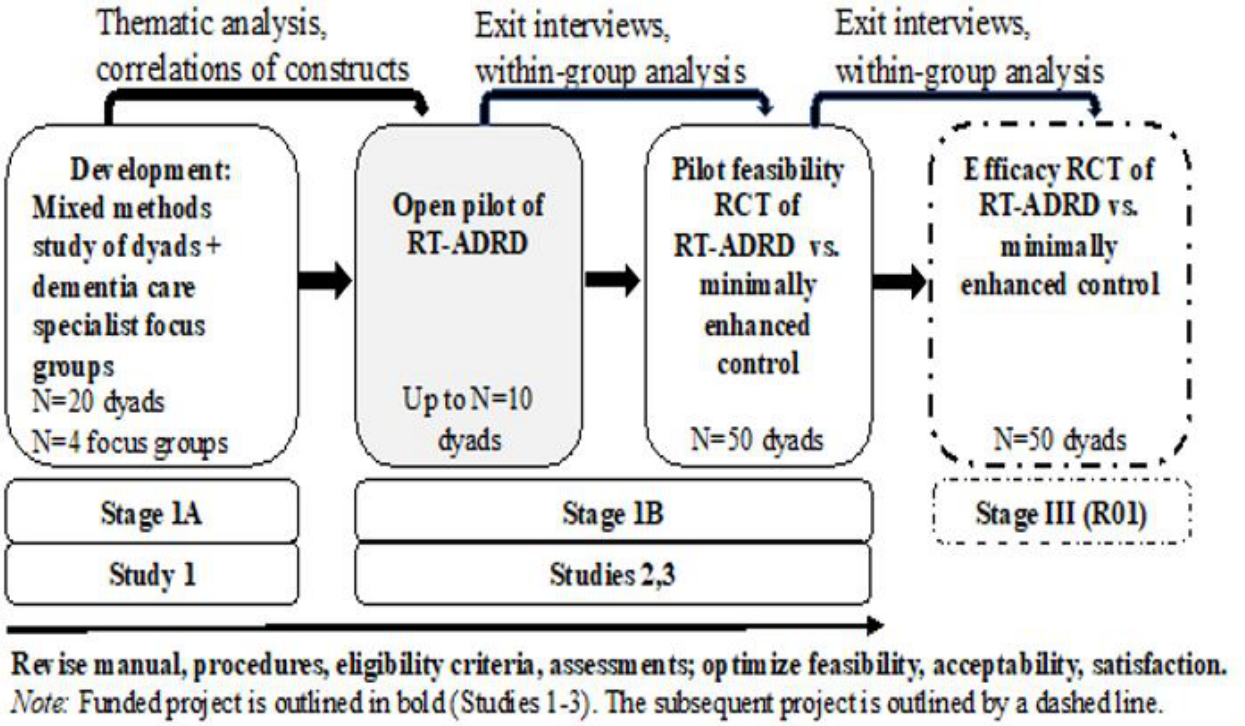
Alzheimer disease and Alzheimer disease-related dementias (ADRDs) are conditions characterized by progressive declines in memory, language, behavior, and personality and produce early symptoms that include increased forgetfulness, communication challenges, and loss of recognition of places, time, and routines [1-3]. These early symptoms tend to worsen over time and undermine the independence, health, and well-being of persons living with ADRDs and their family care partners, many of whom are romantic or spousal partners [4-6]. Because both individuals and their partners (often referred to as "the second patient") experience life disruptions stemming from ADRD symptoms that amplify stress, role changes, and relationship strain [6,7], both individuals and their romantic partners require early support [8]. This need is ever more pressing; by 2030, it is expected that 75 million individuals will be living with ADRD worldwide [5].

In the time following the onset of ADRD symptoms and particularly after receiving a formal diagnosis, many individuals (23%-53%) and their care partners (35%-50%) experience clinically elevated emotional distress (ie, depression and anxiety symptoms) [9-13]. These elevated rates are not surprising given the poor prognosis and lack of disease-modifying interventions for ADRDs, limited resources to assist with early challenges, difficulties engaging in social support, and changes to established roles and responsibilities (eg, caretaking) [14-16]. Early emotional distress is an important intervention target in dyads facing ADRDs for several reasons. First, distress is *interdependent* (ie, correlated and bidirectionally influenced) within dyads. Second, untreated distress is likely to become chronic, and chronic emotional distress is difficult to treat and linked to the deterioration of dyads' physical and mental health, relationship quality, and quality of life [9,14,17,18]. Third, distress interferes with dyads' ability to effectively communicate and cope with early challenges linked to ADRDs, which can impact long-term adjustment [9,14].

Early psychosocial interventions may help individuals with ADRDs and their care partners adjust to challenges and plan collaboratively for the future, which can alleviate distress and maintain overall relationship quality and well-being [8]. Existing interventions for early or moderate-stage ADRDs primarily target family care partners, and several interventions demonstrate lasting improvements in depression symptoms and quality of life [5]. Dyads commonly express strong preferences to participate in interventions together, and dyadic interventions in the first few years of ADRD diagnosis demonstrate promise in reducing dyads' emotional distress as well as neuropsychiatric symptoms expressed by the person living with ADRD [19]. Interventions have historically ignored the "window of opportunity" to meaningfully include persons with ADRDs in interventions shortly after diagnosis, limiting their potential to assist in collaborative treatment and planning before symptoms progress [20-22]. Currently, there are no dyadic psychosocial interventions that prioritize delivery in the first weeks and months after diagnosis to promote dyadic adjustment to ADRDs [20,23-25].

Dyadic interventions may be a more effective, efficient, and economical avenue for promoting positive adjustment to ADRDs for individuals and their care partners earlier in the course of the illness [24,26]. Our team has developed successful dyadic interventions to prevent distress following medical adversity, including Recovering Together, a 6-session dyadic resiliency intervention that addresses emotional distress in patients and informal care partners shortly after neurointensive care unit admission for acute neurological conditions [27,28]. Recovering Together program uses interpersonal theories of adjustment aimed toward preventing chronic stress and transdiagnostic resiliency skills that we expect could also serve as mechanistic treatment targets for other neurological conditions such as ADRDs [29-37]. We then leveraged the NIH (National Institutes of Health) Stage Model for intervention development and in-depth interviews with ADRD clinician experts and dyads (Figure 1) to inform the development of a similar intervention to address early challenges linked to ADRDs [38,39].

Figure 1. Iterative Development of RT-ADRD (Resilient Together for Dementia).



This Study

This study protocol is part of a larger 5-year study that aims to use the prior research, methodology, program content, and procedures of the Recovering Together program as a basis for developing the novel Resilient Together for Dementia (RT-ADRD). Our primary objective is to describe the protocol for the open pilot study of RT-ADRD that will inform a subsequent pilot feasibility trial of the program relative to a control condition (NIH Stage Model Stage 1a). In this study, we aim to gather comprehensive information from dyads regarding the feasibility of assessment, feedback on the intervention components, applicability of study measures, and to identify potential issues prior to the feasibility trial.

Methods

Ethical Considerations

This open pilot study was approved by the Icahn School of Medicine at Mount Sinai Independent Review Board (23-01360) and is registered on ClinicalTrials.gov (NCT06421545). Participants will provide electronic consent to participate via the REDCap (Research Electronic Data Capture; Vanderbilt University) HIPAA (Health Insurance Portability and Accountability Act)-compliant web-based application using a hospital-approved e-consent feature. Prospective participants will be given ample time to review the contents of the consent form as well as speak with the study coordinator who will provide detailed information about the study and answer any questions. The participants will also be reminded that they may decline to participate and can discontinue participation at any time. Participants will be given a copy of the consent form and will be invited to ask questions about their participation at any point over the course of the study. The identity of the participants will not be revealed in the presentation or publication of any results from this project. To protect confidentiality, all data will be deidentified and only identifiable by subject codes. Participants will be individually compensated US $80 for completion of the pre- and posttest assessments, for a total of US $160 per dyad at the end of the program.

Study Design

We will conduct an open pilot of RT-ADRD dyadic intervention involving dyads comprising (1) individuals with a recent ADRD diagnosis and (2) their spousal or romantic care partners, with a target recruitment of up to N=10 dyads, or 20 total participants. This study is designed to gather data that can be used to revise the intervention before a larger pilot feasibility trial.

Inclusion and Exclusion Criteria

Eligible participants will be adult dyads who are partners that currently live together and are willing to participate in the RT-ADRD intervention that are (1) English speaking, (2) patient with newly diagnosed (within 3 months) with an ADRD diagnosis after age 65 years (determined by medical chart review and provider referral), (3) patient with cognitive assessment scores and symptoms consistent with early-stage ADRD, as determined by Clinical Dementia Rating scale scores of 0.5 (very mild) or 1.0 (mild dementia) and Montreal Cognitive Assessment (MoCA) scores of 17-25, obtained via a review of medical records (if patients do not have cognitive assessment scores available, we will administer the MoCA to confirm eligibility), (4) either partner demonstrates clinically elevated emotional distress, as determined by Hospital Anxiety and Depression Scale [40], subscale scores >8 or Geriatric Depression Scale [41], scores > 5, and (5) both partners demonstrate the ability to understand study and research protocol, as determined by the University of California Brief Assessment of Capacity to Consent [42], >12. Individuals will

not be eligible for the study if (1) either partner has a co-occurring terminal illness, and (2) patient was diagnosed with forms of dementia with clinical profiles that would preclude participation (eg, highly symptomatic Frontotemporal Dementia–behavioral variant), as determined by the treatment team.

Study Procedures

Dyads will be recruited from the Mount Sinai Departments of Neurology, Geriatrics and Palliative Medicine, and the hospital system's broader dementia clinical care infrastructure. We will circulate information via flyers, presentations, and word-of-mouth referrals, and dyads can be self-referred or be referred by their treating dementia care providers. The study team will present the aims to all staff at the clinics to explain the purpose of the study, potential benefits to participants, and discuss best ways to facilitate referrals. The study team obtained a waiver of informed consent for the purpose of eligibility screening and will also review electronic medical records of patients treated in relevant clinics to inform providers of potential eligibility prior to diagnostic disclosure visits. All recruitment, screening, and consent procedures will be performed remotely via telephone, electronic survey through REDCap, email, and over a live video using health care system–supported videoconferencing.

Treating providers will obtain permission from the dyad to be contacted by the study team. If self-referred, interested dyads will also have the option to respond to a brief survey via QR code or URL to a secure REDCap platform listed on the distributed study flyers. The study team will contact interested participants via telephone to schedule a telephone or live video call with the study research assistant, who will describe the study to potential participants and conduct screening for eligibility (including capacity to consent). If either dyad member is deemed ineligible based on screening criteria, the study team will provide dyad with a comprehensive list of resources containing local and national resources and document ineligibility in REDCap. If eligible and interested in participating, individuals will complete consent procedures by indicating verbal consent and documenting electronic consent a secure password-protected REDCap platform.

After enrollment, participants will be sent a baseline survey via a secure REDCap link to assess demographics, emotional distress, resiliency factors, and relationship functioning. Participants can also complete assessments via health care system–supported videoconferencing with the help of a trained research assistant. Once the dyad has completed the baseline survey, a member of the research team will schedule the first of 6 RT-ADRD treatment sessions together led by a PhD-level clinical psychologist with expertise in conducting dyadic interventions (SB). In advance of the treatment session, the dyad will be sent copy of the treatment manual to review the skills that will be taught during the 6-week treatment program. Each session will be audio recorded for the purpose of manual refinement. After completing treatment, dyad members will complete a similar set of surveys at posttest. Finally, they will participate in a single 60-minute exit interview together to gather comprehensive feedback on the material to further refine the intervention. Each dyad member will be compensated US $80 for completion of the pre- and posttest assessments, for a total of US $160 per dyad at the end of the program.

RT-ADRD Intervention Content

The RT-ADRD intervention will have 6 weekly live video treatment sessions lasting 30-60 minutes each delivered over health care system–supported videoconferencing; in-person and hybrid session options will be available as well, according to dyad preference. The content and procedures were developed by adapting the Recovering Together dyadic resiliency intervention for neurointensive care unit admitted dyads [27], and then revised using feedback from interviews with dementia care specialists [38], and from dyads interviewed after ADRD diagnosis [39]. Sessions for RT-ADRD contain content and training in resiliency skills that are particularly relevant after ADRD diagnosis for patients and their care partners. RT-ADRD was designed to include individual and interpersonal coping skills that are *transdiagnostic* (ie, relevant across mental and physical health conditions) and drawn from prominent evidence-based therapy approaches (eg, mindfulness, Dialectical Behavior Therapy, and Cognitive Behavioral Therapy). The sessions emphasize ways of using skills to cope with the common challenges experienced early after dementia diagnosis and focus on navigating challenges as a dyadic unit Dyads will also receive links with downloadable recordings of exercises for home practice of skills. The sessions are modular in nature, and dyads will choose 6 modules from a selection of 8 possible modules. The 8 modules are presented in Table 1.

Table 1. Sessions' outlines for the Resilient Together for Dementia (RT-ADRD) program.

Sessions	RT-ADRD topics	Content and skills (all sessions include home-practice of skills)
1	Being in the Here and Now	Deep breathing, mindfulness, and 24-hour block
2	Complex and Conflicting Experiences	Dialectics, mindfulness meditation, and open stress communication
3	Current and Future Challenges	Distress spiral, hands as worries, and acceptance and change
4	Planning and Coping Ahead	Cope ahead, cultivating routines, and coping as a team
5	Difficult Topics	Clarifying goals, effective communication, and relationship repair
6	Relationship Changes	Navigating support and defining roles
7	The Uncertain Future	Goal setting and coping plan
8	Accepting Changes and Making Meaning	Reflection for meaning making

Assessments

After consent, both dyad members will independently complete a pretest survey via a secure REDCap link (~30 minutes each) sent by a research coordinator. If needed, participants will also have the option of completing surveys with the assistance of a trained research coordinator via the videoconferencing "Share Screen" tool. The survey will include validated measures to gather information on hypothesized mechanisms of intervention, intervention targets, and treatment moderators, consistent with the overall conceptual model (Figure 2). The primary intervention targets (Table 2, secondary outcomes) are individuals' emotional distress, relationship quality, and quality of life, which were selected based on their interdependence within dyads and the link of emotional distress to long-term mental and physical health outcomes and relationship functioning [9,14,17,18]. The hypothesized intervention mechanisms (Table 2; described further below) are transdiagnostic resiliency skills that demonstrated links to the same intervention targets in studies of prior dyadic interventions [27]. Following completion of the treatment sessions, dyads will complete a similar posttest survey in REDCap. Responses will be used to compare scores to population norms, examine interrelations among constructs, and inform procedures and the tailoring of RT-ADRD. The primary outcomes for this trial are feasibility and acceptability. In addition, we will use the 6-item Credibility and Expectancy Questionnaire [43] to assess treatment credibility at baseline. We will also use the 3-item Client Satisfaction Questionnaire [44] to assess satisfaction with RT-ADRD at posttest. We will gather comprehensive qualitative feedback on these benchmarks and report detailed information on study screening, enrollment, and intervention deliveries via health care system–supported videoconferencing or in person, to refine feasibility and acceptability benchmarks prior to further testing. A description of study measures is provided below (Table 2).

Figure 2. RT-ADRD Conceptual Model.

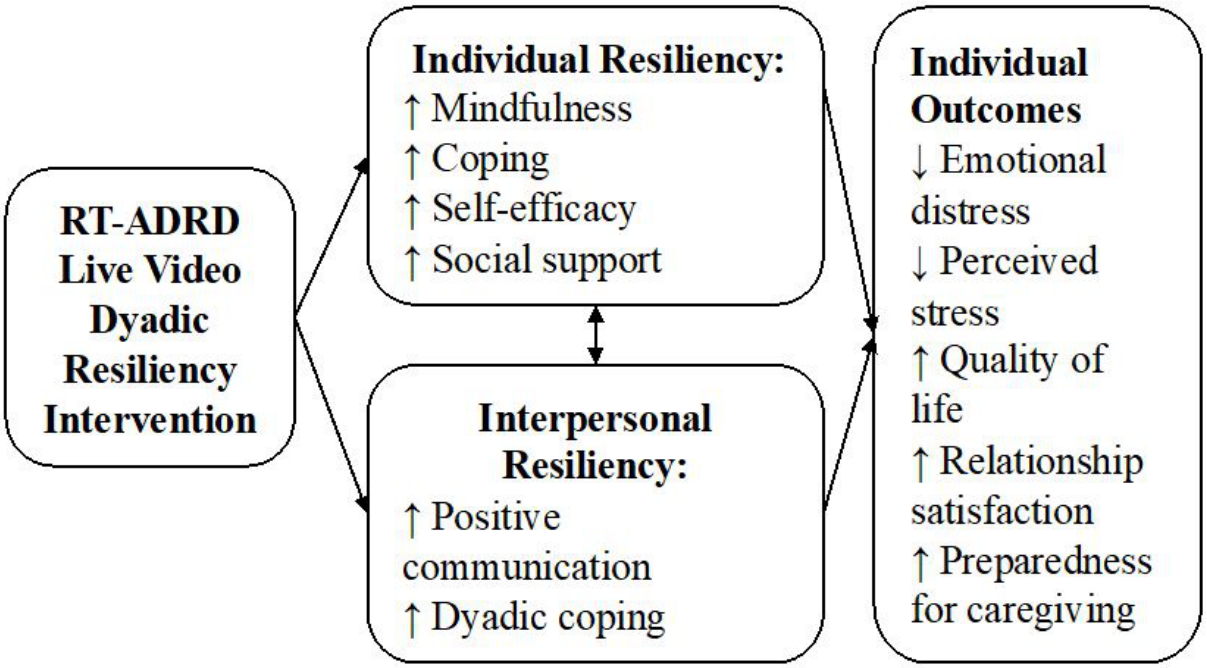


Table 2. Assessment measures.

Construct	Description	Base	Post
Primary outcomes			
Feasibility	• Procedures: suitability and practicality of RT-ADRD[a] and procedures; qualitative feedback from exit interviews	X	X
	• Screening: proportion of dyads who screen eligible of those who undergo screening		X
	• Recruitment and Consent: proportion of dyads who are approached and agree to participate in the intervention		X
	• Engagement: proportion of dyads who are enrolled and complete 4 out of 6 sessions		X
	• Assessment: proportion of individuals who are enrolled and complete baseline and post-test assessments		
Acceptability	• Credibility and Expectancy Questionnaire (6 items)—assess how credible dyads perceive RT-ADRD	*X*	*X*
	• Client Satisfaction Questionnaire (3 items)—a measure of satisfaction with RT-ADRD		*X*
	• Qualitative feedback from exit interviews		
Covariates			
Demographics	• Review of medical records and participant self-report: age, sex and gender, race and ethnicity, education, and income		
Clinical Characteristics	• Review of medical records and participant self-report: type of ADRDb diagnosis, time since diagnosis, and cognitive tests	X	
Secondary Outcomes			
Emotional Distress	• Hospital Depression and Anxiety Scale (14 items)—a measure of emotional distress (anxiety and depression subscales) Geriatric Depression Scale (15 items)—a measure of depression symptoms	X	X
		X	X
Perceived Stress	• Perceived Stress Scale (4 items)—a measure of perceived stress	X	X
Quality of Life	• WHO Quality of Life-Short Form (26 items)—a measure of quality of life	X	X
Relationship Satisfaction	• Couples Satisfaction Inventory (16 items)—a measure of couple relationship satisfaction	X	X
Preparedness for Caregiving (Care partners only)	• Preparedness for Caregiving Scale (8 items)- readiness for caregiving in relation to spouse	X	X
Intervention Mechanisms			
Mindfulness	• Cognitive and Affective Mindfulness-Scale (12 items)—a measure of mindfulness skills	X	X
Coping	• Brief COPE (28 items)—a measure of adaptive and maladaptive coping strategies	X	X
Self-efficacy	• General Self-Efficacy scale-6 (6 items)—a measure of self-efficacy	X	X
Social Support	• Social Support Questionnaire, Short Form—Revised (12 items)—a measure of satisfaction with social support	X	X
Interpersonal Communication and Coping	• Dyadic Relationship Scale (10 items—patients, 11 items—caregivers)—a measure of positive and negative dyadic interactions	X	X
	• Dyadic Coping Inventory (9 items)—a measure of dyadic stress management	X	X

Covariates

We will collect demographic information on participants' gender, age, race, ethnicity, marital status, relationship length, education level (number of years in school), employment (status, occupation, and income), and mental health history. We will also collect ADRD clinical characteristics via electronic medical records, including the type of diagnosis, age at diagnosis, and date of diagnosis.

Secondary Outcomes

Overview

We will use the 14-item Hospital Anxiety and Depression Scale (HADS) [40] total score to assess emotional distress once at

baseline, and again at the completion of the program. We will examine the 7-item depression and anxiety subscales of the HADS separately (HADS-D and HADS-A, respectively). Scores range from 0 to 21, where a score >7 indicates significant depression or anxiety. We will also use the 15-item Geriatric Depression Scale–Short Form [41], to assess depression symptoms over the past week. Scores range from 0 to 15, with scores ≥5 suggesting the presence of clinically elevated depression symptoms. We will assess perceived stress over the past month using the Perceived Stress Scale [45]. Scores range from 0 to 16, with higher scores indicating greater perceived stress. To assess perceived quality of life, we will use the 26-item brief World Health Organization Quality of Life assessment [46], which captures quality of life across 4 subscales (physical health, psychological, social relationships, and environment). The first 2 items provide a global assessment of quality of life, and the subscale scores are calculated by summing items and transforming scores to a 0 to 100-point interval, with higher scores indicating a greater perceived quality of life. To assess relationship satisfaction, we will use the 16-item Couple Satisfaction Index [47]. Total scores range from 0 to 81, with higher scores indicating greater relationship satisfaction. Finally, for spousal care partners we will use the 8-item Preparedness for Caregiving Scale (9) to evaluate readiness for caregiving in relation to their spouse. Total scores range from 0 to 32, with higher scores indicating greater preparedness for caregiving.

Treatment Mechanisms

We selected treatment mechanisms assessing individual and dyadic coping and relationship functioning based on our hypothesized mechanisms underlying changes in proposed outcomes (ie, emotional distress, quality of life). We will use the 12-item Cognitive and Affective Mindfulness Scale, Revised [48], to assess mindfulness. Total scores range from 12 to 48, with higher scores indicating greater engagement in mindfulness practices. We will use the 28-item Brief Coping Orientation to Problems Experienced (Brief COPE) [49], to measure ways of individually coping with stressful events. The Brief COPE includes three subscales that assess coping styles: (1) problem-focused (8 items), (2) emotional-focused (12 items), and (3) avoidant coping (8 items). Scores for each subscale are calculated by taking the mean of all items, with higher scores indicating greater use of that coping style. We will assess perceived self-efficacy with the 10-item General Self-Efficacy Scale [50]. Total scores range from 10 to 40, with higher scores indicating greater perceived self-efficacy. We will use the 12-item brief Social Support Questionnaire (SSQR) [51] to assess social support availability and satisfaction. The SSQR consists of 2 subscales: support network availability (SSQR-N) and overall satisfaction (SSQR-S). Each item assesses support availability and satisfaction in separate parts; participants will be asked to indicate (1) how many people they can count on for various types of support and (2) how satisfied they are with the support. The SSQR-N subscale composite is calculated by taking the mean of all items. For the SSQR-S subscale, total scores are calculated by adding subscale items and range from 6 to 36, with higher scores indicating greater social support satisfaction.

To assess the perceptions of dyadic stress management, we will use the items from the Dyadic Coping Inventory [52,53] subscales: common dyadic coping and negative dyadic coping. The common dyadic coping subscale includes 5 items that assess dyads' ability to cope with problems together and search for solutions. Scores range from 5 to 25, with higher scores indicating greater perceptions of the dyad's use of common coping. Negative dyadic coping will also be assessed using the Dyadic Coping Inventory (4 items). Scores range from 4 to 20, with higher scores indicating greater perceptions of the dyads using negative dyadic coping. In addition, we will assess dyadic relationship strain in the context of caregiving using the dyadic strain subscale of the Dyadic Relationship Scale (DRS) [54], which has a 10-item-Patient version and an 11-item Caregiver version. Subscale scores range from 1 to 10 and 1 to 11 for the DRS-Patient and DRS-Caregiver, respectively, with higher scores indicating greater relationship strain.

Exit Interviews

At the conclusion of the intervention sessions, dyads will participate together in a single 60-minute exit interview over health care system–supported videoconferencing to gather information on session content and procedures to refine intervention methods prior to the feasibility trial. Topics will include: what was most and least helpful about the intervention, topics or skills that were not included that might be helpful, whether additional sessions would be preferred, perceptions of skills, comfort with participating in sessions together, and barriers and facilitators of engagement in RT-ADRD procedures and the intervention. A trained research assistant will complete the interviews using an interview guide (see Supplemental Materials). As part of the interview, the research assistant will also capture observations within session domains, important quotes, and other important notes using a rapid data analysis template.

Data Analysis

Feasibility-related measures will be assessed and compared to our prior dyadic intervention studies [27] using proportions at the individual-level on feasibility markers outlined in Table 2, as well as qualitative feedback from exit interviews. Acceptability will be evaluated with the percentage of individuals with scores above the midpoint on self-report questionnaires (Table 2), as well as feedback from exit interviews. Given our primary goal of establishing feasibility and acceptability, this open pilot was not powered to statistically evaluate signal of improvement in quantitative outcomes. However, we will examine preliminary effectiveness of the secondary outcomes using estimated treatment effects for each measure. We will also assess the relationship among treatment mechanisms and secondary outcomes using bivariate correlations, focusing on whether the direction of the association is consistent with our conceptual model. Qualitative data obtained from exit interview transcripts will be analyzed using a rapid data analysis approach to thematic analysis [55]. We will use overarching themes surrounding feasibility markers and participant suggestions to further refine the intervention.

Results

This study was supported by a grant from the National Institute on Aging (1K23AG075188-02) to SB. It was approved by the institutional review board of the Mount Sinai Hospital in April 2024. Recruitment began in April 2024 and will continue through August 2024. Data collection and analysis is anticipated to be complete by August 2024.

Discussion

Anticipated Findings

ADRDs are conditions that are increasingly common among the aging population and have considerable negative impacts on individuals living with ADRD and their spousal care partners [5]. Currently, these dyads have few resources to assist them in navigating early challenges together and adjusting positively to the diagnosis and symptoms [24,25]. Dyads describe an interest in participating in interventions together early after ADRD diagnosis to assist in navigating support and adjusting to symptoms [8]; however, no such interventions exist. Adapting existing interventions has the potential to be effective and efficient in addressing dyads' challenges to promote dyadic adjustment [27,28], and aid in preventing chronic individual and interpersonal stress. Thus, the RT-ADRD program is a timely potential solution to unmet needs reported by dyads at the time of ADRD diagnosis. The present study aims to refine RT-ADRD, a novel dyadic resiliency intervention for dyads at risk of chronic emotional distress early after ADRD diagnoses that includes individual and interpersonal resiliency training for both dyad members simultaneously to promote adjustment to ADRD.

The larger plan to develop and revise RT-ADRD is guided by the NIH Stage Model for behavioral intervention development [56]. This protocol provides the framework of our open pilot trial of RT-ADRD, stage 1B of the development of RT-ADRD. The intervention is novel and flexible, providing live video delivery of treatment sessions to maximize feasibility and adherence, while also providing the option of in-person sessions upon request. We will use the open pilot results to refine the program and inform the subsequent stage—a larger feasibility trial of RT-ADRD relative to an educational control condition (target N=60 dyads).

Limitations

Currently, we are only conducting the intervention in English and with couple dyads. This results in important limitations for non–English speakers and for other caregiving dyads commonly facing ADRDs (eg, parent-child dyads). We plan to address these limitations with parallel studies and in subsequent trials by creating a version of the program in Spanish using established guidelines for linguistic adaptation. We also plan to conduct additional qualitative studies to identify adaptations needed to address a range of caregiving dyads.

Conclusions

The results from this open pilot trial will be used to inform the development of Resilient Together for Dementia, a dyadic resiliency program for those living with ADRDs and their romantic or spousal care partners. Our study will provide quantitative and qualitative data that we will use to refine the current iteration of the program. We will then test the refined intervention in a larger feasibility trial relative to an educational control condition.

Acknowledgments

We would like to thank the members of the Center for Health Outcomes and Interdisciplinary Research at Massachusetts General Hospital (MGH CHOIR) laboratory members and the MGH CHOIR Recovering Together Working Group for their feedback on proposed open pilot procedures and the first version of the RT-ADRD manual. This study was funded by grants from the National Institute on Aging (1K23AG075188-01A1) to SB, and grants from the National Institute of Nursing Research (R01NR019982-01) and National Center for Complementary and Integrative Health (1K24AT011760-01) to AV. We would also like to acknowledge Dr. Jonathan Jackson for his contributions to the larger study design and proposed procedures that informed the current study protocol.

Data Availability

Data collection and analysis instruments are available in the Multimedia Appendices. The datasets generated during and/or analyzed during the current study are available from the corresponding author on reasonable request.

Abstract

Background: Metastatic spine tumor surgery (MSTS) is often complex and extensive leading to significant blood loss. Allogeneic blood transfusion (ABT) is the mainstay of blood replenishment but with immune-mediated postoperative complications. Alternative blood management techniques (salvaged blood transfusion [SBT]) allow us to overcome such complications. Despite widespread use of intraoperative cell salvage (IOCS) in oncological and nononcological surgical procedures, surgeons remain reluctant to use IOCS in MSTS.

Objective: This study aims to analyze safety of IOCS-leukocyte depletion filter (LDF)–processed blood transfusion for patients undergoing MSTS by assessing clinical outcomes—disease progression: tumor progression and overall survival. This study evaluates whether reinfusion of IOCS-LDF–processed blood reduces ABT rates in patients undergoing MSTS by sorting patients undergoing MSTS who require ABT into patients who consent to receive or not receive SBT.

Methods: We aim to recruit a minimum of 90 patients—30 patients for SBT, 30 patients for ABT, and 30 patients with no blood transfusion. SBT and ABT form the 2 experimental arms, whereas no blood transfusion forms the control cohort. Available patient data will be reviewed to determine tumor burden secondary to metastasis and postoperative survival and disease progression, improvement in pain, and neurological and ambulatory status. Data collected will be studied postoperatively at 3, 6, 12, 24, 36, and 48 months or until demise, whichever occurs first. Outcomes of the experimental groups will be compared with those of the control group. Outcomes will be analyzed using 1-way ANOVA and Fisher exact test. The Kaplan-Meier curve and a log-rank test will be used to study overall survival. A multivariate and competing risk analysis will be used to study the association between blood transfusion type and tumor progression. All statistical analyses will be done using Stata Special Edition 14.0 (StataCorp LP).

Results: This is the largest clinical study on use of IOCS in MSTS from various primary malignancies to date. It will provide significant clinical evidence regarding the safety and applicability of IOCS in MSTS. It will help reduce use of ABT, improving overall blood management of patients undergoing MSTS. A limitation of this study is that not all patients undergoing MSTS will survive for the follow-up period (4 years), theoretically leading to underreporting of disease progression. Study commenced in 2016 and patient recruitment continued till 2019. As of September 2019, we have collected operative data on 140 patients. However, the 2-year outcomes of about 40.0% (56/140) of patients are in the process of collection. The study is aimed to be published in the years 2023-2024.

Conclusions: Results will be disseminated via peer-reviewed publications, paving the way for future studies.

Introduction

Background

The skeletal system is the third most common site of metastases, and cadaveric studies show that spinal metastases can be found in 30% to 90% of patients who die of cancer [1,2]. Surgery for metastatic spine disease (MSD) is complex, often requiring wide resection and extensive reconstruction leading to significant blood loss [1,2]. Emergency surgical treatment is often indicated for spinal cord compression with actual or impending paralysis or for spinal instability with severe pain that reduces the quality of life and mobility [3].

Typical blood loss in a patient undergoing tumor decompression and instrumentation in the thoracic and lumbar spine is about 1500 mL, and this requires an average of 3 units of packed red blood cells [4,5]. This blood loss is currently replenished by allogeneic blood transfusion (ABT) across the world, placing a significant burden on the already limited blood bank resources [6,7]. On the contrary, there is increasing evidence of the deleterious effects of ABT. Many studies have shown an increased incidence of postoperative infections [8] and promotion of tumor growth [8,9], which is thought to occur secondary to immunosuppression and other transfusion reactions.

Despite evidence describing multiple postoperative complications related to ABT [10,11], it remains to be the mainstay of blood replenishment in patients with heavy intraoperative blood loss [12]. These are immune-mediated complications and commonly affect the lungs (eg, transfusion-related acute lung injury) [13,14], wound healing [15-17], and survival duration [11,16]. This has prompted efforts to decrease reliance on ABT and to increase the utilization of alternatives, such as autologous predonation or intraoperative cell salvage (IOCS). Autologous predonation may not always be possible in metastatic spine tumor surgery (MSTS) because of suboptimal patient status, medical comorbidities, and in cases where emergency surgery is indicated.

Patient blood management is an evidence-based, patient-tailored approach aimed at reducing the need for ABT and its associated risks [18]. Patient blood management has both preoperative and perioperative components. Preoperative techniques include patient optimization via cessation of antiplatelet and anticoagulant medications [19,20] and anemia management [18]. Perioperative management comprises achieving surgical hemostasis, reinfusion of intraoperatively salvaged blood, the use of erythropoietic agents, and hemostatic drugs such as tranexamic acid. Randomized [21,22] and nonrandomized [23] studies on the use of IOCS in nononcological surgical procedures indicate that salvaged blood transfusion (SBT) significantly reduces the need for ABT [21-23]. Despite extensive use of SBT in orthopedic, trauma, and cardiac surgical procedures [24], the concern of reinfusion of tumor cells leading to disease progression persists [25-27]. The initial lack of literary evidence on the safety of SBT in oncological surgical procedures has made oncological surgeons reluctant to use SBT in MSTS [25-27].

This reluctance dates to an American Medical Council report from 1986, which stated that SBT was not suitable for use in tumor surgery [28]. This was in turn based on a case report from 1975 where tumor cells were found in salvaged blood [29]. There were concerns that tumor manipulation and resection would result in the spillage of tumor cells into the surgical field [30], which would lead to further metastasis if reinfused via SBT. Recent evidence indicates that circulating tumor cells (CTCs), which are shed by the primary tumor [31], are the most likely cause of tumor metastasis in oncological patients. CTCs have been shown to be eliminated by the reticular endothelial system [32], once they fail to metastasize (unable to complete the process of metastasis). Other CTCs may undergo cellular apoptosis after being retained in the capillary bed or the bone marrow [32]. These host defense mechanisms can prevent metastasis by reducing the metastatic ability of the vast majority of CTCs [33]. Consequently, one can ask, “Can SBT with a limited load of damaged malignant tumor cells cause tumor metastasis and disease progression?”

Investigation on the use of salvaged blood in MSTS started with a systematic review that we published [34]. It was envisaged that there is a place for salvaged blood in MSTS, provided the safety of IOCS in MSTS is established by the following steps. Our first step was to establish *basic cellular evidence* that there are no viable tumor cells in the salvaged blood. Second, we aimed to *quantify the number of tumor cells in the salvaged blood*, if any, and to demonstrate that the CTCs in the patient’s own blood are far more than those present in the salvaged blood. Our proposed *final phase* of study was to provide *clinical evidence* that SBT is safe for use in oncological surgical procedures, without increasing the risk of disease progression or tumor recurrence or resulting in poorer prognosis [32].

Our working hypothesis for the preclinical phase of this study was that the blood salvaged from patients undergoing MSTS does not contain viable tumor cells, and even if it did, viable tumor cells in the salvaged blood would be significantly lower than the number of CTCs present in the patient’s own blood at any given point in time. Therefore, there should be no increase in the risk of disease progression, in terms of further tumor dissemination, decreased survival, or increased tumor recurrence.

To test this hypothesis, we first conducted a study that analyzed the morphology and structural integrity of the tumor cells present in the patient’s circulation, operative field, and pre- and postfiltration samples of the salvaged blood [24,35]. Using the cell block technique, salvaged blood in the pre- and postfiltration samples was shown to mostly comprise cytoplasmic debris with no viable nuclei [24,25], thereby establishing the safety of IOCS in oncological surgery [36]. This is also supported by evidence from other studies [37] stating that upon passing through the

IOCS system, 62% of tumor cells were destroyed, whereas the remaining 38% were morphologically altered.

Using flow cytometric studies, we then compared the number of CTCs present in the patient's own blood with that in salvaged blood [38]. We found that salvaged blood contained a significantly lower number of CTCs than those present in the patient's circulation [38]. Furthermore, we provided corroborative evidence that tumor cells passing through IOCS become nonviable and therefore cannot form new metastatic lesions [36]. We were able to demonstrate that CTCs lost the ability to develop into new metastatic lesions after passing through the IOCS apparatus, even without the use of leukocyte depletion filters (LDFs) [36]. LDFs are used to prevent leukocyte-mediated adverse reactions and have applications in both transplant surgery and treatment of hematological conditions [39]. LDFs are used for filtrating blood and have been proven to have the capability to remove tumor cells from the filtrate [38].

Currently, there is ample evidence in the literature for the clinical safety of salvaged blood used in oncological surgical procedures, including gastrointestinal [40], gynecological [41-43], hepatobiliary [40,44-46], and urological [47-54] surgical procedures (Multimedia Appendix 1 [55-64]). Although patients who received SBT required significantly lower amounts of allogeneic blood, their survival rates [44,49,51,52] and disease progression remained comparable with those who did not receive SBT [42,46,54,65]. Patients who received SBT had lower or similar rates of recurrence compared with the control cohort [47,49,51,53].

Despite the validity of the abovementioned literature, there still is hesitation to use IOCS in MSTS [34]. This can be addressed only by using a clinical study. Hence, we have designed this study to analyze the clinical use of IOCS in patients undergoing MSTS.

Objectives

Primary Objectives

This study aims to investigate the following clinical outcomes: disease progression, in terms of tumor progression (increase in size of existing metastatic lesions with or without the appearance of new metastasis), and the overall survival (OS) in patients who receive *IOCS in combination with LDF* (IOCS-LDF)–processed blood during MSTS. Therefore, this study aims to refute the prevailing conception that cell salvage should be avoided in MSTS owing to concerns of tumor dissemination.

Secondary Objectives

The secondary objectives of the study are to investigate whether reinfusion of IOCS-LDF–processed blood can reduce ABT rates in patients undergoing MSTS. We will also compare the length of stay and overall complication rate of patients who receive salvaged blood and those who receive ABT or no blood transfusion (NBT).

Hypothesis

The working hypotheses of this study are as follows:

1. Reinfusion of IOCS-LDF–processed blood of patients undergoing MSTS does not increase the risk of disease progression, in terms of tumor progression (increase in size of existing metastatic lesions with or without the appearance of new metastasis) and OS.
2. Patients receiving IOCS-LDF blood transfusion require less ABT.
3. Patients receiving IOCS-LDF blood transfusion will experience fewer overall complications and shorter length of stay than patients receiving ABT.

Methods

Recruitment

This study aims to recruit a minimum of 90 patients of whom 30 will receive SBT (with or with no allogeneic blood), 30 will undergo ABT, and the remaining 30 will have NBT. From our experience of treating patients with tumor, there are likely to be very few patients who receive only SBT. The majority of patients receiving SBT are likely to receive both SBT and ABT in various proportions. SBT and ABT form the 2 experimental arms, whereas patients with NBT form the control cohort. We will compare the number of patients receiving only SBT with those receiving ABT, if the sample sizes are sufficient.

Patients will be selected from specialist outpatient spine clinics or inpatient wards. These patients may be referred from an inpatient medical oncology team for management, especially in the setting of MSD with cord compression resulting in symptoms such as pain or neurology. A thorough examination of clinical history, physical examination, and review of imaging will be done, and appropriate patient management options will be discussed by the attending orthopedic surgeon. During the enrollment period, whenever a spine surgeon has obtained surgical consent for MSTS in patients with MSD, the principal investigator (NK) will be informed either by a telephone call or by text messaging.

The *research assistant* who is on-site at the National University Hospital during office hours or any member of the research team who is available will interview the patient. During this interview, the interviewer will confirm whether the inclusion criteria are fully met. The study will be explained to suitable subjects, including the advantages as well as possible intra- and postoperative risks of the reinfusion of salvaged blood. A copy of the *patient information sheet and consent form* will be provided to the patient, detailing the recruitment procedures, our objectives, hypotheses, and background information, and any queries will be addressed. Subsequently, written informed consent will be obtained from the patient.

Blood transfusion details will be collected from anesthetists immediately after the operation. Depending on the type of blood transfusion done during the surgery, that is, ABT only or SBT with or with no ABT or NBT, the patient will be categorized into the appropriate study cohort. All patients undergoing MSTS will receive tranexamic acid as an intravenous bolus before induction of anesthesia as per the department protocol, with subsequent top-up dosages every 4 hours during MSTS. If excessive blood loss is expected during surgery, such as in a

separation surgery, continuous infusion of tranexamic acid is given to the patient.

Postoperatively, all subjects will be followed up individually by their operating surgeons, as per the standard of care at the National University Hospital. No additional patient follow-up sessions by the research team will be required. Clinical data and patient outcomes will be accessed via the computerized patient support system and EPIC system at monthly intervals. All available radiological data and clinical notes from the patients' follow-up by their treating surgeons or physicians will be reviewed by the research team. This is to determine the postoperative outcomes such as survival and disease progression. The collected data will be analyzed postoperatively at 3, 6, 12, 24, 36, and 48 months. The data collection and follow-up of available records will continue over a period of 4 years postoperatively or until the patient's demise, whichever occurs first. The collected outcomes of the 2 experimental groups (patients who received SBT with or without ABT) will be compared with those of the control group (patients who received NBT) as well as with the available historical data from the literature.

Statistical Analysis

We have defined *disease progression* as the increase in the size of an existing metastatic lesion or the appearance of a new lesion in the lung, liver, or the spinal column, which can be visualized by using radiological imaging.

Demographic and clinical characteristics of patients will be summarized using mean (SD) values for continuous variables with approximately normal distribution, median (IQR) values for continuous variables with skewed distribution, and frequency (percentage) for categorical variables. A 1-way ANOVA will be used to compare the mean of a normally distributed variable across the 3 blood transfusion groups, whereas a Kruskal-Wallis rank test will be used for the comparison of medians. A Fisher exact test will be implemented for categorical variables accounting for potential small frequencies.

The association between individual characteristics and OS will be studied by using the Kaplan-Meier curve and a log-rank test. The crude hazard ratio and its 95% CI will be used to measure the association between individual characteristics and OS and will be calculated based on their original definitions. Multivariate Cox proportional hazard regression will then be used to adjust for statistically significant confounders for the relationship between the type of blood transfusion and OS. The proportional hazards assumption will be tested after the final model is obtained.

The association between the type of blood transfusion and tumor progression will be investigated by the competing risks analysis, taking death without tumor progression as the competing event. First, cumulative incidence curves of the 3 blood transfusion groups will be plotted nonparametrically, and then we will model the relation via a subdistribution hazard regression model. The measure of association will be quantified by the crude subdistribution hazard ratio; its 95% CI and *P* value will be analyzed in a univariate analysis. Subsequently, a multivariate analysis will be used to adjust for potential confounders. All statistical analyses will be done using Stata Special Edition 14.0 (StataCorp LP). The statistical tests will be assumed to be 2-sided, with the conventional 5% significance level.

Analysis of Primary Outcome Measures

We intend to compare the proportion of patients with MSTS requiring blood transfusion and the amount of ABT required. The primary analysis will be based on the intention-to-treat principle. A Fisher exact test will be used to compare the 2 arms. The exact 95% CI will also be calculated for the difference in the ABT rate between the 2 arms.

Analysis of Secondary Outcome Measures

The progression of disease will be assessed using the internationally accepted Response Evaluation Criteria in Solid Tumors (version 1.1) [66,67]. Disease progression is defined as at least a 20% increase in the sum of the diameters of measurable target lesions (eg, lymph nodes and bone metastases with soft tissue components), unequivocal progression of nontarget lesions (eg, malignant ascites or pleural effusions), or the appearance of 1 or more new metastatic lesions.

Computed tomography of chest or abdomen and pelvis will be used to assess metastases in the lymph nodes, lung, liver, or any abdominal organ, all of which can be visualized adequately. Magnetic resonance imaging of whole spine and nuclear medicine bone will also be performed because of their increased sensitivity in detecting early new spinal or skeletal metastases [68]. A lesion identified in a follow-up study in an anatomical location that is not present at baseline is considered a new lesion and will indicate disease progression.

The OS rate will be defined as the proportion of patients who survive until the end of the study period. Median survival times and 95% CI will be estimated using Kaplan-Meier curves for experimental and control groups. The median OS times will be compared using a log-rank test. The survival rate at 6 months after surgery will also be estimated using Kaplan-Meier curves.

Ethical Considerations

The domain-specific review board of the National Healthcare Group, Singapore (reference numbers: 2014/00065 and 2022/00866), has granted ethical approval for this study. Written informed consent regarding participation in this research study and receiving SBT will be obtained from each patient before the patient is recruited for the study. Data have been anonymized and deidentified. No compensation was provided to patients for this study.

Results

This study has been funded by the National Medical Research Council of Singapore in November 2016 and approved by domain-specific review board of the National Health Group in April 2016.

Data were collected from November 2016 to present (as of submission date of manuscript). Numbers recruited into study, as of submission of the manuscript, were 140. The status of data analysis and expected results are expected to be published in the years 2023-2024, when the information is available.

Discussion

Study Findings

This is the largest prospective clinical study on the use of IOCS in MSTS from a variety of primary malignancies. It will provide significant clinical evidence regarding the safety and applicability of IOCS in MSTS. The clinical safety of the use of IOCS has been established in oncological surgical procedures involving gastrointestinal [40], gynecological [41-43], hepatobiliary [40,44-46,55-57], and urological [47-54,58-62] specialties (Multimedia Appendix 1). However, the use of IOCS has neither been studied nor practiced regularly in metastatic musculoskeletal tumor surgeries (MMTSs). This may be because of the skepticism among surgeons about the safety of SBT in MMTSs, despite the presence of substantial supporting evidence in other surgical specialties in the field of oncology [40-54,63,64]. Amidst all the apprehension regarding IOCS, a retrospective comparative review has shown that SBT indeed reduces the need for postoperative ABT [69]. More recently, the use of SBT has been studied prospectively, demonstrating its safety for IOCS in MSTS [70]. Nonetheless, these studies did not have a comparative arm and had a small sample size.

This prospective clinical study is founded on substantiating evidence that salvaged blood is free from viable tumor cells, proven in our earlier methodical basic sciences approach [32,38]. We aim to study the OS, as well as tumor progression in MSTS patients through analysis of their various outcome measures. The results from this approach will help debunk the prevailing myth that IOCS contributes to disease progression either in the form of new metastasis or in the form of an increase in the size of the index lesion.

Limitations

The limitation of this study is that not all patients undergoing MSTS will survive for the total follow-up period of 4 years, thereby theoretically leading to potential underreporting of disease progression. The sheer number of possible primary tumors in MSD also inevitably leads to heterogeneity, which can be overcome through propensity score–matching analysis.

Broader Implications

Through the reporting of our analysis, this study will help reduce the use of ABT, reduce the burden on blood banks, and improve the overall blood management of patients with MSTS. This improvement in blood management will prevail even with the improvement of surgical techniques in the management of MSTS, that is, introduction of minimally invasive surgery techniques and the regular use of navigation. This is because the 2 techniques mentioned earlier will reduce blood loss during the steps of spinal instrumentation but are unlikely to have any effect on blood loss while performing decompression. Decompression and separation surgery presently still form a major component of MSTS and will continue to do so, resulting in significant bleeding that requires replenishment potentially in the form of SBT.

In this protocol, we have proposed a prospective observational nonrandomized study design as the ethical appropriateness of blinding or randomizing these patients is a key concern in our region and country. Blinding or randomization of patients with MSD could be deemed unethical, especially among patients who may not agree to receive SBT or ABT as this will limit the blood transfusion type applicable for them. This could be attributed to the current lack of clinical evidence that SBT does not lead to disease progression or shortened survival among patients undergoing MSTS who receive SBT. With this research proposal, we aim to highlight the safety profile of SBT, together with a design protocol applicable for use in patients with MSD. Future research, such as propensity-matched studies, can be done to further validate the outcomes from our current protocol.

Conclusions

We surmise that the results of our proposed study design will pave the way for future randomized studies on the use of IOCS in MSTS and MMTSs, given that the granting bodies and their reviewers would be more open to considering funding for such studies.

Acknowledgments

The authors would like to thank the following from National University Health System: Karthigesh Palanichami for his contribution to the preparation and proofreading of the manuscript; Aye Sander Zaw for her contribution in the preparation of this study protocol; and James Hallinan for his contribution in the radiological evaluation of disease progression

Data Availability

All data generated or analyzed during this study will be included in published manuscripts and their supplementary information files.

Conflicts of Interest

None declared.

Abstract

Background: There are gaps in our understanding of the clinical characteristics and disease burden of the respiratory syncytial virus (RSV) among community-dwelling adults. This is in part due to a lack of routine testing at the point of care. More data would enhance our assessment of the need for an RSV vaccination program for adults in the United Kingdom.

Objective: This study aimed to implement point-of-care-testing (POCT) in primary care to describe the incidence, clinical presentation, risk factors, and economic burden of RSV among adults presenting with acute respiratory infection.

Methods: We are recruiting up to 3600 patients from at least 21 practices across England to participate in the Royal College of General Practitioners Research Surveillance Centre. Practices are selected if they undertake reference virology sampling for the Royal College of General Practitioners Research Surveillance Centre and had previous experience with respiratory illness studies. Any adult, ≥40 years old, presenting with acute respiratory infection with onset ≤10 days, but without RSV within the past 28 days, will be eligible to participate. We will estimate the incidence proportion of RSV, describe the clinical features, and risk factors of patients with RSV infection, and measure the economic burden of RSV infection.

Results: A total of 25 practices across different English health administrative regions expressed interest and were recruited to participate. We have created and tested an educational program to deploy POCT for RSV in primary care. In addition to using the POCT device, we provide suggestions about how to integrate POCT into primary care workflow and templates for high-quality data recording of diagnosis, symptoms, and signs. In the 2023-2024 winter RSV detection in the sentinel network grew between

October and late November. According to data from the UK Health Security Agency, the peak RSV swab positivity was in International Standards Organization week 48, 2023. Data collection remains ongoing, and results from the subset of practices participating in this study are not yet available.

Conclusions: This study will provide data on the RSV incidence in the community as well as rapid information to inform sentinel surveillance and vaccination programs. This information could potentially improve clinical decision-making.

Introduction

Background

Respiratory syncytial virus (RSV) infection in adults is reported to be a substantial burden to health care systems globally [1]. A recent systematic review of the disease burden of RSV in older adults in the United Kingdom reported an average of 175,070 primary care physician episodes and 7915 deaths per season attributed to RSV, equivalent to 1946 primary care physician episodes per 100,000 population and 88 deaths per 100,000 population older than 65 years of age [2,3]. Another meta-analysis reported that RSV caused 4.66% (95% CI 3.34-6.48) of symptomatic respiratory infections in annual studies and 7.80% (95% CI 5.77-10.45) in seasonal studies among adults older than 60 years [4].

However, RSV is not widely recognized as a cause of respiratory infections in adults as its clinical manifestations are often nonspecific [5-10]. Among those with predisposing factors, such as older age, weakened immune systems, or underlying cardiopulmonary conditions, RSV can increase the risk of developing serious acute lower respiratory tract infection (LRTI), cardiovascular sequela, and exacerbation of underlying conditions, all of which are associated with a significant risk of hospitalization and mortality [5,6,11].

Current guidelines do not recommend rapid diagnostic testing for respiratory viruses in primary care in England [12,13] and a recent scoping review showed the paucity of literature on studies of RSV tests in specific populations and settings [14] despite the difficulty of clinical diagnosis and the availability of a number of highly accurate point-of-care tests (POCT) platforms for RSV in the National Health Service (NHS) [9,15]. Recent studies have estimated that limited routine clinical testing can result in more than 100-fold underestimation of RSV incidence in laboratory surveillance studies [16]. RSV disease burden is of considerable interest because of the development of new vaccines and monoclonal therapies [17-19]. The UK's Joint Committee on Vaccination and Immunization advised that an immunization program for RSV be established for older adults aged 75 years and older [17]. More precise contemporary data to estimate the incidence of RSV in the community and understand the clinical and economic burden of RSV infection in adults would assist in planning any new RSV vaccination program.

Deployed at scale, POCT for RSV has the potential to address the gaps in our knowledge about incidence, clinical presentation, and disease burden.

Aim and Objectives

The aim of the Observational Study of Acute Respiratory Infection (ObservatARI) study is to deploy POCT in primary care clinics to provide data about the incidence, clinical presentation, risk factors, and economic burden of virologically confirmed RSV among older adults presenting with acute respiratory infection (ARI).

Our primary objective is to calculate the incidence proportion of virologically confirmed RSV among adults aged ≥40 years, in a primary care-based sentinel surveillance cohort overall and by age, sex, and subgroups of interest.

Secondary objectives include (1) examining the population-level incidence of RSV, (2) the incidence of RSV-LRTI, (3) use of secondary care, (4) clinical profile, and (5) comparison of clinical and economic burden in cases with and without RSV. Prespecified subgroups (sample size permitting) include age and sex.

Methods

Coordinating Center

The coordinating center for this study was the Nuffield Department of Primary Care Health Sciences, University of Oxford, Oxford, United Kingdom.

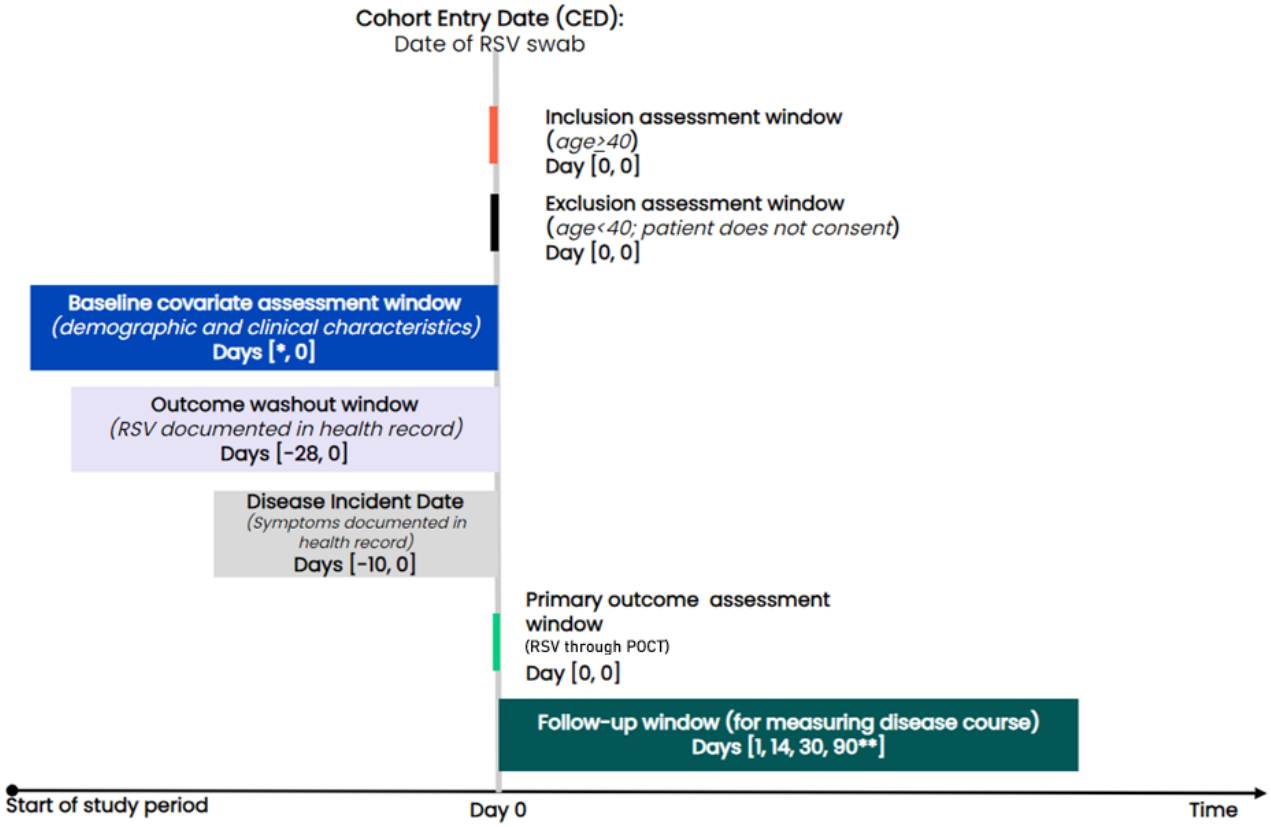
Study Design

The ObservatARI study is ongoing, taking place between November 2023 and November 2024. It is nested within the English national sentinel network, the Oxford-Royal College of General Practitioners (RCGP) Research and Surveillance Centre (RSC), at the Nuffield Department of Primary Care, University of Oxford. This network of over 2000 primary care providers in England, referred to as general practices, is the primary care infectious disease surveillance network for England recruited to be representative of the English population [20]. It has been providing weekly data for over 57 years and is used to monitor trends in infectious disease and investigate real-world vaccine and treatment effectiveness [21].

All practices that contribute data to the RSC are eligible to participate in the ObservatARI study. We will prioritize those practices that currently undertake reference virology sampling for the sentinel network and have previous experience with undertaking respiratory illness studies, including POCT studies. In order to ensure geographic representation, up to 3 practices in each English health region (East of England, London, Midlands, North East, Yorkshire, North West, and South East and South West) have been selected to participate in the study [22]. These sites will receive training on the appropriate use of the POCT device from the manufacturer, which will be documented on a training log. Provision of the POCT device to these sentinel surveillance sites will allow for the collection of data on RSV, which is not routinely tested as part of usual care.

Figure 1 shows the cohort entry date of recruited patients is the date the POCT swab is taken and will serve as the study index date. Baseline covariates are assessed in the period of up to 5 years before cohort entry, and the precise lookback period will vary depending on the variable of interest.

Figure 1. ObservatARI study design. ARI: acute respiratory infection; RSV: Research Surveillance Centre, POCT: point-of-care-testing. The study time period was from November 2023 to November 2024. *Lookback for baseline covariates will vary by variable using windows established by existing sentinel surveillance efforts. **Patients censored due to death or disenrollment from the clinic.



We will follow-up enrolled patients for up to 14 days, 30 days, and 90 days for secondary outcomes of interest, such as clinical outcomes and health service usage. This information will be presented according to the test result from POCT (ie, RSV-positive and RSV-negative).

Case Definition of Eligible Patients

Fully registered primary care patients, of study practices, who present with ARI, with its onset in the last 10 days (including index date), where illness is not due to another plausible diagnosis, are eligible for enrollment in the ObservatARI study. These are the same criteria currently used by the UK Health Security Agency (UKHSA) sentinel surveillance system [23].

Sampling and Data Collection

We are undertaking opportunistic virology sampling [24], with potential participants being identified from fully registered patients and temporarily registered patients who present to the participating study practices with respiratory symptoms described in the case definition.

ObservatARI practices are advised to take 2 swabs, and 1 nasopharyngeal swab for testing using the Cepheid POCT analyzer. Nasopharyngeal swab samples have been studied and validated for the detection and quantification of respiratory viruses and are considered more accurate for RSV than nasal swabs [15,25,26]. The second one is a nasal swab for testing using the UKHSA National Virology Reference Laboratory as per Oxford-RCGP RSC's standard practice [23].

Eligible patients are approached by their practice receive an explanation about the study and are asked for consent to take part when they present for a face-to-face consultation at the practice. Patients are informed that they are free to withdraw from the study at any time without giving any reason and without their legal rights being affected. Study participants will not receive compensation for taking part in this study.

After obtaining consent using a form with a prepopulated study number, the primary care physician or research nurse will take the virology swabs [25,26]. The nasopharyngeal swab is inoculated in a test kit and tested using the POCT analyzer as soon as possible after being taken. Only the patient study number is entered into the POCT machine.

We are using the Cepheid GeneXpert Xpress CoV-2, Flu, RSV plus POCT analyzer for this study. This multiplex polymerase chain reaction system tests for SARS CoV-2, influenza A, influenza B, and RSV. It has demonstrated excellent performance comparable to gold-standard laboratory assays with a sensitivity for RSV of 0.979 (95% CI 0.889-0.996) and specificity of 1.000 (95% CI 0.981-1.000) [27]. It has Conformité Européenne marking in the European Union. In the United States, it is approved by the US Food and Drug Administration and it is also waived for use by the Clinical Laboratory Improvement Amendments for rapid RSV testing. This study will not assess the accuracy of the POCT analyzer but will use the machine for its approved purpose.

The clinician is also asked to enter the following date of onset of four symptoms in the patient's computerized medical record (CMR): (1) the presence or absence of fever because of infection, (2) cough (and if coughing is productive), (3) sore throat, and (4) shortness of breath or wheezing. In addition, the following four signs will be recorded in the CMR: (1) measured temperature (ear or tympanic preferred) ≥38 °C for fever, (2) peripheral oxygen saturation, (3) pulse rate >90 beats per minute for tachycardia, and (4) respiratory rate >20 breaths per minute for tachypnoea (Textbox 1). After the POCT analyzer has finished, the clinician is asked to code the result into the patient's CMR.

To facilitate the standardized collection of symptoms, signs, and POCT or laboratory results for the study, we have developed data entry templates for study practices using either the Egton Medical Information Systems or The Phoenix Partnership computerized medical systems available to participating practices (Figure 2). This allows clinicians in study practices to record respiratory symptoms and signs, and study consent, through dropdown menus and tick boxes. The results of POCT testing and reference laboratory testing will also be entered using these templates. The information from the templates is automatically entered into the patient's CMR as a relevant Systemized Nomenclature of Medicine Clinical Terms, which will be extracted for data analysis as part of this study.

Textbox 1. Key data on symptoms and signs of acute respiratory infection.

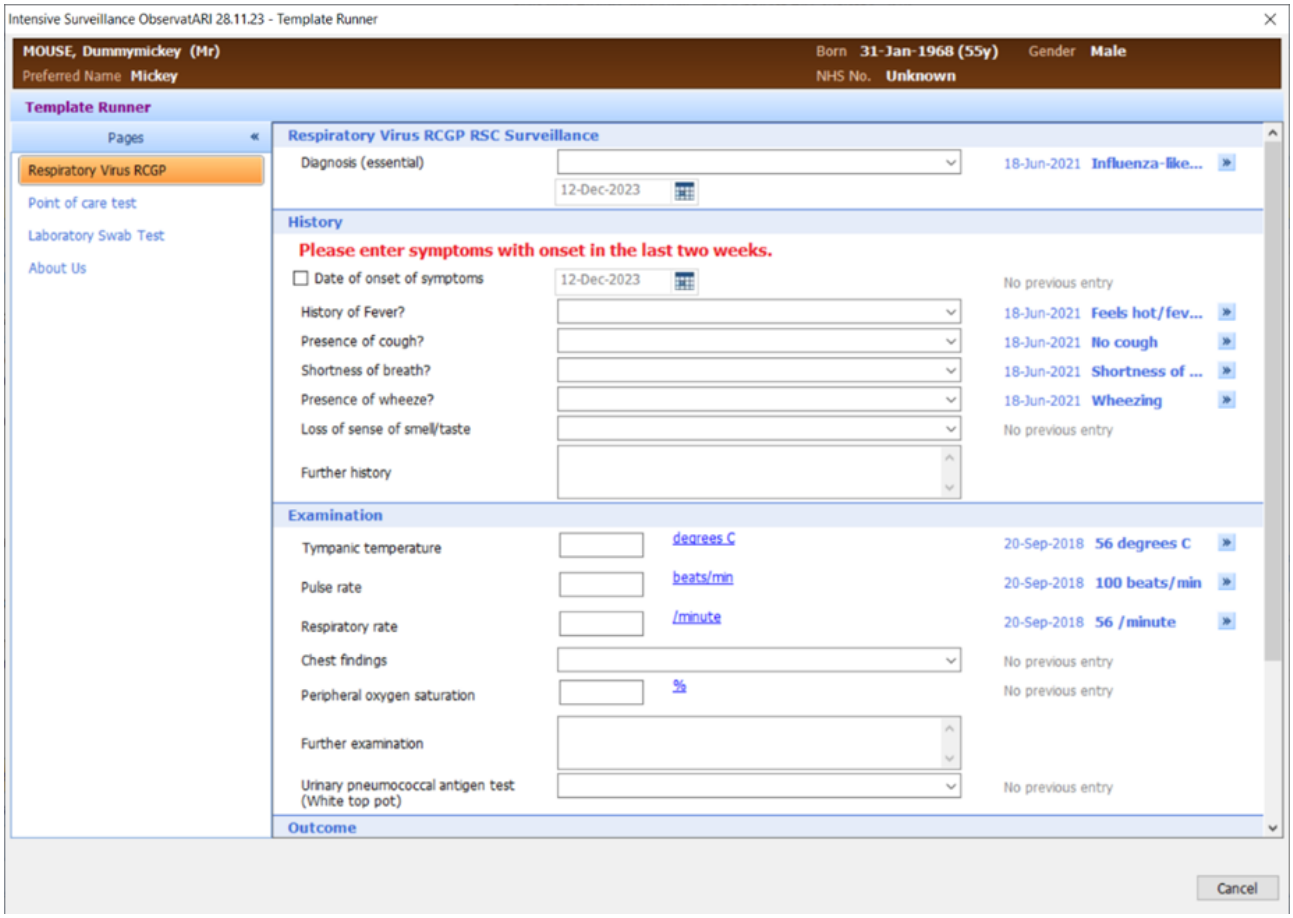
Symptoms data

- Presence or absence of fever because of infection
- Cough (and if coughing is productive)
- Sore throat
- Shortness of breath or wheezing

Signs data

- Measured temperature (ear or tympanic preferred) ≥38 °C for fever
- Peripheral oxygen saturation
- Pulse rate >90 beats per minute for tachycardia
- Respiratory rate >20 breaths per minute for tachypnea

Figure 2. Sample ObservatARI data collection form. ARI: acute respiratory infection; RCGP: Royal College of General Practitioners; RSC: Research Surveillance Centre.



Data Sources

The Oxford-RCGP Clinical Informatics Digital Hub (ORCHID) trusted research environment will house the data required for this study.

We will use a pseudonymized NHS number to allow the linkage of ObservatARI data to national datasets. With appropriate approval, these data assets are held within the ORCHID trusted research environment. Data assets used for this study are as follows.

The primary virology diagnosis will be from POCT data collected from participating ObservatARI practices.

Supplemental data on test positivity will be available approximately a week later from the UKHSA reference laboratory data. In the event of a discrepancy between the POCT and UKHSA reference laboratory data, the POCT test will be selected as the main result with the proportion of discrepant results reported.

In addition, virology data from UKHSA virology sampling during the study period will be accessed to augment data obtained from POCT.

Pseudonymized patient data are also linked to UKHSA National Virology Reference Laboratory data results. NHS England national data collection provides access to hospitalization, intensive care unit admission, mortality, and other national datasets.

Hospital Episode Statistics (HES) is the transformed data, initially part of the Commissioning Data Set, covering patients attending accident and emergency units, admitted for treatment, or attending outpatient clinics at NHS hospitals in England, including details about length of stay and Health Care Resource Groups (HRGs) to enable health economic analysis. HRG consists of patient events that have been judged to consume a similar level of resource, which can be linked to an appropriate NHS tariff. Statistical controls have been applied to HES products. Data on cost will be extracted from HES using HRG. Health care resource use data during hospital admissions are not granularly available and, therefore, HRG codes will need to be used as a proxy for costing.

Emergency Care Data Set collects data from accident and emergency departments.

Civil Registrations include information including date, place, and certificated cause of death from the Office for National Statistics.

Data derived from primary and secondary care encounters are recorded using the Systemized Nomenclature of Medicine-Clinical Terms and *ICD-10* (*International Statistical Classification of Diseases, Tenth Revision*) codes, respectively [28]. The clinical concepts captured include diagnoses, therapy, test results, and other data [29]. Patient medical records in UK general practice have been computerized since the late 1990s, with pay-for-performance incentives introduced in 2004 for chronic disease management [30].

Sample Size Calculation

Up to 3600 POCT swabs will be taken from consented, volunteer patients registered with the 21 ObservatARI general practices. Based upon the annual disease prevalence of 6% and reported sensitivity of 0.979 (95% CI 0.889-0.996) and specificity of 1.000 (95% CI 0.981-1.000) [27], we estimated the number of participants with and without RSV that would test positive and negative with the POCT if we sampled 3600 with ARI (Table 1).

Table 1. Expected counts (±95% CIs) for respiratory syncytial virus (RSV).

	RSV, expected count (95% CI)	No RSV, expected count (95% CI)	Total, n
Positive POCT[a]	211 (192-215)	0 (0-64)	211
Negative POCT	5 (1-24)	3384 (3320-3384)	3389
Total	216	3384	3600

[a]POCT: point-of-care-testing.

Given our estimates of prevalence, sensitivity, specificity, and the total available number of swabs in 21 practices in one season, we would expect to observe approximately 211 POCT true-positive RSV cases, which is sufficient to meet our primary objective of estimating the incidence proportion of POCT confirmed RSV.

We performed additional sensitivity analyses, keeping constant the number of swabs and prevalence of RSV, but assuming lower values of POCT sensitivity (90% and 80%) and estimated that 194 and 173 true-positive RSV cases would be detected, respectively. With smaller RSV case counts, SE of the incidence proportion (primary objective) would remain very similar and precise enough to generate meaningful inferences.

We have previously found that RCGP RSC practices using a POCT to diagnose respiratory viruses collect on average 6 swabs per practice per week over the winter season [31]. Thus, for our study in 21 practices over 12 months, we estimate that the target of 3600 swabs would be achievable.

Covariate Ascertainment

Tables 2 and 3 show the covariates we will use for this study which are known to be associated with the incidence and severity of respiratory syncytial virus [32].

Table 2. Covariates associated with the incidence and severity of the respiratory syncytial virus.

Covariate	Categories
Age	• As whole years • 5-year increments (broader 10-year age bands may be considered)
Sex	• Male or female
Ethnicity	• White, Asian, Black, other, or mixed
Region	• Divided into areas served by an integrated care system
Urban or rural designation	• Urban or rural
Household composition	• Divided into categories 1, 2, 3, 4-5, 6-10, 11, or more
Socioeconomic status will be measured using the index of multiple deprivation [32]	• Quintiles from 1 (most deprived), 2, 3, 4, and 5 (least deprived)
BMI	• Obese or not obese (BMI ≥ or <30), • Also stratified as <18.5, 18.5-24.9, 25.0-29.9, 30.0-39.9, 40.0, or more)
Smoking status	• Current smoker, previous smoker, or nonsmoker
Cambridge Multi-Morbidity Score	• Quartiles • No comorbidities, 1, 2, 3, 4, or more comorbidities
Comorbidities known to relate to increased risk of severe respiratory illness, or suboptimal vaccine response, or vaccine contraindication	• Chronic respiratory disease • Chronic obstructive pulmonary disease • Chronic heart failure • Chronic heart disease and vascular disease • Chronic kidney disease • Chronic liver disease • Chronic neurological disease • Diabetes mellitus • Severe mental illness • Morbid obesity • Asplenia, or dysfunction of the spleen, immunosuppression due to disease, or treatment
Vaccination status within the season	• Influenza vaccination • COVID-19 vaccination • Pneumococcal vaccination

Table 3. Covariates and categories.

Covariates	Categories
Age	• As whole years • 5-year increments (broader 10-year age bands may be considered)
Sex	• Male or female
Ethnicity	• White, Asian, Black, other, or mixed
Region	• Divided into areas served by an integrated care system
Urban/rural designation	• Urban or rural
Household composition	• Divided into categories 1, 2, 3, 4-5, 6-10, 11, or more
Socioeconomic status will be measured using the index of multiple deprivation [32]	• Quintiles from 1 (most deprived), 2, 3, 4, 5 (least deprived)
BMI	• Obese or not obese (BMI ≥ or <30) • Also stratified as <18.5, 18.5-24.9, 25-29.9, 30-39.9, 40, or more)
Smoking status	• Current smoker, previous smoker, or nonsmoker
Cambridge Multi-Morbidity Score	• Quartiles • No comorbidities, 1, 2, 3, 4, or more comorbidities
Comorbidities known to relate to increased risk of severe respiratory illness or suboptimal vaccine response or vaccine contraindication	• Chronic respiratory disease • Chronic obstructive pulmonary disease • Chronic heart failure • Chronic heart disease and vascular disease • Chronic kidney disease • Chronic liver disease • Chronic neurological disease • Diabetes mellitus • Severe mental illness • Morbid obesity • Asplenia or dysfunction of the spleen, immunosuppression due to disease, or treatment
Vaccination status within the season	• Influenza vaccination • COVID-19 vaccination • Pneumococcal vaccination

Statistical Analyses

For the primary objective, the incidence proportion of virologically confirmed RSV will be calculated as the number of swabs testing positive for RSV in the POCT, divided by the number of people fully registered at all 21 sites each month. Exact 95% CIs will be estimated using the Wilson method [33]. We will also calculate percent positivity as the number of positive cases divided by the number swabbed. Estimates will be presented overall and by key demographic and patient characteristics as defined above. Incidence proportions will be calculated by time (eg, moving average and monthly) depending on the sample size.

To approximate the response rate, and investigate potential selection bias, and external validity, we will compare the characteristics of patients for whom a swab was taken, with those who are ≥40 years presenting with an ARI code in the participating practices, and in the whole RSC network, respectively. This analysis will be restricted to the same study period.

For secondary objective 1, the incidence proportions (and 95% CI) estimated from the primary objective will be standardized (using the direct method) to the UK general population based on age or sex distribution [34].

For secondary objective 2, incidence proportions (and 95% CI) of RSV-LRTI will be calculated by dividing the number of cases meeting each of the three case definitions by the number of people at risk, for example, in a subgroup of interest.

For secondary objective 3, descriptive statistics (mean [SD], median [IQR], range [minimum and maximum], frequency [percentage]) will be used to describe the patient's clinical features at presentation, for all patients and RSV-positive patients (eg, signs and symptoms; Textbox 1). For reference, the same information will be presented for patients with ARI who test negative for RSV. We will adjust for variables that are hypothesized to lead to the development of symptoms as well

as RSV positivity. Crude and adjusted odds ratios and 95% CIs indicating the association between these variables and testing positive for RSV (vs testing negative) will be presented.

For secondary objective 4, descriptive statistics will be used to describe the patient covariates listed in Table 2. These covariate characteristics will be examined among all patients, with the information presented according to POCT status (ie, RSV-positive and RSV-negative). As in secondary objective 3, logistic regression will be used to estimate crude and adjusted odds ratios.

For secondary objective 5, the clinical and economic burden of RSV will be assessed by comparing the number of health care visits (eg, visits to the general practitioner, hospitalization, and intensive care unit visits), medication use (eg, antiviral and antimicrobial therapy), receipt of ventilation and supplemental oxygen use up to 6 months after the swab. Additional outcomes of interest will include primary care costs, prescription costs, medical test costs, and secondary care costs.

Our approach to the analysis will depend on the type of outcome variable. For instance, cumulative health care resource costs covering primary and secondary health care services for the cohorts will be calculated for each patient by attaching unit costs to each service encounter. This will enable us to present initial estimates of the costs associated with health care usage across each group in terms of means, SD, median, IQR, minimum, and maximum. We will examine the distribution of the health care costs to identify outliers. This information will be presented according to POCT status (ie, RSV-positive and RSV-negative) and further, by the subgroup of interest. These steps will ensure that we fully comprehend the nature of the cost data [35].

Ethical Considerations

Data for the study are held on dedicated secure servers within the ORCHID TRE. The Research Group's secure network is sited behind a firewall within the University's network. Only staff members or associated members of the Research Group who have been appropriately trained and approved by the Head of Department can access the data from secure workstations or secure laptops with encrypted drives. All staff members of the Research Group working within the team base work from secure workstations or secure laptops with encrypted drives within the Research Group's secure network. The staff of the study sponsor will be provided with aggregate-level study data only. A risk assessment of the physical security of the Research Group's offices and server room has been conducted by the Building and Facilities Manager, the Faculty IT Service Manager, and the Research Group's Information Governance Lead. The University is compliant with the Data Protection Act and UK General Data Protection Regulation and has systems for technical and organizational controls for information security, including a University-level Information Security and Governance Group, chaired by the University Senior Information Risk Owner. The Research Group's private network has its own system-level security policy and is tested for vulnerabilities annually.

Study practices are given a stipend to cover the costs of training staff members and hosting the study. A small remuneration is also provided to practices for each POCT swab and reference laboratory virology sample taken to cover the additional time taken during each consultation to undertake swabbing for this study. Patients are not remunerated for taking part in this study.

The study received ethical approval for England and Wales from the Health Research Authority and Health and Care Research Wales on September 14, 2023 (Integrated Research Application System project ID: 329790, south central Oxford A Research Ethics Committee reference number 23/SC/0320).

The study and data extract were approved by the ORCHID Caldicott Guardian, the Primary Care Hosted Research Data sets Independent Scientific Committee of the Nuffield Department of Primary Care Sciences at the University of Oxford on November 7, 2023 (application reference PD-0030-2023).

Protocol Amendments

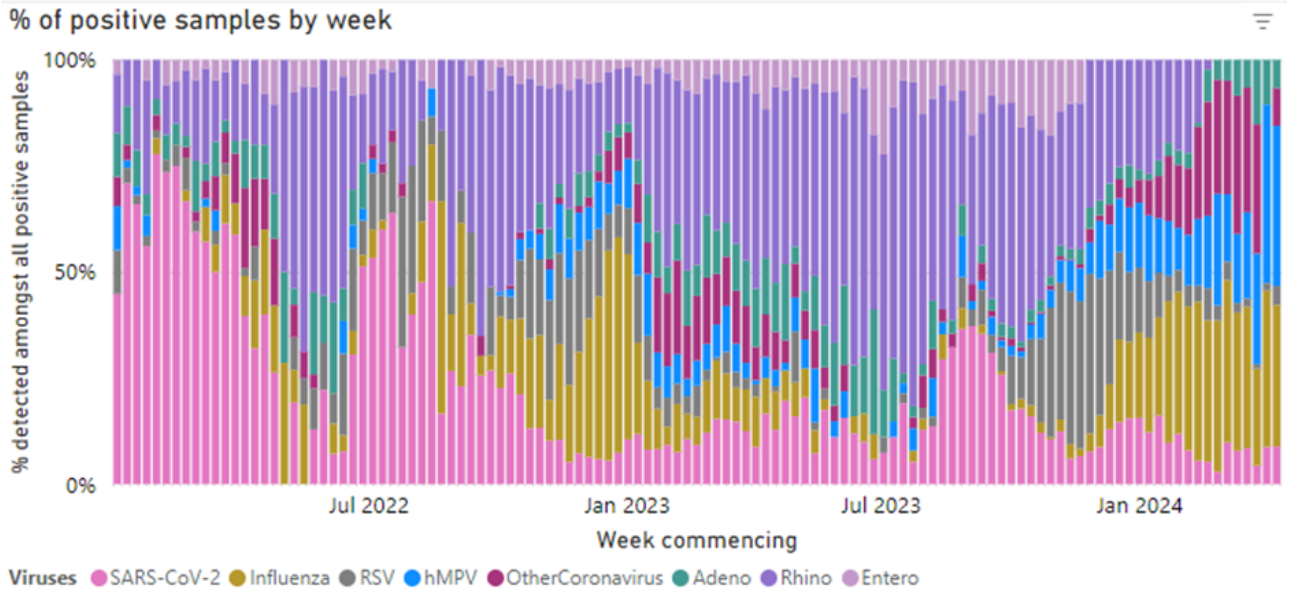
Important protocol amendments will be referred to the English National Research Ethics Committees for ethical approval. Once approved, it will be communicated directly with the recruiting study practices. The amended protocol will be shared with all relevant parties, for example, investigators and clinical research networks in a timely manner.

Results

We have received expressions of interest from 25 practices and have purposively recruited 21 practices from across the English health administrative regions.

In the 2023-2024 winter season, RSV detection in the sentinel network grew between October and late November. According to data from the UKHSA, the peak RSV swab positivity was in International Organization for Standardization week 48, 2023 (Figure 3 [36]). Data collection remains ongoing, and results from the subset of practices participating in this study are not yet available.

Figure 3. The UK Health Security Agency virology swabbing positivity in 2023-2024 [36].



Discussion

Anticipated Findings

This study will generate contemporary data about the clinical presentation and disease burden of RSV among middle-aged and older adults in the community. Our primary outcome is the incidence of virologically confirmed, symptomatic, RSV infection presenting to primary care providers in England.

This study has a number of limitations. First, even with a sampling of 3600 eligible patients with ARI, it is expected that this study will only yield approximately 200 positive cases of RSV with the POCT. While this would be enough to estimate the incidence of RSV cases presenting to primary care with sufficient precision, the low number of cases could impact the number of covariates that we can adjust for in secondary objectives, as well as the estimation of ORs for categories with low frequencies (eg, underweight BMI category) and our ability to conduct subgroup analysis.

Second, there is inherent variation in clinical assessment and, thus, the decision to swab an eligible participant and exclude anyone with an illness due to another plausible diagnosis may potentially introduce bias. To minimize this variation, we will have robust site training available at the start of the study and throughout for new members of staff. We will also quantify any individual selection bias by comparing the characteristics of eligible swabbed and unsampled patients in POCT practices.

Third, a limitation of our opportunistic sampling strategy is that we will sample both fully registered and temporarily registered patients from study practices with eligible symptoms. Temporarily registered patients may include people at increased risk of infection or severe consequences of infection as well as people with less available information in their medical records such as refugee populations. We will quantify the effect this may have by comparing the characteristics of fully registered and temporarily registered patients in POCT practices.

Fourth, the study practices are not randomly selected so the results from the POCT surveillance cohort will not generalize beyond the selected clinics. To quantify any practice selection bias, we will compare the characteristics of patients for whom a swab was taken, with those presenting with an ARI code in the 21 participating practices, and in the whole RCGP RSC network, respectively.

Finally, the use of nasopharyngeal sampling is invasive and uncomfortable for the patient and it requires a trained provider to perform the collection. This may negatively impact the sensitivity of POCT in this older adult population, potentially biasing incidence estimates downwards. However, nasopharyngeal swabs have been validated for the detection and quantification of respiratory viruses [25,26]. They are considered the most accurate method for sampling RSV and practices in the Oxford-RCGP RSC sentinel network have many years of experience with undertaking nasopharyngeal swabs as part of national virological respiratory disease surveillance, which should reduce this risk [21,25,26]. In addition, where the virus has progressed lower in the respiratory tract, a nasopharyngeal swab may not detect these cases and a sputum sample may be required.

The limitations of the study must be considered in the context of its strengths. First, the study is nested within the English sentinel network, which includes participating practices that have developed expertise in identifying respiratory infections for the past 5 decades [21] and have a robust reporting infrastructure that supports rapid, accurate respiratory disease surveillance.

Second, the study uses a robust reverse transcription-polymerase chain reaction multiplex POCT platform that is rapid, accurate, cost-effective, simple to use, and reliable, and will provide viral positivity results for RSV, influenza, and SARS-CoV-2.

Third, the study leverages the NHS data system and a broader network of virology testing within the sentinel surveillance network to expand the breadth of the dataset (eg, clinical, economic, and humanistic variables) and ensure broader

applicability of findings. Thus, we will have the opportunity to leverage the broader dataset of laboratory results and other data from patients from outside the 21 clinical sites in the analysis as needed.

Conclusion

We have started to deploy POCT for RSV in primary care and believe that if done at scale, POCT may provide data on the RSV incidence in the community as well as rapid information to inform sentinel surveillance. This information may also provide data to inform decisions about the benefits of a UK-wide RSV vaccination program for the adult population.

Acknowledgments

We would like to thank participating practices for sharing data and patients and their carers for volunteering to participate in this study. Magentus and Egton Medical Information Systems for their collaboration with pseudonymized data extraction.

Moderna funded and sponsored this study, and reviewed and proposed edits to the study protocol and study documents before submission for ethics approval and peer review publication.

Data Availability

The datasets generated during and/or analyzed during this study are available from the corresponding author on reasonable request and with permission of RCGP RSC [37].

Conflicts of Interest

SdL is the director of the Oxford RCGP Research and Surveillance Centre. Through his university he has received funding for vaccine-related research from AstraZeneca, GlaxoSmithKline (GSK), Sanofi, Seqirus, and Takeda; he has been a member of advisory boards for AstraZeneca, Sanofi, and Seqirus. UH has undertaken continuing professional development podcasts funded by Seqirus and has been a member of advisory boards for Jansen. JR, ABA, CAP, OB, MD, AE, TL, and DM are employees and/or potential owners of Moderna stock.

Abstract

Background: Type 2 diabetes (T2D) is a leading cause of premature morbidity and mortality globally and affects more than 100 million people in the world's most populous country, India. Nutrition is a critical and evidence-based component of effective blood glucose control and most dietary advice emphasizes carbohydrate and calorie reduction. Emerging global evidence demonstrates marked interindividual differences in postprandial glucose response (PPGR) although no such data exists in India and previous studies have primarily evaluated PPGR variation in individuals without diabetes.

Objective: This prospective cohort study seeks to characterize the PPGR variability among individuals with diabetes living in India and to identify factors associated with these differences.

Methods: Adults with T2D and a hemoglobin A_{1c} of ≥7 are being enrolled from 14 sites around India. Participants wear a continuous glucose monitor, eat a series of standardized meals, and record all free-living foods, activities, and medication use for a 14-day period. The study's primary outcome is PPGR, calculated as the incremental area under the curve 2 hours after each logged meal.

Results: Data collection commenced in May 2022, and the results will be ready for publication by September 2025. Results from our study will generate data to facilitate the creation of machine learning models to predict individual PPGR responses and to facilitate the prescription of personalized diets for individuals with T2D.

Conclusions: This study will provide the first large scale examination variability in blood glucose responses to food in India and will be among the first to estimate PPGR variability for individuals with T2D in any jurisdiction.

Introduction

Type 2 diabetes mellitus (T2D) is the leading cause of chronic kidney disease, end-stage renal disease, blindness, and nontraumatic amputation; it also substantially increases the risk of myocardial infarction, stroke, and heart failure [1]. Its prevalence is particularly high in India, which is now the most populous country in the world. As of 2023, more than 100 million people living in India have diabetes, representing more than 11% of the population and an additional 136 million have

prediabetes [2]. These numbers are anticipated to continue to grow rapidly. The lifetime risk of T2D among 20-year-olds who are obese and living in India is estimated to be more than 86% [3]. The rising prevalence of this condition in India is believed to be the result of changing diets, increasingly sedentary occupations, lower levels of physical activity in the context of urbanization, and rapidly increasing rates of obesity [4].

These trends are particularly concerning because of important differences between the presentation and consequences in T2D among individuals of South Asian origin compared with other racial and ethnic groups. These differences, which often referred to as the "Indian Phenotype" or "South Asian Phenotype" [5-7], are characterized by the onset of T2D at a younger age and substantially lower BMI than people of other races and ethnicities [8-10]. Individuals of Indian origin have higher levels of insulin resistance (and for longer periods of time) and premature beta-cell failure [7]. They are more likely to develop the fatal complications of T2D, most notably heart disease [7]. These features are thought to result from a mix of lifestyle, epigenetics, and fetal programming factors [7,11,12].

The fundamental goal of diabetes management is to maintain near-normal glucose levels. A variety of self-management behaviors, in particular adherence to diet and regular exercise, are central to this goal. An extensive body of evidence demonstrates that aiding patients with T2D with self-management behaviors is associated with improvements in a wide range of outcomes including knowledge, self-care behaviors, weight, quality of life, hemoglobin A_{1c} (HbA_{1c}), all-cause mortality, and health care costs [13,14].

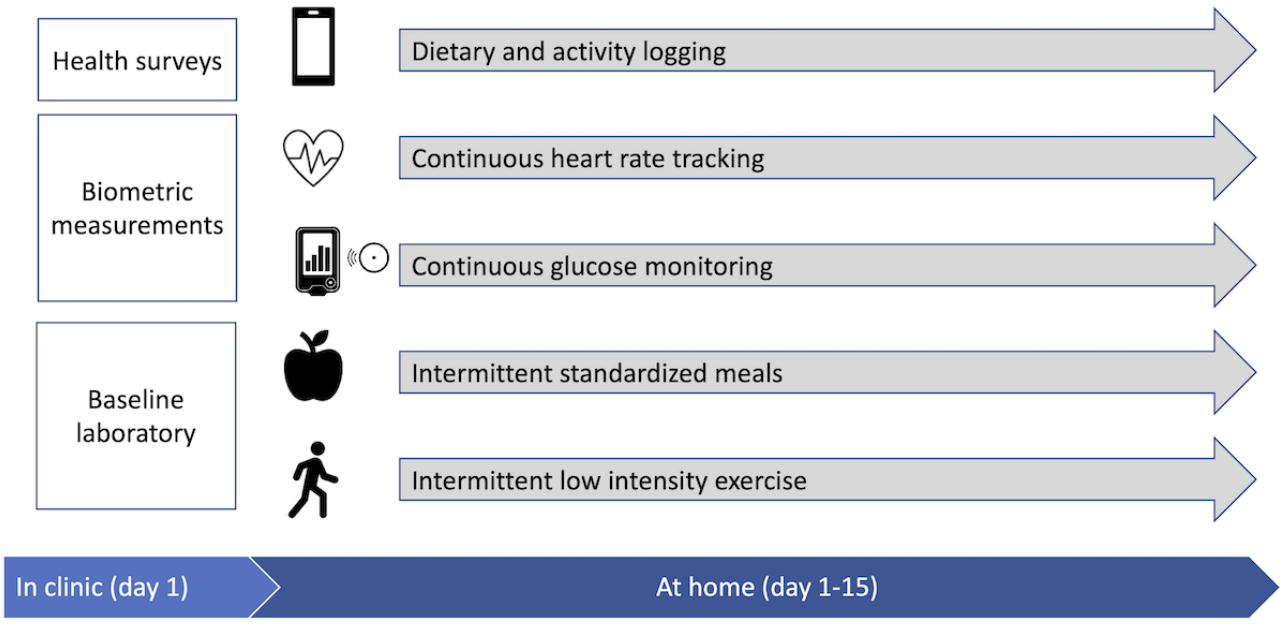
Guidelines recommend that nutritional guidance be personalized based on nutritional status, lifestyle, and metabolic goals [15]. Despite this, most dietary advice for individuals with T2D remains generic emphasizing reductions in calories and minimization of carbohydrates [16]. However, there are marked interindividual responses in postprandial glucose response (PPGR) [17]. A study conducted in Israel found substantial PPGR variability to standardized meals for individuals without diabetes [18]. Similar data has been generated in the United Kingdom, the United States, and China [19-21].

There have been no studies characterizing food responsiveness among individuals living in India and virtually no published data, from any judication, in the variability in PPGR for individuals with T2D [22]. Given the unique Indian diabetes phenotype and differences between Indian and western diets, in specific much higher rates of carbohydrate consumption overall [23] and the centrality of white rice and refined wheat [24], there are very likely to be differences in blood glucose responses to food and exercise in India than observed elsewhere, just as there have been in Indians' responses to diabetes medications [25]. Accordingly, the goal of this study is to characterize and identify factors associated the variability in PPGR among individuals with T2D in India.

Methods

This prospective cohort study seeks to evaluate the relationship between PPGR and self-management activities including diet, exercise, and other daily routines, for individuals with T2D in India (Figure 1).

Figure 1. Overall study design.



Study Setting

This trial is being conducted at 14 outpatient clinics in geographically distinct regions across India with population sizes ranging from 1.2 to 34 million. Sites were identified and managed by IQVIA, a multinational contract research organization, and were included if they specialized in the care of individuals with diabetes, had an established research infrastructure for the conduct of diabetes-related studies including a site principal investigator who is a diabetologist (with clinical training in endocrinology or internal medicine), a local ethics committee to provide study oversight, and a sufficient volume of potentially eligible patients. Study enrollment began in May 2022.

Eligible Participants and Enrollment

The study population consists of adults with diabetes and suboptimal disease control, classified as HbA_{1c} ≥7. Complete inclusion and exclusion criteria are summarized in Textbox 1.

Textbox 1. Eligibility criteria required for participants to be enrolled in the study.

Inclusion criteria

- Age ≥ 18 and <75 years.
- Physician-diagnosed type 2 diabetes treated with ≥1 oral hypoglycemic agents
- Hemoglobin A_{1c}≥ 7.0% recorded within the past 30 days.
- Mobile phone capable of running protocol-specified apps.
- Functional English literacy.

Exclusion criteria

- Unable or unwilling to provide informed consent or comply with the study-specified procedures.
- Current use of prandial insulin including a continuous insulin infusion pump.
- Currently pregnant or planning to become pregnant.
- Estimated life expectancy of ≤12 months.
- Active cancer.
- Myocardial infarction or stroke in the last 6 months.
- Receiving or planned to initiate dialysis for end-stage renal disease.
- Receiving oral or intravenous steroids.
- Any contraindication to using a continuous glucose monitor.

Potentially eligible patients are identified from clinic records and are invited to attend an in-person screening visit at which time eligibility is confirmed and written informed consent obtained. Consenting patients are asked to provide sociodemographic and medical information (specifically, age, sex, predominant diet, health conditions, family history, and current medications) and to complete baseline surveys including the World Health Organization's STEPwise Approach to Non-Communicable Disease Risk Factor Surveillance (STEPS) survey [26], World Health Organization-Five Well-Being Index (WHO-5) [27]. Diabetes Distress Scale [28], Wilson Adherence Scale [29], and the Pittsburgh Sleep Quality Index [30].

Biometric data including blood pressure, heart rate, weight, height, and body measurements at the upper arm, thigh, calf, waist, and hips, are collected by study coordinators at each site. Finally, enrolled participants provide blood samples including a complete blood count, HbA_{1c}, blood electrolytes, creatinine, cholesterol, as well as urinalysis.

After completing baseline assessments, participants are fitted with an Abbott Freestyle Libre continuous glucose monitors (CGM) sensor on their upper, nondominant arm and are provided with a Xiaomi Mi Band Smart Wristband (heart rate monitor) and a Roche Accu-Chek glucometer with testing supplies, and dietary supplements to be consumed with their standardized meals (refer to Follow-up Procedures section). Study-specific apps are downloaded on to the participants' smartphones to allow them to log dietary intake and synchronize their continuous glucose and heart rate monitors. As a back-up, participants are given a paper dietary logbook and a Freestyle Libre CGM reader with which to collect protocol-specified data.

Follow-Up Procedures

Participants are followed for 14 days. They are instructed to wear the CGM and heart rate monitor. The heart rate monitor is to be always worn, including during sleep, and only removed for recharging. Participants are also asked to check their capillary glucose on days 2 through 6 before breakfast and dinner.

Participants log their full dietary intake using the study app or logbook over the 14-day study period, including all standardized test meals and free-living foods (including snacks), beverages (including water), and medications. Participants also log all exercise.

Participants are required to consume protocol-specified meals and to perform light activity, as described in Table 1. The standardized meals consist of vegetarian breakfast foods which participants are to prepare in their homes.

The meals vary in their proportion of carbohydrate, fiber, protein, and fat (refer to Table 2).

Table 1. Meal schedule during the at-home study period.

Day and timing	Meal type
1	
Breakfast	Fasting
Lunch	As desired
Dinner	As desired
2	
Breakfast	Perceived healthy meal
Lunch	Post meal exercise
Dinner	Typical mixed protein with dinner
3	
Breakfast	Fiber supplement with standardized test meal
Lunch	Premeal exercise
Dinner	Alternative mixed protein with dinner
4	
Breakfast	Fiber supplement before standardized test meal
Lunch	As desired
Dinner	As desired
5	
Breakfast	Protein supplement with standardized test meal
Lunch	As desired
Dinner	Alternative mixed protein with dinner
6	
Breakfast	Protein supplement before standardized test meal
Lunch	Added fiber with lunch
Dinner	Alternative mixed protein with added protein
7	
Breakfast	Regular breakfast
Lunch	Added fruit
Dinner	Cooled carbohydrate
8	
Breakfast	Regular breakfast with added protein
Lunch	Added fruit with protein
Dinner	Regular carbohydrate
9	
Breakfast	Protein followed by carbohydrate
Lunch	Water 30 minutes before lunch
Dinner	As desired
10	
Breakfast	Standardized test meal
Lunch	As desired including dessert
Dinner	Protein followed by carbohydrates and vegetables
11	
Breakfast	Standardized test meal with postmeal exercise

Day and timing	Meal type
Lunch	As desired including desert and cinnamon
Dinner	Vegetables followed by protein then carbohydrates
12	
Breakfast	Standardized test meal with postmeal exercise
Lunch	As desired
Dinner	As desired finishing eating by 8 PM
13	
Breakfast	Water before late breakfast + postmeal exercise
Lunch	Low glycemic index lunch
Dinner	Low glycemic index dinner + finish dinner by 8 PM + exercise after meal
14	
Breakfast	Water before late breakfast + exercise after meal
Lunch	Low glycemic index lunch + exercise after meal
Dinner	Low glycemic index dinner + finish dinner by 8 PM + exercise after meal

Table 2. Nutritional composition of standardized test meals.

Meal characteristics	Meal type		
	Carbohydrate	Added fiber	Added protein
Example meal	2 aloo parathas with curd	2 aloo parathas with curd + fiber supplement	2 aloo parathas with curd + protein supplement
Energy (kcal)	474.4	506.4	594.4
Carbohydrate (g)	61.5	64.1	62.9
Fat (g)	12.5	12.5	14.6
Protein (g)	7.7	7.8	31.9
Fiber (g)	8.3	21.9	8.3
Carbohydrate (% energy)	51.9	50.6	42.3
Fat (% energy)	23.8	22.3	22.1
Protein (% energy)	6.46	6.05	21.4

Participants are instructed to fast for a minimum of 8 hours before and 3 hours after consuming the standardized breakfast meal; during these fasting periods, limit exercise and drink only still (not sparkling) water, tea, or coffee in moderation; and eat the meal, in its entirety, within 20 minutes. After completing the postmeal fasting period on standardized test meal days, participants may consume other foods as they normally would unless there are other meal modifications specified by the protocol later the same day.

On other days, participants are asked to consume normal foods with protocol-specified constraints. For example, on different days, participants vary the types of mixed protein (eg, different types of lentils with or without added protein), ordering with the type of foods consumed (eg, protein before carbohydrate vs protein with carbohydrate), consume water before their meal, go for a walk after eating, or eat what they perceive to be a healthy meal. Where applicable, participants are given several options as to which of their usual foods are acceptable for each protocol specified food modification.

During the follow-up period, participants are contacted by phone and text messages to ensure protocol compliance. For participants using the study-specific smartphone apps, a web dashboard is used to monitor the completeness of dietary logging and CGM scanning, with outreach to participants initiated when missing data is detected. Participants using paper logs and a CGM reader, and therefore for whom no dashboard information is available, are contacted daily to ask about protocol compliance. Ad hoc midstudy visits are used to further ensure accurate data collection. If the outreach identifies a problem with a CGM (ie, it was damaged, fell off, or malfunctioned), study staff provide a replacement within 24 hours during which time participants are asked to pause their meal protocol and restart once their CGM has been reapplied and recalibrated. If a test meal was not consumed as intended, participants are provided with the option to repeat the meal.

On day 15, participants are asked to remove their CGM. If need be, study staff help record or correct missing or inaccurate food, activity, and medication data.

Statistical Analysis Plan

The study's primary outcome is PPGR. Following the Wolever and Jenkins method [31], as adapted by Zeevi et al [18], Mendes-Soares et al [20], and Berry et al [32], logged meal times and continuous glucose measurements will be used to calculate the incremental area under the curve. Before conducting analyses, meals logged less than 30 minutes apart will be merged and meals logged within 90 minutes of other meals will be removed. Meals that are very small (<15 g and <70 calories), very large (>1 kg), with implausibly low PPGR values (ie, a PPGR < 5 mg/dL·h after consuming ≥ 40 g of carbohydrates), that are incompletely logged, and which are consumed in the first and last 12 hours of the CGM connection will also be removed. To reduce noise, the median of all glucose values from the 30-minute period before the meal will be taken as the initial glucose level, above which the incremental area will be calculated. Meals that had incomplete glucose measurements in the time window of 30 minutes before and 2 hours after the logged mealtime will be filtered out.

Descriptive statistics will be used to plot the range of PPGRs responses to standardized test meals as well as the correlation between PPGR and the nutritional composition of the logged meals (ie, carbohydrates, fat, and protein).

A machine learning predictor will be developed based on stochastic gradient boosting regression (XGBoost, version 2.2.1; The XG Boost Contributors) [33] using the XGBRegressor class. PPGR will be predicted as the sum of predictions from thousands of decision trees. Trees will be inferred sequentially, with each trained on the residual of all previous trees. The features incorporated in each tree are selected by an inference procedure from features representing meal content (ie, calorie, protein, carbohydrate, and fiber content), meal timing, baseline demographics (ie, age, sex, predominant diet, health conditions, family history, and current medications), baseline survey results (ie, WHO STEPS, WHO-5, Diabetes Distress School, Wilson Adherence Scale, and Pittsburgh Sleep Quality), baseline biometric values (ie, blood pressure, heart rate, weight, height, and body measurements at the upper arm, thigh, calf, waist, and hips), baseline laboratory values (complete blood count, HbA_{1c}, blood electrolytes, creatinine, cholesterol, and urinalysis), as well as CGM, heart rate, and activity data.

Performance will be assessed by holding out 30% of the sample and using 5-fold cross-validation in which cross-validation participants are divided into 5 groups, the model will be trained on the other 4 parts. Random datasets of the same size as the original will be sampled with replacement from the original dataset, and the entire training and validation process will be repeated. The performance will be measured by the ability to accurately predict meals reported by the held-out participants. Prediction results will be aggregated, and Pearson product moment correlation with the measured PPGRs will be reported. The SE for the calculated performance will be assessed using at least a thousand iterations of bootstrapping until the errors stabilize. Model discrimination will be assessed using a binary cut-point for PPGR, set at the 50th percentile of all observed PPGR values, plotting a receiver operating characteristic curve (ROC) and then calculating the area under the ROC.

Sample Size Considerations

A total of 1050 individuals will be targeted for recruitment. Assuming a 5% loss to follow-up, this corresponds to 1000 evaluable individuals at the end of the study. The study has been designed to predict postprandial glucose responses based on individual characteristics and 1000 participants followed for 14-days will result more than 4 million glucose readings (assuming glucose readings from the CGMs every 5 minutes) and 42,000 meals (assuming 3 meals per participant per day). This volume of data will also provide more than 80% power to detect correlations of a magnitude of r=0.13 (R^2=0.02) with P<.005. We will also be sufficiently powered to detect effects of r=0.17 (R^2=0.03, ie, explaining 2.7% of interindividual variation) with P<.001, that is, accounting for 5000 independent hypothesis tests.

Ethical Considerations

This study was approved by the following ethics committees at all institutions enrolling patients: SShrey Hospital Institutional Ethics Committee (DHINDIA_2021_01A04), Inamdar Multispecialty Hospital Ethics Committee (DHINDIA_2021_01A04), Neelima Hospitals Institutional Ethics Committee (DHINDIA_2021_01A04), Jaipur National University Institutional Ethics Committee (JNUIMSRC/IEC/2022/06), Maharaja Agrasen Hospital Institutional Ethics Committee EP/F-174), Ganesh Shankar Vidyarthi Memorial Medical College Ethics Committee (EC/72/March/2022), Mar Augustine Golden Jubilee Hospital Institutional Ethics Committee (DHINDIA_2021_01A04), Medisys Clinisearch Ethical Review Board, Dayanand Medical College and Hospital Drug Trials Ethics Committee (DMCH/DTEC/2020/1242), Chennai Meenakshi Multispecialty Hospital Ethics Committee (CMMHEC/22/02), Sparsh Hospital Institutional Ethics Committee (ZZA78309), Medical College of Kolkata Institutional Ethics Committee (MC/KOL/IEC/SPON/1296/03/22), Ethics Committee Downtown Hospital, and CHL-Hospitals Integrity Ethics Committee.

Results

Data collection commenced in May 2022, and the results will be ready for publication by October 2025. Results from our study will generate data to facilitate the creation of machine learning models to predict individual PPGR responses and to facilitate the prescription of personalized diets for individuals with T2D.

Discussion

Study Implications

This study will provide the first large scale examination of variability in blood glucose responses to food in India and will be among the first to estimate PPGR variability for individuals with T2D in any jurisdiction. We hypothesize that there will be substantial interindividual variability in PPGR and that, based on the data collected from this study, machine learning models will be able to accurately predict individual PPGR responses.

This will facilitate the prescription of truly personalized diets for individuals with T2D.

These results will be particularly important in the context of the rapidly rising prevalence of T2D in India [34]. Along with medications and physical activity, diet is a key tenant of effective blood glucose control [15]. Like in other jurisdictions, guidelines call for individualization of meal planning, which is sometimes referred to as "Medical Nutritional Therapy." Despite this, personalization of dietary plans are generally based upon broad constructs like age, activity level, health status, and preferences, and, for all patients, tend to emphasize overall calorie reductions and minimization of carbohydrate [16]. especially added sugars and refined grains, in favor of the consumption of nonstarchy vegetables and foods that are high in protein [35].

However, emerging data demonstrates that there are marked interindividual responses to food [17], attributed to differences in physical activity [36], gut microbiome [18,19,37], and genetics [38], including in variations in skeletal glucose transporters related to insulin resistance [39]. For example, a study conducted in the United States among nondiabetic individuals with a mean BMI of 27 found PPGR to a standardized meal of bagel and cream cheese ranged from 6 to 94 mg/dL·h [20]. A similar study conducted in Israel enrolled nondiabetic individuals of whom 3-quarters had a BMI ≥ 25 and found mean PPGR to bread and butter of 44 mg/dL·h but the bottom decile had responses of ≤ 15 mg/dL·h and the top decile has responses ≥ 79 mg/dL·h [18]. Similar data have been generated for individual without diabetes in the United Kingdom and the United States [19,20], and for individuals with type 1 diabetes in Israel [40].

There is exceptionally limited data for variability in PPGR for individuals with T2D in the peer-reviewed although it is highly likely that such variability exists [22]. The primary goal of our study is to fill this void and to generate an India-specific machine-learning models on the basis of which PPGR can be predicted with high accuracy for T2D. Similar models have been built in other jurisdictions. For example, a machine learning algorithm trained on CGM data, dietary, activity, anthropometrics, and gut microbiota for nondiabetic individuals in Israel was much more accurate at predicting PPGR than generic models based on the carbohydrate content or the amount of calories in a meal [18]. A separate US-based study had similar findings [20].

Among individuals with diabetes, a study in the Netherlands that included a small number of individuals with T2D along with individuals with prediabetes and normal glucose metabolism, a machine learning model based on CGM data was highly accurate in predicting future glucose values but this study did not specifically evaluate the ability to predict PPGR [41]. A US study of 1000 patients of whom 1-quarter had T2D found that a machine learning model trained on CGM, HRM data and food logs was highly accurate at predicting PPGR but this study has, to our knowledge, only been published in abstract form [22]. These studies have all relied on CGM data to make their predictions. While these devices are increasingly used, practice guidelines do not recommend their long-term use for most individuals with T2D [42]. Accordingly, a key goal of our study will be to explore the ability to predict PPGR response without reliance on CGM data or with very limited blood glucose data from patients.

Limitations

There are several limitations to our approach. Our approach is purposely pragmatic and is intended to simulate real-world circumstances for individuals with T2D living in India. Similar to studies conducted in other jurisdictions, we rely on self-reported dietary and activity information. And, while we are auditing patient logs on an ongoing basis, there may nevertheless be issues with protocol adherence that may undermine the accuracy of the data we collect. Participants are being recruited from clinics, predominantly caring for individuals with diabetes, are required to have functional English literacy and a cellphone capable of running study specific devices. Thus, our results may not be fully generalizable to patients who do not fulfill these criteria. Finally, some of the enrollment has overlapped with the COVID-19 pandemic, which may have influenced access to health care, dietary practices, and glucose control for individuals with T2D.

Conclusion

In conclusion, this study will provide the first large scale examination variability in blood glucose responses to food in India and will be among the first to estimate PPGR variability for individuals with T2D in any jurisdiction. Results from our study will generate data to facilitate the creation of machine learning models to predict individual PPGR responses and to ultimately facilitate the prescription of truly personalized diets for individuals with T2D.

Acknowledgments

The authors wish to thank the site investigators and patients participating in the study as well as IQVIA for their assistance identifying study sites and overseeing the study conduct. This work is supported by Decipher Health, Inc.

Data Availability

The datasets generated during and analyzed during this study are not publicly available as they will be used for commercial application. Data may be available on reasonable request after executing appropriate data use and licensing agreements.

Authors' Contributions

All authors meet International Committee of Medical Journal Editors (ICMJE) criteria. NKC had overall responsibility for the study design and drafted the trial protocol and manuscript. MM is the co-principal investigator, had overall responsibility for the study design, and helped draft the study protocol and manuscript. SP and JS contributed meaningfully to study design and implementation as well as the manuscript. All authors contributed to the refinement of the study protocol and approved the final manuscript.

Conflicts of Interest

NKC and JS receive consulting fees and hold equity in Decipher Health. SP is an employee of Decipher Health. MM is an employee and holds equity in Decipher Health.

Abstract

Background: Heart failure (HF) is a chronic, progressive condition where the heart cannot pump enough blood to meet the body's needs. In addition to the daily challenges that HF poses, acute exacerbations can lead to costly hospitalizations and increased mortality. High health care costs and the burden of HF have led to the emerging application of new technologies to support people living with HF to stay well while living in the community. However, many digital solutions have not involved consumers and health care professionals in their design, leading to poor adoption. The SmartHeart project aimed to codevelop a smart health ecosystem to support the early detection of HF deterioration and encourage self-care, potentially preventing hospitalizations.

Objective: This study aims to provide an overview of the SmartHeart project by describing our approach to designing the SmartHeart system, outlining its features, and describing the planned pilot study to determine the feasibility of the system.

Methods: We used the Integrate, Design, Assess, and Share (IDEAS) framework to guide the development of the SmartHeart system, involving users (people with HF and their caregivers) and stakeholders (health care providers involved in the management of HF) in its design. SmartHeart is a complete remote heart health monitoring and automated feedback delivery system. It includes 2 user interfaces for patients: an Amazon Alexa conversational agent and a smartphone app. The system collects physiological, symptom, and behavioral data through wireless sensors and self-reports from users. These data are processed and analyzed to provide personalized health insights, self-care support, and alerts in case of health deterioration. The system also includes a web-based user interface for health care professionals, allowing them to access data, send messages to users, and receive notifications about potential health deterioration. A single-arm, multicenter pilot trial (N=20) is planned to determine the feasibility and acceptability of SmartHeart before evaluation through a randomized controlled trial. The primary outcome will be a description of the study's feasibility (recruitment, attrition, engagement, and changes in self-care).

Results: The SmartHeart study started in January 2021 on procurement of funding. Recruitment for the pilot trial started in August 2024 and will be completed by March 2025. We have currently enrolled 12 participants. Follow-up of all participants will be completed by the end of May 2025.

Conclusions: We have co-designed and developed a complete remote heart health monitoring and automated feedback delivery system for the early detection of HF deterioration and prevention of HF-related hospitalizations. The next step is a pilot study, which will provide valuable information on feasibility and preliminary effects to inform a larger evaluation trial. SmartHeart has the potential to augment existing health services and help people with HF stay well while living in the community.

Introduction

Burden of Heart Failure and Importance of Self-Care

Heart failure (HF) is a complex life-threatening syndrome associated with high mortality and morbidity, poor quality of life, diminished functional capacity, and substantial health care burden [1,2]. HF affects over 64 million people worldwide [1]. People with HF experience debilitating symptoms, including shortness of breath and fatigue, which significantly impact their daily activities and quality of life [3]. Beyond these persistent daily challenges, individuals experience acute exacerbations, that frequently necessitate hospitalization [4]. These hospitalizations are strongly correlated with increased mortality. In Australia, data indicates that individuals experiencing acute HF exacerbations requiring hospitalization face a 50% reduction in their remaining life expectancy (10 years for those aged 65-75 years) [5]. Research suggests that two-thirds of HF-related hospital admissions could be prevented by enhanced coordination of postacute care and improved self-care [3]. Self-care refers to the process of maintaining health through health promotion and preventive practice [3]. While international guidelines make self-care integral for HF management, people find managing their condition while living in the community difficult, and adherence to clinical guidelines is poor [3].

Toward a Smart Health Ecosystem

There is an urgent need for new scalable models of person-centered health care in which care for long-term conditions such as HF shifts from the clinic to the home [6]. The COVID-19 pandemic was a catalyst for swift, wholesale change to the way we view and provide health care; there has been a significant increase in the use of telehealth and online care services, increased acceptance of digital health technologies by the medical community and the public, and broader recognition of the need to embrace digital health approaches to create a resilient health care system [6]. However, despite the potential for digital health to improve HF management [7], previous approaches to designing digital health interventions have largely failed to include patients and clinicians [8]. This can lead to lower levels of program adoption by users and increased dissatisfaction, stress, and nonadherence [9].

We previously argued for a smart health ecosystem, a holistic approach to support people living with long-term conditions that incorporate sensing, processing, and communication technologies [7]. Such an ecosystem uses a comprehensive network of internet-connected sensors (referred to as the Internet of Things) to collect data about the patient in the home [10,11] and processes these data to provide near–real-time individualized monitoring. It also uses predictive models to anticipate the need for medical intervention (eg, when detecting warning signs of decompensation) and support with self-care activities. While many of these discrete technologies exist, we bring them all together into a single system (named SmartHeart) to support people to better manage their HF at home and in the community. It is proposed that such a system can help maintain health outcomes, improve quality of life, promote independence, and reduce carer burden [12,13].

In this article, we present an overview of the SmartHeart project and describe its design and development approach. We provide a detailed description of the SmartHeart system and outline the planned pilot study to evaluate its feasibility and acceptability.

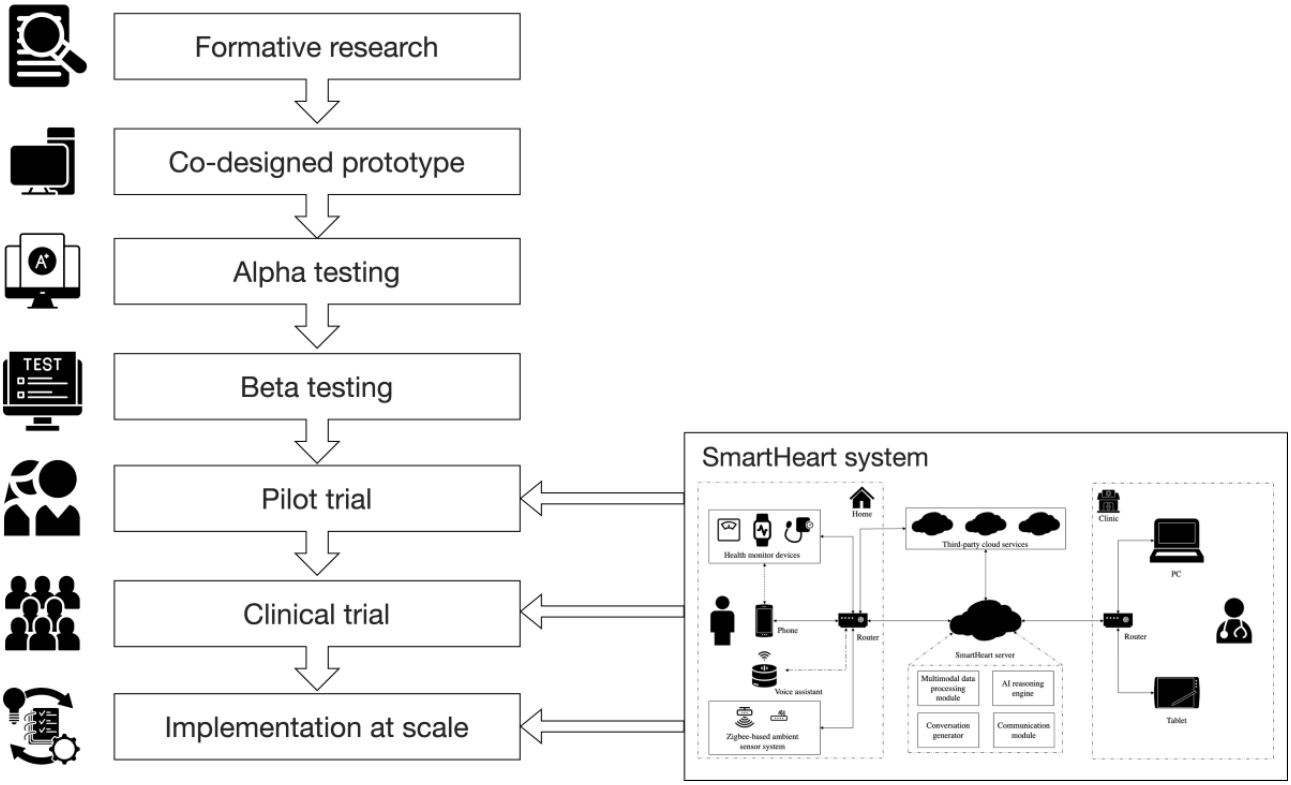
Methods

SmartHeart Project

To guide the SmartHeart project, we used the Integrate, Design, Assess, and Share (IDEAS) framework [14]. The IDEAS

framework is an intervention-specific framework for the development of digital interventions, fitting the nature of our proposed intervention [15]. Moreover, the framework combines behavioral theory with design thinking, which are complementary perspectives that can promote the acceptance and adoption of an intervention [15]. The IDEAS framework proposes ten steps: (1) empathize with target users, (2) specify target behavior, (3) ground in behavioral theory, (4) ideate implementation strategies, (5) prototype potential products, (6) gather user feedback, (7) build a minimum viable product, (8) pilot potential efficacy and usability, (9) evaluate efficacy in a randomized controlled trial (RCT), and (10) share intervention and findings [14]. In addressing steps 1-7 of the IDEAS framework, we undertook a range of studies to co-design and develop the SmartHeart system. As part of step 7, build a minimum viable product, we undertook an additional alpha- and beta-testing phase. The methods and results of these studies are briefly described in this article and the development studies are reported in full elsewhere [16,17]. The protocol for step 8 of the IDEAS framework, pilot potential efficacy and usability, is presented later in this article and will inform the design of a larger hybrid RCT to assess the effectiveness and implementation of SmartHeart, which we hope will guide subsequent delivery at scale. Figure 1 presents the phases of the overall SmartHeart project.

Figure 1. Phases of the SmartHeart project.



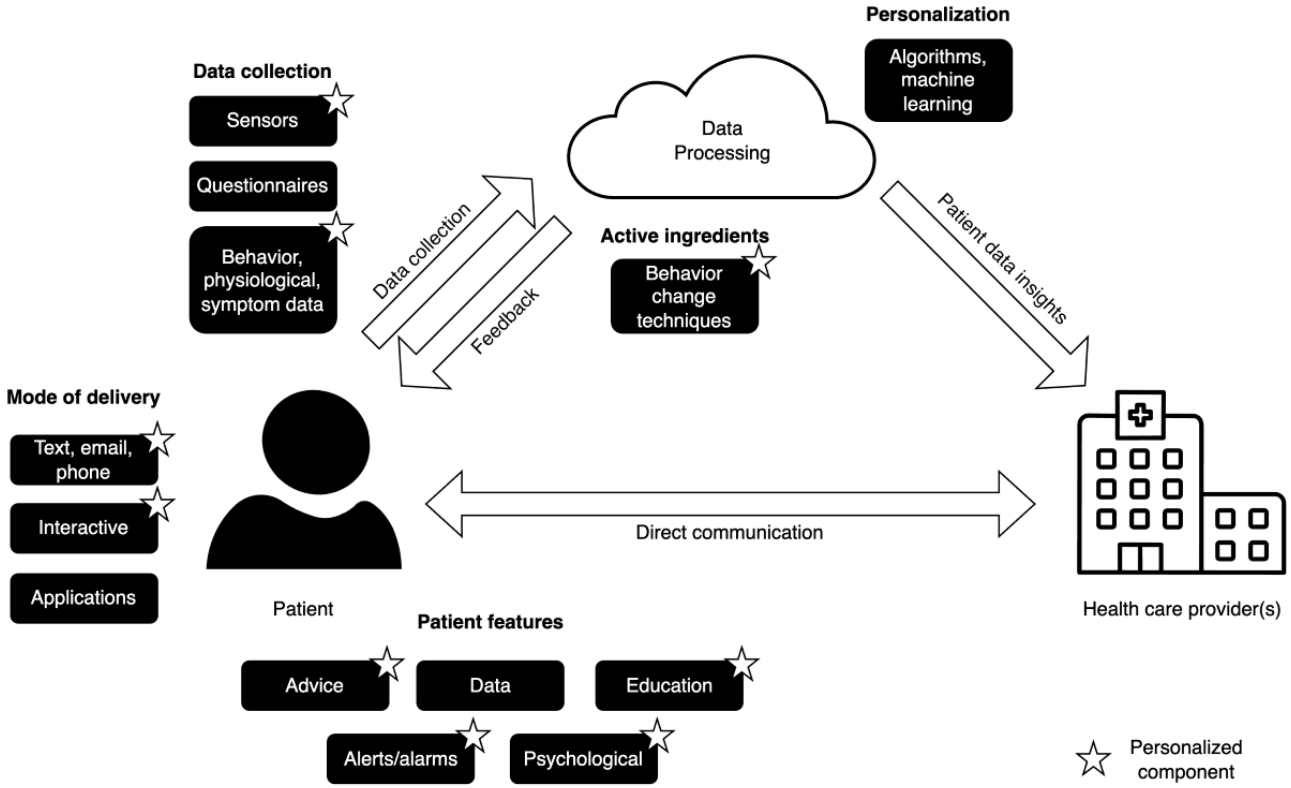
Approach to Designing the SmartHeart System

As part of the formative research phase, we conducted a scoping review of existing smart health ecosystems to support people with HF [18]. This study allowed us to identify data collection, personalization, behavior change, patient-facing, and mode of delivery features of similar interventions (refer to Figure 2). These features provided us with initial ideas for the SmartHeart system.

Then, we sought to better understand the lived experiences of individuals with HF in the community and the self-care strategies they used. This involved conducting in-depth interviews with individuals living with HF (n=9) [17]. Following this, we explored potential components and features for SmartHeart from the user perspective through workshops with individuals living with HF (n=16) and their caregivers (n=4) [16]. To identify consensus-based recommendations for potential intervention features, we used the Delphi method with 15 health care providers with experience caring for people with HF (eg, general practitioners (GP), cardiologists, nurses, pharmacists, and physiotherapists) [19]. We also conducted in-depth interviews with health care providers (n=9) [20].

Building upon these findings, we refined the SmartHeart prototype through a series of co-design workshops. Specifically, we conducted 4 co-design workshops with health care providers (n=15) to gain insight into how the system would work in practice and to refine the initial prototype [16]. Subsequently, 2 further co-design workshops were conducted with people with HF (n=6) to inform the user-facing app features, and optimize the overall design look, feel, and navigation logic.

Figure 2. Intervention features identified in the scoping review.



On completion of the SmartHeart prototype, we conducted alpha testing to evaluate the system's core functionalities, user interface, and performance under controlled conditions. For alpha-testing, four members of the research and development team used the system for 6 weeks, which allowed us to assess the system's responsiveness and identify and resolve any technical issues. Then, beta testing was undertaken to assess the system's responsiveness, data accuracy, and user experience. For beta testing, 5 people with HF used the prototype system for 4 weeks. Participant feedback from this testing was used to improve system onboarding, app performance, and data visualization.

SmartHeart System

In undertaking the design and development process outlined above, we developed the SmartHeart system (herein, SmartHeart), a smart health ecosystem to support the early detection of HF deterioration and prompt action by users with the aim of preventing HF-related hospitalizations. SmartHeart comprises components for patients (and their caregivers) and healthcare providers (ie, cardiologists, HF nurse practitioners, or other nurses).

Patient Components

User interface: Patients and caregivers interact with SmartHeart through an Amazon Alexa Echo Show 8 (second generation), featuring an 8-inch HD touchscreen, which serves as the primary user interface and conversational agent (Figure 3). In addition, a bespoke smartphone app (Figure 4), offers an alternative interface when Amazon Alexa is not available, such as when users are away from home. Amazon Alexa was selected based on access, ease of deployment, and programmability. In its current form, Amazon Alexa can facilitate interaction with people in their own language (currently 9 languages available). The smartphone app also supports multiple languages (for initial testing, we have included Hindi and Mandarin) and time zones.

Figure 3. Screenshots of SmartHeart conversational agent.

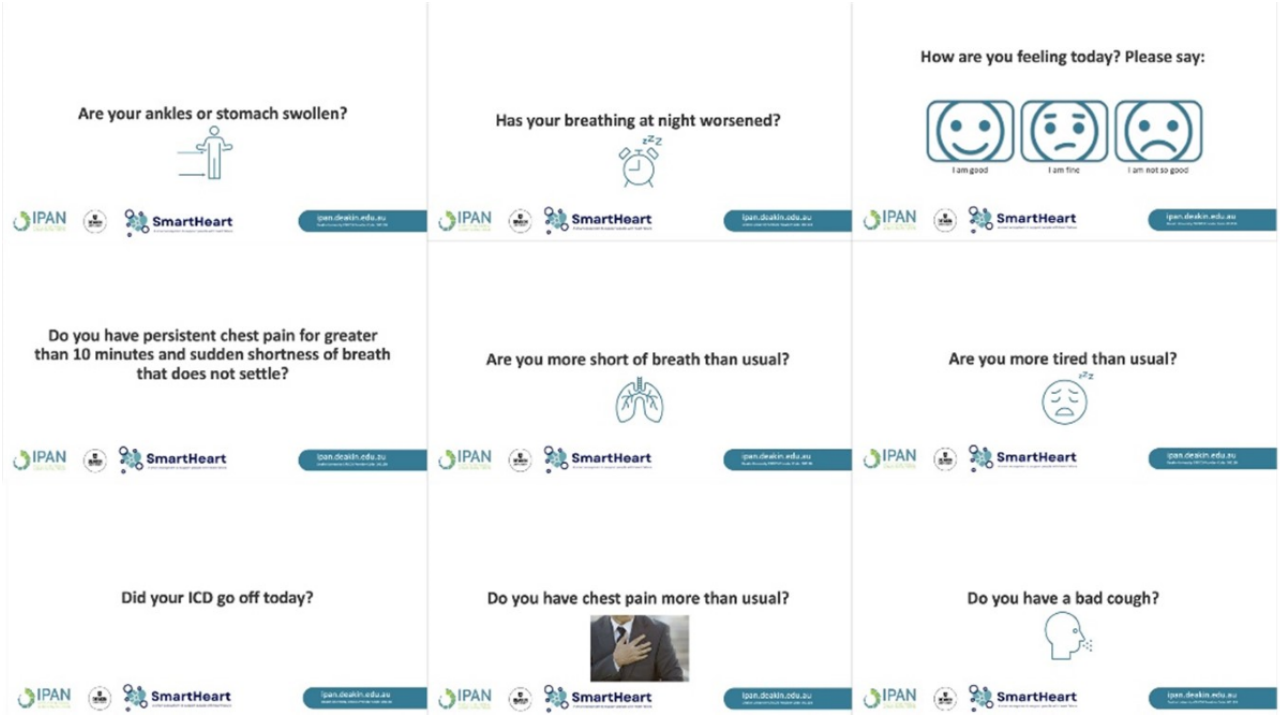


Figure 4. Screenshots of the SmartHeart app.

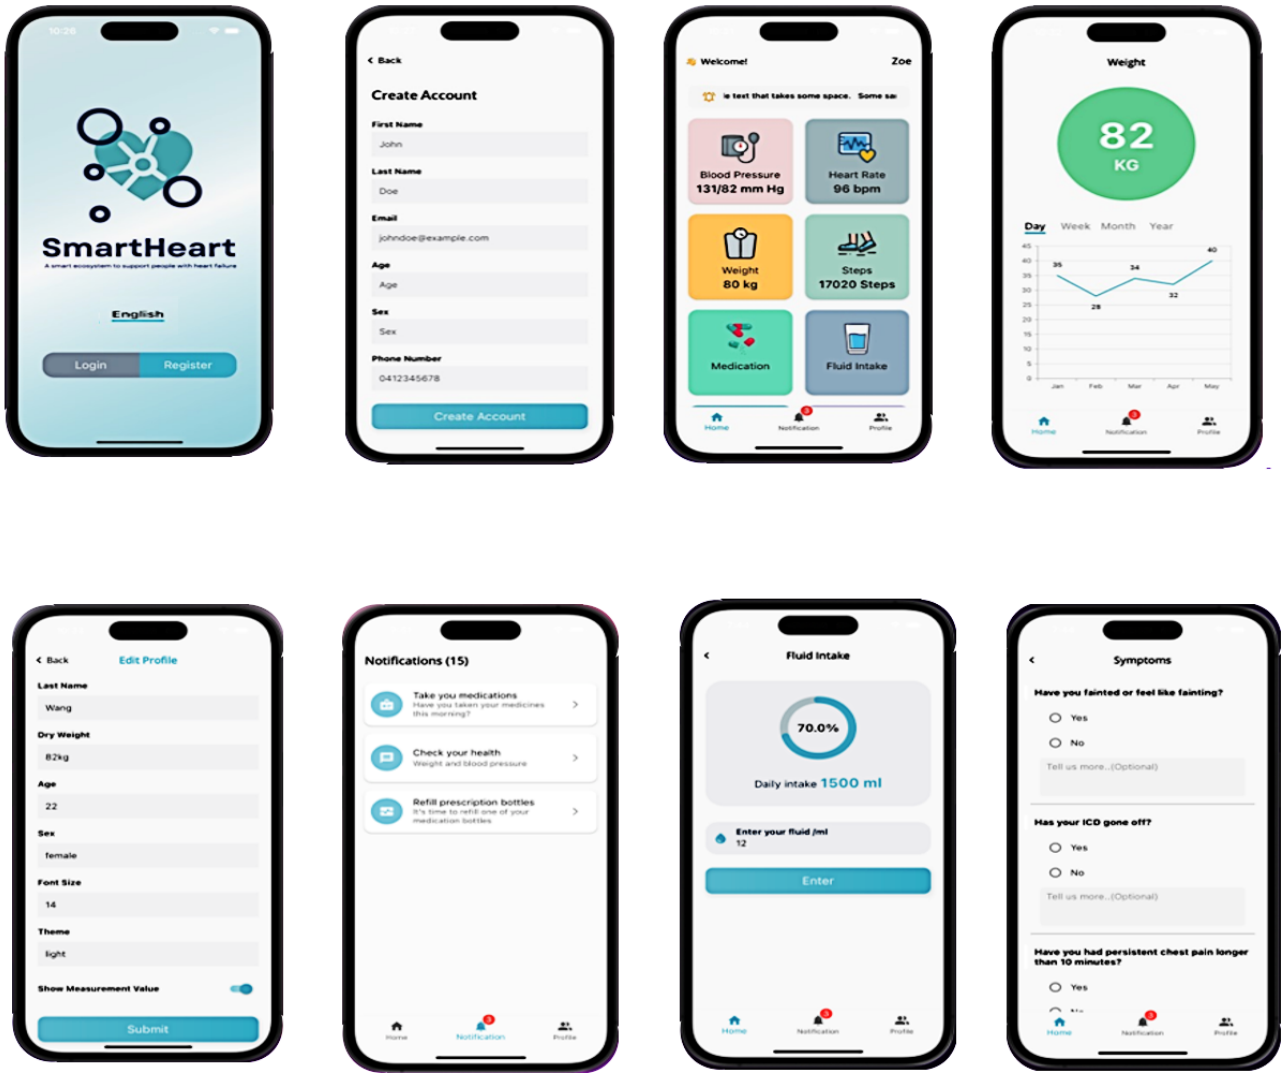

Data Collection

SmartHeart will collect physiological, symptom, and behavioral data through wireless sensors and self-reports. The sensors included and the parameters they measure are outlined in Table 1. Users can also self-report symptoms at any time through the Amazon Alexa or smartphone app. Amazon Alexa will also periodically check in with users through timed ecological momentary assessments to gather feedback on symptoms [21]. The symptom questions are based on current practice, which involves people with HF completing a paper and pencil diary on standard symptoms (eg, shortness of breath, dizziness, cough).

To collect data on medication use, we use a proxy measure of medication access, as measured through a Philips Hue infrared motion sensor placed at the site of medication storage (eg, cupboard, drawer). This sensor will timestamp potential medication access. This approach was adopted to account for the heterogeneity of medications taken and strategies used by participants in managing their medications [16,17]. The pilot study described below will allow us to determine the feasibility of this approach. The motion sensor is connected to the Philip hub using Zigbee, a low-power wireless mesh network for connected devices. The Philips hub handles data transmission to the cloud.

Table 1. Wireless sensors and parameters measured.

Sensor	Parameter
Withings blood pressure monitor connects wireless blood pressure monitor	Blood pressure
Samsung Galaxy Watch Pro 5	Heart rate; activity levels (including physical activity, inactivity, and activities of daily living)
Withing's Body Smart Bluetooth scales	Weight
Phillips Hue infrared motion sensors	Medication access (as a proxy for medication use)

Support Features

The SmartHeart system offers a wide range of features aimed at supporting the early detection of HF deterioration and encouraging proactive self-care.

Through Amazon Alexa, users can access educational materials on topics such as healthy eating and heart health, and a home-based physical activity program. They can also set their own reminders for tasks such as taking medication, monitoring weight and blood pressure, monitoring mood, and attending health care appointments. Health data are presented to users in the form of graphs and charts, allowing them to track and self-monitor their health over time.

SmartHeart delivers alert messages according to a matrix of possible outcome states from all combinations of sensor and symptom measurements and a corresponding rule set to define conversational agent actions. We developed the matrix based on previous work [22], but it was modified to align with the Australian HF Guidelines [2]. Alert messages and actions associated with each outcome state were validated during a face-to-face user panel workshop with health professionals (cardiologists, HF nurses, physiotherapists) at 3 hospitals (Royal Brisbane and Women's Hospital, Bendigo Hospital, and Austin Hospital). For example, combinations of blood pressure, weight gain, and symptoms corresponding to a critical or urgent outcome state (Figure 5) will notify patients via the conversational agent (or smartphone app) to seek immediate medical support and prompt a text message to HF nurses to review data via the health care provider interface.

The numbers represented in Figure 5 are various patient alert messages (see Table 2).

Based on HF guidelines [2] and previous text messaging research in heart disease [23], we also developed a package of self-care support comprising data-driven and nondata-driven messages. In response to sensor data and self-reported symptoms, users will receive educational support and prompts to modify key self-care activities. For example, if the combinations of blood pressure, weight, heart rate, and symptoms correspond to a normal outcome state (Figure 5) users would receive personalized HF education. Alternatively, if low physical activity levels and high fluid intake were recorded, SmartHeart would prompt users to reduce fluid intake and increase their step count. This educational support and prompts will be delivered by the conversational agent or smartphone app.

In addition, users will receive regular unidirectional push notifications through the SmartHeart app only. These push notifications, delivered twice a week (1 message per day on Monday and Friday) are not data-driven and aim to encourage users to take their medication, eat a healthy diet (eg, low salt), manage their fluid intake, participate in physical activity, and reduce sedentary behavior (Textbox 1). Content for these nondata-driven notifications was adapted from our previous interventions [24,25]. Participants can opt in or out of receiving push notifications by toggling this feature on or off through the smartphone app.

Figure 5. Matrix of outcome states from possible combinations of measurements. The numbers represented in Figure 5 are various patient alert messages (refer to Table 2). Ab: abnormal; BP: blood pressure; HR: heart rate; N/A: not applicable; N: normal.

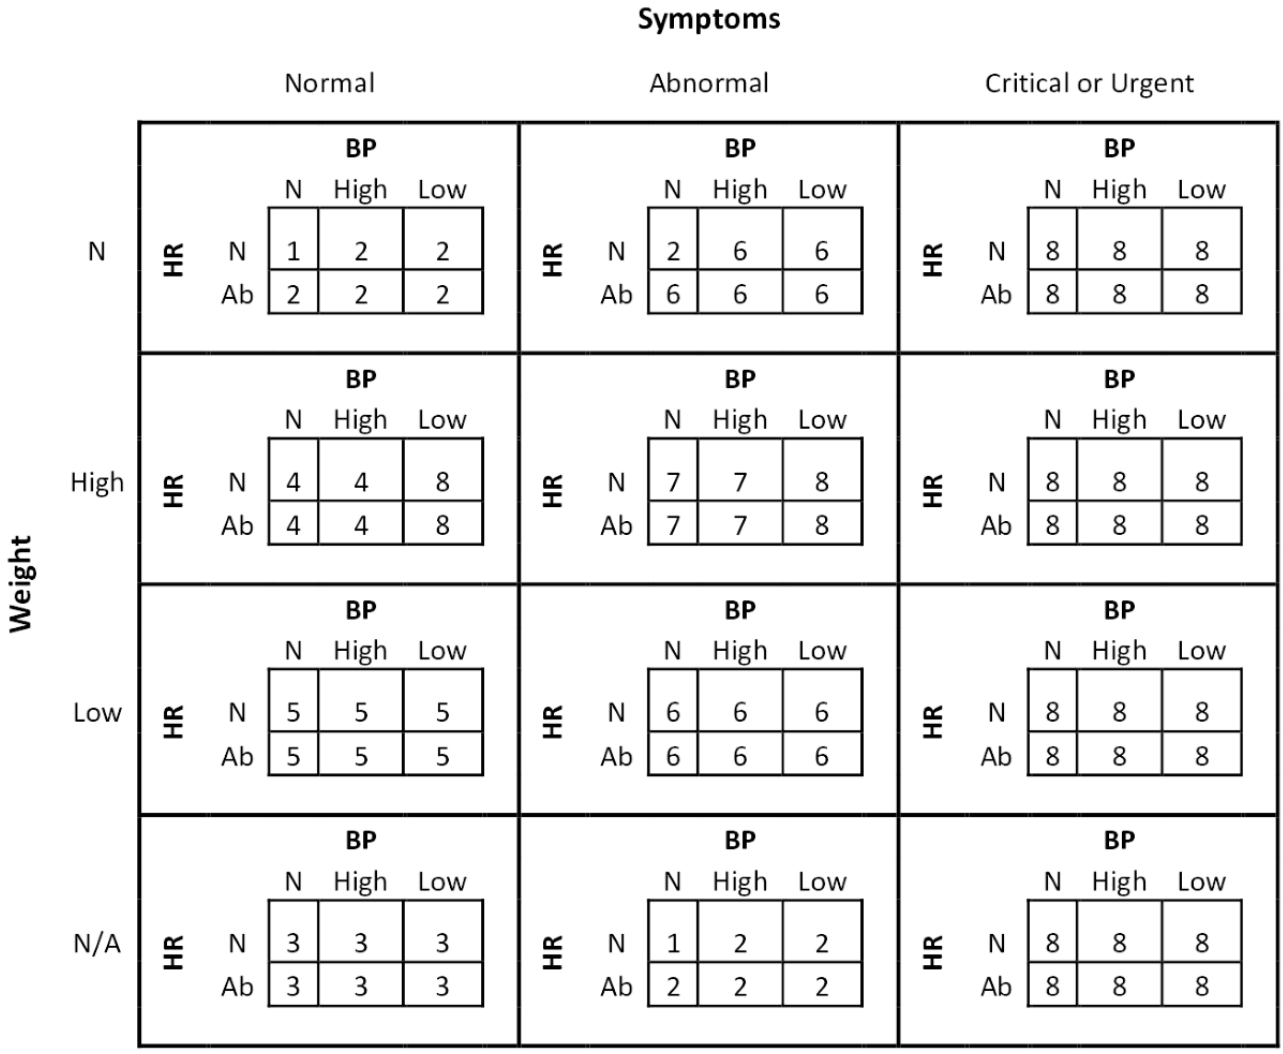

Table 2. Examples of alert messages provided through SmartHeart.

Message number	Example message
1	“Your measurements are fine today”
2-3	“If you feel worse later today, use the system to record your symptoms”
4-5	“Contact your Heart Failure Nurse or General Practitioner (GP). Follow doctor’s orders. Restrict salt and fluids.”
6-7	“Contact your GP now or go to the emergency department if you feel you should. Follow doctor’s orders. Restrict salt and fluids”
8	“Call 000 now”

Textbox 1. Examples of regular SmartHeart unidirectional push notifications by category.

Health

- How much time do you spend sitting every day? Decreasing the amount of time you spend sitting can improve your heart health, even if you engage in regular exercise.
- Although physical activity is useful for heart health, taking the first step can be the biggest challenge. Choose a physical activity that you like, anything that makes you more active.
- Think about barriers that can stop you from being active. Choose an activity that is more fun. Some people find it useful to invite a friend or a family member to join their daily exercise.

Medication adherence

- Encountering obstacles with your medication regimen? You don't need to tackle these challenges by yourself. Your doctor is there to provide assistance.
- Consistently taking your medications is essential for effectively managing your heart condition and preserving the associated benefits.
- Consistently adhering to your medication regimen is essential in managing your condition. If you believe you're having side effects, it's crucial to discuss it with your doctor. They could recommend a different medication that suits you more effectively.

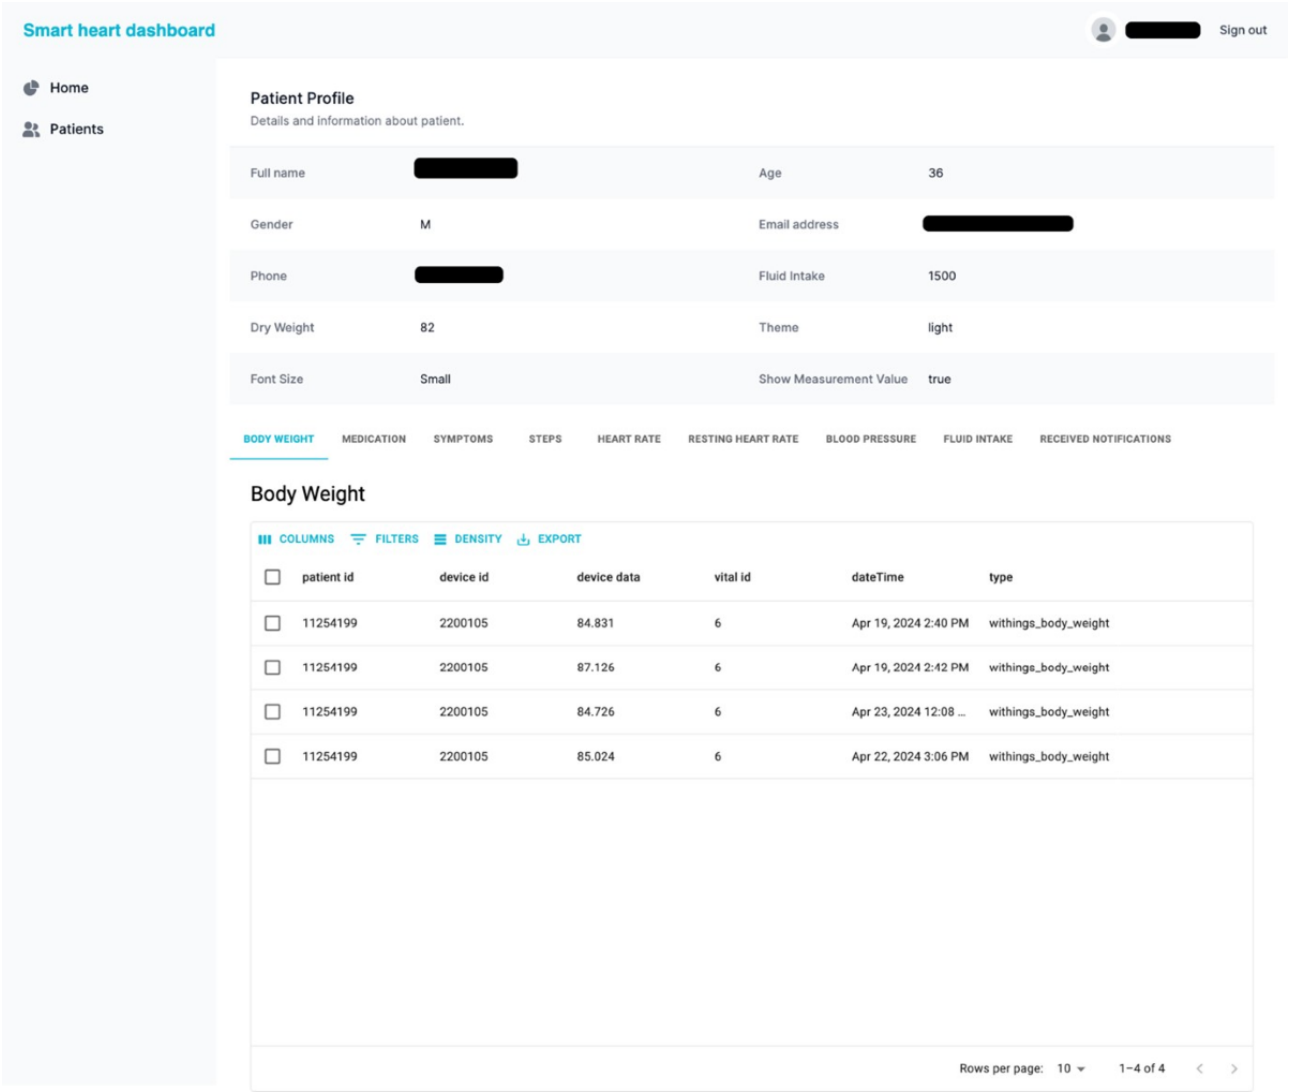
Refill prescription bottles

- Running out of your medication could lead to a few days without it, but this is a preventable situation. Stay prepared by marking your next prescription refill date on your calendar or setting a reminder on your mobile phone.
- Ensuring the continuous availability of your medications is a crucial measure, so be certain you're aware of the upcoming refill date. Incorporating a calendar reminder can be a valuable prompt when required.
- Think about where it would be most suitable for you to store extra medications as a backup strategy.

Health Care Provider Components

Health care providers (ie, cardiologists, HF nurse practitioners, or other nurses) access the SmartHeart web-based user interface to register participants, review health data, and view notifications patients have received. If necessary, and according to clinical practice, health care providers will contact patients directly by telephone (Figure 6).

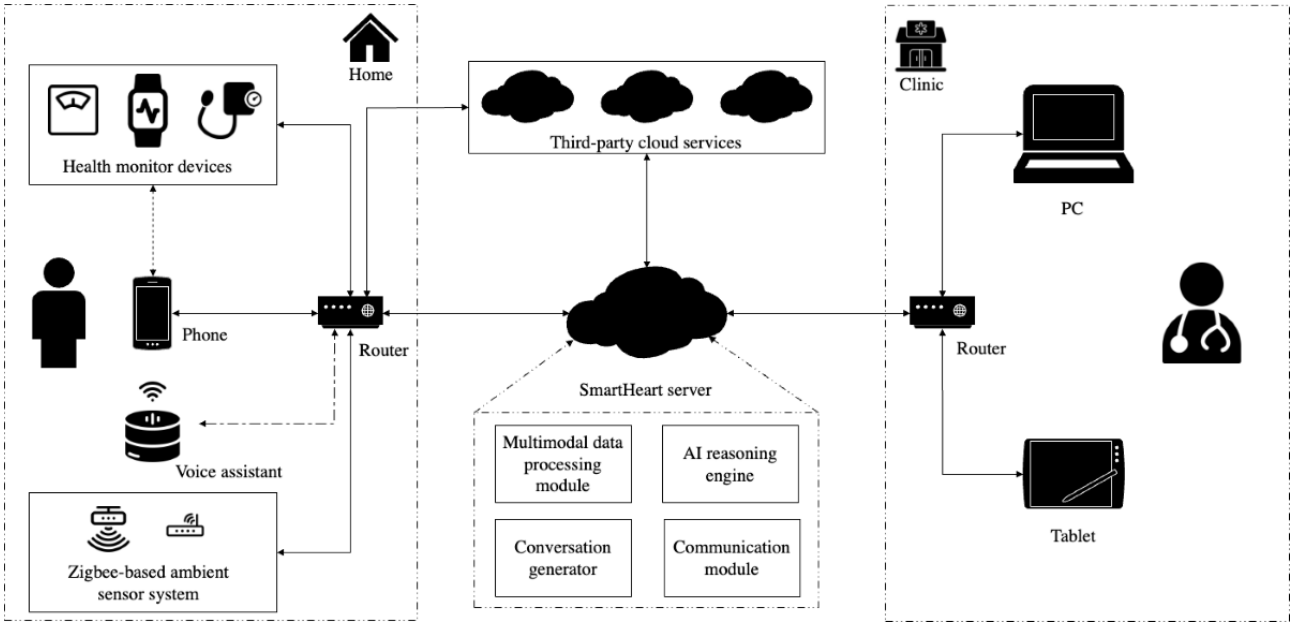
Figure 6. Health care provider interface.



System Architecture and Functions

Cloud-to-cloud integration connects and transmits users' data from third-party (sensor vendor) clouds to the SmartHeart data processing server (Figure 7). This server processes multimodal data (ie, health monitoring device data and self-reported symptoms), and makes logical inferences to generate personalized recommendations for the users in different formats (ie, conversation and report). It also handles all data transmissions between end users and clinicians. Data collected through SmartHeart are stored in a secure cloud-based server hosted in Australia. All data capture, storage, and transmission are secured using state-of-the-art encryption technologies according to Health Insurance Portability and Accountability Act requirements.

Figure 7. SmartHeart system architecture. AI: artificial intelligence.



SmartHeart Pilot Study Protocol

Objectives

This pilot study aims to assess the feasibility and acceptability of SmartHeart and inform the design of a larger hybrid RCT to assess effectiveness and implementation outcomes.

Sample Size

The sample size for pilot feasibility studies should be based on practical considerations including participant flow, budgetary constraints, and the number of participants needed to reasonably evaluate feasibility goals [26]. For this study we aim to recruit a total of 20 participants, which will be sufficient to determine the feasibility of delivering SmartHeart, allowing for exploration of participant feedback regarding acceptability, usability, and uptake.

Participants and Eligibility Criteria

Participants will be 20 adults (aged 18 years or more) with a documented clinical diagnosis of HF, outpatients at the time of recruitment, with access to the internet, and able to read and understand the English language (for informed consent purposes) will be eligible. SmartHeart support is available in multiple languages, so people for whom English is not a first language can use it. Individuals will be excluded if they have difficulty communicating with study personnel or a conversational agent due to speech or untreated hearing problems; are planning to be away from home for ≥4 weeks during the intervention; have progressive neurological disorders including Parkinson Disease and multiple sclerosis; have schizophrenia or bipolar disorder; have renal disease requiring dialysis; have any other disorder of such severity that life expectancy is less than 12 months; or have any cognitive or physical impairment or disability that in the opinion of either the participants' GP or specialist, or the study investigators would result in the participant having difficulty interacting with SmartHeart without support.

Recruitment Process

Participants will be identified by clinical staff at the 2 participating sites (Austin Health and Bendigo Health in Victoria). Research nurses at study sites will identify eligible individuals before hospital discharge and through outpatient cardiac clinics. Nurses will provide potential participants with information and consent forms and refer interested individuals to the research team. Approximately one week after the provision of study information, a researcher will confirm interest, answer questions, and schedule a baseline assessment if individuals indicate an interest in consent.

Procedures

SmartHeart will be installed in participants' homes and demonstrated by a trained researcher. Written, verbal, and audio-visual support will be provided to help participants engage with the system. A loan phone (Android) will be provided free of charge to those who do not own one. With the help of SmartHeart, participants will be asked to record daily measurements of weight and blood pressure and answer questions about their symptoms. All participants will have access to their usual cardiology and general practice care throughout the course of the study.

For this study, HF nurses will have access to the clinician portal through which they can review participants' data, including notifications. HF nurses will receive email notifications to alert them of potential changes to the participants' HF condition. Australian HF guidelines and best practices will be followed when responding to notifications. HF nurses will be available to review sensed data and respond to notifications during their working hours; however, SmartHeart will alert participants to contact their GP as first contact.

Data Collection

Data will be collected at baseline and the end of the 8-week intervention period using self-reported questionnaires and qualitative interviews (refer to Table 3 for an overview).

In addition, to the items in Table 3, a qualitative researcher will conduct one-to-one in-depth interviews with all participants, their caregivers (if applicable), and health care providers involved in the delivery of SmartHeart. Interviews will be based on the UK National Institute for Health and Care Excellence (NICE) Evidence framework for digital health technologies [27] and will address acceptability, demand, practicality, frequency of monitoring, burden to participants, potential of provoking anxiety, scenarios in which the program would be best employed, compliance with functional components, facilitators, and barriers to participation.

Table 3. Summary of outcome measures.

Items	Description or tool used to measure the item	Baseline	During intervention	Postintervention (8 weeks)
Recruitment and attrition	Study recruitment will be recorded by a trained research assistant and will include the total number of participants referred to the study, numbers who agree to participants, and those who enroll in SmartHeart. The research assistant will also record the number of participants that complete the study as a measure of attrition.	✓	✓	✓
Engagement	System use logs will be collected through the SmartHeart system and will provide data on the frequency of use of SmartHeart features. These will not require user input.	—[a]	✓	—
Weight	Withings Body Smart Bluetooth scales	✓	✓	—
Physical activity	Samsung Galaxy Watch Pro 5	—	✓	—
Heart rate	Samsung Galaxy Watch Pro 5	—	✓	—
Blood pressure	Withings blood pressure monitor Connect wireless blood pressure monitor	—	✓	—
Symptoms	Self-reported HF symptoms through the SmartHeart app	—	✓	—
Self-care	Self-Care of Heart Failure Index [28], version 6 [29]	✓	—	✓
Usability	System Usability Scale [30]	—	—	✓
Health-related quality of life	European Quality of Life 5D 5-level questionnaire [31]; Minnesota Living With Heart Failure Questionnaire [32]	✓	—	✓
Medication adherence	Philips Hue Infrared Motion Sensor (proxy); Medication Adherence Rating Scale [33]	✓	✓	✓
Hospitalization	Data provided by sites or study nurses.	—	✓	✓

[a]Not applicable.

Self-Report Measures

Self-Care will be assessed using the Self-Care Heart Failure Index (SCHFI) [28], version 6 [29]. The SCHFI comprises 22 items and collects data on 3 domains (self-care maintenance, management, and confidence). Scores can be summed, but this is discouraged by the authors of the SCHFI. They recommend that the scales (maintenance, management, confidence) be used individually. Each scale is standardized to a score of 100. A score of ≥70 can be used as the cut-point to judge self-care adequacy, although evidence is provided that benefit occurs at even lower levels of self-care [29]. The reliability and validity of this measure have been well documented [29].

The System Usability Scale (SUS) comprises 10 items (each question with a Likert scale ranging from strongly agree to strongly disagree) and was designed as a "quick and dirty" measure of the usability of either hardware or software or both by end users' system [30]. Five questions are positively framed, and 5 questions are negatively framed. The process for computing an SUS score is as follows: (1) subtract 1 from the user's Likert ratings for odd-numbered items or questions, (2) subtract the user's Likert ratings from 5 for even-numbered items, (3) each item score will range from 0 to 4, and (4) sum the numbers and multiply the total by 2.5. This calculation will provide a range of possible SUS scores from 0 to 100.

Previous research has shown that a mean score of 68 is a useful benchmark [34].

Health-related quality of life will be measured using the European Quality of Life 5D 5-level (EQ-5D-5L) questionnaire [31] and the HF-specific Minnesota Living With Heart Failure Questionnaire (MLWHFQ) [32].

The EQ-5D-5L comprises 5Ds: mobility, self-care, usual activities, pain or discomfort, and anxiety or depression. Each dimension has 5 levels: no problems, slight problems, moderate problems, severe problems, and extreme problems. Participants are asked to indicate their health state by ticking the box next to the most appropriate statement in each of the 5Ds. This

decision results in a 1-digit number that expresses the level selected for that dimension. The digits for the 5Ds can be combined into a 5-digit number that describes the patient's health state. It also includes a visual analog scale that captures the participant's self-rated health. This can be used as a quantitative measure of health outcomes that reflects the participant's own judgment. The EQ-5D-5L has demonstrated excellent psychometric properties across a broad range of populations and health conditions [35].

The MLWHFQ is a 21-item multidimensional questionnaire designed to assess the health-related quality of life of people with HF in adults across physical, socioeconomic, and emotional or psychological dimensions. It is scored through a 6-point Likert scale (0-5), with a sum of item responses for total and dimension scores. The MLWHFQ has very good psychometric properties [36].

The Medication Adherence Rating Scale [33] is a 10‐item self‐report adherence scale that assesses both intentional ("I avoid using it if I can") and nonintentional medication nonadherence ("I forget to use it"). Psychometric properties are well established [37]. Scores range from 0-10 with higher scores indicating better attitudes toward medication.

Feasibility Outcomes

To inform decisions to progress to a definitive trial, there must be evidence of achieving key criteria for recruitment, engagement, self-care, and attrition. For this, the criteria in Textbox 2 will be used. These criteria were not based on published data but were developed following expert discussion with the chief investigator team, which comprised 2 cardiologists, an HF nurse specialist, 2 public health researchers, 2 exercise physiologists, one computer scientist, a health economist, and a biostatistician.

Textbox 2. Feasibility criteria and metrics.

Green: If all four green criteria are met, we will consider the study feasible (unless there is a clear indication from the qualitative interviews and our experience that would improve the study)

- At least 80% of the target sample size is recruited within 3 months.
- At least 50% of participants engaged with SmartHeart.
- At least 60% of participants maintained or improved their Self-Care of Heart Failure Index score.
- Attrition ≤20%. A rule of thumb states that >20% attrition poses threats to study validity [38].

Amber: If one or more of our amber criteria are met, we will consider the study as likely feasible but will consider the results of the feedback from the qualitative interviews and our experience to improve whichever criteria are not at the "green light" level before considering a full trial.

- 50%-79% of the target sample size is recruited within 3 months.
- 35%-49% of participants engaged with SmartHeart.
- 45%-59% of participants maintained or improved their Self-Care of Heart Failure Index score.
- Attrition 20.1%-35%.

Red: If one or more red criteria are met, we would consider the study as likely not feasible with the current protocol.

- <50% of the target sample size is recruited within 3 months.
- <35% of participants engaged with SmartHeart.
- <45% of participants maintained or improved their Self-Care of Heart Failure Index score.
- Attrition >35%.

Analysis

Descriptive statistics (mean and SD for continuous data, N and percentage for categorical) will be presented for all quantitative primary and secondary (eg, self-care behaviors, Health-Related Quality of Life) outcomes and will be the primary form of analysis. The EQ-5D-5L questionnaire will be scored using the Australian value set [39]. Within a person, cross-correlation matrices will also be generated [40].

Interviews will be audio-recorded and transcribed. We will use framework analysis to analyze the interviews, using predefined categories according to the NICE Evidence framework for digital health technologies [27].

Ethical Considerations

The study received ethical approval from the Deakin University Human Research Ethics Committee (HREC/76317/MH-202). A participant information sheet and consent form will be sent to participants during the baseline assessment. Written informed consent will be obtained at the baseline assessment before data collection.

Results

The SmartHeart project, including the proposed pilot study, received funding from the National Health and Medical and Research Council grant (grant number 2018698) and commenced in January 2021. This study was conducted in collaboration with health and academic partners in the states of Victoria and Queensland, Australia. Recruitment for the pilot

trial started in August 2024 and will be completed by March 2025. We have currently enrolled 12 participants. Follow-up of all participants will be completed by the end of May 2025. Once analysis from the pilot study has been completed, we will submit the findings for publication.

Discussion

Principal Findings

This article reports on the formative development of the SmartHeart system, a smart health ecosystem with advanced telemonitoring and behavioral support, offering a comprehensive, integrated, and coordinated approach to HF management. We also outline a protocol for piloting SmartHeart to inform a future RCT.

Consistent with the need to integrate consumers in health research [41], we have undertaken extensive user-centered design and engagement with end users. A comprehensive program of research, following the IDEAS framework was used in developing SmartHeart. Reflecting on the design and development process, we benefited greatly from using the IDEAS framework. Our formative work involving a scoping review, stakeholder interviews, and a Delphi survey was important for ideation and informing the prototype features and functions. Co-design workshops were critical in identifying the needs of users and health care providers. We hypothesize that this will likely maximize the acceptability, engagement, and usability of the SmartHeart system. However, the downside to this co-design approach was the much longer development timeframes to achieve the SmartHeart prototype.

SmartHeart incorporates a conversational agent (Amazon Alexa). With ongoing development, conversational agents have evolved into digital systems that aid the delivery of health interventions for individuals at the places most convenient for them. Using voice to interact with these agents is a more natural user interface than traditional mouse, keyboard, or touch interfaces, which may lower barriers to entry for many people, especially older adults, those culturally and linguistically diverse, and people with low literacy [42]. We also provide access to SmartHeart in multiple languages, increasing the accessibility of support to those who speak languages other than English. Furthermore, in Australia, SmartHeart could have a significant impact by providing greater access to health care, especially in high-priority rural and regional areas.

There are some limitations of the current system that warrant consideration. First, the system is currently Android-based; however, we offer participants an Android phone for the duration of the study, and we are developing an iOS version for future use. Second, the Samsung Galaxy watch used to collect data from participants is also only compatible with the Android system. Our future plans are to support most off-the-shelf smartwatches in the market, including Fitbit (Google; iOS and Android), Apple Watch (iOS), and Garmin. Third and finally, we use a cloud-to-cloud approach, which can be problematic when third-party providers (eg, Withings) provide updates affecting data capture. Our team will check and maintain the system on a regular basis to ensure all components are up to date, helping to mitigate this issue.

A risk mitigation strategy plan was developed for the funding application that supported this project. A key risk is the slow recruitment of participants. Our current recruitment strategy includes recruitment from participating partner hospital sites; however, we will mitigate risk by also recruiting from community HF support groups, general practices, and online through social media. The small number of participants may also be a risk as this may not be sufficient to inform feasibility; however, we have indicated in our ethics application that we may extend recruitment to mitigate this risk. Data security is another risk, which will be addressed by ensuring all data are anonymized, and data storage meets Melbourne and Deakin's Research Conduct Policy and the Research Data and Primary Materials Management Procedure. As mentioned earlier, all data will be stored securely on password-protected servers and in accordance with ethical procedures. Finally, because participants are required to provide consent in English, it is possible that the benefit of SmartHeart being available in different languages will not be realized. The requirement for consent in English is based on logistics; we do not have a resource to pay for interpreters; however, most participants in Australia for whom English is not a first language can read English for consent purposes.

The SmartHeart system has significant potential for future expansion and enhancement. While our current prototype uses desktop smart speakers, the integration of conversational agents on mobile devices (eg, phones, tablets, smartwatches) could extend the system's reach beyond the home environment. Furthermore, we are exploring the integration of generative artificial intelligence to enhance user engagement through more natural dialogue and personalized responses, leveraging a curated guideline-based database and retrieved augmented generation techniques. While the project's initial focus targets people living with HF, the system's architecture supports broad applicability to other long-term conditions. This versatility will be particularly beneficial for the increasing number of people managing more than one long-term condition. The system's adaptability is enhanced by the fact that challenges associated with HF significantly overlap with other health conditions, such as other cardiovascular conditions, chronic obstructive pulmonary disease, and diabetes, making the core functionality transferable. Potential adaptations include customizing symptom questionnaires for one or more conditions, implementing different wireless sensors, and refining the algorithms and support messages.

The next step is to assess the feasibility of this version of the SmartHeart system with both people with HF and health care providers. A pilot study will provide valuable information on feasibility and preliminary effects, which will inform the design of a larger proposed RCT. If clinical and cost-effectiveness are subsequently demonstrated, SmartHeart could augment existing health care services to support people with HF to stay well living in the community and living independently. The primary benefit of this solution is to empower people with HF to be more actively engaged in self-care and realize the unfulfilled potential for digital health to transform health care delivery. If proven

feasible, it could improve clinical outcomes (hospital admissions, self-care, health-related quality of life) and reduce the cost burden of the health care system. The SmartHeart concept aligns with recent calls for a health care shift from clinics to the home, with digital health support [6] and a recent European Society of Cardiology position statement [43] to address key elements of digital health implementation.

Conclusion

The SmartHeart system represents a promising, user-centered approach to HF management through advanced telemonitoring and behavioral support, with significant potential for expansion to other chronic conditions. Future research, including a pilot study and larger RCT, will be crucial in assessing its feasibility, effectiveness, and impact on both clinical outcomes and health care costs.

Acknowledgments

We would like to acknowledge all participants who have contributed to the development of SmartHeart as well as the clinical sites who have provided input on the study to date and will help with recruitment for the proposed pilot study.

This study was funded by a National Health and Medical and Research Council grant (grant number 2018698). However, the funding agency did not play a part in the design, execution, analysis, or interpretation of this study.

Data Availability

The datasets generated and analyzed in this study will be made available upon publication of the principal findings.

Authors' Contributions

RM led the conceptualization of this study, procured funding, and provided oversight for the whole study. RN, PJ, and RD led the formative and co-design work. YZ oversaw architecture development. YJ, RV, and RM led the software conceptualization and development. RM wrote the original draft. All authors provided feedback and edits on several revisions of the manuscript and gave final approval before submission. No artificial intelligence was used to support any portion of the manuscript creation.

Conflicts of Interest

None declared.

Abstract

Background: In Alabama, the undiagnosed HIV rate is over 20%; youth and young adults, particularly those who identify as sexual and gender minority individuals, are at elevated risk for HIV acquisition and are the only demographic group in the United States with rising rates of new infections. Adolescence is a period marked by exploration, risk taking, and learning, making comprehensive sexual health education a high-priority prevention strategy for HIV and sexually transmitted infections. However, in Alabama, school-based sexual health and HIV prevention education is strictly regulated and does not address the unique needs of sexual and gender minority teenagers.

Objective: To understand knowledge gaps related to sexual health, HIV prevention, and pre-exposure prophylaxis (PrEP), we conducted the Alabama Youth Survey with individuals aged 14-17 years. In the survey, we also evaluated young sexual and gender minority individuals' preferences related to prevention modalities and trusted sources of health information.

Methods: Between September 2023 and March 2024, we conducted a web-based survey with 14- to 17-year-olds who are assigned male at birth, are sexually attracted to male youth, and lived in Alabama. Half of the study's participants were recruited through community partners, the Magic City Acceptance Academy and Magic City Acceptance Center. The other half were recruited on the web via social media. A 7-step fraud and bot detection protocol was implemented and applied to web-based recruitment to reduce the likelihood of collecting false information. Once data are ready, we will compute frequencies for each measure and construct summary scores of scales, such as HIV and PrEP knowledge, to determine internal consistency. Using multivariable logistic regression, we will examine associations between personal characteristics of survey respondents and key constructs using SPSS 29 (IBM Corp) or SAS 9.4 (SAS Institute).

Results: Analyses are ongoing (N=206) and will conclude in June 2025. Preliminary results include a sample mean age of 16.21 (SD 0.88) years; about a quarter identified as transgender or gender nonconforming, with 6% stating their gender as a transgender woman. A total of 30% self-reported their race as African American or Black; 12% were Hispanic or Latinx. More than half reported being sexually active in the past 6 months. Primary data analyses will be completed in mid-2025. If findings are promising, results will be used as preliminary data to support the development of an intervention to address knowledge gaps and prevention preferences.

Conclusions: If the study is successful, it will yield information on HIV knowledge, PrEP awareness, PrEP preferences, and related outcomes among sexual and gender minority teenagers in Alabama, an underserved, hard-to-reach, but also high-priority population for public health efforts to Ending the HIV Epidemic.

Introduction

Background

In Alabama, the undiagnosed HIV rate is over 20%; youth and young adults, particularly those who identify as sexual and gender minority individuals, are at elevated risk for HIV acquisition and are the only demographic group in the United States with rising rates of new infections [1,2]. Adolescence is a period marked by exploration, risk taking, and learning [3], making comprehensive sexual health education, typically delivered in school systems, a high-priority prevention strategy for HIV and sexually transmitted infections [4,5]. However, in Alabama, school-based sexual health education is strictly regulated [6]; school-based sexual health education must adopt an abstinence orientation, and HIV prevention is typically discussed within the context of heterosexual marriage [7,8]. In response to these structural limitations, community-based organizations have developed their own sexual health and HIV prevention education programs [9]. However, their content is typically delivered inconsistently, relies on funding availability, and is offered only to youth engaged in services. In 2019, pre-exposure prophylaxis (PrEP) was established as safe and effective in preventing HIV among adolescent-aged men who have sex with men (MSM), and the US Food and Drug Administration approved PrEP for individuals weighing at least 77 pounds (~34.9 kg), thereby making it available to adolescents [10,11]. Nevertheless, prescribing PrEP to adolescents remains under ideal levels [12]. Potentially, due to the lack of comprehensive HIV prevention and sexual health education in Alabama schools, there are high rates of HIV among sexual and gender minority youth and low rates of PrEP uptake. This leads to unanswered questions about what adolescents know or do not know about HIV and sexually transmitted infections (STIs) and about characteristics of their psychosocial profile, which may influence the acceptance of PrEP. Furthermore, new PrEP modalities are being developed, and clinicians and researchers alike are interested in learning about what PrEP options may be more acceptable to adolescents.

While the National Institutes of Health–funded Adolescent Medicine Trials Network for HIV/AIDS Interventions and HIV Prevention Trials Network have supported studies that assess PrEP preferences among sexual and gender minority adolescents and young adults [13,14], the age range usually begins at 15 or 16 years, with few studies enrolling as young as 14 years, even though sexual debut is thought to be younger in MSM as compared to the public [15]. There also continues to be a need to examine PrEP preferences of sexual and gender minority adolescents in the southern United States, where stigma related to HIV, sexual orientation, and gender identity is high and resources are limited [16,17]. Some research on adolescent knowledge and preferences related to HIV prevention has been conducted in the region [18,19]; however, studies more often occur with adolescents' support persons, including guardians and providers, rather than the adolescents themselves and occur in clinical settings. Web-based surveys offer adolescents a comfortable and confidential way to share their essential opinions without feeling judged, especially since they heavily rely on digital technologies to build their social networks, receive social support, and obtain health information [5,20-22]. Engaging sexual and gender minority adolescents in research to understand their HIV and STI prevention is critical to reducing rates of HIV transmission but is challenging to do, making this protocol a high public health priority project.

While increasing PrEP uptake among young sexual and gender minorities is urgently warranted [23], and federal and local agencies are supporting behavioral interventions to reach this group [24], adolescent sexual and gender minority individuals will not engage in HIV biomedical prevention if (1) they do not know about PrEP, (2) PrEP options are not acceptable for their developmental period, or (3) they do not understand their risk [25-27]. There is an unmet need to deliver tailored HIV prevention for diverse sexual and gender minority youth, built upon adolescents' existing knowledge and preferences [28,29]. To understand existing knowledge gaps and specifically address them via intervention, we conducted the Alabama Youth Survey to evaluate 14- to 17-year-old sexual and gender minority individuals' preferences and knowledge related to HIV prevention, PrEP, and STIs. The aim of this study was to elucidate knowledge, beliefs, and preferences related to HIV and STI prevention from sexual and gender minority adolescents in Alabama through a web-based survey to inform future intervention development. Because this study is exploratory, no hypotheses are proposed.

Objectives

In this study, we aim to elucidate knowledge, beliefs, and preferences related to HIV and STI knowledge and prevention among sexual and gender minority adolescents in Alabama through a web-based survey to inform future intervention development. If this study yields informative results, we will develop or adapt digital health intervention modules [30,31], a preferred and effective modality for reaching youth to address PrEP uptake while considering preferences and levels of knowledge.

Methods

Ethical Considerations

All study materials and procedures were reviewed and approved by the University of Alabama at Birmingham Institutional Review Board (IRB; IRB-300009255) and the Florida State University IRB (STUDY00003480). Informed assent was collected digitally from all study participants before data collection. Potential participants were informed of the purpose of the survey and anonymity, confidentiality, and voluntary

principles before responding. We received parental waivers from both reviewing IRBs due to the precarious situation of many sexual and gender minority youth in Alabama. Still, an information sheet for parents was made available. Participation in the study was voluntary. Study data have been deidentified and stored on a secure server. Study participants received an incentive of a US $35 digital gift card.

Eligibility Criteria

All potential participants completed a web-based screening survey via Qualtrics to verify their eligibility. To be eligible for the study, potential participants must have been 14-17 years old, assigned male at birth, report sexual attraction to men, and live in Alabama. MSM, transgender women, and genderqueer individuals were eligible if they met the aforementioned criteria.

Recruitment

We partnered with three local agencies for this study. The Magic City Acceptance Academy is the only trauma-informed charter school for LGBTQIA+ (lesbian, gay, bisexual, transgender, intersex, queer/questioning, asexual) individuals in the US Deep South. Magic City Acceptance Academy recruitment was supplemented by recruitment from the Magic City Acceptance Center [32,33]. While both agencies are independent, they have ties to leadership and are connected to Birmingham AIDS Outreach [8,34]. About half of our sample was recruited in person from these sites. The other half was recruited on the web via social media through targeted advertisements on Facebook, Instagram, and Snapchat. Adolescents could access the survey via QR codes linked to an eligibility screener. Eligible individuals were automatically redirected to the Alabama Youth Survey.

Bot Detection and Data Protection

Fraudulent data and fake responses are commonplace in web-based surveys, especially when a monetary incentive is provided. Examples of data fraud include bad actors, such as eligible individuals who submit surveys multiple times for multiple incentives, ineligible individuals who lie to meet eligibility criteria, and programmed bots. Since half of our sample was recruited on the web, we used extensive screening protocols, including (1) requiring the answering of youth-focused qualitative questions that require a typed response that would indicate residence, such as “What’s your favorite local restaurant?” and “What’s your favorite television show?” during screening [15]; (2) embedding multiple reCAPTCHAs throughout with review of Qualtrics bot detection; (3) requiring a US-based IP address; (4) locking surveys to disallow multiple submissions from the same IP address or device; (5) requiring all eligible respondents to provide an in-state phone number, which was then pinged for SMS text messaging verification before sharing the survey link—while many people have out-of-state area codes, this is much less likely for 14- to 17-year-old adolescents; (6) checking that all linked surveys were completed sequentially; and (7) using Zoom (Zoom Video Communications)–based verification audits when data seemed suspicious. Suspicious activities or indicators included but were not limited to submitting more than two surveys back to back, surveys received from the same small town in Alabama, and using an AOL or Yahoo (Yahoo Inc) email address. We also changed the survey links weekly to avoid improper circulation. These procedures were completed for all participants who were recruited on the web to ensure data integrity.

Adolescent Youth Survey

The Adolescent Youth Survey was developed and implemented following the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) checklist [35]. The web-based survey was programmed in Qualtrics to collect data on HIV knowledge, perceived HIV risk, actual HIV risk, PrEP knowledge, preferences related to PrEP modalities, stigmas, and characteristics that are known to be related to HIV prevention among sexual and gender minority individuals. Some constructs were explicitly developed for this study, such as PrEP modality preference, while in other cases, we used validated scales. The measures are shown in Table 1 below. The question order was not randomized. Questions were adaptive, and questions that were not applicable were not presented. For example, if a participant was not sexually active, questions about using protection during sexual intercourse were not presented. Respondents were allowed to go “back” in the survey. However, they could not adjust their responses after pressing the final submit. We aimed to recruit 200 participants and were able to recruit a total of 206 participants between September 2023 and March 2024 via a convenience sample that was shared by those recruited via the Magic City Acceptance Academy, the Magic City Acceptance Center, and the web.

Table 1. Measures collected

Construct	Description or examples	Questions, n
Demographics	Age, gender, sex, race, ethnicity, sexual orientation, residence in Alabama, parental education, and income	10
HIV risk and prevention	Sexually active [36,37], injectable substance use, on PrEP[a], and previous STI[b] diagnosis [38]	10
HIV knowledge	HIV-KQ-18[c] [39]	18
STI knowledge	STI Knowledge Scale [40]	27
Medication experience and preferences	Oral pills, shots, suppositories, patches, etc	13
PrEP familiarity	Seen commercials, types of PrEP, and PrEP brands	6
PrEP awareness	PrEP-COL[d] Scale [41]	10
PrEP preferences	PrEP modalities, PrEP delivery locations, etc	20
Trusted sources	Types of information sources and people	24
Stigma	IHP-R[e] [42] and Everyday Discrimination Scale [43]	14
Depression	PHQ-8[f] [44]	8
Resilience	MOS Social Support Survey [45], GSE[g] [46]	29

[a]PrEP: pre-exposure prophylaxis.

[b]STI: sexually transmitted infection.

[c]HIV-KQ-18: HIV knowledge questionnaire.

[d]PrEP-COL: PrEP Columbia Scale

[e]IHP-R: Revised Internalized Homophobia Scale.

[f]PHQ-8: Personal Health Questionnaire Depression Scale.

[g]GSE: General Self-Efficacy Scale.

Pilot Testing

Study team members aged 20-24 years pilot-tested the survey multiple times to assess its completion time. It was determined to be about 20-25 minutes, depending on how slowly one reads the questions and the time to consider response options. We then pilot-tested the survey with the first 10 respondents and found similar completion metrics, with no complaints or concerns reported.

Data Storage and Analysis

Encrypted data are saved on a Florida State University server with password protection. The database and associated data structures were developed before survey distribution and were not adjusted during the protocol. We asked participants to voluntarily provide emails and cell phone numbers to facilitate the provision of incentives. These personal data were only known to the incentive processors and were kept separate from survey responses. During data collection, we examined data quality weekly (eg, missing data, assessment of distributional assumptions, and identification of outliers) and will do so before statistical analysis is conducted. As a pilot study, missing scale data will not be estimated. Once data are ready, we will compute frequencies for each measure and for each scale to assess variability and internal reliability. We will construct summary scores of scales, such as HIV and PrEP knowledge, to determine if these have adequate internal consistency (Cronbach $\alpha \geq 0.70$) [47]. Using multivariable logistic regression, we will examine associations between the personal characteristics of survey respondents and key constructs. We will use SPSS 29 (IBM Corp) or SAS 9.4 (SAS Institute) for quantitative analyses.

Results

While this study was approved in 2021, data collection began in September 2023 and concluded in March 2024. Since the survey was open, the system could not record the number of unique visitors; thus, a formal response rate cannot be calculated. Data analysis is underway and will conclude in June 2025. The sample included 206 participants aged 14-17 years with a mean age of 16.21 (SD 0.88) years; about a quarter identified as transgender or gender nonconforming, with 6% explicitly stating their gender as a transgender woman. A total of 30% self-reported their race as African American or Black; 12% were Hispanic or Latinx. About half of them reported being sexually active in the past 6 months.

Discussion

Principal Findings

In this study, we aim to elucidate knowledge, beliefs, and preferences related to HIV and STI prevention among sexual and gender minority adolescents in Alabama through a web-based survey to inform future intervention development. If this study yields informative results, data could inform the adaptation or creation of a sexual health and HIV prevention intervention for sexual and gender minority adolescents who

live in southern states, where school-based sexual health education may be unavailable or strictly limited.

While hypotheses were not proposed, based on preliminary analyses and the extant literature, we anticipate finding low levels of knowledge and high levels of poor mental health outcomes. Little is known about PrEP modality preference in this population, so we cannot anticipate findings related to this topic. Findings will provide intervention targets (eg, PrEP education) and the needed dose; very low knowledge will necessitate more significant emphasis on PrEP education. When recruiting on the web, we encountered an enormous amount of fraud and ultimately needed to implement SMS text messaging verification, wherein eligible participants would only be routed to the survey after their unique phone number, with in-state area code, was verified. Even after verification, since Google phone numbers can be created, we audited suspicious submissions, such as surveys that were completed too quickly. A total of 10% of web-recruited submissions were audited via a Zoom call with a trained study coordinator. The web-based survey and fraud detection strategies were feasible; however, completing this survey with data protection and scientific integrity was much more costly and time-intensive than expected. For future web-based survey studies, we recommend implementing SMS text messaging verification at study onset with a random audit of 20% of records. Audits should include a video call (preferred) or a voice call (acceptable). Email verification, while simple, was not reliable, likely due to the ease of creating email accounts.

As noted in the *Introduction*, little is known about 14- to 17-year-olds' knowledge, beliefs, and preferences related to HIV and STI prevention in the United States; thus, comparison to other studies is challenging. Recent research on these topics has been conducted in global settings with mixed findings [48-50]. A unique feature of our survey study is the assessment of PrEP modality preference, including options currently in clinical trials or may be available outside of the United States. Findings on modality preference have the potential to inform clinical care and how providers offer PrEP to sexual and gender minority adolescents.

While the study team was meticulous in bot detection and other fraud measures, some participants did not receive face-to-face interaction, and thus, those recruited on the web may be different from participants recruited from our local community partners. Second, the study may be susceptible to desirability bias, especially from participants recruited via in-person venues. While our sample is large for sexual and gender minority adolescents, a larger sample would increase generalizability. Some domains would have been valuable to assess, such as living circumstances and previous experiences with adverse life events; however, in pilot testing, adolescents felt the survey could not be lengthened.

Conclusions

If the study is successful, we will yield information on HIV knowledge, PrEP awareness, PrEP preferences, and related outcomes among sexual and gender minority teenagers in Alabama, an underserved, hard-to-reach, but also high-priority population for public health efforts to Ending the HIV Epidemic. Data can inform the development of a culturally appropriate (for southern contexts, to be adolescent-friendly) and modular HIV prevention intervention, targeting behavior change related to HIV prevention for sexual and gender minority adolescents, that can be seamlessly integrated into amenable community settings in the southern United States.

Acknowledgments

We thank Dr. Patton Furman, Principal of the Magic City Acceptance Academy, and Amanda Keller and Lauren Jacobs, leadership at the Magic City Acceptance Center, for their support with recruitment. This study was supported by a research grant from Merck Sharp & Dohme LLC Investigator-Initiated Studies Program (MISP) under award 60819. The opinions expressed in this paper are those of the authors and do not necessarily represent those of Merck Sharp & Dohme LLC.

Data Availability

Data are available upon reasonable request through this study's lead author (HB).

Authors' Contributions

HB is the principal investigator and lead author of the study and is involved in all aspects of the study from conceptualization and funding acquisition to writing. IY is the lead statistician and led the formal analysis. JB led data collection efforts with the support of CLB and AJ. JB, CLB, and AJ were involved with project administration and writing the original draft.

Abstract

Background: Freezing of gait (FoG) is one of the most disabling symptoms of Parkinson disease (PD). Detecting and monitoring episodes of FoG are important in the medical follow-up of patients to assess disease progression and functional impact and to adjust treatment accordingly. Although several questionnaires exist, they lack objectivity. Using wearable sensors such as inertial measurement units (IMUs) to detect FoG episodes offers greater objectivity and accuracy. There is no consensus on the number and location of IMU, type of algorithm, and method of triggering and scoring the FoG episodes.

Objective: The objective of this study is to investigate the use of multiple wearable sensors sets to detect FoG in patients with PD during various walking tasks under different medication conditions.

Methods: This single-center, prospective cohort study (DetectFoG) will include 18 patients with PD. Patients will be fitted with 7 IMUs and will walk a freezing-provoking path under different tasks—"single task," "dual motor task," or "dual cognitive task"—and medical conditions corresponding to levodopa medication ("on" or "off"). Passages will be videotaped, and 2 movement disorder specialists will identify FoG episodes in the videos. The accuracy, sensitivity, specificity, positive predictive value, and negative predictive value of the most effective combination of wearable sensors for detecting FoG episodes will be studied.

Results: The study is currently in the data collection phase, having commenced recruitment in February 2024. Once all data have been gathered, the data analysis will commence. As of August 2024, 3 patients have been recruited. It is anticipated that the results will be published by the end of 2025.

Conclusions: Detecting FoG episodes in various medical and clinical settings would provide a more comprehensive understanding of this phenomenon. Furthermore, it would enable reliable and objective monitoring of the progression of this symptom based on treatments and the natural course of the disease. This could serve as an objective tool for monitoring patients and assessing the severity and frequency of FoG.

Introduction

Affecting more than 8.5 million people worldwide in 2019, Parkinson disease (PD) is the second most common neurodegenerative disease [1]. PD is diagnosed using criteria from the UK Parkinson's Disease Society Brain Bank [2] and is defined by the cardinal symptoms of tremor, bradykinesia, rigidity, and postural instability, along with other motor and nonmotor symptoms [3].

Among the various motor symptoms, freezing of gait (FoG), defined as a "brief and episodic absence or marked reduction in the forward progression of the feet despite the intention to walk" [4], is one of the most disabling symptoms of PD. In advanced and severe forms of PD, FoG occurs in 50% to 80% of cases [5]. FoG is correlated with PD severity and disease duration [6]. It increases the risk of falls [7] and loss of independence and affects patients' quality of life [8].

The detection of FoG episodes is an important issue for patient follow-up and treatment adjustment. Various subjective and objective methods can be used to assess these symptoms. Daily completion of a motor diary by the patient is one possibility for assessing these symptoms, but it relies on the patient's subjective judgment and is often discontinued after a few days or is not feasible in the presence of cognitive impairment [9]. Objective scores with predefined exercises (eg, double spot walking, 180° turning, etc) are available to assess FoG episodes during medical consultations; however, these exercises do not always trigger FoG episodes due to several reasons. First, the phenomenon known as the "white coat effect," whereby patients may perform differently in the presence of medical professionals, can alter their natural response and reduce the likelihood of FoG episodes [10]. Second, the structured nature of clinical assessments often causes a switch from automatic to goal-directed pathways, reducing the occurrence of FoG episodes, which typically occurs in more automatic walking scenarios [11]. Finally, the predefined exercises are constrained by time, unfamiliarity, and the artificiality of the clinical environment, which can influence patients' natural gait patterns. Thus, they fail to provide accurate information on the frequency and severity of FoG episodes in daily life [11]. One potential alternative method involves videotaping patients in different contexts and conducting a postscored examination, considered the gold standard, although this approach demands time and expertise [11].

To overcome these limitations, wearable sensors, such as electromyographs, electroencephalography electrodes, or inertial measurement units (IMUs), provide a solution for automatic FoG detection. The combination of accelerometer and gyroscopes data from an IMU seems to be the most widely used solution with high performance (sensitivity: 86%; specificity: 92.9% [12]). This compact sensor is easy to install and allows FoG assessment both in clinical practice and during daily living [9,13].

Despite numerous studies and literature reviews on the use of these wearable sensors for FoG detection, there is as yet no consensus in the literature on the optimal methodology for their use. It is likely that this discrepancy stems from the inherent variability in the protocols used. Indeed, there is considerable heterogeneity in the protocols for triggering [11] (medical condition: "on" or "off" levodopa treatment; freezing-provoking path; and dual-task conditions). In fact, there are few studies that directly compare FoG episodes in "on" and "off" conditions with small cohorts and a low number of participants [11,12,14]. Furthermore, many locations including feet, shin or ankle, thigh, and pelvis have been investigated [15]. The use of multiple sensors provides a more detailed and holistic view of the patient's movements, enabling the capture of subtle changes that may not be detectable with a single sensor [15]. An IMU is cost-effective and straightforward to wear, rendering it suitable for both laboratory evaluation and daily use. Even if patients prefer to wear sensors solely at the wrist, such as a stopwatch, or conceal them beneath clothing at the ankle or on a belt (lower back), as demonstrated by O'Day et al [15], the placement of sensors on multiple body parts could enhance the robustness of FoG detection across various walking tasks and different FoG subtypes. Furthermore, examining FoG under dual-task conditions provides a more comprehensive understanding of how cognitive load impacts freezing episodes, which only a few studies have addressed [16-20]. Finally, several other variables may confound the study, including the wide age range of cohorts (aged 7-118 years) and the diverse range of FoG episodes (50-1110) [21-23]. Therefore, this study is innovative as it stands out for its ability to replicate findings across various conditions, particularly the medical condition. Furthermore, it explores the effects of dual-task scenarios and optimal sensor placement in a larger cohort than those found in the literature, significantly enhancing our understanding of the underlying mechanisms. These multiple dimensions provide a more nuanced and robust perspective, allowing for better generalization of the results and improving practical applications in medical settings.

Regardless of the wearable sensors used or the freezing protocol, the accuracy of detection is sensitive to the type of algorithm [9,11,12,23]. Yet, the algorithms used to detect FoG episodes are controversial, especially for real-time detection. The threshold method provides a straightforward approach to the implementation and interpretation of algorithms. In this context, the freezing index—defined as the ratio between the power bands of freezing (3-8 Hz) and locomotion (0.5-3 Hz)—is the most commonly used feature in threshold-based algorithms [9,11,12,23]. This single feature accurately detects many FoG episodes (sensitivity: 84.3%; specificity: 78.4% [24]), but detection fails when no motion is observed and voluntary stops may be mistakenly classified as FoG [17]. Adding multiple indices can enhance algorithm performance, but it also increases complexity and the difficulty of tuning thresholds [25,26]. To address these limitations, machine learning (ML) algorithms have been developed to improve FoG detection performance. Indeed, ML algorithms could better fit the model to increase the accuracy of the models; this is a subfield of artificial

intelligence that gives an algorithm the ability to learn without being explicitly programmed [12]. Among the various ML algorithms, support vector machine, multilayer perceptron, and ensemble classifiers (eg, random forest or AdaBoost) have proven to be the most efficient. Determining the best ML algorithm is challenging due to the highly heterogeneous nature of the training data. A limitation of ML algorithms is that training the model and processing the data can require high computational cost. Fortunately, advances in computer technology now offer the possibility of early or real-time detection with ML models [12].

The primary objective is to assess the accuracy of the optimal combination of wearable sensors for detecting FoG episodes in patients with PD. The secondary objectives of this study include measuring the specificity, sensitivity, positive predictive value (PPV), and negative predictive value (NPV) of the optimal combination of wearable sensors for detecting FoG episodes. Regarding the setup, we also aim to compare its performance (accuracy, sensitivity, specificity, PPV, and NPV) across various clinical and medical conditions.

Methods

Study Design and Participants

This study is a single-center, prospective cohort trial (DetectFoG) involving patients with PD with FoG at the University Hospital of Rennes. Patients will be recruited from the neurology department of University Hospital of Rennes during their visit to the neurologist. This study aims to include a total of 18 patients. To mitigate potential issues such as withdrawal of consent, absence of FoG during neurologist annotation, loss of follow-up (failure to attend the second visit), or inability to complete the required number of passages (fewer than 6), initially, 20 patients will be enrolled. Participants experiencing any of these issues will be excluded from the study.

Inclusion criteria will include patients older than 18 years diagnosed with PD according to the UK Brain Bank criteria. Patients must self-report as freezers, scoring between 1 and 3 on question 13 of the Movement Disorder Society-Unified Parkinson's Disease Rating Scale (MDS-UPDRS) II [27], and be capable of walking 30 m without assistance to complete the freezing-provoking path. Exclusion criteria will apply to patients scoring less than 20 out of 30 on the Montreal Cognitive Assessment [28] who are unable to give informed consent and those with neurological, orthopedic, or rheumatic comorbidities that could impact gait and ability.

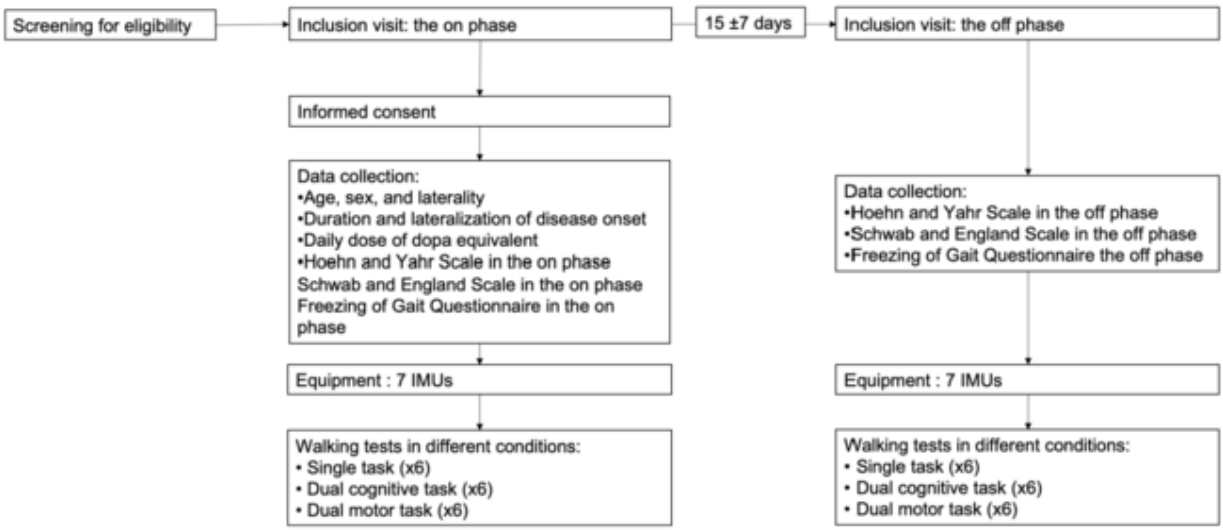
Ethical Considerations

The study design was approved by the ethical committee of Ile de France III (23.01067.000298-MS01) on October 1, 2023. All data collection will adhere to applicable guidelines and regulations. Participants will provide informed consent before enrolling in the study.

Protocol

After verifying the inclusion and exclusion criteria, the neurologist will notify the principal investigator (KJ). The principal investigator will then contact the patients to provide comprehensive and understandable information about the study's objectives, as well as their right to refuse participation or withdraw at any time. If the patients consent and sign the consent form, they will participate in 2 visits separated by 2 weeks (±7 days), encompassing both "on" and "off" phases of levodopa treatment (Figure 1).

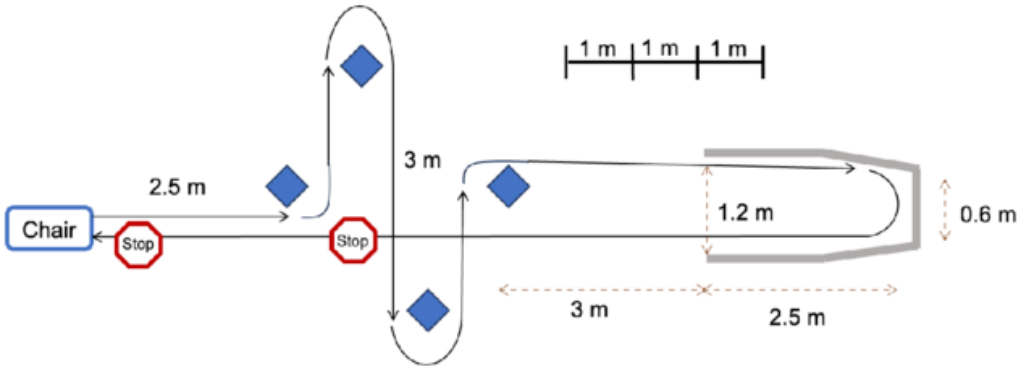
Figure 1. Timeline of study. IMU: inertial measurement unit.



For organizational purposes, the first visit (inclusion visit) will occur during the "on" phase of levodopa medication, while the second visit (follow-up visit) will be during the "off" phase. During the "on" phase, patients will be assessed when oral treatment maximally improves dopa-sensitive PD symptoms (best "on" state, typically 1-2 hours after ingestion). This state will be determined based on patients' subjective assessment, similar to their daily motor self-assessments (home diaries), which has been established as reliable in various studies [29-31]. Assessment during the "off" phase will occur after 12 hours without treatment, preferably in the morning before the first levodopa dose.

During each visit, participants will walk on a freezing-provoking path at a comfortable speed under 3 different clinical conditions (single task [ST], dual cognitive task [DCT], and dual motor task [DMT]). The Pardoel freezing-provoking path, known to induce FoG episodes [32], includes standing up, walking with a slalom (left and right turns), navigating a narrow passage with a 180° turn, and returning straight, with 2 designated stops—one chosen by the patient and another in front of a chair (Figure 2).

Figure 2. Freezing-inducing path (adapted from Pardoel et al [32], which is published under Creative Commons Attribution 4.0 International License [33]).



Participants will undergo testing under different dual-task conditions, which are recognized for promoting FoG episodes [32]. The DMT involves walking with a ball on a tray within a drawn circle, keeping the ball centered. The DCT requires participants to generate as many words as possible starting with a specified letter. Each participant will complete a maximum of 6 blocks, with each block consisting of the 3 conditions (ST, DCT, and DMT), resulting in a total of 18 trials (6 blocks × 3 conditions per block). The sequence of conditions within each block will be randomized to mitigate any order effects. This protocol accommodates varying endurance levels among patients; some may complete each block quickly with few or no FoG episodes, while others may take longer due to frequent tremors that consume energy. This flexible approach ensures that the study is comprehensive and respects each patient's physical limitations. However, participants who complete fewer than 2 blocks (6 trials) will be excluded from the analysis to ensure adequate data collection.

Data Collection (and Preprocessing)

Clinical Data

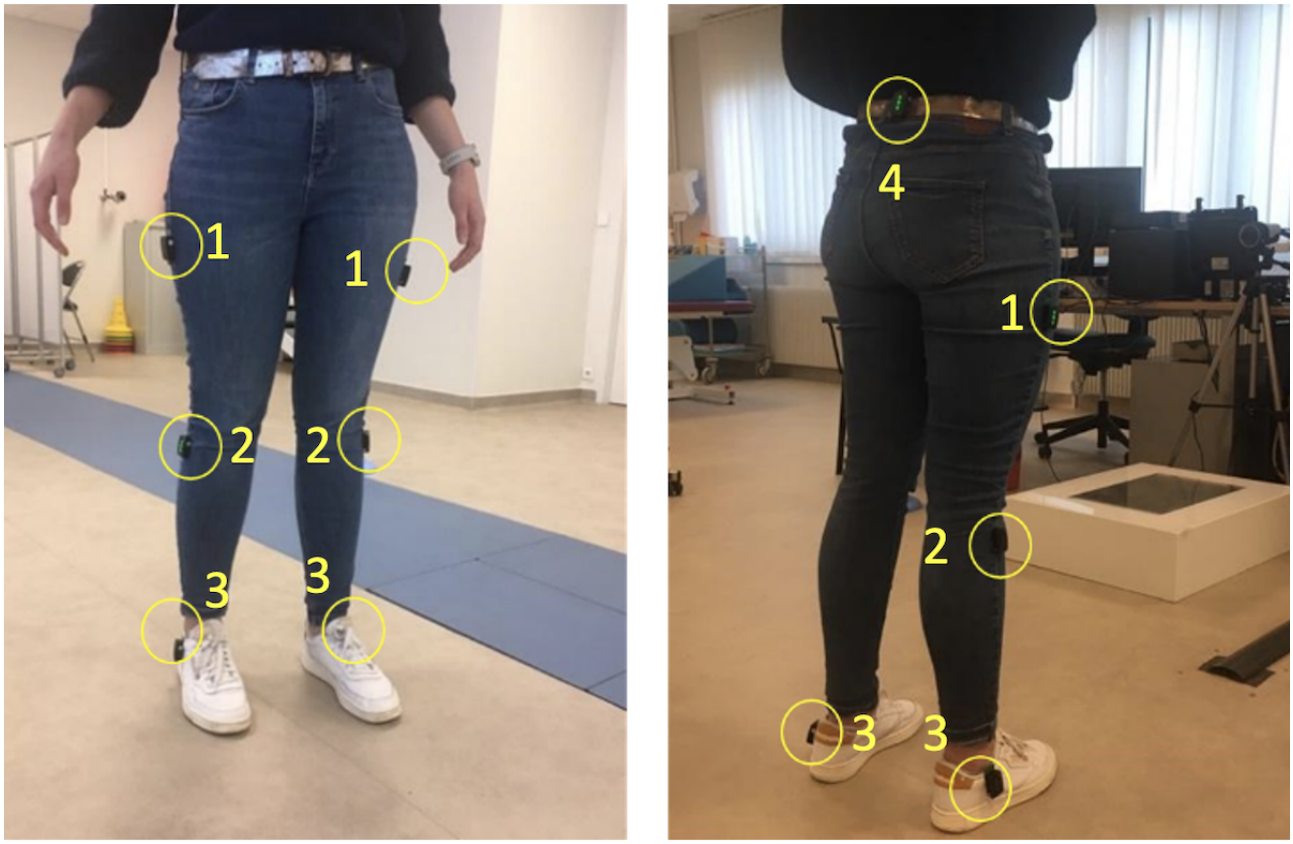
Various patient data are collected, including age, sex, laterality of symptoms, duration of PD, lateralization of symptom onset, daily dose of levodopa equivalent, MDS-UPDRS III score [27], Freezing of Gait Questionnaire (FoGQ; "on" and "off" phases) [34], Hoehn and Yahr Scale ("on" and "off" phases) [35], and Schwab and England Scale ("on" and "off" phases) [36]. The FoGQ is used to assess the characteristics of FoG. The Hoehn and Yahr Scale and the Schwab and England Scale serve as tools for the overall evaluation of patients with PD: the former to gauge disease severity and the latter to evaluate daily life impact, functional status, and level of dependence.

FoG Measurement

IMU Measurements

Patients will wear the Trigno Avanci IMU (Delsys; Figure 3), which includes a triaxial accelerometer, gyroscope, and magnetometer. Data will be transmitted via Bluetooth and collected using the Delsys application programing interface and then transferred to QTM 2020 software (Qualisys). The software manages recording at a sampling frequency of 148.15 Hz and synchronizes with cameras. While this sampling frequency is higher than that in some studies, it has been previously used, similar to the approach taken by Camps et al [37]. This frequency is selected to ensure that all nuances associated with FoG, particularly micromovements, are captured. IMU data will also undergo windowing with a 2-second window length and a 0.4-second shift. A trained operator will position the sensors manually, aligning them with anatomical axes. Seven IMUs will be placed as follows: 1 on each thigh (lateral side, upper third), 1 on each fibula (upper third), 1 on each foot (below the lateral malleolus), and 1 at lumbar level (L5).

Figure 3. Inertial measurement unit placements. 1: Thighs (side, upper third); 2: fibulas (upper third); 3: foot (below lateral malleolus); 4: Lumbar (L5 level).



Video Recording and Window Labeling

During each visit, and during trials designed to induce freezing episodes, patients will be recorded using 14 synchronized Miqus M3 cameras (Qualisys). These cameras will record at a resolution of 1824 × 1088 pixels with a frequency of 25 Hz. FoG episodes will be identified from the videos by 2 movement disorders specialists (FL and SD) independently using QTM 2020 software (Qualisys). The start of a freezing episode is defined as "the moment when the stepping foot does not leave the ground despite a clear intention to step," and the end is defined as "the moment when the stepping foot begins or resumes an effective step" [32]. In cases where there is disagreement about the presence of a FoG episode, the specialists will discuss and reach a consensus. Following the methodology of Pardoel et al [32], the data timeline will be segmented into 2-second windows with a 0.4-second shift between windows (80% overlap). Windows will be labeled as "FoG window" when the entire window corresponds to a period of FoG. Windows not meeting this criterion, either during periods without FoG or during transitions between FoG episodes and non-FoG periods, will be labeled as "no-FoG window." The relative duration of FoG will be assessed by calculating the ratio of FoG windows to the total number of windows. This ratio provides a measure of the freezing time while accounting for the window labeling method used. To ensure comparability with other studies and to mitigate the effect of varying labeling methods across research [32,38], we will also calculate the total number of FoG episodes and the cumulative freezing time based on onset and end events, categorized by task type, session, and patient. This approach will facilitate meaningful comparisons with existing literature on FoG detection methodologies.

Data Management

All data are securely stored in a dedicated folder on a local server with restricted access limited to the research team. Patient's clinical information (such as age, sex, laterality of symptoms, duration of PD, lateralization of symptom onset, daily dose of levodopa equivalent, FoGQ score, Hoehn and Yahr Scale rating, Schwab and England Scale assessment, and MDS-UPDRS III score) along with study results (videos and IMU data) are collected and controlled by the University Hospital of Rennes. A database containing video data is duplicated for each expert responsible for labeling FoG episodes. Time annotations will be exported as events in C3D files along with IMU data before the windowing process, contributing to a final database used for subsequent data analysis. This structured approach ensures the integrity and confidentiality of patient data while facilitating precise event annotation and thorough analysis of collected data.

Data Analysis

Features Extractions

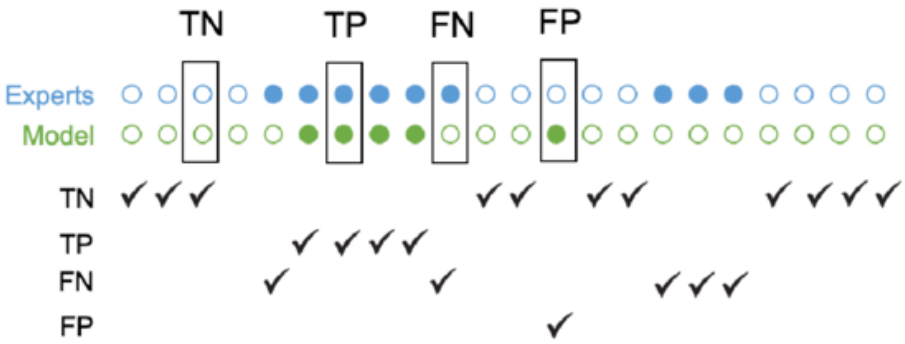
Each window of data will undergo normalization to achieve zero mean and unit variance. Our study distinguishes itself through an exhaustive exploration of features aimed at identifying FoG episodes. From each window, signal features will be extracted from both the time and frequency domains. A comprehensive array of features will be included, such as the number, duration, and length of acceleration or angular velocity

reversals, kurtosis, and skewness [14]. Furthermore, we will incorporate metrics such as the magnitude of mean and SD of signals, as well as specific metrics related to smoothness such as spectral arc length measure [39] and the freezing ratio [40]. Nonlinear modeling features, such as sample entropy or Lyapunov exponent, which quantify gait regularity and complexity, will also be used [41]. Furthermore, measures of inter- and intralimb coordination will be integrated to highlight specific limb dynamics during FoG episodes. Feature selection will be conducted using Relief-F, chosen for its suitability in our application over methods such as minimum redundancy maximum relevance ranking [20]. This approach ensures that the selected features are highly relevant to distinguishing FoG episodes, thereby optimizing the accuracy and effectiveness of our analysis.

Model Training

The top-ranked features identified through Relief-F will be used in a decision tree (DT) model for classifying windows of data. The DT model will be tested using 5 and 10 decision splits and with various sets of top-ranked features ranging from 5 to 20. The performance of the DT model will be evaluated using metrics such as accuracy, sensitivity, specificity, PPV, and NPV. The model's performance will be determined based on the classification of each window as true positive (TP), true negative (TN), false positive (FP), or false negative (FN), comparing the model's classifications with the experts' identification of FoG episodes on video recordings (Figure 4).

Figure 4. Segmentation on true negatives (TNs), true positives (TPs), false negatives (FNs), and false positives (FPs) for each second according to the experts and the model.



The agreement between the model and experts regarding FoG or non-FoG periods will be assessed as follows:

- TP: A FoG period correctly identified by both the experts and the model
- TN: A non-FoG period correctly identified by both the experts and the model
- FP: A FoG period incorrectly identified by the model but not by the experts
- FN: A FoG period incorrectly identified by the experts but not by the model

Performance scores will be calculated using the following equations:

Model Validation

The model validation will use the leave-one-subject-out (LOSO) cross-validation technique to assess its performance across participants and accommodate the considerable variability between participants. While some studies [20,42] advocate for the leave-one-freezer-out (LOFO) cross-validation technique to avoid overrepresentation of patients without FoG in training and validation sets, our study focuses on participants who have experienced at least 1 episode of FoG during their initial visit. Consequently, each patient will have FoG episodes, making the LOSO approach more suitable for our validation process.

Statistical Analysis

Clinical data of the participants will be presented as means (SD) or medians with IQRs for continuous data, depending on their distribution. Categorical data will be reported as counts (with percentages within parentheses).

Primary Outcome

The main objective of our study is to identify the most relevant features and locations of wearable sensors for detecting FoG episodes. The Relief-F technique will rank features extracted from data collected by all sensor segments. The top-ranked features across all subjects will indicate the most critical sensors for detecting FoG episodes, and these features will be used in model training and validation. The LOSO method will be used for validation, and accuracy will be computed for each subject. Furthermore, Relief-F analysis will be conducted individually for each subject to potentially reveal redundancy in the top-ranked features across subjects. Feature extraction, selection, model training, and validation will be implemented using Python 3.0 (PythonLabs) scripts.

Secondary Outcomes

We will investigate the differences in model performance across various conditions to propose recommendations for interpreting the model. Accuracy, sensitivity, and specificity will be evaluated using a mixed-effects model with fixed effects for patients and random effects for the type of condition (ST, DCT, and DMT) and medication state ("on" and "off").

Results

The study is currently in the data collection phase, with recruitment starting in February 2024. Once all data have been gathered, data analysis will commence. As of August 2024, 3 patients have been recruited. We anticipate publishing the results by the end of 2025. The results of this study will be presented at scientific events and published in scientific journals.

Discussion

Strengths and Limitations of This Study

The aim of this study is to assess the accuracy of the most effective combination of wearable sensors in detecting FoG in patients with PD. This setup has been developed following an extensive literature review and clinical evaluation of patients.

To date, consensus on sensor placement remains elusive, necessitating a detailed examination of individual and collective placements [15]. The model used will incorporate a broad array of features from both temporal and frequency domains documented in the literature to maximize accuracy. Moreover, this model will undergo testing on a sizable cohort of patients (n=18), each completing 18 passages on a designated freezing-inducing path, yielding a comprehensive data set. Furthermore, the model will be evaluated on a path known to provoke FoG under different medical ("on" and "off" levodopa medication) and clinical (ST, DMT, and DCT) conditions [32]. This evaluation aims to simulate various walking tasks akin to daily life and assess their potential to induce or alleviate FoG, particularly in dual-task scenarios. Several datasets are available, some with restricted accessibility. Multimedia Appendix 1 outlines several pertinent and comparable datasets. Our dataset's strength lies in its incorporation of multiple sensor placements across varied medication states and task complexities, including cognitive dual tasks. This dataset will be openly accessible or supplied on request, fostering research and collaboration in the field.

One limitation of this study is its reliance on a controlled environment. Despite efforts to simulate ecological tasks that mimic everyday challenges and tend to provoke gait freezes (FoG) under dual-task conditions, it is crucial to acknowledge that the study is conducted under controlled conditions. For future research, conducting tests in real-life settings over prolonged periods would be advantageous. This approach could facilitate the accumulation of larger datasets across diverse situations, thereby enhancing our understanding of FoG in more complex real-world scenarios.

Perspectives

The miniaturization of sensors is unlocking new opportunities for monitoring patients with PD, particularly in detecting episodes of FoG. Extending this capability across all medical and clinical settings would offer a more comprehensive understanding of this phenomenon, which remains incompletely understood. Moreover, it would facilitate dependable and objective monitoring of symptom progression, influenced by treatments and the disease's natural trajectory. This could serve as an objective tool for patient monitoring, assessing both the severity and frequency of FoG.

Objective evaluation is crucial for identifying suitable medical and nonmedical treatments, including rehabilitation or deep brain stimulation [43]. Research has underscored the significance of personalized treatment tailored to individual patient needs and circumstances [44]. Real-time detection facilitates the integration of FoG episode identification with external stimuli, such as sensory, auditory, or visual cues, offering a significant opportunity to mitigate FoG episodes [45].

Conclusions

This study aims to enhance the detection of FoG in patients with PD through the use of multiple wearable sensors. By evaluating various sensor placements and the accuracy of detection algorithms, the study aims to determine the most effective combination of wearable sensors for detecting FoG episodes. Despite the study being conducted in a controlled laboratory environment rather than real-life settings, the findings are expected to significantly advance understanding and monitoring of FoG. The anticipated results will provide crucial insights into optimal sensor configurations and detection methodologies, ultimately supporting the development of more precise and personalized treatment strategies for patients with PD. Publication of these results by the end of 2025 will contribute valuable data to ongoing efforts aimed at improving patient care and enhancing quality of life for individuals affected by PD.

Acknowledgments

This work was supported by the COReSP 2023 of University Hospital of Rennes.

Data Availability

No data are currently available, but the results of the trial will be disseminated either with all the accompanying dataset or on request from the authors.

Authors' Contributions

All authors contributed to designing the experimental protocol. KJ oversaw ethics and dissemination aspects. SC, AD, FB, and KJ will carry out the study. SD and FL will identify FoG episodes from the videos. SC will be responsible for developing and validating the setup. SC, AD, KJ, and IB will analyze the data, and KJ, SC, and IB will interpret the findings. All authors will participate in writing the paper. Finally, all authors have reviewed and approved the final version of the protocol.

Conflicts of Interest

None declared.

Abstract

Background: To support lifelong health promotion and disease prevention, Santé publique France studied the methodology for building a social marketing scheme with a digital intervention targeting middle-aged adults, specifically socioeconomically disadvantaged groups. The digital intervention aims to encourage people aged 40-55 years to look after their health in the short and medium terms by adopting small actions relating to 8 health determinants: nutrition, physical activity, smoking, alcohol, stress, cognitive health, sleep, and environmental health. In the long term, the intervention intends to prevent frailty and reduce the burden of multimorbidities in older age, particularly for lower socioeconomic groups.

Objective: This study aims to measure behavior changes among registered users of the future website. The protocol assesses the impact of the website based on users' implementation of small actions relating to the 8 health determinants. Specifically, it intends to evaluate the website's performance in terms of engaging a specific population, triggering behavior change, raising awareness about a multifactorial approach to health, and encouraging user interaction with the website's resources.

Methods: The methodology is based on clinical assessments developed alongside the website according to the functionalities offered to registered users in their personalized space. The assessment tool design draws on logic models for digital interventions, and their consistency for digital applications is verified. The target audience is clearly defined from the outset. The protocol sets out a 3-step assessment: upon registration, after 3 weeks of use, and after 10 weeks of use (end of assessment). Users are divided into 2 groups (socioeconomically disadvantaged users and others) to characterize differences and make corrections. The protocol uses a mixed assessment approach based on website traffic and user login data. Specific and identifiable behavior changes are documented by monitoring the same individuals from T0 to T2, using verbatim comments to classify them into profiles and conducting semistructured individual interviews with a sample of users.

Results: The protocol creates a multidimensional assessment of digital intervention, showing that during a given timeline, interactions with users can reveal their capabilities, opportunities, and motivations to adopt healthy lifestyles. The protocol's principles were integrated into the development of a personal account to assess users' behavior changes. Given the delayed launch of the website, no recruitment or effects analysis of the protocol took place.

Conclusions: As no multidimensional assessment protocol is currently available for digital behavior change interventions, our methods reveal that the different framework stages can strengthen the effect measurement, consolidate the choice of assumptions used within the logic model and steer the digital intervention toward action while reducing the burden of information. The suitability of the assessment protocol remains to be evaluated given the delayed launch of the website.

Introduction

Background

Today, expert consensus recommends that people should strengthen disease prevention actions from the age of 40 years [1-3] to avoid loss of independence due to the accumulation of chronic diseases. Different studies show a correlation between the number of healthy behaviors (physical activity, diet, stop smoking, and reduction of alcohol consumption) and healthy aging. Santé publique France has been working on the planning stages of a social marketing scheme that includes a digital behavior change intervention. The digital intervention was designed in tandem with its assessment protocol in the hope that engineering feedback would improve its applicability. An overview of the literature on the assessment of digital tools for health promotion and disease prevention found proven evidence for the following: (1) the added value of a multidimensional assessment of a digital intervention [4,5], (2) the challenge of distinguishing between effect measurement and implementation measurement [6] since "a crucial implication of explicitly recognizing the distinction between engagement with the technological and behavioral aspects of the intervention is that intervention usage alone cannot be taken as a valid indicator of engagement" [7], (3) the importance of being able to qualify the maintenance of a target behavior over time [8], and (4) the absence, to our knowledge, of a mixed quantitative and qualitative assessment protocol [4,9-11].

It was precisely this gap that prompted the drafting of this assessment protocol for a nonclinical intervention. We explored the literature on assessments in the fields of medicine and medical informatics as a basis for consolidating some of our following methodological choices.

- The framework stages to develop an assessment protocol: preliminary diagram, study design, operationalization of the methods, project schedule, execution, and conclusion [12-14].
- The lesson that an evaluable result consists of the internet user's loyalty to the logic models used and not the loyalty necessary for a program to be effective [15]: "The distinction in digital health evaluation from traditional evaluation is that there is not always a need to evaluate health outcomes as direct effects of the digital health intervention" [13].
- The decision to document the initial impact of an intervention as well as its additional impact compared to existing digital interventions by Santé publique France [13].
- The decision to take into account the unexpected effects of health IT [16].

Digital Intervention for Behavior Change in Midlife

Based on a holistic and person-centered approach, the digital intervention provides information on the main risk factors for health, taking into account the barriers to and drivers for adopting healthy behaviors as well as the specific living conditions and environments of those aged 40-55 years. This digital intervention is based on the quantified self to support behavior transformation [17,18]. The design of the intervention is explained in a separate study (under review) that illustrates the complementary nature of the theories used in relation to the targeted behavior changes. To become familiar with the user and guide them toward behavior changes, the initial access to the site requires them to fill out a questionnaire on their lifestyle habits, which generates personalized feedback according to a traffic light system in order to introduce recommendations for protective behaviors. At this stage, the user has the option of downloading their report with an overview of the feedback in the form of a table. The next click opens a feed page with action cards and studies that the user can "like," save to their account, and use to navigate further around the site. The personal account is designed as a self-coaching tool intended to support motivation, increase the power to act, and help the user understand health as an interaction between several health determinants applying to all life areas (Table 1).

Table 1. Personalized space of the digital intervention with the available resources and functionalities.

Sections of the personalized space	Resources or functionalities available
Home page	The following items are displayed as a dashboard: answers to the "lifestyle habits" questionnaire, feedback in a traffic light system, feed page with action cards and study pages that can be liked, and liked actions and study pages following website navigation.
My favorite content and goals	A list of liked actions automatically categorized by determinants—users have total freedom to use drag-and-drop to modify the layout according to their needs (eg, from the easiest to the most difficult; based on a time frame) and to delete or add material; and a list of liked studies automatically categorized by determinant—users have total freedom to use drag-and-drop to modify the layout according to their needs (eg, from the easiest to the most difficult; based on a time frame) and delete or add more.
My assessment	An option to repeat the "lifestyle habits" questionnaire to see how habits have changed with the traffic lights and feed page being updated and a history of previous questionnaires is displayed.
My successes	A list of actions that have become everyday behavior.

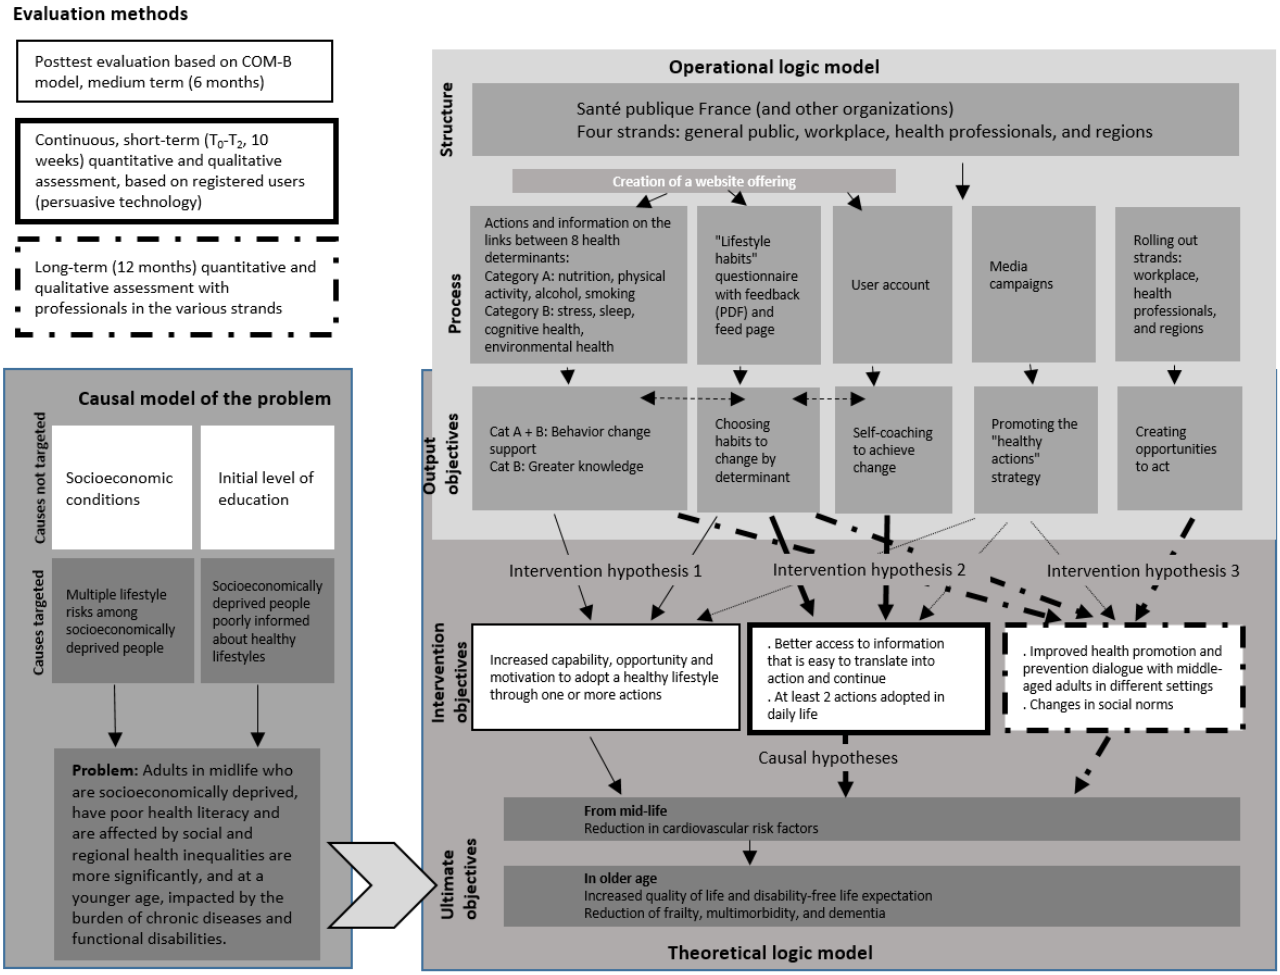
As no gold standard questionnaire on lifestyle habits is available, the present one is a concatenation of different examples taken from the literature and pretested with a target group of midlife adults during a qualitative study.

The personalized space for registered users was leveraged to form the basis of the assessment as the users' actions could be tracked via the content management system. The assessment could then be carried out continuously or in waves.

Conceptual Framework: Intervention Model

The first step was to identify the causes of the problem, shown in the "causal model of the problem" in Figure 1 [19], then to translate them into an objective in the "theoretical logic" part and finally to deduce the output and intervention objectives (operational logic model), leading to 3 evaluable working hypotheses.

Figure 1. Modeling the social marketing scheme to support the adoption of healthy lifestyles in midlife (adapted from Brousselle et al [19]). COM-B: capacities, opportunities, motivations-behavior.



The protocol aims to assess the impact of the website based on the small actions triggered among users to the different health determinants. Specifically, it is intended to evaluate the website's performance in terms of the following objectives: (1) engaging a specific population, (2) triggering behavior change, (3) raising awareness about a multifactorial approach to health, and (4) encouraging user interaction with the website's resources. The paper describes the methods and their relevant limits when constructing an assessment protocol for digital interventions. It questions the value of digital self-assessment and the time frame necessary to evaluate the adoption of healthy lifestyles, as no expert consensus is available on this topic. Finally, the article explores how behavior change models can strengthen the effect measurement of an assessment protocol.

Methods

Objectives of the Digital Intervention

The effect of the intervention on protective behaviors in midlife is communicated through 8 health determinants: diet, physical activity, smoking, alcohol, stress, sleep, cognitive health, and environmental health. The digital intervention is intended to help people aged 40-55 years, and in particular, socioeconomically disadvantaged people to (1) adopt multifactorial preventive actions in their daily lives; (2) increase their knowledge about lesser known determinants (stress, sleep, cognitive health, and environmental health); (3) support dialogue with health care professionals; and (4) develop psychosocial skills, especially the ability to resist social pressure.

Theory of Assessment of a Digital Intervention

The 3-pronged approach of "perceive, prepare, act," resulting from existing digital behavior change interventions [8,20], correlates with the functionalities of the website—questionnaire, actions, personalized space—designed using the behavior change techniques of capacities, opportunities, motivations-behavior (COM-B) [21].

Table 2 shows the indicators that can be used to answer the assessment questions.

- The mechanisms and factors that influence the choice of one or more actions and contribute to whether they are adopted are shown in "1. goals and planning—perceive, prepare, and act" as well as in the column "prepare" when a user likes one or more actions.
- The influence of personalized space on the adoption of actions (preferably multifactorial) and on the self-assessment of lifestyle habits can be understood on the basis of the items listed in the "act" column.
- The factors likely to influence target users' perception of their chosen health-promoting action are reflected in the fact that the questionnaire is repeated (2.4) and that behaviors are practiced, repeated, and changed (from 8.1 to 8.4).

Table 2. Transposing the BCT[a] of COM-B[b] onto the digital behavior change intervention context: perceive, prepare, and act.

COM-B	Digital behavior change intervention [8]		
	Perceive (website + questionnaire)	Prepare (actions)	Act (personalized space)
1. Goals and planning	1.6. Discrepancy between current behavior and goal (questionnaire)	1.1. Goal setting (behavior) 1.4. Planning behavior	1.5. Review behavior goals (increase practice) 1.6. Discrepancy between current behavior and goal (doing the action) 1.7. Review outcome goal(s) 1.9. Commitment (to be done, etc.)
2. Feedback and monitoring	2.2. Feedback on behavior (questionnaire)	—[c]	2.3. Self-monitoring of behavior 2.4. Monitoring of behavior outcomes (redo the questionnaire)
3. Social support	3.1. Social support (unspecified; internet resources) 3.2. Social support (practical) 3.3. Social support (emotional)	—	—
4. Shaping knowledge	4.2. Information about antecedents	4.1. Instruction on how to accomplish a behavior	—
5. Natural consequences	5.1. Information about health consequences 5.2. Salience of consequences 5.5. Anticipated regret	—	—
6. Comparison of behavior	6.2. Social comparison	6.1. Demonstration of the behavior	—
7. Associations	7.8. Associative learning (favorable environment and multifactorial approach)	—	7.1. Prompts or cues
8. Repetition and substitution	—	8.3. Habit formation	8.1. Behavioral practice or rehearsal 8.2. Behavior substitution 8.3. Habit formation 8.4. Habit reversal
9. Comparison of outcomes	9.1. Credible sources 9.3. Comparative imagining of future outcomes	—	—
10. Reward and threat		—	10.4. Social reward
11. Regulation	11.3. Conserving mental resources	—	—
13. Identity	13.1. Identification of self as role model	—	—
15. Self-belief		—	15.3. Focus on past success

[a]BCT: behavior change technique.

[b]COM-B: capacities, opportunities, motivations-behavior.

[c]Not applicable.

The typology of a target user, as described earlier in the objectives, can be combined with the indicators of the perception, preparation, and action stages to complete an assessment in advance.

Mixed Assessment Protocol

Three evaluative questions emerge concerning the personalized account and, by extension, the website.

- What mechanisms and factors influence the choice of one or more actions and contribute to the user adopting them?
- What influence does personalized space have on the adoption of actions that are preferably multifactorial and on the self-assessment of lifestyle habits?
- What factors are likely to influence target users' perception of their chosen health-promoting action?

Our protocol combining quantitative and qualitative assessment is based on data collected from the personalized space, which was designed with the objective of "outsourced self-regulation" [17], supplemented by additional questionnaires and individual interviews. The mixed assessment evaluates behavior changes made at different time points in the data collection process rather than the increase in quality of life and disability-free life expectancy. As mentioned earlier, the evaluable result is the user's loyalty to the logic models used [13] and not the loyalty necessary for a program to be effective [15]. Kelders et al [22] described the typical components through an analysis of 83 digital interventions: modular, updated once a week, use of persuasive technologies, and potential to interact with the communicator and peers [23].

The features of an assessment protocol are as follows.

- Before the digital intervention is launched: it supports the design and modeling of digital intervention.
    - Once launched, (1) it checks whether the users of the personalized space are between the ages of 40 and 55 years, whether they are socioeconomically deprived, and whether they have a low level of literacy; (2) it creates typologies of registered users; (3) it measures the effects (ie, changes in the behavior of registered users) through evaluable criteria and indicators such as adopting and maintaining a new healthy behavior, increased knowledge, improved psychosocial skills, and improved health variables [6,24]; and (4) it continually improves the website and personalized space to support the desire to change behavior in midlife [18,25].

Recording unexpected effects [16] sheds light on the adjustments needed in order to continually improve the intervention. Several hypotheses for these have been formulated: (1) the questionnaire does not engage users or it is never repeated; (2) the initial request does not correspond to the determinant that the user is "coached" on in their personalized space; (3) a highly disparate choice of actions makes it difficult or even impossible to implement them (no actions are adopted); and (4) actions are liked without a time objective being set.

Assessment Objectives

As stated above, the intention was to split the individuals included in the assessment into 2 groups. The 7 measurement objectives presented below apply to both groups. A detailed description of the objectives is given in Multimedia Appendix 1.

- Objective 1: To assess whether the user's profile matches the purpose of the site, namely, to reach socioeconomically disadvantaged people with a low level of health literacy and aged between 40 and 55 years at T0.
- Objective 2: To record lifestyle habits that deviate to some extent from public health recommendations at T0, T1, and T2.
- Objective 3: To record liked actions and articles while distinguishing actions in category A (change in behavior: diet, physical activity, smoking, and alcohol—additional contribution compared to other Santé publique France social marketing schemes) from those in category B (greater knowledge: sleep, stress, cognitive health, and environmental health—initial contribution given the absence of other Santé publique France resources). The assumption made is that the user chooses actions for category A and study pages for category B. Data are collected at T0, T1, and T2.
- Objective 4: To assess willingness to change behavior at T0.
- Objective 5: To assess the evolution of the behavior change between T0 to T1 and T1 to T2; to assess the frequency and routine nature of actions at T1 and T2.
- Objective 6: To assess re-engagement at T2.
- Objective 7: To assess lapsed connection to the personalized space before T1 and before T2 [26].

Assessment Time Frame

A digital behavior change intervention consists of several stages with a total average duration of approximately 10 weeks [8], although there is no consensus between experts over the time frame. Engagement with the digital intervention involves registering to create an account with a personalized space and then signaling preparation for behavior change (phase 1), followed by the adoption of 1 or 2 actions (phase 2), and a phase of lapsed activity on the site (phase 3). Reengagement with the intervention (phase 4) is prompted by the need to solve a problem, renew motivation, identify a new action, and so on. [7]. Split into 3 evaluable phases—T0, T1, and T2 (respectively phases 1, 2, and 4 according to Yardley et al [7], in Table 3). The expected results and collection methods are presented in Table 3. It is based on the assessment work of the VERB™ campaign (in normal type) [27], the lessons learned on health information-seeking behaviors (in italics) [28], the theory of small actions (in bold) [29], and digital behavior change interventions (in bold and italics) [7].

Table 2 presents the interaction between perceiving, preparing, and acting, which can be repeated randomly at the 3 assessment intervals set out in Table 3.

Table 3. Timing of the assessment process, evaluable results, and assessment indicators: engagement with physical activity.

Action verbs	Actions	Outcomes	Assessment or indicators
Phase 1 (T0): use of the digital intervention			
To be aware of and to understand	Campaign	—[a]	Quantitative posttest evaluation of social media campaigns
To access	*Information*	—	—
To engage with	**Information**	**Site log-in and completion of the questionnaire**	**Log-in data (quantitative)**
To choose	***A small target behavior***	***Actions or liked content pages, account created in the subscriber space, and healthy lifestyles***	***Interaction with the site and subscriber space data (quantitative and qualitative)***
Phase 2 (T1): use of the digital intervention and engaging with behavioral change			
To change in	—	Subjective norms, beliefs, self-efficacy, and perceived behavioral control	Qualitative data: questionnaires, verbatim comments, and individual interview
To use	*Information*	—	—
To intend to do	Physical activity	—	—
To engage with	**Behavior changes**	**Site log-ins and actions in the subscriber space**	**Qualitative and quantitative data from the subscriber space**
To choose	***A small target behavior and a concatenation of smaller goals***	***Actions or liked content pages and healthy lifestyles***	***Interaction with the site and subscriber space data (quantitative and qualitative)***
Phase 3: engaging with behavioral change			
—	—	—	—
Phase 4 (T2): use of the digital intervention and engaging with behavioral change			
To commit to and to maintain	Physical activity	Health outcomes	Log-in data (quantitative); interaction with the site and subscriber space data (quantitative and qualitative); and qualitative data: questionnaires, verbatim comments, and individual interview
To make	*Physical activity*	*Empowerment/ locus of control, satisfaction, activities of daily living, and health outcomes*	—
To choose	**A new small target behavior**	**Liked, validated actions**	—
To re-engage with	***Information if needed***	***Site log-ins and actions in the subscriber space***	—

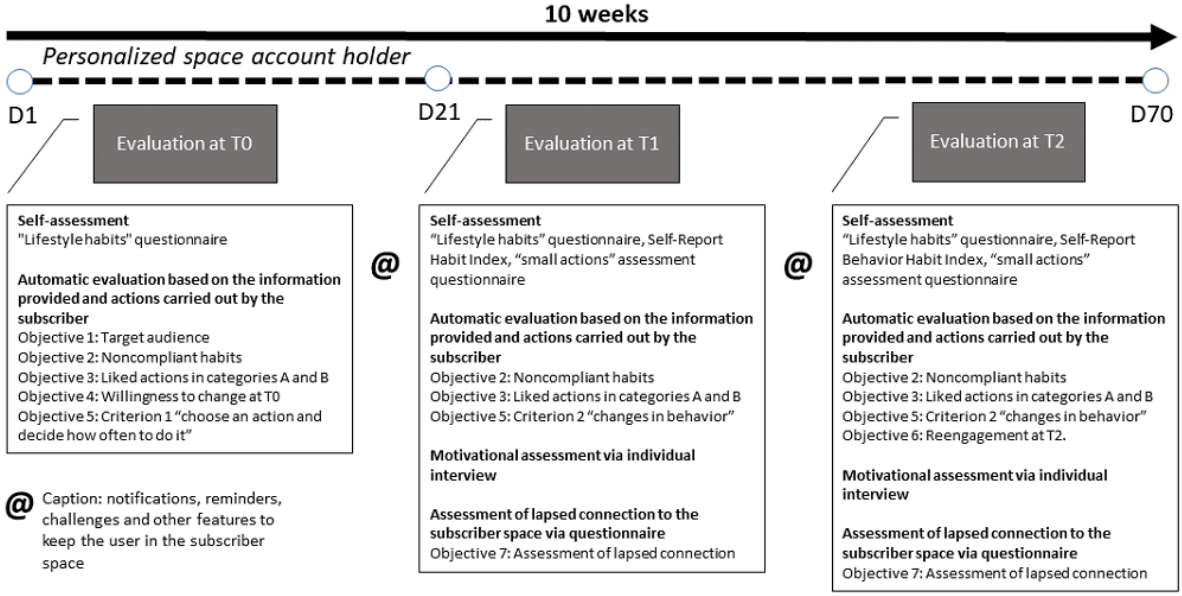
[a]Not applicable.

Furthermore, it is particularly important to determine (1) T1 (changes related to subjective norms, beliefs, self-efficacy, and perceived control of behavior), (2) T2 (level of empowerment, degree of satisfaction, activities of daily living, and self-reported health outcomes), and (3) between T0 and T1 and then between T1 and T2, there are 4 reasons for lapsing—forgetting, having a technical problem, permanently giving up on self-quantification, and suspending usage—but these do not necessarily mean that the adopted action has been abandoned [26].

Assessment Methods From T0 to T2

As detailed in Figure 2 [30], the assessment of the digital intervention at T0, T1, and T2 is intended to be explanatory, combining a quantitative and qualitative approach based on recording for both groups of users: (1) log-in data for the site and user account with personalized space, (2) data relating to specific and identifiable behavior changes by monitoring registered users from T0 to T2 via the content management system, (3) verbatim statements from users for classification into user profile; and (4) information about capabilities, opportunities and motivations via semistructured individual interviews with a sample of users.

Figure 2. Assessment methods from T0 to T2 (adapted from Trottier et al [30]).



Self-Assessment at T0, T1, and T2

The "lifestyle habits" questionnaire is the basis of the initial self-assessment at T0, then again at T1 to visualize the changes that have taken place and finally at T2 to identify developments (Table 4). Other suggested tools at T1 are the Self-Report Habit Index [31] to assess the power of the "frequency" factor for the action performed most often and the "small actions" assessment questionnaire. At T2, the Self-Report Behavior Habit Index is intended to show whether the behavior has become routine, supplemented by the "small actions" assessment questionnaire.

Table 4. Expected outcomes and measurement tools of the assessment protocol [32].

Objective	Domains	Measures	Source	Time frame	Measuring or recording tools
First results					
2. Lifestyle habits	Lifestyle habits more or less comply with public health recommendations	Results of lifestyle habits questionnaire	Server log files	T0, T1, and T2	"Lifestyle habits" questionnaire
3. Liked actions and articles	Adopting categories A and B actions related to one or more health determinants	Classification of actions by the user (including verbatim comments)	Server log files	T1, T2	Classification of actions
3. Liked actions and articles: multiple health factors	Understanding that health depends on multiple factors	Classification of actions by the user (including verbatim comments)	Server log files	T1, T2	Classification of actions
4. Willingness to change behavior	Statement of wanting to change a behavior	Classification of actions by the user (including verbatim comments)	Server log files	T0	"Lifestyle habits" questionnaire and Lapsing assessment questionnaire
5. Evolution of behavior change	Change in one or more lifestyle habits	Lifestyle habits questionnaire is repeated with one or more lifestyle habits changing	Server log files	T1, T2	"Lifestyle habits" questionnaire and classification of actions
5. SRHI[a]	Frequency of performing action	Self-assessment by SRHI	Server log files	T1	SRHI
5. SRBHI[b]	Extent to which action has become routine	Self-assessment using SRBHI	Server log files	T2	SRBHI
6. Re-engagement	Assess re-engagement	Classification of actions by the user (including verbatim comments); self-assessment by SRBHI	Server log files	T2	Classification of actions
7. Lapsed connection	Assess lapsed connection to the personalized space	Results of the assessment questionnaire on lapsed connection	By email	Before T1 and before T2	Lapsing assessment questionnaire
Mediators					
Effectiveness of mediator	Self-efficacy	Sense of personal efficacy [33]	Individual interview by group 1 and group 2 profile type	T1	Sense of personal efficacy scale
Effectiveness of mediator	Motivation	Situational motivation [34]	Individual interview by group 1 and group 2 profile type	T2	Situational motivation scale
Effectiveness of mediator	Capability, opportunity, and motivation	Information provided by the user through the individual interview	Individual interview by group 1 and group 2 profile type	T1, T2	Interview guide
Effectiveness of mediator	Frequency of personalized space log-in	Quantitative analysis of the user journey	Server log files	Continuous	Number of log-ins, liked actions and articles, incorporated or abandoned actions; time spent logged in; and interconnection between the determinants
Other results					
1. User profile	Biographical data	Categorized into group 1 or group 2: age, profession, level of health literacy, and absence of chronic disease	Results of lifestyle habits questionnaire and results of the "small actions" assessment questionnaire	T0	"Lifestyle habits" questionnaire and "Small actions" assessment questionnaire

Objective	Domains	Measures	Source	Time frame	Measuring or recording tools
1. User profile	Relationship between initial contribution (category B) and additional contribution (category A)	Personalized space: liked actions and studies	Server log files	T0-T2	Number of liked actions and articles by category
1. User profile	Any difference in behaviors between group 1 and group 2	Processing quantitative and qualitative data provided by registered users	Server log files	T1, T2	"Lifestyle habits" questionnaire, "Small actions" assessment questionnaire, and individual interview
1. User profile	Rate of lapsed activity in the personalized space	Lack of log-ins to the personalized space	Server log files	T0–T2	Number of log-ins between T0 and T2 and Lapsing assessment questionnaire

[a]SRHI: Self-Report Habit Index.

[b]SRBHI: Self-Report Behavior Habit Index.

To further support the objectives mentioned earlier, an automatic assessment at T0, T1, and T2 retrieves the information provided and actions carried out by the user.

The aim of the semistructured individual interview at T1 and T2 by groups 1 and 2 profile type and sampling is to reveal the impact of the capabilities, opportunities, and motivations on behavior change by combining the methodology of the COM-B, the theoretical domains framework [35] and the tiny habits theory. Taking a human-machine interaction perspective, it is very difficult to determine whether the choice of an action is based on conscious or unconscious motivation [8].

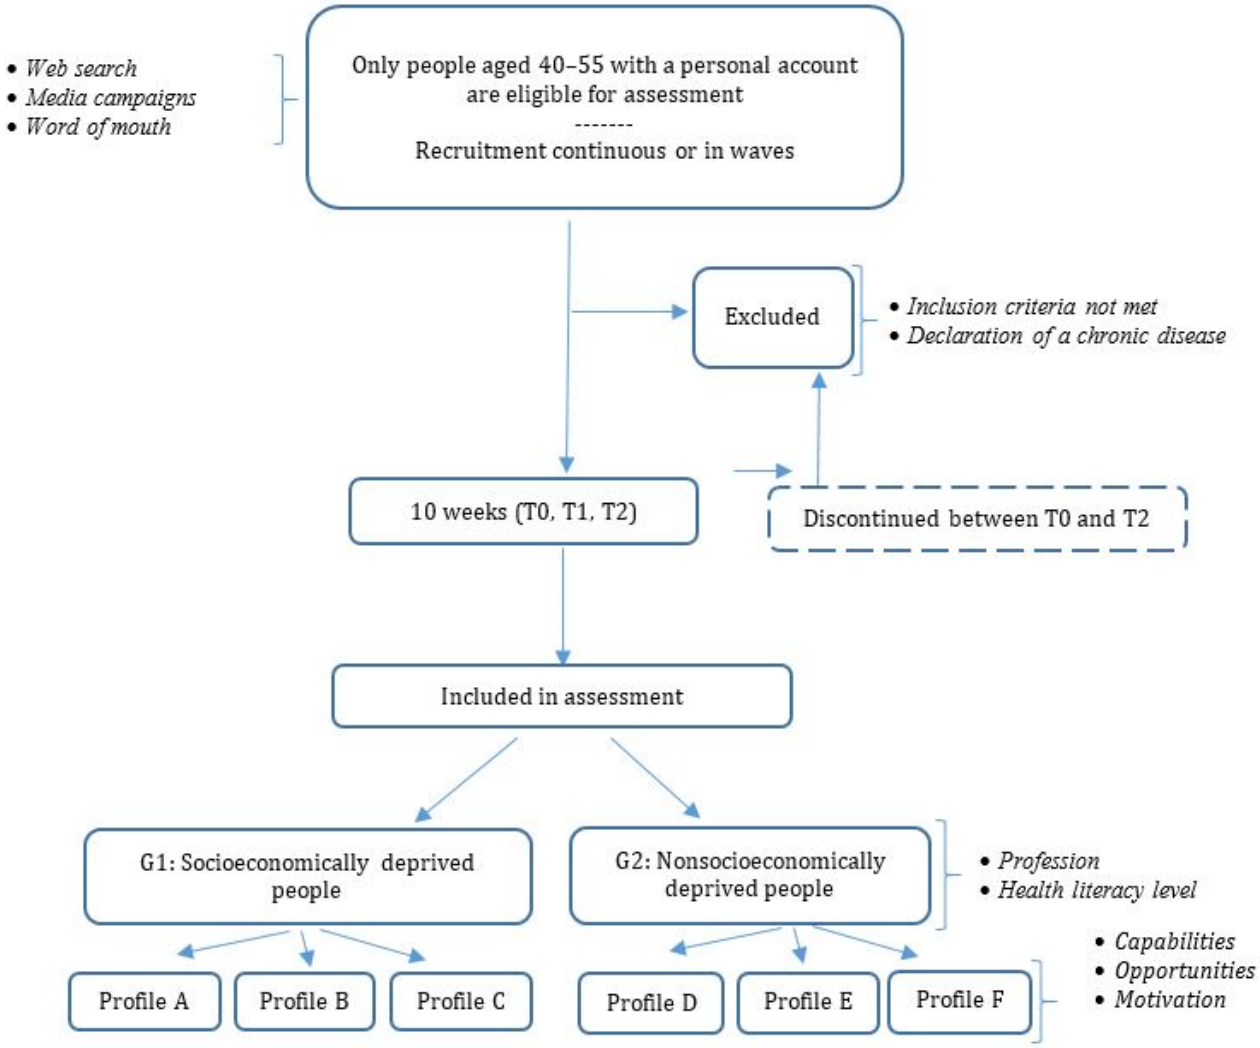
The assessment of lapsed connection to the personalized space before T1 and before T2 will be carried out via a questionnaire sent by email to the concerned users. The objective is to identify the reasons for the lack of use (with the aim of continually developing the personalized space) and the number of actions maintained without logging in.

Objectives 2, 4, and 5 make it possible to assess any unexpected effects: (1) the questionnaire is not the draw for the user or is never repeated (meaning that the user cannot view their progress in the personalized space; objective 2); (2) actions are liked, but no goal is set (objective 4); (3) a highly disparate choice of actions makes it difficult or even impossible to implement them (no actions are adopted; objective 5, criterion 1); and (4) the initial request differs from the action that the user is "coached" on in the personalized space (objective 5, criterion 2).

Assessment Population

The internet users, included in the assessment will be between the ages of 40 and 55 years, have registered to create an account on the website with a personalized space, and have carried out actions in their space during the 3 assessment stages: T0 (date of personal account creation), T1 (3 weeks after creation), and T2 (10 weeks after creation) (see Figure 3). Users will be divided into 2 groups. Group 1 will include socioeconomically deprived people and group 2 all other users. Each group will then be subdivided based on the "motivations," "capabilities," and "opportunities" expressed. By characterizing users into these 2 socioeconomic groups, the diversity of behaviors can be questioned, and corrections can be made to support group 1. Classification into group 1 will be based on 2 conditions: belonging to the lower socioprofessional categories and having a level of health literacy below 3.39 on domain 8 of the French Health Literacy Questionnaire [36].

Figure 3. Assessment diagram.



When people create their personal account, in accordance with the General Data Protection Regulation in force in Europe, registered users will need to consent to the use of their quantitative and qualitative data for study purposes and agree to be contacted as part of the assessment. No sensitive medical data will be recorded, and the data from the content management system will be separated from the information collected through the personalized space. The digital security officer at Santé publique France verified the compliance of this data management approach with French data protection regulations (Commission nationale de l'informatique et des libertés).

The protocol currently allows testing in a given context and on a regional scale, for example.

Results

This first version of the protocol responds to the objective to create a multidimensional assessment of a digital intervention based on the statement that during a given timeline, interactions with users aged 40-55 years can reveal their capabilities, opportunities, and motivations to adopt healthy lifestyles.

The assessment protocol based on the interactions with users in their personalized space of the digital behavior change intervention includes the evaluation of the following.

- Increased capability, opportunity, and motivation to adopt a healthy lifestyle through one or more actions.
- Improved access to information that is easy to translate into actions and to continue.
- At least 2 actions adopted in everyday life.

However, the protocol cannot evaluate improved health promotion and disease prevention dialogue with adults in midlife in different settings or assess changes in social norms.

As the construction of the website is currently delayed, no recruitment or effects analysis of the protocol could take place. The creation of a steering committee was abandoned.

Discussion

Expected Findings

As mentioned above, the protocol assesses the impact of the website based on the small behavior changes that it triggers among users in relation to different health determinants. The protocol has four aims: (1) engaging a specific population, (2)

triggering behavior change, (3) raising awareness about a multifactorial approach to health, and (4) encouraging user interaction with the website's resources. The research takes an interest in challenging the time frame necessary to evaluate the adoption of healthy lifestyles. It focuses on how the usage of behavior change models (COM-B) combined with the techniques of digital behavior change interventions [8] can strengthen the effect measurement of an assessment protocol. The assessment protocol is based on typical digital functionalities such as a user account, self-evaluation of healthy lifestyles (questionnaire), and feedback to engage people with behavior change. It fosters a continuous short-term evaluation of digital behavior change interventions.

Main Results

This appears to be the first assessment protocol for digital health promotion interventions. It documents the potential of the digital intervention in various respects, supporting it on the basis of the chosen models that led to the design of the personalized space and contributing to its continued development both in terms of its technical features and written content. The mixed assessment method delivers a granular analysis that sheds light on the effectiveness and even the efficiency of the website through its personalized space. To our knowledge, our assessment protocol for a digital personalized space, designed with the aim of changing health promotion and disease prevention behaviors, is the first of its kind in the sense that it goes beyond the measurement of the implementation and expressly targets the measuring effect. According to literature reviews, the effects in question will be behavioral change, greater knowledge, improved psychosocial skills, development of a support network, and improved health variables [6]. The protocol cannot be likened to assessments in investigational designs such as randomized controlled trials, which have been dismissed by some experts as unsuitable by some experts due to the complexity of health promotion interventions. The open design is considered effective "for the institutions that set it up and its flexibility matches the characteristics of health promotion interventions" [6].

Limitations

The breadth of the mixed assessment may make the process of interpreting the lessons learned more complex if the power of each item of "collectible" information proves to be insufficient. The absence of an expert consensus on the duration necessary for behavior change to occur throws into question the time frame of 70 days. The weakness of the protocol relates to the lack of real application given that the launch of the website is delayed.

Conclusions

Drafting an assessment protocol is a significant aid in the design of a digital intervention. This makes it possible to consolidate the choice of hypotheses for constructing the logical models used and the objectives targeted. A protocol helps to steer the digital intervention toward the action and regularly checks that it meets the needs of its target audience. The assessment protocol meets the SMART (specific, measurable, achievable, relevant, and time-bound) criteria.

The research presented here will impact digital interventions in health promotion and disease prevention. As the protocol demonstrates, both the implementation and effects can be assessed. Health promotion and disease prevention stakeholders may prefer an assessment of the program, but this is rarely carried out. Without assessments, a digital intervention can claim to be "evidence-inspired," although, with assessments, it is closer to "evidence-based."

Conflicts of Interest

None declared.

Abstract

Background: The lack of osteoporosis treatment initiation after fragility fractures is a significant gap, especially in primary care. It is unclear whether barriers for primary care physicians (PCPs) arise from uncertainty about investigations, treatment initiation, or medication side effects. Key questions remain about whether active learning platforms improve treatment initiation rates better than passive methods and how PCP demographics affect learning outcomes. With PCPs increasingly using web-based platforms for continuing professional development due to time constraints and heavy workloads, an interactive community fracture capture (CFC) tool may serve as an effective alternative to in-person learning. Our CFC pilot study tested this new program's design and content, showing promising potential.

Objective: We aim to evaluate the interactive, case-based, web-based CFC Learning Hub, examining user acceptance and engagement with the platform, focusing on participants' interactions, satisfaction levels, and overall experience.

Methods: Participating PCPs are recruited through Praxhub, a web-based medical education platform, and provide electronic consent for data use after deidentification. They have been allocated into small groups (12-20 members) and join the CFC Learning Hub, a secure web-based community. This hub includes a web-based discussion forum with participant-contributed case studies and a knowledge repository. Over the 6-week program, participants will receive weekly modules with instructions, resources, discussion threads, and quizzes, along with interactive discussions moderated by experienced PCPs and physicians. The platform also hosts web-based surveys that, in combination with platform analytics, allow assessment of baseline knowledge gaps, level of activity or engagement, and improvements following the course completion. This study protocol demonstrates the creation and proposed evaluation of the CFC Learning Hub, featuring an interactive, case-based, small-group web-based learning platform equipped with flexibly scheduled, tailored modules to address the fracture treatment gap within the community. Both qualitative (via thematic analysis) and quantitative (by using 2-tailed paired *t* tests, Wilcoxon signed rank tests, and multivariable regression

analysis) analyses will be used to assess levels of engagement and acceptance and changes in PCPs' knowledge and confidence after engagement with the CFC Learning Hub.

Results: Recruitment of participants started in May 2022. Data collection, analysis, and reporting will be completed following the completion of four 6-week cycles of the program.

Conclusions: The study described in this protocol will provide important insights into the function and effectiveness of the CFC Learning Hub. This information will guide the expansion of the program. This initiative offers a simple digital solution for promoting current bone health practices tailored to PCPs' needs and thereafter to expand the rollout of the e-learning hub and implementation of fracture liaison models at a primary care level in Australia and elsewhere. Future applications may extend to other clinical areas and professions.

Introduction

Osteoporosis: A Growing Global and National Concern and the Unmet Challenges in Fracture Prevention and Management

Osteoporosis affects around 200 million people globally, resulting in more than 8.9 million fractures each year, equivalent to 1 fracture every 3 seconds worldwide [1]. Furthermore, this disease burden is projected to increase dramatically in the coming decades as the global population is aging [2]. By the year 2050, the global occurrence of hip fractures is estimated to rise by 310% for men and 240% for women, compared with 1990 rates [3]. In Australia, osteoporosis incurred a societal cost of Aus $2.6 billion (~US $1.638 billion) in 2022 [2]. Despite the alarming increase in the prevalence of osteoporosis and the morbidity, mortality, and economic costs associated with low-trauma fractures in the aging population [4-6], there remains a substantial deficit in the implementation of effective interventions to prevent fragility fractures [7-9]. Despite the presence of effective diagnostic tools (eg, dual-energy x-ray absorptiometry [DXA]), fracture risk assessment tools (eg, FRAX) [10], and medications known to mitigate fracture risk, a substantial treatment gap exists in osteoporosis care, with only about 20% to 30% of individuals who sustain fragility fractures receiving guidelines-based care [2,11]. International and Australian data have unequivocally demonstrated the cost-effectiveness of hospital-based fracture liaison services (FLS) in secondary fracture prevention to address this treatment gap among patients presenting with low-trauma fractures, including in our own institution [12,13]. However, many patients with low-trauma fractures that may not require tertiary care (eg, vertebra, radius, and others) are investigated and managed purely at the primary care level and therefore may escape hospital-based services [14]. Furthermore, a recent survey of the International Osteoporosis Foundation Capture the Fracture program also noted a relative paucity of FLS centers in Australia [2]. The probability of initiation of osteoporosis medication following hip fracture within 12 months after discharge has been falling, despite these patients having the highest risk for imminent refracture [15,16]. The same investigation gap exists in primary fracture prevention among primary care physicians (PCPs); since 2016, there has been a plateau in subsidized bone density requests for Australians older than 70 years, despite the rapidly aging population [9,12,14,17].

Adapting Fracture Prevention Models: The Urgent Need for Improved Primary Care Strategies

A rational approach to improving fracture prevention outcomes in the community setting would be to adapt the hospital-based model of care at the primary care level. However, unlike the hospital-based FLS that depends on the coordinator to facilitate investigations and clinic appointments, community-based fracture capture relies solely on PCPs to detect, investigate, and treat osteoporosis [18]. Despite compelling evidence for efficacious treatments to manage osteoporosis in primary care, and in particular the initiation of therapies to minimize the likelihood of refracture, the application of evidence and guidelines into clinical practice, particularly by PCPs, remains unacceptably low in Australia and many other countries such as the United States, Malaysia, Singapore, Germany, France, and Canada [9,19-24]. Consequently, many Australians are not receiving optimal, timely care in the community. For example, despite being eligible for osteoporosis-related investigations (eg, DXA) and antiresorptive therapies (eg, denosumab and bisphosphonates), a large proportion of Australians are neglected in this respect. While the hospital FLS model focuses on secondary fracture prevention with the motto of "Stopping at One Fracture," the additional focus among PCPs should be primary fracture prevention with the aim of "Stopping the First Fracture" [25].

Empowering PCPs: A Novel Approach to Bridging the Osteoporosis Treatment Gap Through Live, Interactive Learning Hubs

PCPs are faced with enormous challenges in daily practice to deal with multiple chronic health conditions, their sequelae, and comorbidities within a limited consultation time. Despite this, PCPs are required to continuously extend their knowledge to ensure that evidence-based practice is applied to their patients [26,27]. PCPs are increasingly seeking information on the web for their continuing professional development (CPD) [28-31], which is a viable alternative to face-to-face learning that

potentially can be managed in their own time [32]. Hence, incorporating social media technologies for CPD has become a commonplace mechanism encouraging PCP learning in web-based group settings [29,33,34]. Including our Community Fracture Capture (CFC) Learning Hub pilot study, only a few recent studies have investigated the ability of web-based learning activities to mitigate the crisis in osteoporosis care by providing education, leveraging the scarce resources of the health care system, and enabling practitioners to offer better and more accessible skeletal health care locally and at a lower cost [35,36]. Our investigation of challenges PCPs face in using virtual communities of practice (VCoPs) for continuing medical education emphasizes the importance of trust building, efficient time management, and collaborative learning among health care professionals in building efficacious VCoPs [37]. We therefore aim to address the community osteoporosis treatment gap using a novel, live, and interactive CFC Learning Hub that provides a health VCoP to facilitate knowledge transfer to overcome barriers to osteoporosis recognition and management.

Although this program incorporates some elements typical of conventional courses, its distinctive combination of features and the unparalleled extent of flexible engagement opportunities set it apart. This uniqueness underscores our rationale for the study and the importance of conducting a formal research evaluation to fully assess its operational features, effectiveness, and potential impact on participants. Building on the feasibility study results, we aimed to create a more advanced version of the CFC Learning Hub with enhanced features. Therefore, this study aims to develop the CFC Learning Hub, an interactive web-based platform with case-based modules to improve fracture treatment among Australian PCPs and assess the impact of the CFC training model, while also examining the relationship between PCP demographics, clinical experiences, and knowledge gaps in treatment.

Methods

Study Context

The general design, development, and content planning for the interactive, patient-focused CFC Learning Hub have already been piloted to a small group of PCPs with favorable feedback and demonstrating excellent metric properties [35]. The CFC Learning Hub will be built from lessons learned from this feasibility study with the aim of enhancing PCPs' awareness and competence in caring for patients with osteoporosis. The hub was conceived, designed, and developed by an interdisciplinary team of experts, comprising specialist physicians with expertise in osteoporosis and bone health, experienced PCPs, information technology and data science experts, and a project manager. It took time and resources for specialists to discuss and agree on major decisions for the program. Therefore, the timing and resource for such projects require appropriate support because of the need to understand terms, expectations, deliverables, and measurables across disciplines. The project team, situated in Melbourne, Australia, drew on its learning, teaching, and clinical experience to define the following important design criteria for PCP participants and elements in the project:

1. Practicing PCPs registered for the training have been provided with case studies and asked to provide their own case study with anonymized patients to encourage engagement.
2. There is interactive engagement between all parties involved.
3. Experienced PCP peers lead the group as facilitators, with guidance where needed by specialist "advisors," promoting case discussions and guiding discussion of content according to its relevance and importance.
4. There is a minimum time commitment required for the award of CPD credits for participation.

Importantly, the CFC Learning Hub format is flexible in terms of the timing of participants' input. Comments can be posted and discussions can be viewed at any time of the day, in order to accommodate participants' workload and personal commitments. This learning platform provides an alternative to attending an on-site lecture or a webinar wherein a specific time slot needs to be set aside for attendance including discussion. The CFC Learning Hub will be driven by three principles: (1) sound learning pedagogy that is aimed at changing attitudes and behavior, supported by clear assessment structures; (2) learning analytics at the back end of the CFC Learning Hub to understand the development of the participants through studying their web-based participation in the discussion forum; and (3) usable and accessible features of the hub to ensure maximization of uptake of the system.

Education Platform

Education has been delivered via Praxhub [38], an Australian-based web-based platform for health care professionals to access CPD resources from leading health care organizations. At the time of publishing this paper, Praxhub is used by thousands of health care professionals from more than 150 countries and aggregate education from more than 50 health care organizations. The CFC Learning Hub represents a departure from the main model of webinars and web-based learning modules for PCPs on a wider scale by including a range of increased opportunities for engagement and interactions with the participants.

The Praxhub platform allows for "groups" to be set up, in which participants can join and each week's education modules can be hosted and made available to the participants. Before starting the CFC cycles, an early decision was made to make each of the groups "private"—meaning that only those participants invited into that group would have access to the modules and visibility of that group's activity (ie, conversations within the discussion thread). It was considered important to quarantine the activity within the group from the remainder of Praxhub's membership to create a more supportive and encouraging environment for individual participation. By extension, it was considered that a public group, in which conversations could be viewed by the broader Praxhub membership of health care professionals, may have the propensity to limit conversations (ie, active engagement) due to concern about criticism or professional judgement, as well as to avoid redundant discussions.

After assignment of participants to a designated private group, they attended an approximately 1-hour orientation session, conducted via a Zoom (Zoom Video Communications, Inc) meeting, to familiarize them with navigating the group and accessing the modules. Participants were informed by email (with a link in the email) of the availability of a new module each week. Within each module, participants were provided video or written instructions of the activities to be completed in that week, additional resources or materials to download and read, and a facilitated discussion thread in which to post questions to the specialists or PCP coordinator. The composition of each module is shown in Table 1. A weekly quiz was also made available for participants to probe their understanding of the week's materials.

An additional consideration in selecting Praxhub as the system to deliver the CFC Learning Hub program was its robust data collection. While Praxhub strictly uses these data to enhance the user experience and report completions of CPD activities on the platform, in accordance with its privacy policy, participant consent was provided to Praxhub for the limited disclosure of their deidentified data for the purposes of this study (see the *Data Collection* and *Ethical Considerations* sections).

The research measured various user-system interaction points to allow us to quantify the participants' engagement with the education program. These included dates and times (particularly time of day) when participants engaged with the education modules, whether videos were viewed or materials were downloaded, their engagement with other participants and the PCP coordinator and specialists via the discussion thread, and the responses to weekly quizzes.

These data were reviewed each week during the program to monitor participant-level engagement and at the end of each 6-week cycle to construct and understand how the participants engaged with the education and determine the performance in the program against the overall objectives.

Table 1. A summary of Community Fracture Capture Bone Hub 6-week content design.

Characteristic	Week 1	Week 2	Week 3	Week 4	Week 5	Week 6
Cases	Live webinar + 1× case	1× case	2× case	2× case	2× case	Live webinar + 1× case
Hot topics	Osteoporosis introduction and investigation	Assessment of risk factors	Osteoporosis effects	Treatment and side effects	Treatment failure	Difficult osteoporosis cases
Surveys	Premodule survey	N/A[a]	N/A	N/A	N/A	Postmodule survey
Quizzes	N/A	1×	1×	1×	1×	N/A

[a]N/A: not applicable.

Education Program

The CFC Learning Hub is a web-based resource center for case studies, related resources to support PCP learning, and a web-based community discussion forum. Once enrolled, participants are required to watch a mandatory familiarization program to learn the function and capability of the hub and to submit 1 or 2 patient cases for discussion. Facilitators and specialist advisers will filter and select case studies that enable coverage of a syllabus of topics predetermined by members of the project team for this CPD course. Facilitators ensure that the posted case studies are anonymized and contain suitable, high-quality content for discussion. Each CFC Learning Hub cycle is scheduled for 6 weeks and comprises three main learning pillars: (1) osteoporosis investigation and treatment initiation, (2) treatment maintenance and monitoring, and (3) troubleshooting treatment side effects and treatment failure. In some cycles, a short video presentation will be delivered by a bone specialist to introduce the theme of that week. Participants will be exposed to a range of case studies over these modules and have access to resources to facilitate learning and novel paradigms of thinking about osteoporosis to address the treatment gap. In addition, there will be opportunities for peer-to-peer interactions and learning; the experience is enhanced and personalized by discussing difficulties that registrants encounter in their very own deidentified submitted cases. The CFC Learning Hub platform has two resources for PCP interactions: (1) a web-based knowledge repository (the "Knowledge Hub") containing prepopulated evidence-based research papers, guidelines, position statements, and other resources relevant to that week's topic curated by our team's subject matter experts, and (2) a web-based social network forum (the "discussion forum") where PCPs can freely post web-based comments including questions for discussion posted by facilitators; case studies as a way to encourage PCPs to learn and share their knowledge based on shared experiences and relevance to their immediate clinical practice; and topical discussions as either hot topics deemed relevant for PCPs, posted by our osteoporosis specialists, or other topics that were open for a wider discussion (ie, introductions (facilitators and PCPs introduce themselves) and burning questions (PCPs and facilitators post inquiries on osteoporosis; these will focus on significant issues arising during a group's participation). The platform's topical discussions section includes (1) diabetes and bone health, (2) atypical femoral fracture, (3) when to consider changing an osteoporosis therapy, (4) how to get the most from your patients' bone density testing, (5) an "Introduction" topic for all users to introduce themselves, and (6) a facility for PCP participants to post inquiries based on seeking specific information about osteoporosis. Facilitators can also raise questions to promote discussion. These inquiries are organized under the term, "Burning Questions." The Knowledge Hub will act as an accessible knowledge repository for all users at any time. It will be a dynamic source of information, being expanded

and adapted in response to participants' learning needs. Participating PCPs will complete 4 knowledge quizzes (1 quiz in each of weeks 2-5) and a questionnaire regarding osteoporosis caseload and demographics, confidence in case finding, investigations and treatment initiation, and barriers to osteoporosis case finding, investigations, and treatment initiation. The knowledge assessed will be in accordance with The Royal Australian College of General Practitioners (RACGP) and the Healthy Bones Australia (formerly Osteoporosis Australia) Osteoporosis Management and Fracture Prevention Guideline 2024 [39], a position statement developed by national experts to provide PCPs with clear guidance concerning the identification, investigation, and treatment of persons at risk for fragility fractures. In addition, pre- and postparticipation multiple-choice questions will be used for testing to assess knowledge transfer, change in confidence, and behavior (Table 1). The forum will be highly interactive (active learning) and case based and is supported by the RACGP and the Australian College of Rural and Remote Medicine approving the award of CPD points or hours to their fellows for active participation in the CFC Learning Hub (RACGP: 40 CPD points [2020-2022 triennium] and 12 activity hours [2023-2025 triennium], and Australian College of Rural and Remote Medicine: 8 Professional Development Program hours [February 23, 2020 framework] and 12 activity hours [2023-2025 framework]).

Description of the Platform, Setting, Recruitment, and Participants

Platform

Praxhub has developed a web-based community (web and mobile apps) to support the delivery and distribution of medical education. It is free of charge for doctors to register and their credentials are validated against the government-held register of doctors. Praxhub already has a preexisting large network of registered PCPs in Australia and has been recruiting participants through their web page and internal member communication system.

The invitation to participate in the CFC Learning Hub will be distributed via PCPs professional bodies and using the existing pool of PCPs registered with Praxhub. Interested PCPs will contact the project manager, after which they will be screened for eligibility to participate in the program and subsequently enrolled if they satisfy the selection criteria and consent to participate in the project, approving to take part in the 6-week web-based educational program, answer pre- and postparticipation surveys, and allow the CFC Learning Hub to use their data for auditing and research purposes.

Once registered, all participants will be allocated to a private group, through which they can access the topical presentations, cases, and discussion forums. Participants and facilitators will have a profile, which shows their professional qualifications, experience, practice location, awards, and achievements, in accordance with the information that is required for the program, in addition to a profile picture (avatar) for personalization and easy identification. Participants will be able to engage in case studies and discussion topics and access and post comments, text, images, links to videos, and documents at their convenience.

The aim is to enroll 12-16 PCPs to participate per CFC Learning Hub cycle, and participants can drop in and out based on their interest in the content and their availability.

PCPs will be eligible to participate in the program if they (1) are a medical practitioner currently active in general practice in Australia, (2) submit at least 1 (preferably 2) suitable case studies with discussion or learning points from their own clinical experience that include patients at risk or those with prevalent osteoporosis, and (3) have web access.

PCPs will be excluded if they are unable to commit at least 6 hours to the anticipated time required to meet appropriate CPD guidelines.

Measures

Data related to sessions and activities of participants in the CFC Learning Hub will be collected for all cycles. Our primary focus, at this stage of the project, is detecting participation patterns to characterize the interactions of participating PCPs with the platform and specifically with respect to osteoporosis investigation and treatment initiation, learning, and knowledge-sharing behaviors related to participation and engagement in the CFC Learning Hub.

We will define the following terms from Praxhub analytics:

1. A session includes all user-related activities from initial logging in to logging out of the CFC Learning Hub. All activities made between the logging in and out activities will be grouped within a session.
2. An activity includes downloading of content, viewing posts and content, and posting comments.

Measuring sessions and activities will discover participants' full active and passive engagement with the web-based system, which can be used to help measure the success of the platform (eg, high-session count means PCPs are frequently logging in, undertaking 1 or more activities, and then logging out). PCPs can actively engage through posting in a case study or topical discussion, while they can also engage passively via browsing and watching a brief video presentation in a case study or topical discussion. Initially, in the Knowledge Hub, we anticipate that PCP participation is likely mainly to be passive as PCPs browse the Knowledge Hub database. In addition, PCPs can actively engage with the Knowledge Hub by posting comments or queries. In measuring discussion forum use, the usage behavior for each case study and topical discussion will be assessed. For each case study and topical discussion, usage is measured from the creation date (on a Monday of each cycle's week) until the end of the cycle).

Interactive Learning Hub

Once the 6-week program commences, the weekly content for 1 or more topics, along with a short video presentation on some topics (cycles 3 and 4), delivered by senior PCP and bone specialists to introduce the theme of that week, will be released by the moderators at a predefined scheduled time. This is communicated to participants via customized electronic

correspondence allowing them to access and discuss. The content of these weekly modules is based on and selected from the following topics:

1. What is osteoporosis and why is it important?
2. Prevention strategies for osteoporosis and secondary fracture.
3. Who is at risk? Tools for assessing fracture risk.
4. Application in primary care.
5. The roles of allied health professionals—practice nurse, physiotherapist, and dietitian.
6. Physical activity and exercise: benefits and risks, beliefs about exercise.
7. Osteoporosis diagnosis and further evaluation. Appropriate initial workup.
8. DXA: Applications. What are its strengths and limitations?
9. Treatment: Approach to the choice of treatment and initiation of specific osteoporosis therapy.
10. Engaging patients in shared decision-making.
11. Calcium and vitamin D: Primary therapy and adjunctive therapy.
12. Monitoring for safety and effectiveness of therapy.
13. Recognizing and managing treatment "failure."
14. Issues with long-term therapy and "treatment holidays"?
15. Osteonecrosis of the jaw and atypical fractures associated with treatment.
16. Why are patients being missed?

The hub will direct participants to resources and organizational websites in line with the week's topic and case study. Along with the release of the educational resources, a relevant case study will be presented for discussion. Interactive and flexible discussion throughout the week will take place on predefined discussion boards within the CFC Learning Hub and will be moderated by PCP facilitators and experienced physicians.

Moderators and Data Gathering

Moderators will access the discussion boards during each topic discussion to monitor and participate in discussion at least once daily during each cycle. The time and way in which participants engage with the site will be quantitatively monitored throughout the duration of participation in the Learning Hub. Specifically, data that will be collected include (1) total number of discussion posts by each participant; (2) individual response time for each new discussion board opened on the web-based forum; (3) number of users who have actively participated in individual discussion board on the web-based forum; (4) the average time to reach a final resolution in each discussion on the web-based forum; (5) the accrued time that each participant spends logged onto the learning hub; (6) the total time that each participant spends on the web-based forum and individual pages on the learning hub, (7) the number of times internal and external websites are visited by each participant from the learning hub links; and (8) the overall popularity of web-based forums, as measured by number of page views, downloads, comments, rating, and followers of individual posts.

Data Collection

Sample Size and Justification

The aim is to enroll 12-16 PCPs to participate per CFC Learning Hub cycle. A relatively small number of participants in a VCoP (ie, 12-20) who are learning and seeking knowledge is desirable as participants are likely more incentivized to be an active rather than passive user [40-44]. For example, the study by Barnett et al [41] reported that PCPs felt less isolated and more motivated to exchange knowledge after joining a small VCoP for their family physician training.

Qualitative Analysis

The qualitative analysis will aim to (1) identify common themes related to barriers and facilitators of web-based learning, PCP perceptions, and attitudes toward the program, and (2) examine barriers to effective detection and management of osteoporosis in general practices in Australia (ie, PCPs using a virtual space for their specific learning needs rather than physical seminars).

To achieve this, the relational content analysis will be undertaken [45,46]. More specifically, 2 researchers within the team will inductively identify codes independently in the first instance. In this initial step, researchers will use both semantic (capturing explicit and obvious meanings of the text) and latent (capturing tone, intention, and underlying assumptions) coding approaches to explore a wider range of codes. Subsequently, in the second phase, the 2 researchers will discuss and debate on the codes to assess for patterns that coalesce around key themes. The codes are then presented as subthemes of the themes that are identified. Finally, all data will then be counted against the list of subthemes to explore how strongly each subtheme is represented in the dataset by a single researcher and a random sample will be validated by a senior researcher.

Due to the innovative nature of the e-learning hub, themes will be created from participants' transcriptions and validated through rigorously evaluating past and current initiatives made in this area (if any) in the literature. As the program progresses, we will seek to make necessary adjustments to the design and content of the e-learning hub.

The results of thematic analysis will be reported using a top to bottom approach with main (high level) themes reported first, following the subthemes emerged. All results will be supported by exemplary or representative quotes provided by participants.

We will also try to understand the differences in aforementioned areas based on PCPs' years of experience and level of web-based activity (subject to diverse participation and data availability). Overall, feedback by participants will be used to reevaluate and redesign the e-learning hub in terms of navigating and searching for relevant content for PCPs learning needs. The qualitative analysis will aim to identify common themes related to barriers and facilitators of web-based learning, PCP perceptions, and attitudes toward the program. We will also try to understand the differences in aforementioned areas based on PCPs' years of experience and level of web-based activity (subject to diverse participation and data availability). Due to the innovative nature of the e-learning hub, themes will be created from participants' transcriptions and validated through rigorously evaluating past

and current initiatives made in this area (if any) in the literature. As the program progresses, we will seek to make necessary adjustments to the design and content of the e-learning hub. Overall, feedback by participants will be used to reevaluate and redesign the e-learning hub in terms of navigating and searching for relevant content for PCPs' learning needs.

Quantitative Analysis

The data from all cycles will be analyzed separately and combined. The between-cycle differences in participants demographic data (ie, years in practice) and level of activity, including time spent on the platform, number of various resources accessed during the training, and number of modules or education activities they have participated in, will be assessed using Kruskal-Wallis test. Changes in participants' level of knowledge, measured using the proportion of correct responses provided to pre- and posteducation quizzes, will be assessed using either 2-tailed paired *t* tests or Wilcoxon signed rank tests, whereas multivariable regression analysis will be used to examine factors associated with levels of change in knowledge and confidence, while controlling for PCPs' experience, level of participation in the program, and baseline level of knowledge or confidence. Other potential confounders will be considered, subject to the data availability and sufficient power. The level of significance for the quantitative analysis is set at $\alpha < .05$.

Ethical Considerations

The Melbourne Health Human Research ethics committee approved this project (site reference 2016.24), adhering to institutional ethical review processes for research involving human participants. Electronic consent from PCP participants who joined the CFC Learning Hub was obtained to use their deidentified data for research and auditing purposes. The electronic consent process included a waiver of consent for case study patients, whose anonymized information was also used in the project. The data collection and management of electronic consent were carried out using Praxhub tools, ensuring appropriate safeguards for privacy and confidentiality. The data used in this study were fully anonymized to protect participant identities. No compensation was provided to participants in this program.

Results

Recruitment of participants started in May 2022 through initial contacts with PCP members on the Praxhub platform. The recruitment continued until August 2023. The expected quantitative and qualitative data on outcomes are currently being collected and their analysis will be available in early 2025.

Discussion

Overview

We hypothesize that (1) the CFC Learning Hub can provide a novel, peer-to-peer learning experience, offering up-to-date knowledge of primary and secondary fracture prevention strategies among a diverse range of PCPs, and (2) the improved confidence and motivation to investigate and treat osteoporosis, gained via interactive live web-based discussion among PCP peers and bone expert facilitators, can be quantified using predefined analytics tools.

International and Australian studies clearly establish the cost-effectiveness of hospital-based FLS for secondary fracture prevention, aiming to bridge the treatment gap for patients with low-trauma fractures [12,47]. Nevertheless, a considerable number of patients with low-trauma fractures receive investigation and management solely or predominantly from PCPs, potentially bypassing hospital-based services, or alternatively, they receive their ongoing care from their regular PCPs once acute fracture care is provided by hospital services [48]. Therefore, it is imperative for PCPs to maintain currency with fracture prevention protocols and primary care service delivery models. The translation and application of evidence and guidelines for osteoporosis management in primary care, particularly by PCPs, are unacceptably low internationally including in Australia, leading to underdiagnosis, underinvestigation, and undertreatment of osteoporosis in many countries [12,47,49-52]. Furthermore, a significant number of Australians are not receiving timely and appropriate management in primary care, as evidenced by the lack of access to osteoporosis-related investigations and therapies despite eligibility for such interventions [27,48,53]. An Australian review of 88,000 postmenopausal women attending PCPs found that 29% (20,248/69,358) of the targeted cohort had sustained at least 1 osteoporotic fracture, yet less than one-third of these women with fractures were receiving specific treatment for osteoporosis and 7% (3825/57,088) of these women were taking calcium alone [14]. Another Australian study reported that 76% (87/109) of men who had sustained an incident fracture remained untreated for osteoporosis 12 months after sustaining the fracture, despite being eligible for osteoporosis treatment [27]. These studies indicate that PCPs in Australia need additional resources to support primary care management of fragility fractures. Our education modules target the knowledge gaps specifically to address the issues of osteoporosis underdiagnosis and undertreatment and the need for timely and appropriate osteoporosis management.

Regarding the sufficiency of medical resources to cope with osteoporosis-related health issues, a recent paper presenting system dynamics modeling of the potential impact on fracture care of increasing hospital-based FLS demonstrated the probable inadequacy of these services to cope with the predicted fracture burden in years to come [54]. These observations underline the critical need to upgrade such care in the community, which inevitably will require high levels of PCP involvement. These analyses add emphasis to the need for effective education programs in this field.

Comparison With Prior Work

PCPs encounter substantial daily challenges in providing optimal care for patients with various chronic health conditions, necessitating the application of evidence-based treatment approaches to enable the best outcomes [35,37]. Therefore, VCoPs for CPD may represent suitable alternatives for PCPs, being primary health care providers, to overcome barriers they encounter such as time constraints to accessing educational activities and a preference for face-to-face learning. Our

collaborative group explored the challenges faced by PCPs in using VCoPs for their CPD, identifying seven themes crucial for designing and sustaining effective VCoPs: (1) low trust and risk perception, (2) patient information sharing, (3) timely responses, (4) relevant website access, (5) individual learning styles, (6) communication gaps between PCPs and specialists, and (7) the need for diversity and interactivity [37]. Following that exploratory study, few studies aimed to design virtual, interactive, and PCP-targeted bone health programs. In the United States, the Bone Health Tele Extension for Community Health Care Outcomes (TeleECHO) program [55] was proposed as one strategy that aimed at improving PCPs' knowledge related to treatment gaps in osteoporosis care, using real-time videoconferencing to mentor health care professionals in rural and underserved communities [36]. In that study, 263 health care professionals from various countries participated over 21 months, showing substantial improvement in self-confidence across 20 domains of osteoporosis care with the TeleECHO intervention and addressing the osteoporosis treatment gap through enhanced education and knowledge-sharing among health care professionals. Quantitative and qualitative assessments were made of participating PCPs' experience in our pilot program, which was developed because PCPs from different demographics might differ in their knowledge gap. Evidently, this CFC Learning Hub provided an innovative and interactive educational web-based tool to assist with increasing PCPs' knowledge of osteoporosis management models and in turn the application of these guidelines to improve patient care [35]. The pilot program revealed the hot topics (eg, about osteoporosis, risk assessment of osteoporosis, and treatment and prevention strategies) that triggered the most discussion, indicating lack of confidence or knowledge gaps in these areas that are addressed in our current learning modules to ensure more widespread distribution of this knowledge. In our published pilot program of the CFC platform, PCPs were engaged in practice-based, web-based learning where they discussed their own cases with peer facilitators and specialist advisors [35]. In that program, our prototype CFC Learning Hub recruited 7 PCPs, as a convenience sample of PCPs interested in bone health topics, and it included 2 key components: a web-based discussion forum and a knowledge repository (the Knowledge Hub). The discussion forum contained anonymized case studies (contributed by PCP participants) and topical discussions (topics that were not case studies). Using 2 complementary tools (Google Analytics and Igloo Statistical Tool), we characterized individual participating PCPs' engagement with the hub. The discussion included questions from participants directly to the facilitators regarding management dilemmas: this is a more practical tool to deliver knowledge than traditional questionnaires and quizzes. We measured the PCP participants' behavior by quantifying the number of web-based sessions attended by the participants, activities undertaken within these web-based sessions, written posts made per learning topic, and their time spent per topic. We calculated time spent in both active and passive engagement for each topic. The baseline questionnaire highlighted the knowledge gaps and the facilitators, specifically directed discussion to address these gaps during the hot topic discussions. This project draws on findings from the pilot study and insights gained from implementing assessment tools to expand the CFC Learning Hub.

Strengths and Limitations of the Program

Our educational program is positioned to deliver distinct outcomes compared with traditional face-to-face lectures and stand-alone, web-based webinars, offering PCPs time flexibility and leveraging the advantages of peer-to-peer and PCP-to-specialist interactions through web-based posts. It anticipates a departure from the traditional unidirectional nature of lectures by placing a strong emphasis on cultivating an interactive learning environment characterized by introspection and peer-to-peer discourse. This approach is designed to encourage participants to engage in more profound cognitive processing of the material, thereby fostering a nuanced comprehension. The integration of peer-to-peer discussions is a pivotal departure from conventional methods, establishing a collaborative and nonjudgmental forum for the exchange of insights, diverse perspectives, and shared learning experiences. This departure from traditional modes of education is anticipated to enhance the program's efficacy, providing a more profound and enriching educational encounter for participants due to its multifaceted nature. Osteoporosis presents diverse challenges across age groups and between sexes, requiring tailored approaches in primary and secondary fracture prevention. The absence of a universal solution adds complexity, necessitating nuanced insights for specific cohorts, such as those undergoing oncological treatment, relying on glucocorticoids, or in the posttransplant phase. With various modalities such as pharmaceutical interventions, over-the-counter supplements, and exercise-based strategies, the program's interactive and case-based nature is anticipated to align aptly with the intricate landscape of osteoporosis management, fostering a deeper understanding of this complex medical domain. For instance, our successful pilot study showcased the effectiveness of the program's innovative approaches in tracing the path from engagement to practice change as recognized by obtaining CPD accreditation for the activity, thereby affirming the rationale for informing a larger study with a specific focus on creating and facilitating more practice-based topics for PCP participants [35].

The limitations of this study include transferability of this work beyond Australia since there is a shift toward community-based rather than hospital-based fracture prevention programs, and PCPs are encouraged to develop subspecialty interests in chronic condition such as osteoporosis. This in-depth subspecialty education might be beyond the scope of PCPs elsewhere in the world. The success of this approach is dependent on PCPs' motivation to incorporate osteoporosis care into their workflow when it might be easier to refer to specialists. Personalized peer-to-peer discussion is more expensive to deliver per participant than traditional webinars and lectures and therefore might not be sustainable.

Principal Findings

The main contribution of this protocol paper is a detailed description of how to conduct and analyze co-design, interactive, peer-to-peer PCP learning activities to develop a digital collaborative environment that promotes up-to-date bone health practice among PCPs. The program platform has capacity and

agility to improve and adjust in real time based on participants number and needs.

The CFC Learning Hub will provide insights into the barriers to community-based osteoporosis identification and treatment initiation from the PCP perspective, as well as the effectiveness of a VCoP facilitated through an innovative web-based platform, along with methods for evaluating participation. The barriers identified might differ depending on region of practice and the experience level of the PCP. The pre- and postparticipation surveys permit quantification of knowledge and confidence gained. If successful, the CFC Learning Hub can be expanded to specifically target rural areas where interactive knowledge transfer and delivery can be logistically challenging.

Conclusions

There is an urgent need to address the treatment gap in osteoporosis care, particularly within primary care settings where PCPs play a central role. The identified challenges, such as low trust of web-based content, patient information sharing, timely responses, and communication gaps, underscore the importance of tailored educational interventions such as the CFC Learning Hub. The pilot program's success in engaging PCPs and addressing knowledge gaps suggests the potential of the CFC Learning Hub program and its innovative, web-based tools in improving osteoporosis management and patient care within primary care settings.

Acknowledgments

The study is funded by Amgen Australia Pty Ltd and Theramex. The funding bodies were not involved in the study design, content development, study conduct or data collection, analysis, and interpretation.

The authors thank The Royal Australian College of General Practitioners and the Australian College of Rural and Remote Medicine for approving the Community Fracture Capture (CFC) Learning Hub as an accredited professional learning activity, and The University of Melbourne Department of Medicine at The Royal Melbourne Hospital and the Faculty of Engineering and Information Technology of The University of Melbourne for supporting the research team and providing required resources.

Data Availability

The datasets generated during and analyzed during this study are available from the corresponding author on reasonable request, once the relevant findings have been published.

Authors' Contributions

AMF, CC, RA, SC, and JDW contributed to study conceptualization, writing of the original draft, and project administration; AMF, CC, RA, SC, SS, CJY, RB, SP, LC, and JDW contributed to the methodology and investigation; JDW, CC, RA, RB, CYJ, SC, and LC contributed to conducting the learning sessions; SS contributed to providing regular liaison with Praxhub; AG, AMF, CC, RA, SC, and JDW contributed to the data curation; and JDW, CC, and SC contributed to study supervision. All authors have read, provided feedback, and agreed to the final version of the manuscript for publication.

Abstract

Background: In the United States, the landscape of unpaid care delivery is both challenging and complex, with millions of individuals undertaking the vital role of helping families (broadly defined) manage their health care and well-being. This includes 48 million caregivers of adults, 42 million of whom are caregivers of adults aged 50 years or older. These family care partners provide critical and often daily support for tasks such as dressing and bathing, as well as managing medications, medical equipment, appointments, and follow-up care plans.

Objective: This study aimed to implement a novel patient portal–based intervention to identify, engage, and support care partners in clinical settings.

Methods: The project team collaborated with 3 health care organizations (6 primary care practices in total) to design and implement a patient portal–based intervention. Three days in advance of a visit, patients were invited to log on to their patient portal account and answer a brief questionnaire as part of the routine electronic check-in process asking them to (1) identify themselves as the patient or someone answering for the patient, (2) report major life changes, (3) set the agenda for the upcoming visit, and (4) report on care partner responsibilities. Respondents' answers to this brief questionnaire were available to providers ahead of the visit. Patients with care partner responsibilities, as well as care partners answering the questionnaire on behalf of patients, were provided a link to the ARCHANGELS Caregiver Intensity Index to measure the intensity of their caregiving role and motivate care partners to connect with suggested state and local resources.

Results: The intervention was launched in September 2022 at Organization A. Organization B launched in May 2023 in one clinic and June 2023 in the other. In focus groups, staff and clinicians reported that the intervention was easy to implement and did not cause workflow disruption. At 6 months post implementation, across both organizations, a total of 22,152 patients had received questionnaires and 13,825 (62.4%) had submitted completed questionnaires. Full data will be reported at the completion of the intervention period.

Conclusions: Early results suggest that the intervention could be an easily scalable and adaptable method of identifying and supporting care partners in clinical settings.

Introduction

Caregiving in the United States

In the United States, the landscape of unpaid care delivery is both challenging and complex. Millions of individuals undertake the vital role of helping someone else manage their health care and well-being. This includes 48 million caregivers of adults, 42 million of whom are caregivers of adults aged 50 years or older [1]. Family (broadly defined) care partners provide critical and often daily support for tasks such as dressing and bathing, as well as managing medications, medical equipment, appointments, and follow-up care plans [2-4]. The role of a care partner can be fulfilling as well as challenging. Many care partners report a sense of purpose and fulfillment related to the care they provide, and some research suggests that caregiving has a protective health effect [5-8]. Other studies suggest that having caregiving responsibilities can also be correlated with poorer mental and physical health, finding substantial rates of chronic illness and poorer mental health over time [9-13].

Surveys of care partners taken during the COVID-19 pandemic noted particularly high levels of stress and adverse mental health symptoms, including anxiety, depression, and suicidality [10-12], possibly due to the reduced availability of services related to social distancing and closures by home care services and caregiver respite services [13]. A survey of more than 10,000 US adults conducted between late 2020 and early 2021 revealed significant mental health issues. A total of 70% of all care partners reported experiencing at least one adverse mental health symptom such as anxiety, depression, or suicidal thoughts, in comparison to 32% of respondents with no care partner responsibilities [10]. While the pandemic represented an extraordinary challenge to care partners, surveys conducted before the pandemic also found significantly higher rates of adverse mental health conditions among this population [14,15].

Providing care partners with psychosocial support has been shown to help both care partners and their care recipients [16,17]. However, identifying care partners and linking them to services remains challenging [18]. While care partners frequently interact with the health care system on behalf of patients, they often lack a way to access support for themselves [19,20]. A visit to a care recipient's health care provider rarely includes a discussion of care partner stress. As well, adding time to discuss caregiving responsibilities and available resources to an already busy clinical visit is often not feasible [21]. Identifying care partners (both patients who are care partners and care partners of patients) before or during clinical visits and connecting them to resources, without adding to clinical work, could be beneficial to patients, care partners, and clinicians.

Use of Patient Portals

Electronic health records (EHRs) and secure patient portals offer a ready opportunity to identify care partners in need of services. Most health care providers use EHRs and have online patient portals through which their patients can access their medical information, message their clinicians, renew prescriptions, schedule appointments, and more [22]. Previsit questionnaires, administered through the patient portal in preparation for a visit, have become more commonplace [23]. These questionnaires can provide an opportunity for clinicians to learn more about patient needs and concerns before a visit [24]. In addition to previsit data collection, portals offer the opportunity for interventions and the provision of resources outside of the clinic visit [25]. Studies suggest that portal-based interventions can lead to improvements in psycho-behavioral outcomes, such as health knowledge, self-efficacy, and decision-making [25,26]. While these benefits are typically focused on patients' reported health care needs, they can also be extended to other aspects of patients' lives, including their caregiving responsibilities.

Here we report on a multisite intervention designed to implement a method of identifying, engaging, and supporting care partners in office-based clinical settings using the patient portal. Specifically, we sought to create a model of care that identified care partners through a previsit questionnaire ahead of their own health care appointments, engaged them through the incorporation of their self-reported visit concerns and priorities into the questionnaire data, and activated them to understand their caregiver intensity and connect with resources without requiring additional action from the care team. We report here on the intervention design and interim feasibility data. The intervention took place for 1 year and the interim data were gathered at 6 months.

Methods

Intervention Components

Caregiver Intensity Index

The ARCHANGELS Caregiver Intensity Index (CII) [27] is designed as a self-assessment instrument of caregiver intensity across multiple dimensions. Individuals who complete the CII are provided with a numeric score between 0 and 100, a color (clear: low intensity; yellow: moderate intensity; and red: high intensity), and the top two drivers and top two buffers of their caregiver intensity. Those completing the CII are then directed to a microsite with resources specific to their needs and the community in which the patient receives care. The project team collaborated with each implementing site to ensure that the resource page was comprehensive.

In-Clinic Materials

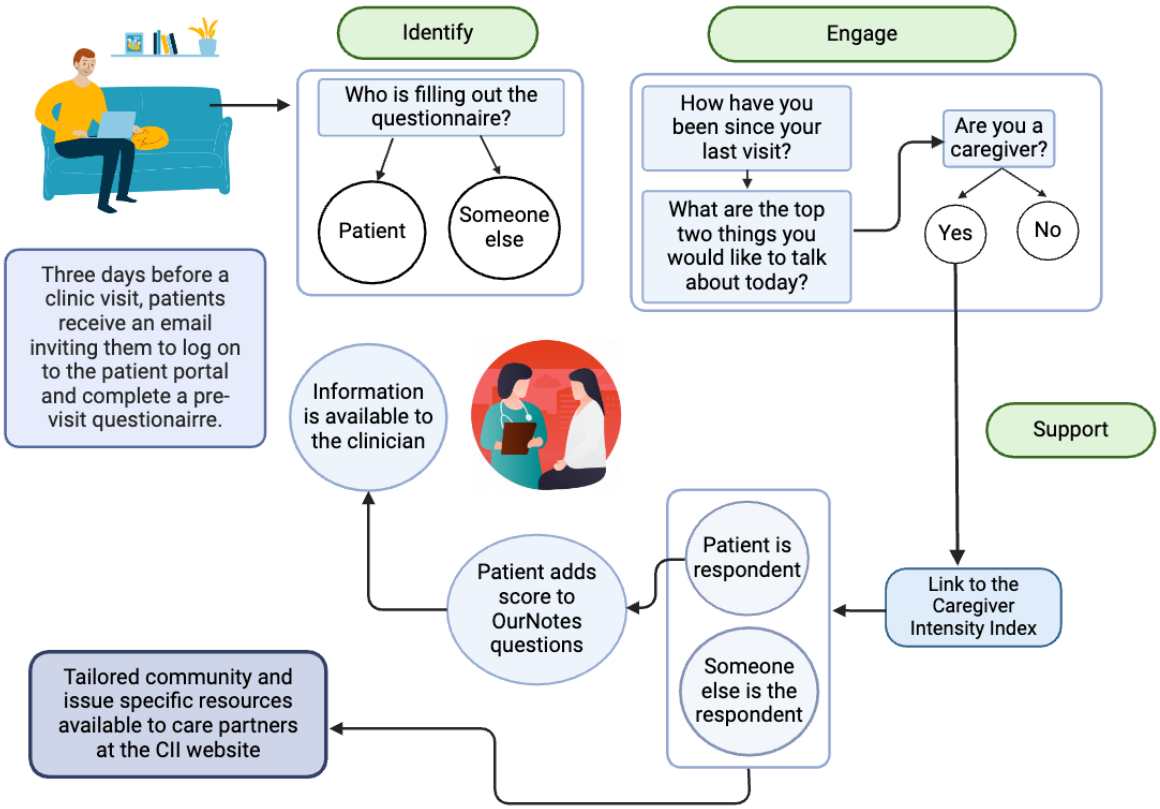
Each participating site was provided with in-clinic posters, wallet-sized handouts (referred to as "Care Cards"), and tip sheets for clinicians and staff. The posters and Care Cards included scannable QR codes that linked patients to the CII. These QR codes were specific to each site and modality, which allowed tracking of how resources were accessed (whether via poster, Care Card, after-visit summary, or previsit questionnaire). The tip sheets for clinicians and staff contained information on how to talk with patients about caregiving responsibilities and how to find patients' completed questionnaires in the EHR.

Previsit Questionnaire

The team at Organization A convened regularly with the project team to draft and refine the previsit questionnaire, adapting a previously tested questionnaire [24] with input from clinic staff and clinicians as well as feedback from patient and family advisors in the organization's Patient and Family Advisory Council. The final previsit questionnaire was also tested at Organizations B and C.

The final previsit questionnaire, to be sent to all patients aged 18+ years with an upcoming visit (except those whose upcoming visits were Medicare annual wellness visits, annual physicals, or telehealth visits), comprised the following items (see Multimedia Appendix 1 for complete survey branching logic and the exact wording of the questions): (1) Identification: respondents were prompted to specify if they were the patient or were completing the previsit questionnaire on the patient's behalf (either as a designated portal proxy or by logging in as the patient; note: if someone other than the patient is filling out the questionnaire, they are answering the questions for the patient, not for themselves). (2) Life changes notification: respondents were asked to communicate significant life changes since their last clinic visit. (3) Visit agenda-setting: respondents were asked to identify the one or two most important things they wished to discuss at the upcoming visit. (4) Care partner responsibilities: respondents were asked if they had caregiving duties and to share for whom they provided care. (5) Receipt of care partner support: respondents were prompted to indicate if they received help managing their health and health care from another person. (6) Caregiver intensity index: respondents reporting caregiving responsibilities were given a link to the CII and provided with an opportunity to report their color and score in the previsit questionnaire. Those who answered the previsit questionnaire on behalf of the patient were given the CII link but were not given the option of sharing their score (Figure 1).

Figure 1. Previsit questionnaire flowchart.



We integrated previsit questions into the EHR for testing, assessing both the patient-facing interface within the patient portal and the corresponding view for clinic staff and clinicians upon submission of responses.

EHR Macros

Two macros were developed: 1 for clinicians to incorporate information about the CII in the patient visit summary and another enabling clinicians to integrate questionnaire responses into their notes.

Education for Clinicians and Staff

Before implementation, the project team conducted sessions with staff and clinicians from participating practices to demonstrate how to access the previsit questionnaire within the EHR, identify workflow adjustments, and provide an overview of the in-clinic materials. The project was approved by the institutional review boards at all project sites.

Stakeholder Input

The project team met with staff and clinicians at each participating site at 3 and 6 months, both in person and virtually. These meetings were held to identify and address implementation issues, provide ongoing education and support to clinic staff and clinicians, and surface feedback and concerns about the initiative.

Plans for Statistical Analysis

Upon the intervention period's completion at all sites, we will summarize the study participants' demographics, their usage of the CII, and the Caregiver Intensity scores. To compare the characteristics between groups, we will use the chi-square test or Fisher exact test for categorical variables and the Student *t* test for continuous variables. Multivariable regression models will be used to explore the associations between the Caregiver Intensity score and patient demographic factors. We will also use qualitative analytic methods to identify key themes and subthemes in the free-text responses. All statistical analyses will be performed using SAS software (version 9.4; SAS Institute Inc).

Ethical Considerations

The protocol was approved and deemed exempt from full review by the institutional review boards at Beth Israel Deaconess Medical Center (IRB protocol # 2021P000928) and the University of Michigan (IRB protocol # HUM00225451). Per the exempt status of the intervention, informed consent was not required. Patients were informed about their right to opt out of the intervention in the invitation email. All data will be deidentified in the analytic data file. No personally identifying information will be included in the analytic file. Participants were not compensated.

Results

We engaged 3 health care organizations to collaborate on the design and implementation of the intervention (Figure 1). The first site (Organization A) is a prominent academic medical center network in the Northeast. Within this network, we partnered with three clinics situated in suburban areas outside

a major metropolitan hub. Our second partner (Organization B) is a large academic medical center based in the Midwest. Within this center, we collaborated with two primary care clinics: a general internal medicine practice and a combined general internal medicine and pediatrics practice. Our third partner organization (Organization C) is a nonprofit health care entity serving primarily urban communities in the Northeast. The clinic associated with this organization predominantly serves low-income and racially diverse populations.

Two of these organizations are situated within regions commonly supported by the Ralph C Wilson Jr Foundation (the project funder), namely western New York and southeastern Michigan. The selection of the third site was based on existing strong professional relationships between project team members and the organization's leadership, coupled with the organization's keen interest in participating. Characteristics of participating health care organizations are shown in Table 1.

Table 1. Site characteristics.

Characteristics	Organization A	Organization B	Organization C
Total number of clinicians	• Clinic 1: n=2 • Clinic 2: n=6 • Clinic 3: n=5	• Clinic 1: n=22 • Clinic 2: n=20	2
Total number of clinic staff	• Clinic 1: n=17 • Clinic 2: n=13 • Clinic 3: n=15	—[a]	11
Clinic location	• Clinic 1: suburban • Clinic 2: suburban • Clinic 3: suburban	• Clinic 1: mixed • Clinic 2: mixed	Urban
Organizational payer mix, %			
Medicaid	14	28	57
Medicare	10	30	21
Private commercial insurance	72	40	20
Uninsured	2	2	1
Other unknown	3	—	—

[a]Not applicable.

Each organization established a dedicated work group that convened regularly with the research team (Table 2). These groups consisted of clinical champions, clinic leadership, project managers, and information technology staff. All partner organizations use the same electronic health record system.

[a]EHR: electronic health record.

Organization A launched the intervention on September 30, 2022, and Organization B launched on May 17, 2023, in one clinic and June 1, 2023, in the other. Organization C was not successful in implementing the previsit questionnaire in their EHR and withdrew from the initiative. This was due to a mix of factors, including the lack of a clinical champion, the low usage of the patient portal among its patients combined with a higher reliance on paper documents by staff, and varied methods across clinics and staff as to if and how questionnaires submitted from the portal are identified and reviewed ahead of visits.

Adult patients at least 18 years of age were eligible to participate in the initiative. As shown in Figure 1, patients with a patient portal account and with an upcoming clinic visit were sent an invitation through the patient portal, 3 days ahead of a visit, to complete the previsit questionnaire. All visit types were included in the initiative with the exception of Medicare annual wellness visits, annual physicals, and telehealth visits. Annual wellness visits and physicals were excluded by request at participating sites because patients were already asked to complete a substantial number of questionnaires before those visits. Telehealth visits were excluded due to clinician concern that asking patients to fill out the previsit questionnaire would serve as a barrier to the telehealth login process and cause a delay in care. As shown in Figure 1, all the information provided by patients, or by others on patients' behalf, through the previsit questionnaire was available to clinicians in the EHR. Patients and care partners who did not complete the previsit questionnaire could access the CII through QR codes on the in-clinic materials (eg, care cards, posters, or the after-visit summary).

At the 3- and 6-month check-ins, clinic staff and clinicians reported few challenges with implementing the intervention. The primary challenge was learning to access patients' previsit questionnaire responses in the clinician and staff EHR view. Clinic staff and clinicians reported that some patients expressed appreciation for the opportunity to share and discuss their caregiving responsibilities. Further, they reported that few patients complained about being asked to fill out the previsit questionnaire. Clinic staff and providers said they felt better prepared to discuss care partner responsibilities with patients because they had resources to offer. Based on clinician and staff concerns with lengthy patient responses to the life changes and agenda-setting questions, the project team made minor wording changes to those questions and instituted character limits on the free text responses (see final questionnaire in Appendix). Finally, staff reported minimal disruption to workflows after adjustments to reduce the character limits of agenda-setting questions.

At 6 months post implementation, 25,611 surveys were assigned to 13,299 patients at Organization A and 16,265 questionnaires to 8853 patients at Organization B. At Organization A, 7076 questionnaires were received from 5350 patients. At Organization B, 6749 questionnaires were received from 4982 patients. Because the previsit questionnaire was tied to clinical visits, patients with multiple visits during the observation period received more than one invitation to complete a previsit questionnaire (Table 3).

Data for the full intervention period will be published in a future paper.

Table 3. Questionnaires assigned and submitted.

Disposition of questionnaires	Organization A	Organization B
Number of questionnaires assigned to patients, n	25,611	16,265
Number of questionnaires submitted by patients, n/n (%)	7076/25,611 (27.6)	6749/16,265 (41.5)
Number of patients assigned at least one questionnaire, n	13,299	8853
Number of patients submitted at least one questionnaire, n/n (%)	5350/13,299 (40.2)	4982/8853 (56.3)

Discussion

Principal Findings

We report on the rationale, development, and early uptake from the first 6 months of implementing a practice-based intervention aimed at identifying, engaging, and supporting care partners in office-based clinical settings using the patient portal. Early results from this work suggest that the intervention is acceptable to clinicians and staff and simple to implement. While we did not directly ask patients and care partners about their willingness to complete the previsit questionnaire, our robust response rate suggests that the intervention is feasible for patients and that it is possible to identify care partners before or during a clinical visit and connect them to resources.

To our knowledge, our intervention represents the first systematic attempt to identify, engage, and support care partners in clinical settings through a previsit questionnaire. Previous work focused on identifying patients' visit priorities using a similar methodology and found much lower rates of patient uptake than our preliminary findings suggest [24]. Understanding the extent to which the local clinical environments and patient populations affected implementation will be a critical area of focus for the final evaluation [28]. Our preliminary findings suggest that patients were generally receptive to completing the previsit questionnaire through the patient portal. The usage of previsit questionnaires is becoming more prevalent for assessing Social Determinants of Health and identifying resources or referrals that may benefit patients [29]. Incorporating caregiver-related responsibilities within Social Determinants of Health assessment efforts could also merit attention as a strategy for raising awareness of caregiver needs and integrating care partner identification and support within care delivery if our findings hold in the final evaluation.

While the role of a care partner can be fulfilling, it can also be fraught with numerous challenges, leading to elevated rates of mental and physical health issues among care partners [28]. Identifying care partners is a first step in understanding their capacity and needs, and in facilitating access to appropriate resources. Doing so within care delivery enables clinicians to become aware of caregiving responsibilities; however, busy clinical practices may struggle to address these needs. By providing resources outside of the clinical visit, our intervention could help to support caregivers, clinicians, and staff. Staff reported minimal burdens and disruptions to their workflow and the intervention was relatively simple to implement.

Our protocol has several limitations that should be noted. First, while the protocol includes in-office materials for patients and clinicians, patients must have access to the internet in order to

take the CII and explore the resources offered. This requirement may exclude a subset of patients with lower digital literacy. Future efforts could explore the possibility of, for example, text-based options using mobile devices. Second, our protocol is implemented in 5 primary care practices associated with academic medical centers. These centers may have resources for implementation that are not available in community-based practices. Finally, our protocol was designed for and implemented in health care organizations with the same commercially available EHR system. Implementing in other EHR systems may require adjustments to the protocol.

In the final 6 months of the project, we will monitor whether staff continue to report minimal workflow disruptions, whether patient feedback remains predominantly positive or neutral, or if there is an increase in complaints. If current results hold, and we find that patients with caregiving responsibilities are using the CII, this portal-based intervention could be a scalable and adaptable method of identifying, engaging, and supporting patients and their care partners in clinical settings. Should that be the case, we will widely disseminate our findings through the peer-reviewed and gray literature, as well as develop and disseminate "how-to" toolkits for primary care practices. Further studies focused on implementation in a larger number of diverse settings, by patient population, electronic medical record vendor, types of care delivery organizations, and geographic regions, will also be important as we seek to engage and support care partners through the health care system.

Conclusion

Millions of adults help another person with their health and care, and their needs are often unidentified and unmet. Despite the impact of caregiving responsibilities on physical and mental health, often their own health care providers do not know about their responsibilities. The early assessment of this unique pilot seeking to identify care partners through previsit questionnaires and in-office materials indicates that this low-burden effort may be an effective tool for identifying and supporting care partners. Future analyses of data from the full one-year pilot will give a more complete picture of the results and the possibility of adapting and scaling this intervention beyond the individual clinics involved in the study.

Acknowledgments

The authors would like to thank the Ralph C. Wilson, Jr. Foundation for its support of this work. We would also like to express our gratitude for the work of our clinical partner sites and the thousands of patients and care partners who completed the questionnaire. The research presented in this study was funded by the Ralph C. Wilson, Jr. Foundation.

Data Availability

The datasets generated during and analyzed during this study are not publicly available per the requirements of the participating organizations to maintain strict confidentiality and disclosure standards for patent data obtained during the course of routine care. For this reason, the data are also not available from the corresponding author.

Authors' Contributions

CMD contributed to conceptualization, methodology, investigation, formal analysis, writing-original draft, and writing-review and editing. DW contributed to methodology, investigation, formal analysis, writing-original draft, and writing-review and editing. ZD assisted with formal analysis, writing-original draft, and writing-review and editing. AD contributed to conceptualization, writing-original draft, and writing-review and editing. IH handled investigation, writing-original draft, and writing-review and editing. JA contributed to methodology, investigation, writing-original draft, and writing-review and editing. AC assisted with methodology, investigation, formal analysis, writing-original draft, and writing-review and editing. NC contributed to methodology, investigation, writing-original draft, and writing-review and editing. JM assisted with methodology, investigation, writing-original draft, and writing-review and editing. JN handled methodology, investigation, writing-original draft, and writing-review and editing. KO'D assisted with methodology, writing-original draft, and writing-review and editing. CW contributed to methodology, investigation, writing-review and editing. SSW assisted with methodology, investigation, formal analysis, writing-original draft, and writing-review and editing. JY contributed to investigation, formal analysis, and writing-review and editing. JLW assisted with methodology, writing-review and editing. The sponsor recruited Organization C.

Conflicts of Interest

AD and SSW are the cofounders of ARCHANGELS. ARCHANGELS sells services designed to support care partners, including the use of the CII. AC is employed by ARCHANGELS. AD is a member of the BIDMC trustee advisory board.

Abstract

Background: Individuals with intellectual disabilities or autism spectrum disorder (ID/A) sometimes require supportive services from direct support professionals (DSPs). The supportive care provided to individuals with ID/A by DSPs can vary from assistance with daily living activities to navigating society. The COVID-19 pandemic not only exacerbated poor outcomes for individuals with ID/A but also for DSPs, who report experiencing burnout in the aftermath of the pandemic. DSPs are critical to providing much-needed support to individuals with ID/A.

Objective: The goal of this study is to evaluate the impact of the community resilience model on DSP burnout and neurodivergent client outcomes using the Project ECHO (Extension for Community Healthcare Outcomes) telementoring platform as a dissemination tool.

Methods: This protocol leverages community resilience theory and telementoring through the Project ECHO model to foster resilience in DSPs and their neurodiverse client population. ECHO participants' resilience behaviors will be evaluated via surveys including the Connor Davison Resilience Scale and the WHO-5 Well-Being Index. These surveys will be administered preprogram, at the end of the 8-week ECHO program, and 90 days after the ECHO program's completion. Pre-post relationships will be assessed using generalized estimating equations. The main outcomes will be self-reported changes in knowledge, self-efficacy, and resilience.

Results: All ECHO program cohorts and follow-up data collection have concluded, with 131 survey participants. The project team is currently analyzing and interpreting the data. We anticipate having all data analyzed and interpreted by February 2025.

Conclusions: DSPs provide critical services to individuals with ID/A. By providing skills in resiliency via the ECHO model, participants will be able to apply resiliency to their own professional lives while fostering resilience within their neurodiverse client base, leading to increased positive outcomes for both groups.

Introduction

Intellectual disabilities and autism spectrum disorder (ID/A) are lifelong, complex neurodevelopmental disorders characterized by social, cognitive, and adaptive skill deficits [1,2]. These skill deficits vary in levels of severity for each individual with ID/A and may require supportive care [2]. Direct support professionals (DSPs) provide supportive care to individuals with ID/A in the form of community integration, including employment navigation, assistance with daily living activities, and advocacy [3].

Individuals with ID/A are especially vulnerable to trauma and may struggle more to identify and implement successful coping strategies. Pairing this with undereducation in recognizing and responding to trauma among the service provider community creates a significant gap in services available to individuals with ID/A. Stress responses in individuals, including those with ID/A, can be moderated by factors that increase resilience. Resilience is defined as a process of interactive adaptation that facilitates coping in the face of adversity linked with a person's neurological and psychological makeup and socioecological contexts [4]. Fostering resilience for both service providers and individuals with ID/A can enhance their adaptive stress responses across all domains of functioning. Currently, there are limited resources in the community that can adequately address building resiliency, specifically in this population.

Prior to the COVID-19 pandemic, DSPs were already in the midst of a workforce crisis long characterized by low wages, training challenges, and high turnover rates [5]. However, DSPs working with those in the ID/A community reported experiencing lower quality of life and even higher percentages of burnout during the COVID-19 pandemic [6,7]. Evidence suggests that the COVID-19 pandemic exacerbated already-existing support system weaknesses, resulting in the displacement of DSPs that strained an already short-staffed workforce, increased hours worked by those not displaced, and worsened work-life quality [6,8]. These issues, compounded by the complexity of providing supportive care for this population during a global public health crisis, presented the need for resilience training and improved support for DSPs. Resiliency is associated with the achievement of life satisfaction, positive well-being, competent functioning, and improved quality of life after experiencing stressors or adversity [9]. Therefore, fostering resilient behaviors in DSPs as well as their neurodivergent clients is critical to strengthening and empowering neurodivergent individuals and creating more inclusive neurodiverse communities.

To better support individuals with ID/A, DSPs require new and advanced knowledge and skills to provide best-practice care. Providing training and resources in resiliency-building skills would allow DSPs to assist these often-overlooked populations while also providing DSPs with the tools needed to navigate post–COVID-19 working conditions. Further, it is well-known that individuals with ID/A who receive services and support from DSPs experience better personal outcomes, especially when the same DSP is engaged over time [10]. Identifying training and supportive opportunities for DSPs that improve DSP resilience, improve the health and resilience among the ID/A community, and improve the well-being and retention of the DSPs could significantly improve care for adults with ID/A. Unfortunately, current resources and supports that address building resiliency for DSPs are limited. In response to this service gap and the COVID-19 pandemic, Project ECHO (Extension for Community Healthcare Outcomes) at Penn State College of Medicine developed the "Fostering Resilience for Neurodiverse Communities ECHO" program for professionals serving neurodivergent individuals. The goal of this program is to share strategies to build resilience and better support those in their care to address trauma and stress needs as they reintegrate following the COVID-19 pandemic. These strategies were intentionally designed to have wide application so that service professionals could also benefit. The intent was to create resources and strategies that the neurodivergent clients and their service providers could use together in an embrace of more inclusive neurodiverse community building. This protocol aims to detail the Fostering Resilience for Neurodiverse Communities ECHO program conduction, curriculum, data collection, and planned outcomes analysis to facilitate further use of the ECHO model with other audiences, including those supporting neurodiverse populations. Our program's intended outcome is to invoke positive change in the knowledge, confidence, and resiliency of DSPs after participation in the ECHO program.

Methods

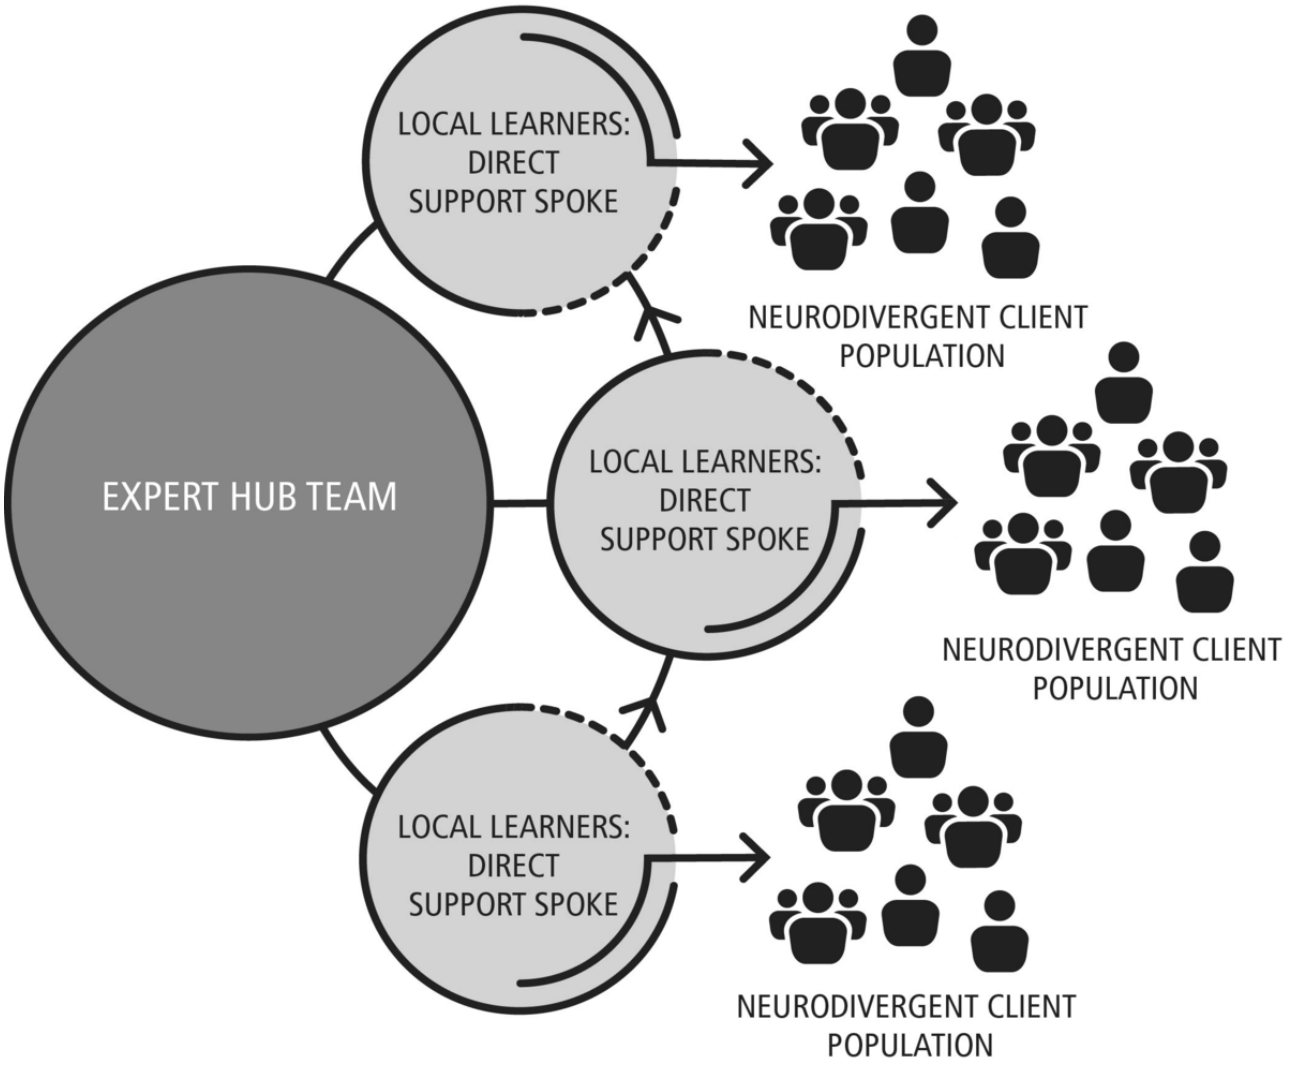
Project ECHO

The Fostering Resilience for Neurodiverse Communities ECHO program used the ECHO platform to provide DSPs with evidence-based knowledge and skills to best support their neurodiverse clients in building resiliency following the COVID-19 pandemic. Project ECHO is an evidence-based educational model with the power to rapidly transfer knowledge and exponentially increase capacity to deliver best-practice care to underserved populations [11-18]. The ECHO model's "all teach, all learn" approach is the infrastructure for knowledge-sharing in underserved communities around the world. The heart of the ECHO model is its hub-and-spoke knowledge-sharing networks, led by expert specialist teams (hub), mentoring multiple DSPs (spokes) via teleconferencing (Figure 1). The ECHO model is not "telemedicine" where specialists assume the care of the client; rather it is a guided model aimed at practice improvement, in which DSPs retain responsibility for clients, and operate with increasing independence as skills, confidence, and self-efficacy grow. Unlike traditional learning, Project ECHO facilitates rapid dissemination of knowledge and increased capacity to deliver

best-practice care by utilizing case-based, collaborative learning to support the discussion of learners' challenges and barriers to guideline implementation.

The ECHO model has 4 core principles: (1) use technology to leverage scarce resources; (2) share best practices to reduce disparities; (3) use case-based learning to master complexity; and (4) monitor outcomes to ensure benefit. DSPs and other professionals (spokes) who serve neurodiverse populations participated in weekly web-based ECHO sessions with a multidisciplinary specialty team at Penn State College of Medicine (hub) with behavioral health, psychiatry, and community resource expertise. Project ECHO used Zoom, a user-friendly, Health Insurance Portability and Accountability Act–compliant, cloud-based software application for video conferencing.

Figure 1. The ECHO (Extension for Community Healthcare Outcomes) hub-and-spoke learning model.



ECHO sessions featured presentations of deidentified client cases by DSPs and team members and brief lectures by specialists. The ECHO specialists and DSPs collaborated to discuss the case and develop recommendations for the DSP and the client. The hub team provided technical assistance and training on resilience building and facilitated the discussion of cases provided by spokes. Together, hub experts collaborated with spoke participants to share knowledge, expertise, best practices, and experiences while discussing deidentified cases and developing recommendations. Over time, spoke participants developed expertise while also engaging in a wider community of learners. Spoke participants were empowered to address the difficulties faced by their clients in their communities. As a result, ID/A clients gained access to best practices and resources through DSP participation in the ECHO sessions.

The Fostering Resilience for Neurodiverse Communities ECHO hub team consisted of multidisciplinary experts who provide care to neurodiverse patients. This team included the Clinical Director and Associate Clinical Director of the Division of Autism Services at Penn State Health Milton S. Hershey Medical Center, a psychologist with experience in behavioral health, a board-certified psychiatric nurse practitioner, a licensed clinical social worker, and a board-certified behavior analyst. Additionally, the expert specialist team also consisted of a neurodivergent self-advocate to provide a client perspective and expertise to case discussions. The project team included a project manager, education specialist, and program director from Project ECHO at Penn State College of Medicine who support the day-to-day operations of the ECHO model.

Proposed Approach: Community Resilience Model

This protocol details the use of the community resilience model (CRM) to train DSPs to foster resilience in themselves as well as their neurodiverse clients, including individuals with ID/A, through the Project ECHO platform [19]. The overarching objective of the Fostering Resilience for Neurodiverse Communities ECHO series was to teach the skills of the CRM to professionals who serve neurodiverse clients to promote psychological flexibility in themselves and their clients.

The CRM is a community-based approach for coping with acute and chronic stress states [19]. It is a sensory-focused approach aimed at increasing mental well-being and greater resilience, which has been successfully used in diverse populations and settings, including front-line health workers at the height of the COVID-19 pandemic [20,21]. Its neurobiological basis is aimed at down-regulating stress responses in the body through a skills-based approach that has wide applicability. CRM is a community-based approach where community members not only help themselves but also support others within their social networks. CRM aims to create "resiliency-focused communities," an approach well suited for the intended outcomes of this project [19].

Using CRM, the hub team developed a curriculum addressing trauma, stress, anxiety, improving resilience, and more. A portion of the Fostering Resilience for Neurodiverse Communities ECHO curriculum promoted using the iChill App to teach the CRM through a set of self-help skills [22]. Participants registered for one cohort of the Fostering Resilience for Neurodiverse Communities ECHO program. Each ECHO cohort consisted of 8 weekly 75-minute ECHO sessions. A comprehensive list of topics can be found in Table 1. Goals aligned with the approach are found in Textbox 1.

Table 1. Fostering resilience for neurodiverse communities ECHO[a] series topics.

Session	Didactic topic
1	What is trauma? Traumatic stress, expressions of trauma, and trauma responses
2	Anxiety: Intolerance of uncertainty
3	What is resilience? Introduction to CRM[b]: why is it important? Resilience zone and widening the zone
4	Resilience skills I: Tracking, resourcing, and grounding
5	Resilience skills II: Gesturing, shift and stay, help now!
6	Crisis risk reduction and safety considerations
7	Adapting skills for those with brain differences
8	Fostering community reengagement

[a]ECHO: Extension for Community Healthcare Outcomes.

[b]CRM: community resilience model.

Textbox 1. Intended programmatic goals.

1. Increased awareness and better recognition of trauma issues related directly to the COVID-19 pandemic and past trauma issues that have been exacerbated by it
2. Better understanding of the community resilience model and the importance of developing greater resiliency for both providers and neurodivergent clients
3. Ability to guide direct support professionals and other team members into effective use of available resources to better meet the needs of the individuals they are supporting

Participants and Recruitment

Participants for this program were DSPs and those supervising DSPs who participated in Fostering Resilience in Neurodiverse Communities ECHO sessions. Within Pennsylvania, DSPs directly supporting neurodivergent individuals, as well as direct supervisors of DSPs, were recruited through targeted email listservs. An informative recruitment flyer was disseminated directly to DSPs through the Pennsylvania Department of Human Services' Office of Developmental Programs. The project team also leveraged social media platforms through the autism services, resources, education, and training network to promote the ECHO program.

The initial recruitment survey was distributed via flyer with a public-facing survey link. However, participants were screened after entering basic demographic or contact information, at which point study staff would invite eligible participants to complete questionnaires. Screening criteria included those employed currently as a DSP or as a direct supervisor of DSPs. Once approved by study staff, participants received surveys via email with personalized links, ensuring that all surveys except for the initial recruitment survey were not publicly available. After completion of all preprogram surveys, participants were invited to participate in ECHO sessions.

Survey Administration

All surveys were hosted electronically and, aside from the public recruitment survey, were only accessible via email. Project data were collected and managed using REDCap (Research Electronic Data Capture), developed by Vanderbilt University

and hosted at Penn State Health Milton S. Hershey Medical Center and Penn State College of Medicine, which was supported by Penn State Clinical and Translational Science Institute. REDCap is a secure, web-based application designed to support data capture for research studies [23].

Survey responses were collected across multiple cohorts from August 2022 to August 2024. Initial survey completion was mandatory for participation in the ECHO series, but completion of session evaluations, final program surveys, and follow-up surveys was voluntary.

Survey questions were not randomized and were displayed on a single page per survey. Adaptive questioning was utilized in every survey to minimize survey fatigue. Participants did have the ability to review and change answers before submitting each survey.

Participants answered several demographics (eg, geographic location) and professional questions (eg, credentials, job title, provider type). Participants were also asked about their experience in providing care to neurodiverse populations and how the acuity of care provided to their neurodivergent clients has changed throughout the COVID-19 pandemic. Participants completed several educational evaluations at baseline and postprogram to measure programmatic impact.

The recruitment survey contained 36 questions. The preseries assessment, which was only administered to participants who were screened as eligible for participation by study staff, contained 59 questions. The session evaluations were completed after every ECHO session and contained 14 questions. The final program evaluation contained 83 questions. The 90-day follow-up survey contained 35 questions.

Response Rates

Survey view rates were not available for this study. Study staff closely monitored response rates. The public recruitment survey was closed once at least 40 eligible participants were enrolled. Study staff screened for eligibility as participants completed the surveys. Additionally, study staff monitored the completion of preprogram questionnaires to ensure that only those who completed the preprogram questionnaires were invited to join the ECHO sessions. Session evaluations, final program evaluations (n=66), and follow-up evaluations (n=51) were also closely monitored by study staff to ensure completion and data integrity.

Questionnaire Development

Upon registering for a Fostering Resilience for Neurodiverse Communities ECHO cohort, participants answered several demographics (eg, geographic location) and professional questions (eg, credentials, job title, provider type). Participants were asked about their experience in providing care to neurodiverse populations and how the acuity of care provided to their neurodivergent clients has changed through the COVID-19 pandemic.

Participant self-efficacy was measured at baseline and postprogram using adapted versions of measures identified in the literature [22,24]. Respondents completed each item with their respective level of confidence on several items on a 5-point Likert scale ranging from “not confident” to “highly confident.” Next, participants rated their respective level of confidence on a 6-point Likert scale, ranging from “no confidence” to “highly confident” [21,23]. In postprogram evaluation, participants self-reported changes in clinical knowledge and the application and dissemination of knowledge learned from the Fostering Resilience for Neurodiverse Communities ECHO series. This was measured using a series of questions using a 5-point Likert scale, ranging from “strongly disagree” to “strongly agree,” and included “I applied or shared knowledge learned in ECHO sessions to the neurodiverse clients who have ID/A support,” “I applied or shared knowledge learned in ECHO sessions to the direct support professional I supervise,” “I applied or shared knowledge learned in ECHO sessions with my colleagues in similar roles as mine,” “I applied or shared knowledge learned in ECHO sessions with my supervisors and/or agency management team,” and more.

The Connor-Davison Resilience Scale [25] and the WHO-5 Well-Being Index [26] were used to determine the impact on participant resiliency. Participants were asked to report the use of CRM skills. Additionally, participants’ use of the iChill app [22] that is promoted through the ECHO series is explored through a sequence of questions including, “do you use the iChill app on your phone or tablet,” “if yes, how often do you use it,” and “how helpful is the app?” Participants also responded to several questions related to their experience and satisfaction with the Fostering Resilience for Neurodiverse Communities ECHO series.

Planned Data Analysis

All variables will be summarized using descriptive statistics to assess their distributions and missing data. Pre versus post, pre versus 90-day follow-up, and post versus 90-day follow-up comparisons will be made for all outcome variables. For binary and ordinal (5-category Likert scale) categorical outcomes, we will use binomial or ordinal generalized estimating equation models, which account for the correlation between multiple observations made on each subject over time, to estimate odds ratios between the time points. The magnitude and direction of the odds ratios will allow us to assess the effect size of any significant changes over time. The *P* values for odds ratios that relate to the comparisons between time points, which generally will be all 3 possible comparisons, will be adjusted for multiple comparisons using the Tukey method for each outcome variable. This will maintain a familywise error rate of 0.05. Using this approach will also allow us to include any significant covariates in the model for adjustment if necessary. A sensitivity analysis will be applied to the ordinal outcome variables using quantile regression of the median by using the difference between the outcome responses for each pair of time points as the outcome variable in the model. This will also allow us to adjust for any covariates and use the same Tukey method of adjustment for multiple comparisons. All analyses will be performed using SAS software (version 9.4; IBM Corp) developed by the SAS Institute.

Ethical Considerations

Approval for this project was obtained from the Penn State Institutional Review Board at the Penn State College of

Medicine in Hershey, Pennsylvania (STUDY00018204). Our program was given a not-human subjects research determination because it did not meet the definition of human subject research as defined in 45 CFR 46.102(e) and (l). This determination was made because the intention of this protocol is to assess and improve ECHO processes rather than contribute to generalizable knowledge. Because our program was determined to be a quality improvement activity, consent from ECHO participants was not required. The project data were only accessible to project staff. Participant data were deidentified and aggregated by ECHO staff before use in reporting and analysis.

Monetary incentives were provided for follow-up survey completion for September 2022, January 2023, and April 2023 cohorts only. Monetary incentives were based on the number of surveys completed: completion of at least 7 of 8 session evaluations: US $200; completion of only the 90-day follow-up survey: US $25; and completion of at least 7 of 8 session evaluations AND completion of the 90-day follow-up survey: US $225.

Reporting Guidelines

We used the Checklist for Reporting Results of Internet E-Surveys (CHERRIES) [24].

Results

The ECHO cohorts ran from September 2022 to May 2024, with final follow-up survey data collection occurring in August 2024. There were 131 unique participants who attended ECHO sessions across the 6 cohorts. Participants were DSPs or supervisors of DSPs located in Pennsylvania, although 2 participants indicated that they were from other states (New Jersey and Oregon). Participants were from rural (n=35) and urban (n=94) counties, while other participant rurality is unknown (n=2). Data analysis is planned to be concluded by January 2025.

Discussion

The COVID-19 pandemic has shed further light on the pressing need to provide neurodiverse populations with the skills and resources necessary to successfully navigate society and the ongoing workforce crisis impacting the DSPs serving these populations. In response to the need presented to equip DSPs with resilience-building tools for themselves and their neurodivergent clients, Project ECHO at Penn State College of Medicine launched the Fostering Resilience for Neurodiverse Communities ECHO series. This ECHO series trains DSPs in ways to foster resilience in their neurodivergent clients and themselves. We anticipate that DSPs participating in the ECHO program will report feeling more confident and resilient in their roles.

The CRM has been implemented in other audiences, including health care professionals such as nurses, and it was found that brief resiliency trainings using CRMs for nurses resulted in improved well-being and resiliency among participants [25]. Additionally, the Project ECHO model has been used in resiliency training for first responders, resulting in increased confidence in resiliency skills [26]. The application of the CRM paired with the Project ECHO model for DSPs outlined in this protocol is a novel approach to resiliency training. Other applications of the CRM occur over shorter periods, with one training session lasting 3 hours [21,25]. The application of the CRM in this protocol will give DSPs tools to apply CRM principles in 75-minute ECHO sessions, held once per week over 8 weeks, leveraging active learning, engagement, and community-building, which defines the Project ECHO model. While our study is innovative and comprehensive, it is not without limitations. We rely on self-reported measures of knowledge acquisition, self-efficacy, resiliency building, and satisfaction, potentially resulting in self-report bias of over or underreporting a change in the above-mentioned outcomes. Other less biased outcome measures include supervisor-reported questionnaires, usage data of the iChill application, and retention rates of DSPs, which can be incorporated into future studies.

The Fostering Resilience for Neurodiverse Communities ECHO program introduces a unique opportunity for the application of resilience-building strategies across a variety of contexts to individuals who can apply them directly to their work and in real time. Common themes already identified within the ongoing ECHO program indicate the need for more trauma-informed training among DSPs and other professionals who serve neurodiverse populations, particularly in underserved and marginalized communities. We anticipate this training will result in increased self-efficacy, improved well-being, and expanded application of resiliency skills for DSPs and their neurodiverse clients.

Acknowledgments

The authors would like to acknowledge Dr Gregory Cherpes for his support of this project. The authors would also like to acknowledge the Project ECHO team at Penn State, specifically Ellie Hogentogler, Jackie Sabol, and Caitlin Kline. We would also like to acknowledge the members of the Project ECHO expert hub team, including Nicholas DeMarco, Erin Edwards, Keely Hirsch, Mary Krupa, Andrea Layton, and Jesse Northridge. Additionally, we would like to acknowledge Kara Bowers and Emily Heilbrunn for their contributions to the first draft of this protocol. Last, we would like to thank all the community providers who attended and presented cases in the ECHO sessions. This project was funded by the Pennsylvania Department of Human Services through the Money Follows the Person program. The project described used REDCap, which was supported by the National Center for Advancing Translational Sciences, National Institutes of Health, through grant UL1 TR002014. The content is solely the responsibility of the authors and does not necessarily represent the official views of the NIH.

Authors' Contributions

Abstract

Background: Amyotrophic lateral sclerosis (ALS) leads to rapid physiological and functional decline before causing untimely death. Current best-practice approaches to interdisciplinary care are unable to provide adequate monitoring of patients' health. Passive in-home sensor systems enable 24×7 health monitoring. Combining sensor data with outcomes extracted from the electronic health record (EHR) through a supervised machine learning algorithm may enable health care providers to predict and ultimately slow decline among people living with ALS.

Objective: This study aims to describe a federated approach to assimilating sensor and EHR data in a machine learning algorithm to predict decline among people living with ALS.

Methods: Sensor systems have been continuously deployed in the homes of 4 participants for up to 330 days. Sensors include bed, gait, and motion sensors. Sensor data are subjected to a multidimensional streaming clustering algorithm to detect changes in health status. Specific health outcomes are identified in the EHR and extracted via the REDCap (Research Electronic Data Capture; Vanderbilt University) Fast Healthcare Interoperability Resource directly into a secure database.

Results: As of this writing (fall 2024), machine learning algorithms are currently in development to predict those health outcomes from sensor-detected changes in health status. This methodology paper presents preliminary results from one participant as a proof of concept. The participant experienced several notable changes in activity, fluctuations in heart rate and respiration rate, and reductions in gait speed. Data collection will continue through 2025 with a growing sample.

Conclusions: The system described in this paper enables tracking the health status of people living with ALS at unprecedented levels of granularity. Combined with tightly integrated EHR data, we anticipate building predictive models that can identify opportunities for health care services before adverse events occur. We anticipate that this system will improve and extend the lives of people living with ALS.

Introduction

Amyotrophic lateral sclerosis (ALS) is a rapidly progressing neurodegenerative disorder that usually leads to death within 3 years of symptom onset and within 2 years from diagnosis [1]. The sequence and rate of ALS progression can vary widely depending on the phenotype, age at onset, and diagnostic delay [2,3]. Pharmacological developments (eg, Riluzole and Radicava) can slow disease progression, but the result is always premature death, typically due to respiratory failure, pneumonia, or heart failure [4,5].

Treatment in a specialized, multidisciplinary ALS clinic is among the strongest predictors of quality of life and prolonged survival among people with ALS [6]. In the United States, these clinics take the form of ALS Association Certified Treatment Centers of Excellence, which, by definition, must include a multidisciplinary team with treatment standards based on the American Academy of Neurology Practice Parameters [6,7]. Even in this best-case treatment setting, though, weeks or months may pass between clinic visits. Rapid physiological and functional declines between visits mean that a person with ALS can be hospitalized or deceased before the care team is aware of their change in status. The time between clinic visits represents a critical gap in the multidisciplinary care of people with ALS. A reliable, noninvasive system for passively detecting physiological and functional decline between visits would give the multidisciplinary team unprecedented ability to predict outcomes and, more importantly, make near–real-time treatment recommendations to counteract disease progression, prolong independence, and maintain quality of life. Rates of respiratory decline and lower extremity functional decline, in particular, are reliable prognostic indicators for ALS survival time [1]. In addition to pharmacological options, targeted nonpharmacologic interventions can reduce perceived fatigue, improve manual dexterity, prevent falls, promote myriad cognitive improvements, and preserve the overall quality of life among those living with ALS [8]. These interventions, enabled by early detection of decline, are most effective when delivered in the context of multidisciplinary programs, resulting in longer survival and higher quality of life [6,9].

To monitor the decline, members of the research team have developed a passive, in-home, sensor-based system for monitoring physiological biomarkers and functional status through a combination of hydraulic bed sensors, motion sensors, and privacy-preserving depth sensors [10]. The system can reliably capture pulse, respiration rate, bed restlessness, room activity, gait speed, stride length, and falls. It has been deployed in more than 300 senior housing units and private homes throughout the midwestern United States since 2005. The system was developed and tested in two phases with support from the National Institutes of Health (National Institute of Nursing Research 1R21NR011197-01, Rantz, principal investigator). The first phase was retrospective [11-13], reviewing 3 years of significant health events from previous study participants. Parameters deemed important for an aging-in-place population include increasing or decreasing bed restlessness, pulse, respiration, time in bed, increasing bathroom activity, and decreasing general activity and time away from home [10,14-16]. Previous iterations of the system have been described extensively elsewhere [17,18]. The current iteration is a closed-source implementation purchased from Foresite Healthcare and maintained by the research team.

Our previous work makes clear that it is possible to detect and track very early signs of health changes using passive in-home sensing. In some cases, the onset of clinical declines may be detected before patients are aware of changes [18-20]. The system captures a variety of important biomarkers and functional data, including the key variables for predicting decline among people with ALS. The purpose of this work is to adapt the existing sensor system to predict physiological and functional decline in people living with ALS. This approach relies on a myriad of multimodal data, including robust sensor signals and structured electronic health record (EHR) data from distinct platforms. Here, we describe a necessarily federated approach to combining these distinct data types into a single dataset for the generation of the prediction algorithm. We hypothesize that this approach is feasible.

Methods

Design

The goal of the parent study is to adapt the existing sensor-based alert system to facilitate early detection of physiological and functional declines among people living with ALS. To this end, the study considers three hypotheses: (1) the enhanced sensor system is feasible for collecting biometric data and health outcomes from people living with ALS; (2) enhanced sensor system data, processed through an unsupervised machine learning approach, may enable early detection of health status changes among people living with ALS; and (3) changes in health status detected by the multidimensional streaming clustering approach can predict adverse health outcomes, including pneumonia, hospitalization, and death among people living with ALS.

This paper specifically addresses the methodology for hypothesis 1, testing the feasibility of the federated collection, storage, and analysis of data from the sensor system and EHR. Data collection is scheduled to continue through December 2025, and interim findings are reported in the *Results* section below. Full results of this process will be reported elsewhere upon completion of the study.

Recruitment

Participants are recruited from the ALS Association Certified Treatment Center of Excellence at University of Missouri Health Care. Inclusion criteria are age 18 years or older, a clinical diagnosis of ALS by a qualified neurologist as documented in the EHR, home zip code within 100 miles of the clinic, and

either the presence of a live-in caregiver (eg, spouse or adult child) or a Montreal Cognitive Assessment (MoCA) score >22. Recruiting coordinators are allowed to omit scoring individual MoCA items if, in their clinical judgment, response difficulties are due to speech or motor deficits resulting from ALS, rather than cognitive impairment. ALS genotype and phenotype, enrollment in clinical trials, and any other treatments are not considered inclusion or exclusion criteria.

Sensor System

We use three types of in-home sensors: hydraulic bed mats, thermal depth sensors, and motion tags, to monitor participant health. The sensor systems function effectively regardless of lighting conditions, providing a noninvasive, passive way to monitor participant health. The bed sensor is installed beneath the participant's mattress, where signals are best captured during rest. It uses a hydraulic pressure transducer to gather composite ballistocardiogram signals, which are deconvolved into components of sleep restlessness, respiration rate, and pulse. Ballistocardiogram signals are a mechanical measure of blood flow produced by cardiac activity, analogous to electrocardiogram signal patterns. The composite signals are partitioned into their respective components using signal-filtering algorithms. The ballistocardiogram component is subjected to a sixth-order bandpass filter with a 0.7-10 Hz cutoff. The respiration component is subjected to a sixth-order low-pass filter with a 0.7 Hz cutoff. Instances of heightened bed restlessness appear in the signal data as periods marked by higher amplitude and increased noise.

A wall-mounted thermal depth sensor generates a series of depth images, where each pixel corresponds to a coordinate measurement within the scene [17]. The depth images contain 3D point-cloud coordinates of the participant during walks. Validated algorithms extract gait parameters from these depth images. Gait parameters for stride time, stride length, walking speed, and participant height are derived from the point cloud silhouettes. To overcome the limitations posed by the sensor's field of view, which can be potentially occluded by furniture or other objects, a centroid-based gait parameter estimation technique has been developed. This approach permits the collection of additional gait parameters, such as gait bounce, trunk sway, asymmetry, and entropy across all 3 axes (X, Y, and Z), as well as the XY diagonal with partial leg occlusion during stride. In addition to gait parameters, a standardized Timed Up and Go fall risk assessment score is computed from the average in-home walking speed, as captured by the depth sensor [17]. In the event of a detected fall, the depth sensor performs a dual function: sending an immediate alert to designated contacts and generating a short video clip of the fall event for subsequent investigation or diagnosis.

Passive infrared motion sensors are deployed using the ZigBee (Connectivity Standards Alliance) protocol, a high-level radio communication protocol designed for low-power wireless data transmission. The motion sensors are installed in key locations such as the bathroom, bedroom, living room, kitchen, and front door to capture room-level activity. Abnormal activity in these spaces, based on the time of day or night, may suggest potential health issues, such as a urinary tract infection or the onset of cognitive decline. As the motion sensors detect movement in infrared light, they are effective at identifying activity regardless of lighting conditions. In addition to motion counts, we calculate room activity density, represented as the number of motion events within a unit of time for a respective sensor, providing an overall level of activity for each room.

The system has been tested in a multiresidential environment and can handle the presence of visitors, distinguishing them from residents based on gait patterns [18]. In a commitment to maintain privacy and comply with HIPAA (Health Insurance Portability and Accountability Act) standards, all data collected from these sensors are anonymized and time stamped with a study-specific participant identifier, which is used to deterministically link with sensor data. The data are stored in a secure AWS instance.

EHR Data Integration

We leveraged the REDCap (Research Electronic Data Capture; Vanderbilt University) Fast Healthcare Interoperability Resource (FHIR) interface to extract participants' most recent clinical information directly from the backend Oracle Health EHRs Database system of University of Missouri Health [21-23]. The REDCap FHIR interface enables interoperability with EHR systems, allowing real-time data extraction. By leveraging the FHIR interface, we can extract relevant data elements, such as laboratory results, vital signs, and clinical assessments, to populate the registry with up-to-date information. To ensure data accuracy and completeness, we map the extracted EHR data to the corresponding REDCap data fields using standardized terminologies, such as *ICD-9-CM* (*International Classification of Diseases, Ninth Revision, Clinical Modification*), *ICD-10* (*International Statistical Classification of Diseases and Related Health Problems 10th Revision*), LOINC (Logical Observation Identifiers Names and Codes), SNOMED CT (Systematized Medical Nomenclature for Medicine–Clinical Terminology), and RxNorm. This mapping process facilitates seamless data integration and enables efficient data retrieval for further analysis. Once the EHR data are extracted and mapped to REDCap data fields, the data are stored in the REDCap database. REDCap provides a secure and user-friendly platform for managing research data, allowing researchers to more easily access clinical information on people with ALS. However, the current FHIR interface does not support real-time extraction of unstructured notes, which were manually extracted and uploaded into the same REDCap project, along with an additional outcome ascertainment form for collecting monthly evaluations of the ALS Functional Rating Scale-Revised (ALSFRS-R). All EHR data collected into REDCap are anonymized and time stamped, with a study-specific participant identifier created to deterministically link with sensor data.

Data Management Plan

The extracted EHR data from REDCap and sensor data are loaded into a single study-designated cloud storage via Secure Shell File Transfer Protocol or Transport Layer Security 1.2 Protocol, hosted on a HIPAA-compliant, cloud-based data enclave. Data are integrated and analyzed via the self-service "Analytic Workbench," hosted within the same data enclave. Uninterrupted monitoring of accesses and activities occurs on

the study database following established best practices that have been implemented at the system level. Researchers' access details are required to be reviewed on an annual basis according to current data use protocols. Access to the study database is restricted to the study period, plus an additional 5 years after the end of the study period, to facilitate subsequent requests to validate and reuse the database for future analyses and retrospective projects [24].

Data Analysis

Sensor Feature Engineering

We will test the preliminary efficacy of the expanded sensor platform for detecting changes in health status among people living with ALS. The Center for Eldercare and Rehabilitation Technology has previously developed a multidimensional streaming clustering algorithm that can simultaneously monitor all of the inputs of the existing sensor platform and detect cumulative deviations from expected patterns. The multidimensional streaming clustering approach applies principal components analysis and t-distributed stochastic neighbor embedding to identify the "normal" relationships between multiple biometric variables. The change in each variable over time can be treated as a vector, and those vectors can effectively be summed to produce a single vector leading to a single point in feature space. The point represents the patient's cumulative health status for the day, and the vector indicates day-to-day changes in that overall health status. When tracked over time, these changes reveal a cluster of expected behavior. The cluster is defined not only by its central mean value but also by the degree of typicality of the values. Typicality is an indicator of the consistency within the cluster, comparable with SD. Importantly, those clusters remain relatively stable and identifiable within a given period. Potential alterations in function can then be identified by retrospectively tracing the daily point trajectory as it approaches or leaves the cluster boundary. This deviation from typicality is often a warning sign of health decline caused by injury or illness. Outliers indicate potential moments of acute health decline, triggering a warning to health care staff. This same approach will be leveraged using expanded sensor platform data (including input from the Garmin 245 wearable sensor) to generate and monitor clusters of baseline data for people with ALS.

To establish the preliminary efficacy of the system, we will follow the methods demonstrated by Wu et al [25]. We will retrospectively compare outlier points to any adverse health outcome indicators from the EHR to explore whether detected outliers occurred in the period immediately preceding adverse health outcomes. This process begins with an exploratory visual analysis conducted by the Center for Eldercare and Rehabilitation Technology and Clinical Teams. We can then bin outliers into true and false positives and bin adverse health events into caught and missed events, establishing the sensitivity and specificity of the outliers as alerts to health status change. These results will achieve two important goals. First, they will answer the preliminary efficacy question, providing our first indication of whether this system can potentially detect health status changes in people living with ALS. We will also investigate the associations between the outliers and ALSFRS-R score changes and irregularities.

Early Detection Modeling

We will develop multiple state-of-the-art machine learning models (including but not limited to regularized logistic regression, least absolute shrinkage and selection operator, support vector machine [26], random forest [27], gradient boosting, and deep neural networks [28]) to achieve optimal performance for predicting future ALSFRS-R scores. Machine learning approaches broadly involve three phases: training, validation, and testing. In the training phase of a supervised learning approach, investigators define the relevant predictors (eg, biometric sensor data and outlier warnings) and outcomes (eg, ALSFRS-R score change, EHR indicators of pneumonia, hospitalization, and death) of interest. The system feeds the predictors and outcomes into a recurrent neural network first to extract sequential features, and then each of the identified algorithms creates a predictive model that can subsequently predict outcomes in novel datasets. We will perform the training phase on the first 12 months of retrospective sensor and EHR data. When the training and validation phases involve continuous collection of data from a single or growing dataset, the holdout method suggests a 2:1 ratio of training to validation data. Therefore, we will complete the validation phase with the final 6 months of prospective data collection. In the validation phase, inputs (eg, biometric data, gait, and sleep) are fed into the model and predicted outputs (eg, adverse health outcomes) are compared to real-world outcomes (eg, EHR outcome indicators of pneumonia, hospitalization, and death) [29]. Validation tests are then conducted for both traditional sensitivity and specificity, as well as for overfitting of the model. The validation phase allows us to fine-tune the relative weights of each factor in the model, improving its predictive validity. The optimal predictive model will be selected based on testing accuracy.

Ethical Considerations

This study was approved by the University of Missouri Institutional Review Board (project number 2084262) and the U.S. Army Medical Research and Development Command (USMRDC) Office of Human Research Oversight (log number E03062.1a). All participants provided informed consent. Sensor data are deidentified on the device before transmission to the REDCap database. EHR data are deidentified in the REDCap FHIR process before transmission to the REDCap database. Participants are not compensated.

Results

User Statistics

A total of 4 participants have been recruited (Table 1). None of the 4 participants required accommodations to complete the MoCA. Preliminary data from participant 1 are summarized in the preliminary analysis below (Figures 1-4). Specific dates of diagnosis and enrollment are not provided, as they could be combined with general geographic information to effectively deidentify participants with a rare condition. Sensor feature engineering and early detection modeling, based on all 4 participants, will be analyzed and reported in 2025.

Examples of monitoring results are shown in Figures 1-4, all scaled to the identical period from September 11 to December 29, 2023.

Figure 1 depicts motion density in the home, with the most motion detected during a prolonged family visit in November and considerable time spent out of the home around the December holidays (black boxes).

Figure 2 illustrates the number of movements detected in different rooms of the home, featuring spikes in time spent in bed (tall yellow lines) and confirming several nights spent outside the home in December (absence of yellow and red lines).

Figure 3 displays in-bed respiration rate (bottom purple plot) and four techniques for estimating pulse rate: energy [30] in brown, Hilbert transform [31] in red, k-means clustering [32] in black, and windowed peak-to-peak deviation [33] in blue.

Figure 4 depicts, from top to bottom, average gait speed, stride length, and stride time. Notably, reductions in average gait speed are indicated by orange lines on December 3 and 10, 2023. These represent system-generated alerts. The December 3, 2023, alert reads:

> *Walking Speed Decrease: The average walking speed of 91.4 cm/s observed during the current 7-day period ending on 12/03/2023 is 3.4 cm/s (3.6%) lower than the average walking speed of 94.8 cm/s observed during the 7-day baseline period which ended on 11/26/2023.*

Table 1. Participant characteristics.

Characteristics	Participant			
	1	2	3	4
Age (years)	62	70	55	45
Sex	Male	Male	Male	Male
Race	White	White	White	White
Days since Dx[a] at enrollment, n	617	41	24	56
Initial ALSFRS-R[b] composite score	31	20	38	27
Deceased	No	Yes	No	No
Days of data collected, n	330	48	86	59

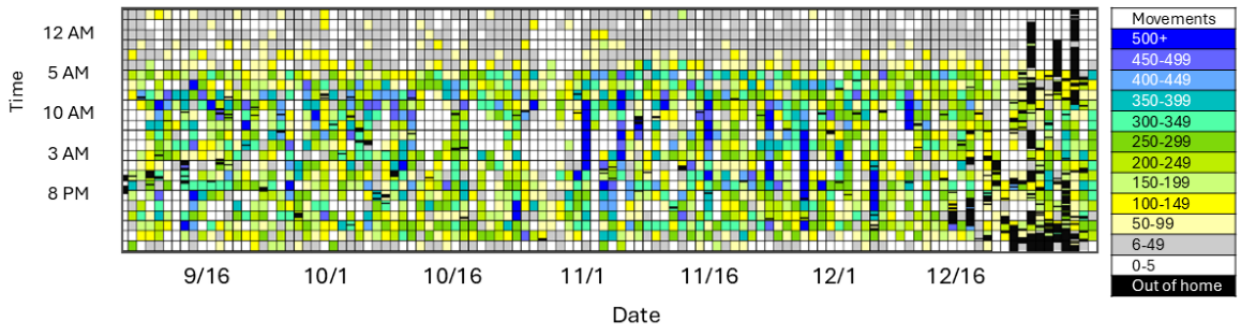

Figure 2. Per-room movement detections over 24-hour periods from September 11 to December 29, 2023. Red: bathroom; yellow: bedroom; green: front door; lavender: kitchen; purple: living room.

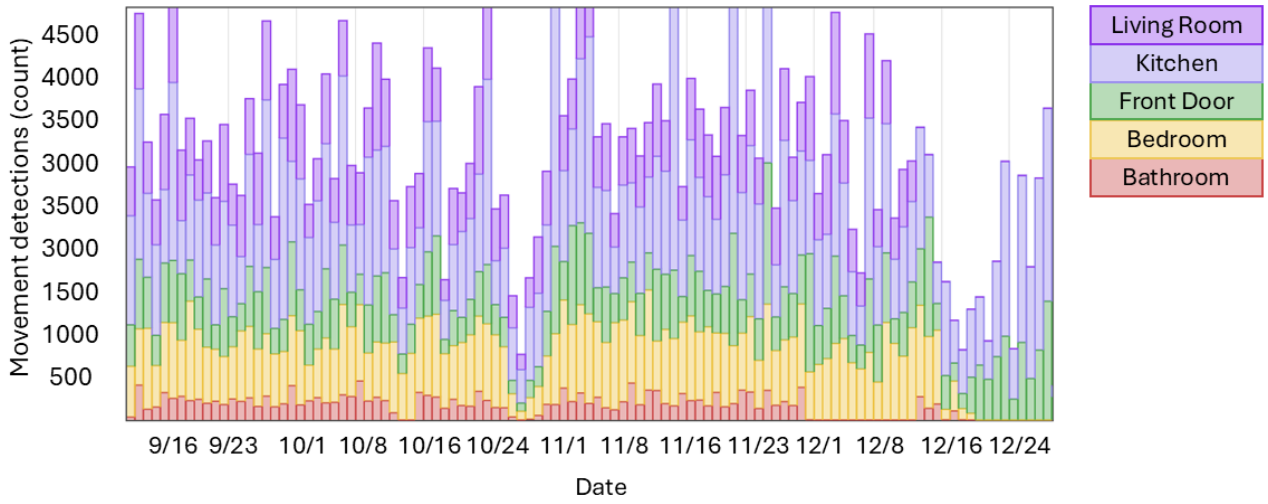

Figure 3. Heart rate and respiration rate by day from September 11 to December 29, 2023. Brown: energy; red: Hilbert transform; black: K-means clustering; blue: windowed peak-to-peak deviation; purple: respiration rate.

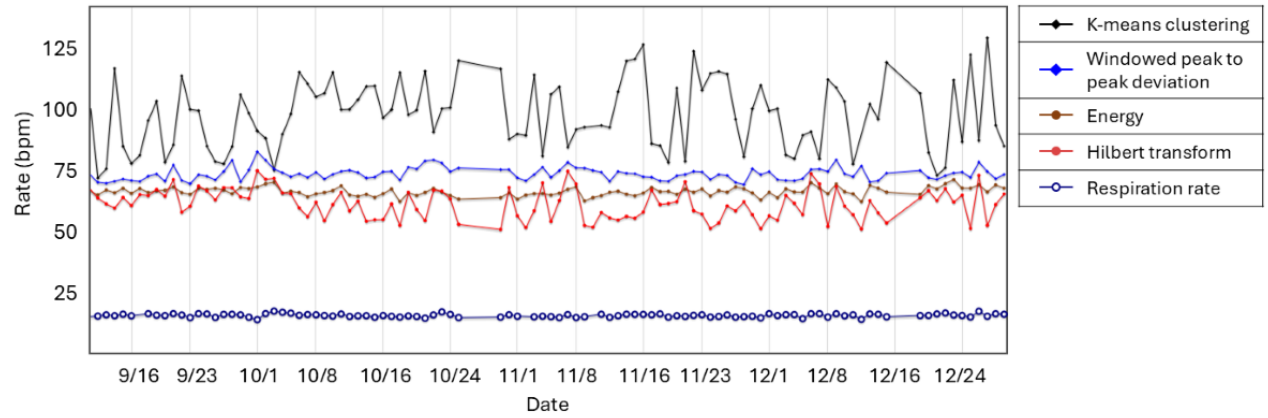

Figure 4. Gait data by date from September 11 to December 29, 2023. Light green: stride length (cm); dark green: average speed (cm/s); yellow: stride time (s); orange: system-generated gait alerts.

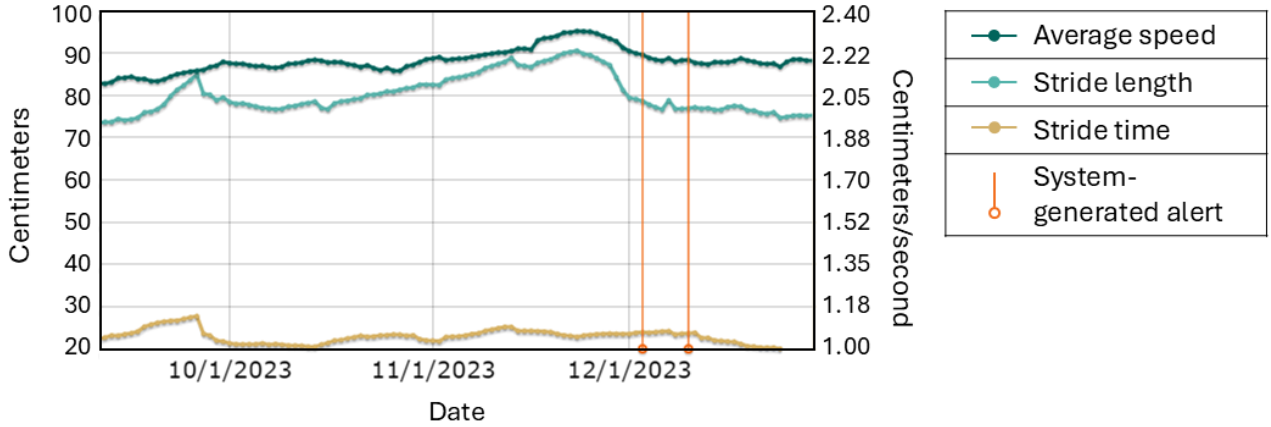
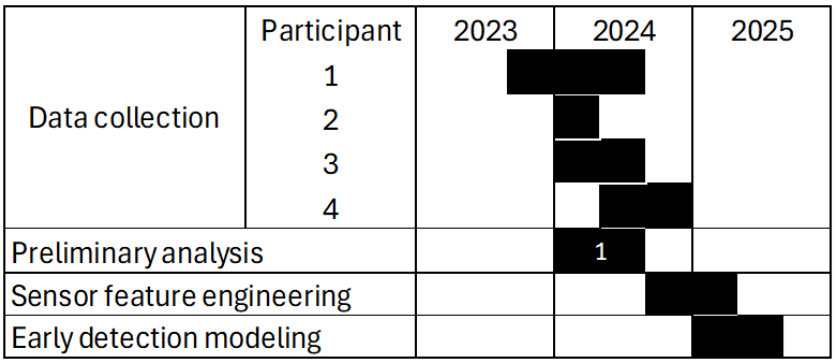


Evaluation Outcomes

As of this writing (fall 2024), sensor feature engineering is underway, and early detection modeling will be reported upon completion. The timeline of this work-in-progress is provided in Figure 5.

Figure 5. Timeline. "1" indicates the phase of work presented in this paper.



Discussion

Preliminary Results

This paper describes a federated approach to the collection of in-home sensor data and the extraction of EHR data to create predictive models of health status change in people living with ALS. This approach is feasible for collecting both biometric data and health outcomes from people living with ALS. The sensors are nonintrusive and privacy preserving by design, making them acceptable to participants. Similarly, the FHIR process is nonintrusive and ensures timely, secure extraction of records for machine learning purposes.

In the next phase of this work, we will process the data using both supervised and unsupervised machine learning approaches to detect health status changes and predict adverse health outcomes, including pneumonia, hospitalization, and death among people living with ALS. We anticipate that the results generated by this protocol will inform subsequent clinical trials for the prediction of ALS progression, providing guidance for interventions and their optimal timing.

Impact

This work represents a novel application of a remote sensor monitoring platform that has been previously validated in other settings and populations, such as stroke and independent living. This approach has tremendous potential in ALS, where progression is often rapid and, until now, unpredictable. It allows us to capture around-the-clock health state parameters, including during the critical late stages of decline. The system may provide important insight into physiological changes in late-stage ALS and suggest new intervention strategies to slow the rate of decline throughout the course of the disease.

Limitations

We anticipate several challenges during the course of this study. The sensor data are limited to physiological measures, gait parameters, and household-level motion activity, which may not adequately capture the full spectrum of deficits observed in ALS and are reported through clinical evaluations such as the ALSFRS-R. Recruitment has been lower than projected, which could reduce our ability to develop a reliable predictive model. Even if the sample size meets projections, there remains concern regarding whether the sample will be representative of the larger population of people living with ALS due to the geographic limitations of our single-site study. Our sampling frame results in a sample that is disproportionately White and non-Hispanic. This is an inherently criterion-referenced, single-subject approach, where each patient's biometric indicators are evaluated only in terms of deviation from their own established historical norms. In contrast, hypothesis 3 will involve creating a predictive model based on historical data. A model built from a homogeneous sample may overfit the characteristics of that sample. Overfitting occurs when relatively few outcome events are represented in the data, thus overweighting their contribution to the model. As a result, the model becomes tuned to detect cases that match the original training phase cases but cannot adapt to novel cases that differ from the training cases. As such, our initial model may not perform as well with people with ALS from non-White and Hispanic backgrounds, including Black people with ALS, who are known to receive later diagnoses and have faster rates of decline [34]. Our validation phase will recognize the limited diversity available in our sample. Importantly, we will design the initial model to evolve with additional data.

Future Work

The project described in this paper will conclude in 2025. The authors have secured additional funding from the ALS Association (24-AT-722) to develop models to predict ALSFRS-R scores from sensor data and develop sensor-derived clinical alerts. That multisite project will provide a more diverse sampling frame to improve representation in the model. Future plans include clinical trials to establish the efficacy and effectiveness of this approach for delaying adverse outcomes.

Conclusions

This study will provide important new insights into the progression of ALS at a previously impossible level of granularity. The federated system described in this paper will facilitate the development of predictive algorithms for illness, falls, hospitalization, and death. This approach has the potential to transform the clinical assessment workflow through the implementation of decision-support predictive analytics, enabling more proactive and personalized care strategies. By integrating sensor-informed care for clinicians and caregivers, we hope that this work may lay the foundation for clinical trials to intervene ahead of adverse outcomes with the goal of extending and improving the quality of life of people living with ALS.

Acknowledgments

This work was supported by the Department of Defense Office of the Congressionally Directed Medical Research Programs through the Amyotrophic Lateral Sclerosis Research Program Clinical Development Award under W81XWH-22-1-0491. Opinions, interpretations, conclusions, and recommendations are those of the authors and are not necessarily endorsed by the Department of Defense. The Department of Defense was not involved in the implementation of any stage of this work. Foresite Healthcare was not involved in the implementation of any stage of this work. No generative artificial intelligence was used at any stage of this work. The authors wish to acknowledge the invaluable contributions of Mr Zachary Selby, software support analyst.

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author on reasonable request. This paper adheres to the Guidelines and Checklist for the Reporting on Digital Health Implementations (iCHECK-DH) checklist, a copy of which is available from the corresponding author upon reasonable request [35].

Authors' Contributions

WEJ contributed to the conceptualization, funding acquisition, investigation, methodology, project administration, resources, supervision, visualization, writing of the original draft, and review and editing. NM contributed to data curation, formal analysis, investigation, methodology, software, validation, visualization, writing of the original draft, and review and editing. XS contributed to data curation, formal analysis, funding acquisition, investigation, methodology, resources, supervision, validation, and writing of the original draft. MP contributed to the conceptualization, funding acquisition, methodology, supervision, and writing of the original draft. ASMM contributed to the conceptualization, funding acquisition, methodology, resources, supervision, and writing of the original draft. JHE contributed to data curation, investigation, and project administration. VJ contributed to funding acquisition, project administration, and resources. MS contributed to conceptualization, funding acquisition, methodology, resources, and supervision.

Conflicts of Interest

The University of Missouri and MS have minority ownership stakes in Foresite Healthcare, which produces the sensor platform. MS also serves on the Advisory Board of Foresite Healthcare. These conflicts are managed by the University of Missouri Conflict of Interest Committee to ensure objective research conduct.

Abstract

Background: Exacerbations of chronic obstructive pulmonary disease (COPD) are one of the main causes of mortality, and early detection of exacerbations is thus essential. Telemedicine solutions have shown promising results for the detection of exacerbations in COPD and have increasingly been used. However, the effect of telemedicine is divergent. According to several studies, respiration rate (RR) increases before, during, and after an exacerbation and the change is measurable with several contactless devices. Despite this, RR is rarely measured, and telemedicine solutions only use wearable devices for measuring RR, even though wearable respiratory monitoring devices have been associated with certain drawbacks. Contactless devices are often used during sleep, as measurements conducted during sleep minimize the risk of disturbance from physical activities. However, the potential of measuring RR and heart rate (HR) during sleep for the detection of exacerbations in COPD remains unclear.

Objective: The aim of this observational study is to investigate whether contactless measurement of RR, HR, and sleep stages can be used to detect exacerbations in people with COPD.

Methods: An observational study including 50 participants with COPD will be conducted. The participants reside in Aalborg municipality, located in the North Denmark Region. Participants will use a contactless monitor (Sleepiz One+) near their bed during sleep for a period of 4 months. After data collection, descriptive statistics will be used to identify any extremes or variations in RR, HR, or sleep stages in the nights preceding an exacerbation. Correlation analysis will be performed to evaluate the relationship between the number of exacerbations and extremes or variations in RR, HR, or sleep stages. Finally, qualitative interviews will be conducted with 12 participants to explore their experiences of sleeping with the monitor nearby.

Results: Recruitment started at the end of April 2024. A total of 12 participants have been recruited, and the remaining participants are expected to be recruited during March and April 2025. Six out of 12 participants have completed the data collection and qualitative interview stages. Overall data collection is expected to be completed by September 2025. The results are expected to provide insight into the potential for identifying extremes or variations in RR, HR, or sleep stages in the days preceding an exacerbation. Additionally, the results are expected to assess the correlation between the number of exacerbations and extremes or variations in RR, HR, and sleep stages.

Conclusions: The findings from this study may clarify the possibility of using a contactless monitor to detect exacerbations in COPD. Furthermore, the results may have the potential to improve the ability to predict exacerbations in the future.

Introduction

Chronic obstructive pulmonary disease (COPD) poses a global health challenge. In 2019, around 212 million people were diagnosed with COPD, and it was the third leading cause of death with approximately 3.3 million deaths [1,2]. COPD is associated with significant economic costs, which increase with the progression of the disease [1]. In the European Union, the direct expenses related to respiratory diseases are estimated to comprise approximately 6% of the total annual health care expenditures, with COPD accounting for 56% of respiratory disease expenditures [1].

Exacerbations in COPD are characterized by exacerbation of shortness of breath and/or coughing with increased sputum over a period of <14 days. These escalating symptoms may be accompanied by rapid breathing and/or rapid pulse [1,3]. Frequent exacerbations are associated with reduced quality of life (QoL), increased risk of rehospitalization, and higher mortality rates compared to fewer exacerbations [4]. Hence, it is essential to prevent exacerbations.

Timely treatment of exacerbation reduces the risk of hospitalization and increases QoL [5,6]. Identification of the first symptoms of exacerbations is therefore essential to initiate early treatment. For early detection of exacerbations, telemedicine solutions are increasingly used, which seem to have a positive effect on QoL and hospital admissions [7,8]. However, the effectiveness of telemedicine solutions in preventing exacerbations is not convincing, and the results are generally divergent, indicating the need for further research [7-11].

In telemedicine, monitoring of physiological parameters is widely used for early detection of exacerbations. Primarily, oxygen saturation and heart rate (HR) are measured and used for detection of exacerbations [11-14]. However, the telemedicine solutions are generally based on studies with a low methodological quality, highlighting the need for robust, well-designed clinical trials [14].

According to several studies, both respiration rate (RR) and HR increase before, during, and after an exacerbation [15-17]. Despite measurement of RR being more effective than HR for early detection of exacerbation, only a few telemedicine solutions include measurements of RR [11-14]. The lack of RR measurement may possibly be attributed to the general challenge of measuring RR over an extended time period at home [18]. Moreover, respiratory monitoring equipment has been associated with certain drawbacks such as discomfort and difficulty in use [19]. Overall, the usability of respiratory monitoring systems is sparsely investigated [18].

Various contactless devices are capable of measuring RR [20], including contactless radar-based monitors [21,22]. Existing telemedicine solutions only use wearable devices for RR measurements [19,23-25], even though it seems possible to measure a change in RR during exacerbation using contactless devices [26]. Contactless devices enable free movement and eliminate the discomfort associated with wearable devices. Discomfort can hinder measurement over an extended time period [22,27,28], and contactless devices are therefore increasingly used for measurements of physiological parameters [29]. However, contactless devices require the user to be near the device and are therefore often used for overnight measurements, where the user remains close to the device for an extended time period [20]. During sleep measurement, it is essential that the equipment is contactless to minimize the impact on sleep quality [30]. Sleep monitoring minimizes the risk of measurements being influenced by factors such as physical activity. Several contactless devices are capable of measuring both RR and HR [20-22]. To the best of our knowledge, no previous studies have conducted frequent contactless measurement of RR and HR during sleep for detecting exacerbations in people with COPD.

The overall objective of the study is to investigate whether physiological variables such as RR, HR, and sleep stages can be used to detect exacerbations in people with COPD. This study is based on the hypothesis that data from frequent measurement of RR and HR during sleep can be used to detect exacerbations in COPD. Ultimately, these data may improve the prediction of exacerbations in COPD.

Methods

Study Design

This study is a longitudinal observational study and is expected to run from April 2024 to September 2025 [31,32]. This study will recruit participants from the Danish telemedicine service, TeleCare Nord (TCN), which is part of routine care in the North Denmark Region [33]. The telemedicine service includes measurements of oxygen saturation, pulse, blood pressure, weight, and patient-reported outcomes once a week [34].

Eligibility Criteria

Inclusion Criteria

People aged ≥18 years with a diagnosis of COPD will be included in the study, and both men and women are qualified. Moreover, people residing in the Aalborg Municipality will be deemed eligible to participate.

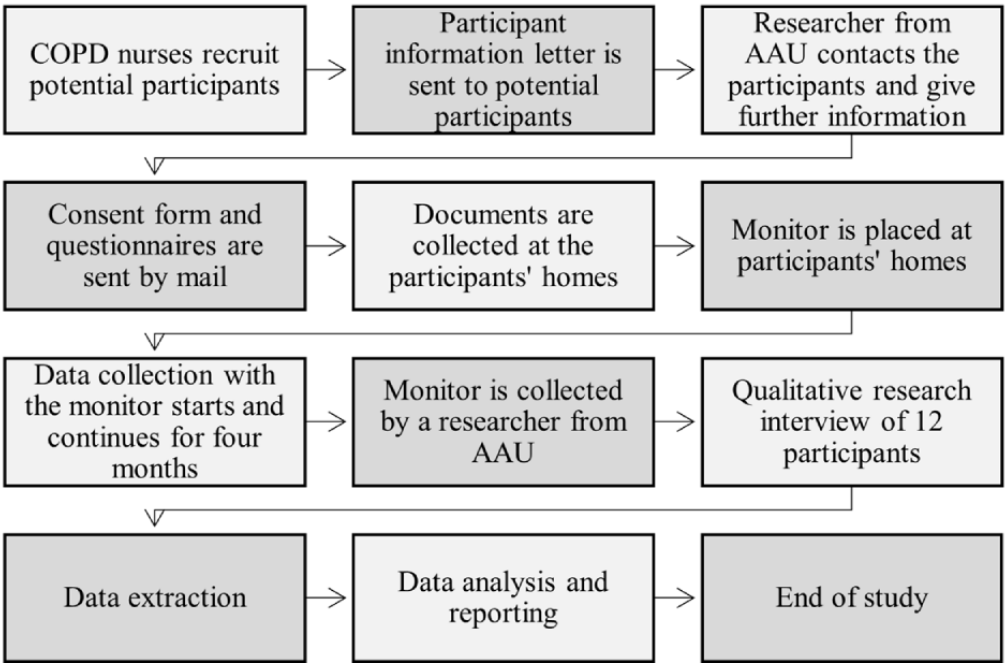
Exclusion Criteria

The exclusion criteria are the inability to complete questionnaires, pregnancy, nursing, electronic implants, and children or pets sleeping in the same bed as the participants, as it can disturb the measurements.

Recruitment

For the observational study, 50 participants will be recruited from Northern Jutland, Denmark. Initially, recruitment is conducted by specialized COPD community nurses (or a related clinician; Figure 1). The specialized COPD nurse gives a short introduction to the trial and in case of someone is interested in participating, a researcher from Aalborg University (AAU) will send a participant information letter by mail. Hereafter, the participants are contacted by a researcher from AAU who will provide further information about the study. If the individual is interested in participating, a consent form and questionnaires regarding baseline information will be sent by mail.

Figure 1. The study procedure from recruitment until the end of the study. AAU: Aalborg University; COPD: chronic obstructive pulmonary disease.



Study Setting

After the participants have received and completed the questionnaires and consent forms, a researcher from AAU will collect the documents at the participants' homes. Subsequently, a contactless radar-based monitor (Sleepiz One+) will be placed near the participants' bed. The monitor measures RR, HR, and sleep stages, including rapid-eye-movement sleep, light sleep, and deep sleep. The participants are asked to take measurements throughout the study period. The monitor measures changes in distance originating from breathing activity and heart contractions by using Doppler radar. These distance changes are analyzed using signal processing algorithms to extract RR and HR every fifth second.

The monitor is positioned on a stand 5-10 cm above mattress level, 40-50 cm from the participant pointing to the lower part of the chest. The monitor measures the participant during sleep and only measures the person who is positioned closest to the monitor. Therefore, the participants will be instructed to stay closest to the monitor during sleep, since it would disrupt the measurements if partners were sleeping closest to the monitor. Furthermore, participants will be instructed to turn on the monitor before going to sleep and turn it off upon waking throughout the entire study to ensure consistent data collection. This approach also prevents the monitor from recording data from partners who may go to bed earlier or stay in bed longer than the participants.

Neither the nurses nor the participants will have access to the data from the monitor during the study. Data from the monitor are solely used retrospectively to investigate whether it is possible to identify changes in RR, HR, or sleep stages preceding exacerbations. After the researcher from AAU had placed the monitor at the right position and ensured that the monitor works, data collection was carried out for 4 months.

The data will automatically be transmitted through Wi-Fi to a web application connected to the monitor, enabling data extraction. This web application allows users to view and analyze data collected by the contactless monitor. Participants will be registered as users in the web system by a researcher from AAU, who will also connect a monitor to each individual participant.

The questionnaires will be used to explore health status and health literacy. The health status involves baseline information (gender, age, civil status, educational level, deployment, years since COPD diagnosis, smoking status, and comorbidities), the COPD Assessment Test (CAT) [35], the Medical Research Council (MRC) dyspnea score [36], and The European Health Literacy Survey Questionnaire (HLS-EU-Q16) [37,38]. Additionally, the Danish Short Test of Functional Health Literacy in Adults (DS-TOFHLA) [39] questionnaire will be distributed to assess health literacy.

In cases of missing data for more than 2 consecutive nights, the participants will be contacted by a researcher from AAU by telephone to clarify the underlying reason and resolve that. Once data collection for 4 months (±10 nights) is completed, the monitor is collected by a researcher from AAU.

Data will be extracted from the web application connected to the monitor, TCN, and the National Patient Registry to determine the number and dates of exacerbations. Exacerbations are defined as hospitalizations caused by COPD or self-initiated treatment with antibiotics and/or steroids [40]. To obtain the exact dates of exacerbations, hospitalizations related to COPD will be extracted from the National Patient Registry. Similarly, to determine the dates of exacerbations related to self-initiated treatment, participants are already registering their use of antibiotics and steroids as part of TCN. If self-initiated treatment is registered, a researcher from AAU will contact the COPD nurse to obtain information about when the treatment began, thereby obtaining the exact date of the exacerbation.

User Experience

A total of 12 participants will be asked to participate in a qualitative research interview, focusing on the experience and acceptance of sleeping with the monitor nearby over an extended period. The number of informants for the qualitative research interviews is expected to be sufficient, as data saturation is typically achieved with 12 participants [41]. However, the final number of informants may vary slightly, depending on when data saturation is achieved. To explore the participants' perspectives on using the monitor, the qualitative research interview will be supplemented with the System Usability Scale (SUS) [42] to gather additional information regarding the usability of the system.

Interviews and surveys will be conducted after participants have used the monitor for at least 2 months, allowing them to gain a more realistic understanding of the long-term use.

Data collected during the interviews will be analyzed using the thematic analysis approach developed by Liamputtong [43] and Braun and Clarke [44]. The SUS score will be calculated in accordance with the guidelines presented by Lewis and Sauro [45]. The scores will be analyzed descriptively by using statistical tools in Excel (Microsoft 365 MSO; version 2406, build 16.0.17726.20222).

Statistical Analysis

Overall, the data analysis will include descriptive statistics and logistic regression. Descriptive statistics will be used to calculate mean, SD, and variance for RR, HR, and the time spent in different sleep stages. Logistic regression is particularly relevant when working with binary outcomes to calculate the probability of an event occurring based on one or more independent variables. Since this study investigates whether changes in physiological parameters occur in the nights preceding an exacerbation, logistic regression is an appropriate method for analysis. Logistic regression will be used to calculate the probability of developing an exacerbation based on the descriptives derived from RR, HR, and sleep stages as independent variables. Odds ratios based on logistic regression and the F statistic ($P<.05$) will determine whether each descriptive is independently associated with developing an exacerbation. Furthermore, correlations between the descriptives will be examined.

Sample Size

A sample size of 40 participants will provide 90% power to demonstrate a significant correlation coefficient of 0.5 between the number of exacerbations and extremes or variations in RR, HR, and sleep stages. Considering a presumed dropout rate of 25%, based on previous findings in a study among people affiliated with TCN (ClinicalTrials.gov NCT05218525), 50 participants need to be recruited in this study.

Ethical Considerations

The study has been approved by the Regional Ethical Committee for Medical Research in the North Denmark Region (N-20230072). The study will be performed in accordance with the tenets of Helsinki Declaration [31] and the principles of Good Clinical Practice. Written consent will be obtained from each participant after detailed verbal and written information about the study has been given and will be obtained before inclusion in the study [31]. Data will be anonymized and stored securely in compliance with the Danish Data Protection Rules [32]. The protocol will not be modified unless a new approval from the Regional Ethical Committee is obtained. The participants will not be provided with any compensation for their participation. There are no expected risks associated with participation in the trial. There is no increased risk of exacerbations, as the participants are not exposed to any interventions that could contribute to the development of exacerbations in COPD.

Results

The study received final approval from the Regional Ethical Committee for Medical Research in the North Denmark Region on April 10, 2024 (N-20230072). In April 2024, the first participant information letter was sent by mail to the initial potential participants. The first participant was recruited in May 2024. A total of 12 participants have been recruited so far. Six out of 12 participants have been completed. These participants have also participated in qualitative research interviews at the end. The delivery of the remaining monitors has been delayed and is expected to be underway in March and April 2025. The remaining participants will be recruited once the delayed monitors are received. Data collection will begin as participants are recruited. The first participant completed the data collection stage at the beginning of October 2024 and the last participant is expected to complete this stage by September 2025.

Discussion

Anticipated Findings

The main finding of this study is presumed to be a new way to detect COPD exacerbations using contactless sleep monitoring. The study aims to provide knowledge regarding the possibility of detecting COPD exacerbations through frequent measurements of RR, HR, and sleep stages collected by using a contactless monitor during sleep. If the study proves that exacerbations can be detected by contactless measurements, the results have the potential to improve the ability to predict exacerbations in the future. Predicting exacerbations enables the possibility of initiating early treatment, which is expected to reduce hospitalizations and increase the quality of life among people with COPD.

Additionally, the study is also expected to provide knowledge regarding the experience of using the monitor more permanently. This is considered valuable knowledge about the potential of the monitor, as users' experience and acceptance are important to consider when developing and implementing new technologies [46,47].

An expected strength of this study is the high frequency of measurements conducted over an extended time period. To our knowledge, no previous studies have monitored RR by a contactless monitor with a high frequency of measurements over an extended time period in people with COPD. However, continuous data collection can be crucial in this study because

missing data from the nights preceding an exacerbation can reduce the ability to detect exacerbations, as symptoms primarily change a few days prior to onset [48]. While the recommendation to turn the monitor on/off throughout the entire project period is expected to meet the participants' needs regarding privacy in the bedroom, this recommendation can also increase the risk of missing data. Therefore, it is important to be aware of missing data throughout the study period.

Another expected strength is that the measurements are conducted during sleep without physically touching the participants. This is expected to eliminate the discomfort associated with wearable equipment. Moreover, conducting measurements during sleep reduces the risk of data being influenced by factors like physical activity, which can be challenging to control when people perform the measurements at home during the day on their own. Øverst på formularen

This study may be limited by the risk of observing too few exacerbations during the project period. To address this, most participants will collect data during the winter, when exacerbations are more frequent. However, participants will also collect data at different times of the year, and thus across different seasons, which will help increase the generalizability of the results. Additionally, to mitigate this potential limitation, exacerbations of varying severities will be included to increase the likelihood of capturing exacerbations. This approach was also chosen because it is of interest to examine whether it is possible to detect changes or patterns in the days preceding different severities of exacerbations. The study has the potential to improve the ability to detect COPD exacerbations and thereby initiate early treatment to reduce hospitalization.

Dissemination Plans

The results are expected to be published in international scientific journals. All results will be reported anonymously. The results will be published irrespective of whether they are positive, negative, or inconclusive. The authorship will be admitted to persons who have participated to the design, interpretation, conduct, and reporting of the trial. The results will also be communicated to participants who have indicated that they wish to be informed.

Acknowledgments

We would like to express our thankfulness to the TeleCare Nord administration office and Telma for making it possible to carry out this observational study. We would also like to thank Sleepiz AG for providing monitors. Complete funding for the observational study, with a total budget of 42,000 DKK (US $6100.75), has been provided by Sleepiz AG. The budget will be used for salary of the clinicians, transport costs, submission to the Regional Ethical Committee in the North Denmark Region, meetings, and publication of results.

Data Availability

Data will not be made publicly available as the study participants have not consented and their data fall under General Data Protection Regulation regulations.

Abstract

Background: Pre-exposure prophylaxis (PrEP) is an effective approach for preventing HIV infection, but it is underutilized by populations who may benefit the most, including people living in the Southern United States and those involved in the criminal legal (CL) system. Improving the access and use of PrEP for these groups could decrease HIV-related health disparities. Beyond individual outcomes, HIV prevention for CL-involved people can have a significant public health impact on HIV incidence due to a high turnover between jails and the community.

Objective: We will develop, implement, and evaluate a multicomponent PrEP implementation strategy for the Dallas County Jail (DCJ) to increase the initiation of this HIV-preventive intervention for CL-involved individuals.

Methods: This is a type 3 hybrid implementation-effectiveness study that takes a combined approach by assessing the implementation of a strategy to identify candidates for PrEP at the DCJ and linking them to PrEP providers upon community re-entry while also gathering information about clinical outcomes. The approach is guided by the EPIS (exploration, preparation, implementation, sustainment) framework. Initial formative work (exploration) involves qualitative interviews of diverse key stakeholders to identify factors that may influence linkage to PrEP after jail release. These findings will undergo rapid qualitative analysis (preparation) to inform the adaptation of a multicomponent jail PrEP implementation strategy protocol. This approach, which will include an electronic health record (EHR) prediction model and integration of a PrEP patient navigator into the jail health team, will allow medical providers and the navigator at the DCJ to engage individuals most likely to benefit in shared decision-making about PrEP and navigate them to community PrEP care (implementation) in a process that begins before release from jail and ends with successful care linkage. Regular quantitative and qualitative evaluations of this approach will allow for ongoing stakeholder input, refinement of the implementation strategy, and maintenance of the program (sustainment).

Results: Findings from 26 qualitative interviews (9 formerly incarcerated individuals, 9 county jail staff, and 8 employees of community organizations) have been obtained, analyzed, and mapped to an implementation strategy formalized in a jail PrEP protocol. An HIV risk prediction model based on EHR data to identify individuals most likely to benefit from PrEP has been

developed and internally validated and is ready to be deployed. We anticipate the availability of preliminary study findings in 2026.

Conclusions: This study will provide key insights into the feasibility and effectiveness of a PrEP implementation strategy among people at increased risk of HIV acquisition in an urban jail in Southern United States. This practical and scalable strategy can be used as a model for other urban jails to address HIV-related inequities.

pre-exposure prophylaxis; PrEP; HIV; HIV prevention; jail; incarceration; health disparity; electronic health records; EHR; southern United States

Introduction

It was estimated that there were 31,200 new HIV infections across the United States in 2021 [1], with a disproportionately high percentage of new diagnoses occurring in the South [2]. New HIV infections disproportionately affect men who have sex with men (MSM) and Black and Hispanic populations [3]. HIV prevention with pre-exposure prophylaxis (PrEP) can reduce the risk of HIV acquisition by 99% [4,5], but its public health impact depends on connecting populations at risk of HIV to PrEP care and continuing care over time [6-9]. Uptake of PrEP is increasing among White MSM on the east and west coasts but remains limited in minority groups in the South [10-12] where HIV incidence is the highest [13]. The PrEP-to-need ratio, defined as the number of PrEP users divided by new HIV diagnoses [14], is lower in the South than in any other region, particularly among racial and ethnic minorities, further highlighting inequitable access [15].

To decrease HIV incidence, there is a need to improve PrEP use in populations most heavily impacted by HIV. Launched in 2019, the federal *Ending the HIV Epidemic* (EHE) initiative provides an evidence-based framework for decreasing HIV incidence in the United States by 90% by 2030 [16]. The EHE initiative identifies that a critical component of epidemic control is to focus prevention efforts on geographic hotspots, including the 48 counties with the highest incidence, which are disproportionately in the Southern United States, and 7 states with major rural HIV epidemics. Active multisector partnerships among local public health departments, health care facilities, academic institutions, and community organizations are pivotal to achieving the EHE initiative's goal [8,17].

Dallas County in Texas is one of the largest HIV hotspots in the South, with high rates of new HIV infections and major racial and ethnic disparities in HIV incidence and access to preventive services. In 2021, Dallas County had one of the highest rates of persons newly diagnosed with HIV at 38 per 100,000 population, compared to the national incidence of 11.5 per 100,000 population [18]. The rate of new HIV diagnoses was even higher for Black individuals in the county, at 72 per 100,000 population [19]. Despite the dense HIV epidemic in Dallas County, only 25% of the estimated number of people with indications for PrEP were prescribed it in 2023 [3]. Barriers include high rates of uninsurance and poverty [20,21], medical mistrust and stigma [22,23], low HIV risk perception [15], and high rates of incarceration [24].

About 1 in 7 people with HIV pass through US jails and prisons each year, making the justice system a potentially high-impact setting for HIV testing and prevention [25]. In Texas, the Department of Justice estimated in 2021 that 1.4% of the prison population is living with HIV, which is 4 to 5 times greater than the prevalence in the general US population [26]. Individuals in the criminal legal (CL) system, including those who are in jail, in prison, or under community supervision (ie, probation and parole), also remain at disproportionate risk for HIV infection due to higher rates of sexually transmitted infections (STIs) [27], condomless sex [28,29], transactional sex [30], shared injection drug use equipment [31], dissolution of primary intimate partnerships [32], and broader socioeconomic barriers to medical care (eg, unemployment and homelessness) [33]. Opt-out HIV testing in jails is feasible and can identify many new infections while avoiding the burden of requesting a test among patients [34]. Testing uptake when offered in a nonjudgmental opt-out manner is 80% to 95% [35-37] and should be followed by linking incarcerated individuals to appropriate HIV treatment or preventive care [38-42]. Yet, despite recommendations for the practice of opt-out HIV testing by the Centers for Disease Control and Prevention (CDC), only about a third of US jails offer opt-out HIV testing [43].

Given that most individuals spend less than a month in jail and often cycle multiple times between incarceration and the community [44], there is a high potential public health impact of HIV prevention strategies in jails. Barriers to PrEP implementation in jails exist at several ecological levels and include limited knowledge of PrEP among those likely to benefit and their providers [45,46], lower perceived than actual risk of HIV [47,48], and distrust of institutions [49]. The timing of HIV prevention interventions is also significant, with the transition to living in the community being a particularly pivotal period when HIV transmission–risk behavior is increased and other personal needs take priority during community re-entry [50,51]. For these reasons, effective PrEP implementation strategies in jails may require multiple components to be successful [52-54]. For example, interventions at the individual level have included supporting HIV prevention after incarceration through a mobile app with customized wellness goals and incentives [55]. Building on evidence from CL-involved people with HIV transitioning to the community, peer education and patient navigation are being explored as

approaches to improving HIV prevention [56-59]. At the dyadic level, patient-provider shared decision-making around PrEP, which has been used in the community, is also being applied in correctional settings [60-63]. The objective of our study is to assess specific needs and recommended strategies and use these findings to develop, implement, and evaluate a multicomponent PrEP implementation strategy for the Dallas County Jail (DCJ), which is the 8th largest jail in the nation and located in an HIV hotspot [64].

Methods

Study Setting

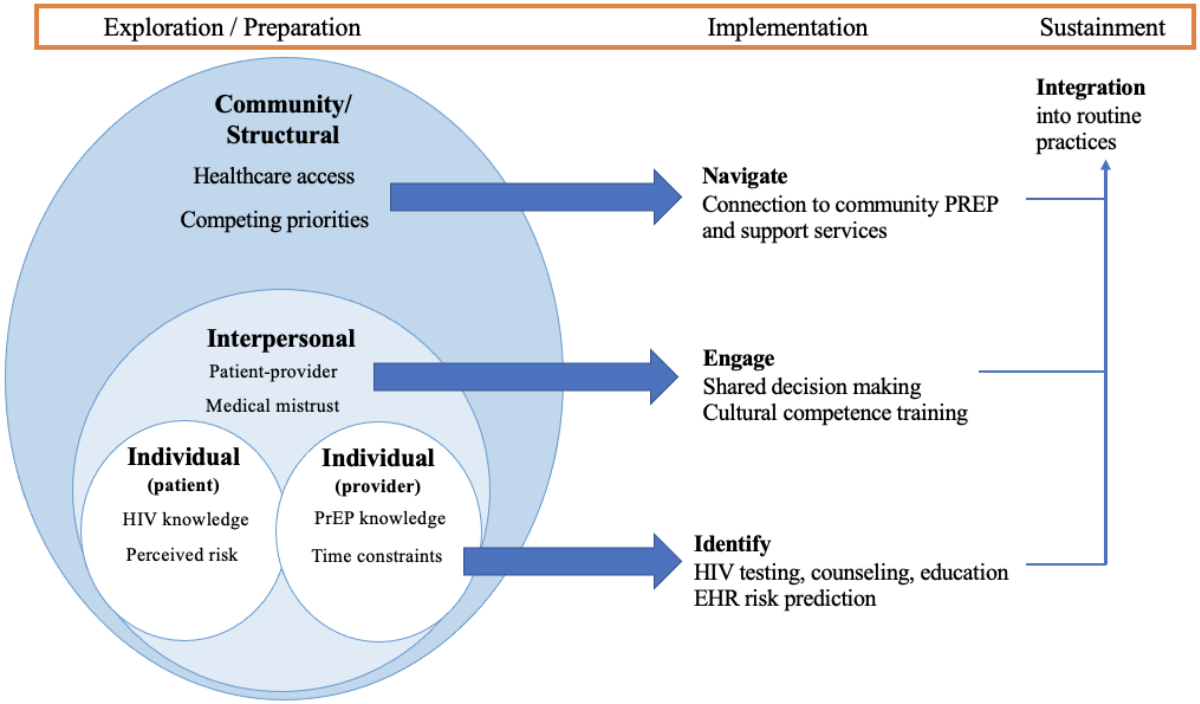
The DCJ is the main jail facility for Dallas County, with 51,000 incarcerated individuals per year (86% men, 48% Black, and 30% Hispanic) and approximately 275 individuals entering and leaving the jail daily. The mean length of stay is 45 days, and 11% of people transfer to prison [65]. Parkland Health, a teaching hospital for UT Southwestern Medical Center, provides health care services at the jail for approximately 6200 patients monthly. Health care for individuals experiencing incarceration is paid for by Dallas County.

Of over 12,000 HIV/STI tests performed each year at the DCJ, there are approximately 50 to 100 new HIV diagnoses (personal communication by Dr Barry-Lewis Harris, April 2024) and high STI positivity (5% syphilis, 5% gonorrhea, and 11% chlamydia) [35,66], which is a recommended indication for PrEP use. The approach to HIV testing at the DCJ is a combination of opt-in and opt-out. All persons entering the jail complete a nursing intake questionnaire to review medical history, receive the option for HIV/STI testing (opt-in), and, for men, indicate if they want to be in separate housing for MSM as a safety precaution. All individuals who undergo blood draws are offered opt-out HIV testing. Individuals with negative HIV test results are not routinely counseled about the results, and few, if any, receive information about PrEP. Currently, new initiation of PrEP is not permitted at the DCJ, and thus, the study will focus on linkage to PrEP after release.

Study Design

This is a type 3 hybrid implementation-effectiveness study, which takes a combined approach in assessing implementation while also gathering information about clinical outcomes associated with implementation [67]. We will track established implementation outcomes (eg, feasibility, acceptability, and penetration), effectiveness (eg, attending PrEP visits and new HIV/STI diagnoses), and sustainability, including integration into routine processes at collaborating agencies and duration of any positive effects in care processes and outcomes. We will use the EPIS (exploration, preparation, implementation, sustainment) framework [53,54] to guide our efforts to identify and address performance gaps in DCJ PrEP care. Although originally developed for public service sectors, the EPIS framework has since been widely applied in health care, including in jails [54]. As shown across the top portion of Figure 1, our key study concepts and activities reflect EPIS framework components.

Figure 1. Conceptual socioecological model of pre-exposure prophylaxis (PrEP) implementation for criminal legal–involved people. EHR: electronic health record.



Study Aims

Aim 1: Exploration

Using the socioecological model as a conceptual model [68], we will identify and describe specific individual, interpersonal, and community/structural factors that influence PrEP implementation through qualitative interviews and focus groups with key stakeholders in the jail and Dallas community (Figure 1).

Participant Characteristics and Recruitment

Participants will be individuals aged 18 years or older who are medical providers or administrators in the DCJ or in the surrounding community, people formerly incarcerated in the DCJ, representatives of community-based organizations serving those affected by HIV or with criminal justice involvement, and members of the public health department. Of note, due to restrictions on recording individuals at the DCJ and due to the benefit of addressing the postincarceration transition, the individuals we recruit will be formerly incarcerated rather than currently incarcerated. Formerly incarcerated individuals will be referred by their health care providers in community clinics or can self-refer in response to Institutional Review Board (IRB)-approved flyers posted in community-based service organizations. Health care professionals will be recruited at routine staff meetings and via email invitations. Administrators will be contacted about participation via email or personal contact from members of the study team.

Data Collection

We will conduct 20 to 30 semistructured interviews, which, based on our previous work, should be sufficient to reach saturation (ie, the point at which no new information is being uncovered through additional interviews). Individual interviews are preferred for formerly incarcerated individuals, jail staff, and members of community organizations due to the sensitive nature of questions and the convenience of scheduling.

Separately, we will also conduct a focus group with 10 to 12 members of the HIV/AIDS Re-Entry Coalition (HARC) in Dallas County during one of their quarterly teleconferenced meetings. The HARC is a group comprised of individuals from diverse community organizations who regularly collaborate to enhance the delivery of health and supportive services to individuals who have been recently released from incarceration. Feedback is especially valuable from these group discussions given the breadth and length of experience of the members. Lastly, we will conduct 2 focus groups during a summit event in which we will invite PrEP-providing organizations to compare their experiences and challenges in providing PrEP and related services amid the dynamic funding landscape and to assess opportunities for collaboration.

Semistructured interview and focus group guides will be tailored to each target group, and topics will reflect the range of factors relevant to PrEP implementation across different socioecological levels, as shown in Figure 1. All participants will also be asked to provide feedback on how to adapt and optimize the components of our implementation strategy for local populations, settings, resources, and norms. All interviews and focus groups will be audio recorded and conducted by research staff experienced in qualitative methods.

Data Analysis

We will conduct both a rapid qualitative analysis during data collection and a systematic thematic analysis when all data have been collected. The purpose of the rapid analysis is to promote consistent data capture, facilitate communication among the members of the research team about findings, and monitor progress toward saturation [69]. The thematic analysis will systematically categorize patterns in findings across interviews within a group (eg, patients) and across groups (eg, patients, jail providers, and health care leaders), using iterative thematic analysis in accordance with best practice techniques [70,71]. All data will be managed in NVivo 12.0 (QSR International). The study's principal investigators in conjunction with a study co-investigator who is an established qualitative methodologist will jointly develop a thematic codebook based on a review of the rapid analysis data and 20% of the interview fieldnotes, with codes mapped to the socioecological model presented as part of Figure 1. Trained research staff will double-code all interview transcripts, resolving discrepancies through discussion and conferring with the qualitative co-investigator as needed. A synthesis of the major findings will be presented to stakeholder groups to confirm appropriateness [72].

Aim 2: Preparation

In aim 2, our qualitative findings from aim 1 will inform the refinement of a multicomponent PrEP implementation strategy for CL-involved individuals. We will adapt and hone approaches to identify incarcerated people at increased risk for HIV using electronic health record (EHR) clinical decision support tools and patient-reported data to prompt providers to conduct HIV/STI tests and discuss PrEP with those most likely to benefit; engage CL-involved individuals in shared decision-making about PrEP using adaptations of previously developed patient decision aids; and navigate these individuals to existing PrEP services in the Dallas area after release.

Datasets to Identify Individuals at Increased Risk for HIV

The Parkland Center for Clinical Innovation (PCCI) has developed and validated an automated matching algorithm to extract data from the DCJ EHR (PEARL) and match it to data from Parkland's EHR (Epic) from 2010 to the present. Records will be matched based on multiple variables, including patient name, preferred name, date of birth, gender, sex assigned at birth, race or ethnicity, and social security number as available. We will exclude any individuals younger than 18 years. Individuals may have multiple encounters in both the jail and Parkland EHRs due to repeat jail incarcerations or medical visits, and these data will be incorporated as summary variables (eg, number of prior episodes of gonorrhea) with statistical adjustments for repeated measures in an individual. This combined dataset will provide rich data for identifying PrEP candidates and allow us to develop an HIV prediction model. This component of the study will involve the collection of existing data and the development of tools and protocols, and therefore, a waiver of consent will be obtained. Furthermore, matching of records using the identifiers above will be performed behind the firewall of the PCCI, and all datasets will

be deidentified prior to sharing with the rest of the research team.

Validation of the HIV Risk Prediction Model

We will use our prior models for predicting incident HIV [73,74] to identify candidate variables for our HIV prediction model. Subsequently, the use of temporal validation will assess how well our model will perform prospectively, dividing our dataset into a derivation dataset (2015-2021) and a validation dataset (2022-present). We will train our model to predict incident HIV diagnoses, defined as positive HIV screening and confirmatory tests or new HIV diagnosis codes without prior evidence of HIV in the EHR [73-75]. We will have ample data on new HIV diagnoses to train our models, as Parkland has a robust HIV testing program and diagnoses more new cases of HIV than any other entity in Dallas [76]. Jail EHR data may be more limited in scope because the jail generally provides short-term episodic care. However, given high recidivism rates [77], many incarcerated individuals will have multiple data points in the jail EHR to inform HIV risk prediction, including data on prior HIV/STI testing and substance use.

We will compare the performance of parsimonious versus full models in the validation dataset based on their ability to discriminate between patients with and those without incident HIV using the C-statistic or area under the receiver operator characteristic curve and the Hosmer-Lemeshow goodness of fit test. Additionally, we will use multiple complementary approaches for estimating HIV risk to capture the greatest number of individuals with indications for PrEP. This will include anyone who identifies as transgender, requests MSM housing, has had a recent STI, or opts-in for HIV/STI testing, in addition to those flagged by our EHR model. We will compare EHR models against these criteria to measure the added value of each approach (eg, number of individuals identified by our model as likely to benefit from PrEP who are missed by patient-reported data and vice versa).

Protocol Development

In conjunction with our risk prediction model, the findings from our aim 1 stakeholder interviews will directly inform our protocol for identifying persons who are at increased risk for HIV and likely to benefit from PrEP. This will include elements, such as which practitioners receive EHR alerts about potential PrEP candidates and the content of staff trainings for collecting and acting on patient-reported data and EHR alerts. We will select a final process for identifying candidates for PrEP discussions based on sensitivity (ie, missing as few persons at increased risk as possible), feasibility, and efficiency, while taking into account priorities identified by stakeholders in aim 1.

A key consideration for sexual health discussions in the jail setting is privacy. Feedback in aim 1 will inform how and where these discussions will take place. Providers may also desire additional training in assessing sexual risk, as knowledge of PrEP among correctional nursing staff and clinical providers is vital for successful implementation [78]. Furthermore, the approach to incarcerated individuals about sensitive topics, such as sexual health and substance use, will be informed by best practices, including having these screenings conducted one-on-one by medical staff and partnering with community-based organizations [79]. Any paper materials given to patients will be adapted to the American Medical Association's recommended 6th grade reading level and worded to avoid disclosing the health status.

Navigation for Individuals Likely to Benefit From PrEP

Individuals who are identified as being at increased risk for HIV and who test negative for HIV will be considered PrEP candidates. We will develop a PrEP decision-support tool to be used with the diverse populations present in the jail, informed by stakeholders' preferences from aim 1. This will include presenting information on sexual health and HIV prevention for multiple populations (eg, transgender people and cisgender women), local details on HIV epidemiology, and ways to afford and access PrEP. Individuals identified as PrEP candidates will meet with medical providers or navigators (depending on stakeholders' preferences) to review HIV prevention options and our patient decision-support tool. Patients will be informed that they will not be charged for these visits, as for all care related to communicable diseases in the DCJ. At this visit, the provider or navigator will assess the patient's knowledge of and interest in PrEP. Together with the patient, they will work through the decision-support tool. If the patient plans to pursue PrEP care after incarceration, the navigator will initiate the navigation protocol.

PrEP Care Navigation and Linkage Following Release

Those interested in PrEP will receive intensive navigation that includes both in-person and electronic referrals. Similar to existing navigation protocols (eg, for hepatitis C [80]), the navigator will initiate this process while the individual is still in jail. The navigator will obtain detailed patient contact information, identify and address the patient's health priorities and potential barriers to care, and create a personalized step-by-step process for accessing PrEP services after release. Patients will also be able to contact the navigator after jail release directly by phone or SMS text messaging.

Multiple PrEP providers in the Dallas community employ peer outreach workers who accompany patients to their PrEP visits. We will work with these providers to develop a protocol for seamless hand-off from the jail-based navigator to the community-based peer. For electronic referrals, we will integrate stakeholders' preferences for details regarding the transfer of information to community PrEP sites, including what information to communicate, how to communicate, and the timing of communication. Findings from our aim 1 qualitative data will help us pinpoint solutions to barriers or competing priorities to PrEP that patients identify. In some cases, we anticipate that multiple referrals will be necessary for patients to successfully access PrEP.

Aim 3: Implementation and Sustainment

In aim 3, we will deploy our multicomponent strategy at the DCJ and assess its impact on implementation and clinical outcomes for PrEP, as specified in Table 1.

Table 1. Quantitative implementation outcomes, metrics, timing, and data source.

Hybrid type 3 domain and outcome	Metrics (among patients with high risk)	Timing (month range)	Data source[a]
Implementation			
Feasibility	HIV/STI[b] testing offered	1-24	EHR[c], navigator
Feasibility	PrEP[d] discussions offered	1-24	EHR, navigator
Feasibility	Shared decision-making tool offered	1-24	EHR, navigator
Feasibility	PrEP navigation visits offered	1-24	EHR, navigator
Feasibility	PrEP referrals offered	1-24	Navigator
Penetration	Providers discuss/refer for PrEP	1-24	EHR, navigator
Acceptability	HIV/STI testing completed	1-24	EHR
Acceptability	PrEP discussions completed	1-24	EHR, navigator
Acceptability	Shared decision-making tool used	1-24	EHR, navigator
Acceptability	PrEP navigation visits completed	1-24	EHR, navigator
Acceptability	PrEP referral completed	1-24	Navigator
Effectiveness			
PrEP	PrEP visits in the community	1-24	Navigator
PrEP	PrEP prescription	1-24	Navigator
PrEP	PrEP use at 3 months	1-24	Navigator
HIV/STI	New HIV/STI diagnoses	1-24	EHR
Sustainment			
All	Reassess all study outcomes	25-30	All

[a]Qualitative assessments (3 times per year) complement quantitative metrics for all outcomes.

[b]STI: sexually transmitted infection.

[c]EHR: electronic health record.

[d]PrEP: pre-exposure prophylaxis.

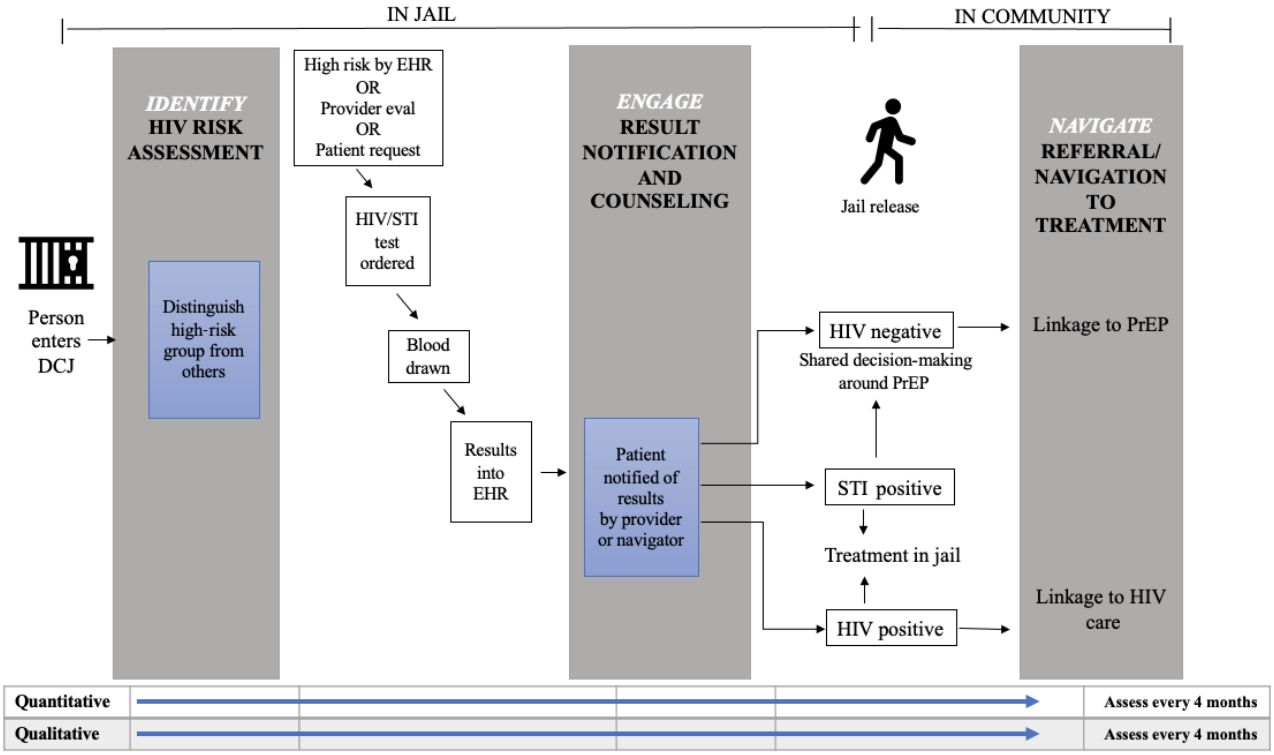
Training of DCJ Staff

The project principal investigators will conduct a 2-session interactive group training for frontline DCJ practitioners to introduce our PrEP implementation strategy. Session 1 will be adapted from trainings on culturally competent sexual health care, HIV, and PrEP [81], including clinical indications for PrEP and barriers and facilitators to its adoption in the jail and local community. Session 2 will introduce the rationale and practical aspects of using patient-reported and EHR data to identify PrEP candidates, as our prior qualitative work suggests that providers are more likely to trust, adopt, and use HIV risk assessment tools if they understand how they work [82]. The session will also review how providers and navigators can engage patients in the shared decision-making process and will include demos of PrEP decision-support tools. Lastly, session 2 will cover PrEP navigation processes, including PrEP resources in Dallas County, and navigation protocols. Postsession evaluations will be conducted for rating quality and usefulness.

Steps for Strategy Implementation

Our strategy will include the following detailed steps that can be visualized as part of the continuum (Figure 2): (1) identify, (2) engage, and (3) navigate.

Figure 2. Intervention steps in the jail-to-community continuum. DCJ: Dallas County Jail; EHR: electronic health record; PrEP: pre-exposure prophylaxis; STI: sexually transmitted infection.



In the "identify" step, when individuals enter the jail, a jail EHR record will be created (or an existing record will be opened for those with prior DCJ incarceration). Our automated algorithm will match the jail EHR to the Parkland EHR and generate an individual HIV risk score. For people with predicted HIV risk above a prespecified threshold that maximizes sensitivity without causing alert fatigue among providers, an automated prompt will appear in the jail EHR for providers to discuss PrEP and order HIV/STI testing. As illustrated in Figure 2, providers will also be prompted to order HIV/STI tests for any patients who report risk factors at intake or during a clinical assessment (eg, transgender identity and requests to be housed with MSM) or who request testing directly. Prompts will persist until orders are completed as a "nudge," a behavioral economic intervention to maximize ordering [83], and results are entered into the EHR.

In the "engage" step, positive HIV tests will prompt referrals to the jail HIV clinic for rapid initiation of antiretroviral therapy according to the current practice, and STIs will be treated based on CDC guidelines [84]. Persons with negative HIV tests will meet one-on-one with a provider or PrEP navigator and receive counseling informed by our PrEP decision-support tool. The navigator we hire will be experienced in working with CL-involved people. Counseling will be person-centered and culturally tailored, with positive sexual health framing.

In the "navigate" step, for patients interested in PrEP, the navigator will review a list of PrEP clinic locations and assist with selecting a provider. Once an individual is released from the DCJ, the navigator will facilitate PrEP linkage by contacting that individual (by phone or SMS text messaging) and providing personalized care navigation. A hotline will be available for released individuals to call for assistance with PrEP referrals. The navigator will continue to follow referred patients for 3 months after any PrEP initiations, recording these contacts and clinical outcomes in REDCap, a secure online data capture system [85].

For this aim of the study, the patient navigator will obtain verbal consent from patients to proceed with a discussion on sexual health and to contact them after release from jail. The navigator will use a script to inform patients about the goals of the project, including the metrics to be collected, and reinforce that the meeting with the navigator is voluntary and will not affect the legal status of the patients.

We will track quantitative and qualitative metrics related to our implementation strategy during a 24-month period of iterative assessment and refinement. Our study metrics map directly to the EPIS framework at key steps in the PrEP care continuum (Figure 2). As shown in Table 1, we will assess quantitative effects, including the number of patients who attend a community PrEP visit, initiate PrEP, and persist with PrEP use for ≥3 months, which is a robust HIV prevention outcome [7]. We will track the rates of new and previously known HIV diagnoses and STIs in the DCJ through EHR chart review.

Feasibility

Feasibility refers to the extent to which a practice change can be successfully used or carried out within a specific setting [86]. We define feasibility as >65% of eligible patients being offered HIV/STI testing and one or more PrEP discussions, our patient PrEP decision-support tool, a PrEP navigation visit, or a PrEP referral in jail.

Penetration

Penetration refers to the extent to which a practice is integrated within a specific setting [86]. For this metric, we will track the

proportion of providers who discuss PrEP or refer to a navigator for at least one eligible patient.

Acceptability

Acceptability refers to the perception among setting stakeholders that a practice is agreeable, palatable, or satisfactory [86]. We will calculate the proportions of patients who accept offers for one or more HIV testing, STI testing, PrEP discussion, navigator contact, or PrEP referral, with acceptance of >80% of test offers and >65% of discussion offers considered acceptable based on prior studies [35,87-89]. We will evaluate differences in feasibility and acceptability among patients by age, sex, gender identity, and race or ethnicity to identify imbalances in the offering and uptake of testing and referrals.

Effectiveness Regarding PrEP Outcomes

Additionally, on a monthly basis, we will measure the proportion of individuals who test negative for HIV, the proportion of this subgroup who receive notifications of their HIV test results, and the proportion of all those tested who are candidates for PrEP based on US Public Health Service practice guidelines for PrEP [90].

Among these PrEP candidates, we will assess how many are released to the community and how many are successfully contacted by the jail navigator after release. We will track the proportion of candidates attending ≥1 PrEP visit after jail release, the proportion prescribed PrEP, and the proportion using PrEP at 3 months after initiation (using direct patient assessments by the navigator). We will complete a run chart, which we will adapt from quality improvement methodologies [91], to evaluate trends in the PrEP care cascade [92] on a monthly basis during the 24-month intervention period and the additional 6-month sustainment period.

Effectiveness Regarding New HIV/STI Diagnoses

We will also track STIs and new and previously known HIV diagnoses in the jail among priority groups and the general jail population. STI positivity will be calculated as positive tests per the total number of tests completed. New HIV diagnosis rates will be calculated as confirmed positive test results in persons without a prior diagnosis of HIV per the total number of tests completed within a given time period. We will use an interrupted time series analysis using monthly data points to compare rates during the 24 months before and 24 months after our intervention is implemented. Our primary analysis will involve a comparison of the longitudinal rates before and after the intervention, and a mixed effects model for interrupted time series will be used as a secondary analysis. We will conduct linear regression analyses to determine if there is a significant difference in new HIV diagnosis rates before and after the intervention.

Sustainment

Sustainability refers to the extent to which a new practice is maintained or institutionalized within a setting's ongoing operations [86]. We will assess how well the strategy components are maintained as part of existing jail processes for 6 months after the formal 24-month study period, including tracking retention in PrEP care for up to 6 months (through navigator follow-up). Our research team includes dissemination consultants, who are medical providers working in jails in Austin, TX; Chicago, IL; and Boston, MA, and who will offer input on refining our strategy components for ongoing use at the DCJ and the potential transfer and integration into other jail settings.

For PrEP linkage, current rates of linkage are essentially zero. Thus, in lieu of a pre/post comparison, we will report the proportion of patients linked to PrEP care during the implementation period with 95% CIs. Power analysis is performed for the interrupted time series analysis of monthly HIV positivity rates, assessing the difference in the mean between the 24 months before and after implementation. Over the preimplementation period, an anticipated 250 tests will be performed monthly with 3 new HIV diagnoses per month. In the postimplementation period, of 500 HIV tests per month, an increase to 9 new diagnoses per month is anticipated due to the focus on individuals identified by the prediction model as being at increased HIV risk. Furthermore, we assume a correlation of 0.2 among monthly observations. Based on a mixed effects Poisson regression model, we can detect the difference in the mean HIV-positive rate between the 2 periods with >80% power at a 2-sided type I error of 0.05. We will also perform subgroup analyses, comparing testing rates by sex, age group, and race or ethnicity.

Evaluation of Qualitative Effects

We will also evaluate the qualitative effects of our implementation strategy through structured observations and discussions at the DCJ to assess changes (positive or negative) in knowledge and opinions of PrEP, workflow, and cross-agency collaboration in line with Dallas County's goal of a coordinated HIV response [93]. Observations will be conducted by individuals with postgraduate training in qualitative methods who have undergone additional training with the DCJ and Parkland Health and who are approved to conduct observations under the protocol approved by the IRB at UT Southwestern Medical Center. Observations will be focused on specific interactions pertinent to the research questions (eg, between the navigator and person soon to be released). Qualitative data on effectiveness and implementation outcomes will be rapidly analyzed in real-time using structured analysis of field notes from observations and discussions. The resulting iterative findings will be presented to a study advisory panel every 4 months to assess evolving attitudes and practices surrounding HIV testing and PrEP (ie, acceptability), gather perceptions of feasibility and penetration of the intervention, and solicit feedback about the ways to improve outcomes.

Ethical Considerations

Each aim of the study has undergone a separate review of procedures and protocols by the UT Southwestern Medical Center IRB, with details of human subject protection outlined in the protocol by aim. This IRB has a prisoner representative, and all IRB-approved protocols were reviewed by Parkland Health and approved by the DCJ correctional health leadership before beginning study activities. To date, the IRB has approved the protocols for aim 1 (STU 2021-0763) and aim 2 (STU 2021-1172). In addition, the Office of Human Research

Protection has reviewed and approved the inclusion of prisoners in human subject research for the overall study protocol in 2022.

For all participants in focus groups and individual interviews in aim 1, the research team has obtained verbal consent. To ensure informed consent, researchers also provided information about the nature and purpose of the study, confidentiality and privacy, HIPAA (Health Insurance Portability and Accountability Act) regulations, potential risks, discomforts and benefits of participation, and the option not to participate or start then stop participating in the interview at any time. In addition, stakeholders were encouraged to contact the study team at any time with questions or concerns they may have about the study. Eligible participants (ie, individuals not employed by UT Southwestern or Parkland Health according to institutional policy) were paid US $25 as compensation for their time for each interview or focus group attended.

Regarding EHR usage for aim 2, all study data were collected from existing EHRs, including medical intake forms at the DCJ and EHRs from Parkland Health and Hospital Systems, to identify potentially eligible subjects for the research. Records were matched based on multiple variables, including patient name, preferred name, date of birth, gender, biological sex, race or ethnicity, and social security number, as available. The medical record data include data collected as part of the medical intake process at the jail and routine clinical care at the jail and Parkland, including demographics, information from clinical encounters, prescription information, laboratory tests and results, and billing information. For those who did not receive medical care or treatment at Parkland Health, only data from the jail EHR were used. There was no additional direct collection of specimens, records, or data from subjects, and the IRB approval allowed secondary analysis without additional consent to identify research subjects and build the prediction model.

Data are not deidentified, as individuals meeting the basic eligibility criteria will be contacted by the researchers for recruitment into the study. No additional research procedures or continued access to identifiable private information will occur until after subjects have given valid consent to participate in the research study. The risk of this activity is minimal to the subjects because the information collected will be limited only to information allowing researchers to determine eligibility for the study and contact information. Only the minimum information necessary to determine eligibility will be recorded. Researchers have been granted access to the medical record data by the institutions and will protect the data they use and record for this activity according to institutional and HIPAA standards for protecting privacy and maintaining confidentiality. If the subjects identified decline participation in the research, the data collected will not become part of the research data. If subjects agree to participate in the research, the identifiable data collected will become part of the subjects' research records and will be stored according to the research confidentiality plan. Because of the nature of the detailed inclusion criteria, it is not feasible for researchers to advertise and screen for eligible subjects. The Office of Human Research Protection highlights this as an acceptable activity to waive informed consent to permit investigators to obtain and record identifiable private information for the purposes of identifying potential subjects [94].

Results

The study was funded by the National Institute of Mental Health in April 2022. Progress has been made on various aims to date. Qualitative interviews have been completed with 26 individuals, including 9 formerly incarcerated individuals, 9 county jail staff, and 9 employees of community organizations (1 individual was both a formerly incarcerated individual and an employee of a community organization). A focus group with 10 additional individuals has also been conducted. All interviews have been transcribed, coded, and analyzed, and a manuscript highlighting the key themes is in progress.

In addition, summaries of field notes for each interview have been organized into key barriers; facilitators; suggested approaches to overcome barriers; resources needed to overcome barriers; and specific strategies to improve risk assessment, HIV testing, sexual health or PrEP education during incarceration, and postrelease linkage to PrEP. Findings from these interviews have been applied to formulate a jail PrEP implementation protocol using rapid qualitative analysis.

An HIV risk prediction model based on jail EHR data to identify individuals most likely to benefit from PrEP has been developed using records from 33,458 individuals who have undergone HIV testing in jail. This model has been optimized using machine learning, has been internally validated, and is ready to be deployed. Future exercises will include integration with health system EHR data from Parkland Hospital and comparisons to parsimonious models, which will guide the iterative development of the model. We anticipate that preliminary study findings on the implementation and effectiveness of the jail PrEP implementation strategy will be available in 2026.

Discussion

Expected Results

We anticipate that the implementation of the multicomponent strategy will promote robust linkage to PrEP care for many individuals at risk for HIV, which currently does not occur at the DCJ. Moreover, we expect to identify a higher number of new HIV infections and STIs than in the 2 years prior to implementation. Our final product will be a well-integrated sustainable multicomponent PrEP implementation strategy that starts upon jail entry and ends with linkage to community-based HIV prevention, which can address major HIV-related inequities for CL-involved populations.

Potential Limitations and Alternative Approaches

In the process of refining the implementation strategy in our second aim, EHR models may be hampered by limited or missing data. We will minimize the missingness of EHR data by combining jail and Parkland data and extending this dataset over a 10-year timespan. We will explore the use of the missingness of EHR variables (which may be a proxy for not being engaged in primary care) as indicators to understand the

effect on model performance. If model performance is suboptimal, we will rely primarily on patient-reported data to identify HIV risk. For EHR alerts, we will proactively address potential alert fatigue [95] by employing rigorous user-centered design principles [96]. We will also train providers on how to respond to alerts about HIV risk, as providers may be unaccustomed to these.

Delays in the generation of electronic HIV risk scores could result in the identification of individuals likely to benefit from PrEP after their release from jail. If this occurs, we expect to identify many of these individuals using patient-reported data. However, the model we have developed will generate scores on day 3 of each person's incarceration, which will mitigate delays. We will also generate future EHR prompts for HIV/STI testing and PrEP if the patient returns to jail, and the navigator will contact the patient to encourage HIV testing and PrEP evaluations with community providers. Though patients may decline visits to discuss PrEP, we will maximize patient interest by training staff to present PrEP in a positive, discreet, and patient-centered manner and will offer our decision-support tool for patients to review independently. Since barriers, such as medical mistrust, transportation, and anticipated stigma, may limit patients' access to PrEP, we will hire and train a navigator who is able to build rapport with diverse populations, use principles of trauma-informed care [97-99], and teach at many education levels. Additionally, we will access existing resources, such as care coordination, offered by community partners.

Study Impact

Despite these possible limitations, this project will generate a valuable approach to prevent HIV in the disproportionately burdened population of CL-involved individuals in the Southern United States. As these individuals often have fragmented health care and may not be reached with approaches targeting primary care or STI clinics [100], our multicomponent implementation strategy has the potential to efficiently reach many persons likely to benefit from PrEP in a nontraditional but well-defined setting with rapid turnover to the larger community. Future projects will focus on adapting this strategy for dissemination to other urban jails, including those represented by our dissemination consultants, in HIV hotspots nationally to maximize its impact on the HIV epidemic for underserved minority communities.

Acknowledgments

The research reported in this manuscript is supported by the National Institute of Mental Health of the National Institutes of Health under award number R01 MH 129185.

Conflicts of Interest

AEN has received research funding from Gilead Sciences. DK has participated in research with funding from Gilead Sciences and Merck to his institution, has received personal funds from UpToDate, Inc and Medscape to develop medical education content on HIV prevention, and has received funds from PrEP4All for travel to an advisory conference.

Abstract

Background: Despite the availability of highly effective HIV pre-exposure prophylaxis (PrEP), uptake and adherence to PrEP among young men who have sex with men (YMSM) remains low, limiting its impact on the prevention of HIV infection. Strategies that incorporate an array of prevention options and provide YMSM and their providers with tailored education and support tools, including tools to support shared decision-making, are needed.

Objective: The goals of the Centers for Disease Control and Prevention (CDC)–funded PrEP Choice study include the development and deployment of CDC guideline–consistent PrEP provider training and the implementation of evidence-based provider- and client-facing PrEP education and support tools. Under this initiative, the CDC funded 2 research projects, Florida State University (the Expanding PrEP in Communities of Color [EPICC] project), and Columbia University (the mChoice project).

Methods: Providers from both projects will complete the PrEP Choice online training, which was developed to educate providers on PrEP options and how to engage clients in open discussions around sexual health and PrEP options. EPICC project providers will also attend online tailored motivational interviewing (TMI) training sessions, and mChoice project providers will view a training video on cultural competency and humility in PrEP care. Following training, each project will enroll a cohort of 400 participants receiving care from study providers and follow them for 12-18 months. Participants will complete online surveys every 3 months and provide biomarkers to assess PrEP adherence. Electronic health record (EHR) data will be collected every 6 months to provide additional information on clinic attendance, PrEP prescriptions, and HIV/sexually transmitted infection (STI) testing. Each project will provide cohort participants with a unique digital health tool to support the PrEP choice and ongoing adherence. The study will assess the effectiveness of training and educational and support tools in practice and the critical factors associated with the successful uptake of and adherence to PrEP by participants. The study will also monitor patterns of PrEP use among YMSM, including types of PrEP and switching between types.

Results: Formative work to develop and prepare the tools for implementation was completed in 2023. The EPICC project began provider training in early 2024, and the mChoice project began in spring 2024. Cohort enrollment for both projects began after provider training began.

Conclusions: Given the changing PrEP landscape, implementation of provider education and tools to maximize uptake and adherence is needed. By delivering culturally competent and interactive provider training on PrEP options, the study will help providers counsel and guide participants on the effective and safe use of PrEP. The digital health tools created will support participant adherence to help them optimize PrEP benefits. Through the cohort design, the PrEP Choice study will provide real-world data about PrEP use that will be critical for informing future guidelines and tools.

Introduction

Background

Young gay, bisexual, and other young men who have sex with men (YMSM) are the population most affected by HIV in the United States. Among all HIV infections diagnosed in 2021, 67% were found in MSM [1]. Racial and ethnic disparities persist in HIV diagnoses among MSM, with 36% of diagnoses among Black or African American (Black) MSM and 33% among Hispanic or Latino (Hispanic) MSM, compared with 25% among White MSM, despite smaller overall populations of Black and Hispanic MSM compared with those of White MSM. HIV can be prevented with the use of HIV pre-exposure prophylaxis, or PrEP [2]. The US Food and Drug Administration has approved the use of 3 antiretroviral drugs for PrEP by MSM: oral emtricitabine and tenofovir disoproxil fumarate (F/TDF) in 2012, followed by the availability of generic F/TDF in 2021; oral emtricitabine and tenofovir alafenamide (F/TAF) in 2018; and long-acting injectable cabotegravir (CAB-LA) in 2021. Clinical trials of sexual event-driven PrEP regimens or 2-1-1 PrEP using F/TDF have demonstrated it to be highly effective for HIV prevention among MSM [3,4]. These options provide MSM with choices about their preferred PrEP regimen; however, little is known about the PrEP choices men make, their switching between PrEP options, and the reasons for these decisions.

PrEP coverage continues to increase markedly among men [5]. However, findings from analyses of limited race and ethnicity data for PrEP users suggest racial and ethnic disparities exist in coverage. These PrEP use disparities are especially concerning in the context of large racial and ethnic disparities in HIV diagnoses, because men who might most benefit from PrEP are not being prescribed it, and among those prescribed, adherence remains suboptimal [6-9]. To accomplish the goals of the “Ending the HIV Epidemic in the US” initiative to reduce new HIV diagnoses by 90% by 2030, increase PrEP coverage to 50% of individuals with indications, and achieve health equity [10], it is imperative to overcome racial and ethnic disparities in PrEP use.

The implementation of effective interventions is needed to increase PrEP initiation, adherence, and persistence among YMSM. YMSM need tailored education with autonomy-supportive communication related to the growing array of PrEP options, and providers who serve these clients also need education and clinical decision-making support. Implementation of resources that discuss all PrEP options and emphasize shared clinical decision-making have the potential to enhance PrEP outcomes among YMSM, including PrEP initiation, adherence, and persistence [11]. Increased understanding of PrEP use patterns, including switching among PrEP options, is needed to optimally support lifetime HIV prevention among YMSM. Using evidence-based PrEP care as a guide, provider and patient education and support tools have been developed to assist in the provision of PrEP care. Evidence-based provider and patient education and support tools (EBTs) are available but are not being routinely used in clinical settings to increase PrEP screening, counseling, initiation, adherence, and persistence by YMSM [2,12,13]. To date, there has been a lack of research on the impact that existing informational materials have on PrEP provision or how tailoring these materials to meet the needs of providers and YMSM from diverse backgrounds could enhance their effects. Further, although EBTs for both providers and YMSM are available, these resources do not acknowledge or incorporate information about a growing arsenal of prevention products nor do they maximize opportunities to engage in a shared decision-making process about these products [14,15].

Provider education can support clinicians to provide recommended PrEP services and to maintain up-to-date knowledge of PrEP options. Patient education using adapted EBTs can help men understand how PrEP can support their sexual health and learn about the PrEP options available to them. Adherence and persistence support tools, such as user-friendly apps, can support men prescribed PrEP to take their medication as directed and to continue to use it for as long as they can benefit from its protection. Increased understanding of PrEP use patterns, including switching among PrEP options, is needed to optimally support YMSM to use PrEP that is appropriate for them at various times in their lives.

Aims and Objectives

The goals of the Center for Disease Control and Prevention (CDC)–funded study, known as the PrEP Choice study, include the development and deployment of CDC guideline–consistent

PrEP provider training and the implementation of evidence-based provider- and participant-facing PrEP education and support tools [13,16]. PrEP support tools include innovative, customized mobile apps. The study will also conduct a longitudinal assessment of YMSM who are initiating or persisting with PrEP to understand their preferences for PrEP modalities and changes in PrEP use over the course of the study. The study will assess the implementation context, assess the effectiveness of provider training and EBTs in practice, and analyze the critical factors associated with successful uptake of and adherence to PrEP by participants enrolled in the study.

Under this initiative, the CDC funded 2 research projects, at Florida State University (the Expanding PrEP in Communities of Color [EPICC] project) and at Columbia University (the mChoice project). The PrEP Choice study is a 5-year initiative; funding began on September 30, 2021. In this paper, we discussed both EPICC and mChoice Studies, as they are supported under the same funding announcement, use the same PrEP training modules, use similar instruments for their longitudinal cohorts, share the same eligibility criteria, and incorporate digital health tools.

Through these 2 studies, we will test the effectiveness of provider training to increase provider knowledge of and comfort with PrEP modalities in clinical practice; evaluate the feasibility and acceptability of implementing provider training; describe the barriers and facilitators impacting the implementation of new PrEP modalities in clinical practice; test the effectiveness of provider training and digital tools to increase PrEP adherence and persistence among YMSM; and describe real-world PrEP use, including factors influencing the selection and change of PrEP regimens.

Methods

Ethical Considerations

This works follows a protocol reviewed and accepted by the Institutional Review Boards of Florida State University (approval number 00003623) and Columbia University (approval number AAAT8812). Participants will provide informed consent prior to beginning any study activities. The consent form includes standard consent sections describing the purpose of the study, the procedures to be followed, and the risks and benefits of participation. The consent form went through multiple reviews by team members to ensure the language was sufficiently simple. A certificate of confidentiality was obtained from the CDC. All data and records will be stored on password-protected servers. No identifiable data will be published.

EPICC project providers will be compensated US $50 for completing the pretraining survey; US $50 for completing online PrEP training modules, tailored motivational interviewing (TMI) training sessions, the posttraining survey, and the first standard patient interaction; and US $50 for the 3-month posttraining standard patient interaction. Cohort participants will be compensated US $50 for the baseline survey and app download, US $50 for an optional onboarding visit, US $25 for the 3-month follow-up survey, US $50 for the 6-month follow-up survey, US $25 for the 9-month follow-up survey, US $50 for the 12-month follow-up survey, US $25 for the 15-month follow-up survey, and US $50 for the 18-month follow-up survey. For home-based dried blood spot (DBS) collection, cohort participants will be compensated US $50 for the baseline, 6-month, and 12-month collections and US $75 for the 18-month collection. A US $50 bonus will be provided to participants who complete the first 3 collections. Participants who complete the exit interviews will be compensated US $50. Providers who complete focus group discussions will be compensated US $75.

mChoice project providers who complete the pre- and postassessment will be compensated US $50. Providers who complete an in-depth interview will be compensated US $100. Cohort participants will be compensated US $40 for the baseline survey and app download, US $45 for the 3-month follow-up survey, US $55 for the 6-month follow-up survey, US $60 for the 9-month follow-up survey, US $70 for the 12-month follow-up survey, and US $80 for the 18-month follow up survey. Cohort participants who complete an in-depth interview will be compensated US $35. Providers who complete an in-depth interview will be compensated US $100.

Study Design

The EPICC project includes 2 distinct aims. Aim 1 includes provider training. Providers will be trained on the use of education tools adapted in the formative work and the process of screening, counseling, initiation, and follow-up with clients interested in or already taking PrEP through our PrEP training modules and will complete TMI training. The effectiveness of the training will be measured quantitatively. Aim 2 is a longitudinal cohort study designed to test the newly adapted education tools through a hybrid type 2 effectiveness implementation cohort to assess PrEP uptake and adherence to PrEP among YMSM and provider provision of PrEP and competence with education tools to increase PrEP services. Aim 2 will include a mixed methods analysis. Figure 1 provides an overview of the EPICC project's design. Formative work can be found elsewhere [17].

The mChoice project includes 3 aims. Aim 1 of the mChoice project is to conduct a hybrid type 2 trial testing the effectiveness of the mChoice clinical intervention to increase PrEP adherence and persistence among YMSM using PrEP. Aim 2 is to conduct in-depth interviews to assess multilevel factors at the patient level associated with selection of a PrEP regimen and switching patterns. Aim 3 is to provide training to health care providers to improve knowledge of PrEP clinical recommendations and enhance provider communication. Figure 2 provides an overview of the mChoice project design. Formative work findings can be found elsewhere [18].

Figure 1. EPICC project design. EPICC: Expanding Pre-Exposure Prophylaxis (PrEP) in Communities of Color; YMSM: young men who have sex with men.

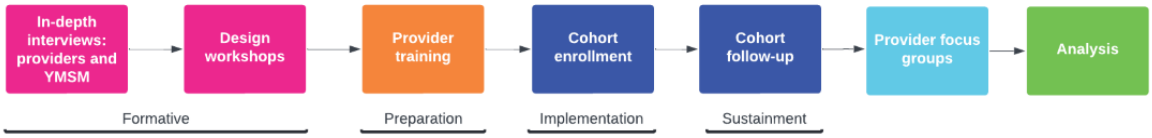

Figure 2. mChoice project design.

Data Collection

Every 6 months, study sites (EPICC and mChoice) will complete a clinic assessment that will include information around PrEP prescriptions issued, clinic services, financial assistance, and PrEP support services. This information will be collected prior to the provider training and will continue for the duration of the study to assess implementation efficacy. There will be a clinic assessment baseline and final, which is completed at the beginning of data collection and at the end and a shorter clinic assessment every 6 months. These assessments will capture data on clinic demographics, PrEP uptake and follow-up and provision of HIV and PrEP education.

The EPICC project's aim 1 provider training consists of the completion of surveys prior to and after training components. Providers are rated on their use of TMI during standard patient interactions immediately after training and three months post training. Aim 2 data collection will occur using surveys every three months, project app paradata, and exit interviews. Additionally, we will conduct focus group discussions with providers at the end of the longitudinal cohort.

The mChoice project's aim 1 data collection will occur using surveys every three months, and project app paradata. Aim 2 data collection will occur using in-depth interviews with a subsample from aim 1. The mChoice project's aim 3 provider training consists of the completion of surveys prior to and after training components and an interview following completion of the training.

Provider Training

Each project will enroll participants for both provider training and the cohort from unique study sites. Figure 3 includes a map of each project's enrollment sites.

The EPICC project team developed online PrEP training modules to educate providers on currently available PrEP options and how to engage clients in open discussions around sexual health and PrEP options. The goal of these open discussions between providers and clients is to encourage shared decision-making on PrEP options. The flexible and interactive modules were created using the Easygenerator online authoring tool, which allows learners to complete their assigned courses over multiple sessions at any time. The interactive features used throughout the modules are designed to keep providers engaged. Some of these features include checks for understanding, embedded videos, and links to external content. Each module also contains at least 1 case-based scenario. These scenarios are based on real-world interactions that study team providers experience during interactions with clients.

The EPICC project team developed these modules using a variety of content sources, including CDC-produced guidelines and materials, research papers, and expert guidance. In addition to modules covering PrEP regimens, we also included modules on the need for PrEP, PrEP screening and startup, postexposure prophylaxis (PEP), and PrEP adherence and persistence. The modules were refined to their final form through an iterative feedback process with subject matter experts within the EPICC project team. Both EPICC and mChoice project teams will use these modules in their respective provider training. Table 1 lists the titles and brief descriptions of each module.

Figure 4 includes screenshots of content within the modules that highlight interactive elements used throughout the course. The video image shown is from "Let's Talk About Sexual Health" [19] produced by the CDC and BeSmartBeWell.com.

In the EPICC project, after completing the online PrEP training modules, providers will attend live, online TMI training sessions led by a member of the motivational interviewing (MI) network of trainers. The training has been split into distinct training modules: (1) introduction to TMI and PrEP choice; (2) TMI spirit, cultural humility, antiracism, and stigma reduction; (3) managing counter change talk and discord with empathy and autonomy support; and (4) eliciting and motivation for PrEP. There will be 2 training sessions lasting approximately 3 hours conducted virtually over 2 days. The training uses videos of

PrEP providers demonstrating TMI integrated with antiracism and cultural humility that were created specifically for this study. The workshops are structured with cooperative learning activities, video examples, and behavioral skill acquisition steps (modeling, verbal and behavioral rehearsal, feedback). After the live, online training is completed, providers will complete a 15-minute standard patient interaction assessment, where a member of the study team will act as a client and the provider will attempt to use TMI techniques during their interaction. The conversation will be coded by a study team member using the MI Coach Rating Scale [20], and a feedback report will be generated and sent to the provider. The report will include strengths and areas for improvement, with video links featuring skills identified as areas for improvement. Three months after completing the TMI training sessions, providers will complete an additional standard patient interaction assessment with the same feedback format. Providers will also complete a brief survey prior to starting the online modules, which will include demographics; PrEP familiarity and attitudes; and PrEP use and future intentions. Providers will complete another survey after the TMI training sessions are over, which will include similar questions to the first survey to assess for change after completing online modules and TMI training.

After completing the online PrEP training modules, providers in the mChoice project will watch a 10-minute video on cultural competency and humility in PrEP care training developed specifically for this study. This module consists of an introduction to cultural competency and humility and exemplifies how these concepts are key components to PrEP care. Like the EPICC project team, sources for the video include information from CDC guidelines, CDC-produced materials, and peer-reviewed journal–cited research papers. For example, the CDC's 5Ps approach to gathering sexual history is highlighted as a critical step in the context of PrEP care. More information about the 5Ps approach can be found on the CDC's website [21]. Useful tips, such as using layperson's terms that are also anatomically correct, making eye contact, and not appearing to be in a hurry, are mentioned throughout. Simultaneously, this module emphasizes the importance of making clients feel comfortable and respected and allowing the client to guide the conversation. This module aims to inform providers about how to best interact with clients and demonstrate racial and ethnic diversity among clients through the use of dynamic graphics. The module also provides training to facilitate provider-client communication so that there can be effective shared decision-making. It will be included in the PrEP Choice provider series launched through Easygenerator.

Figure 3. Map of EPICC and mChoice project enrollment sites. EPICC: Expanding Pre-Exposure Prophylaxis (PrEP) in Communities of Color.

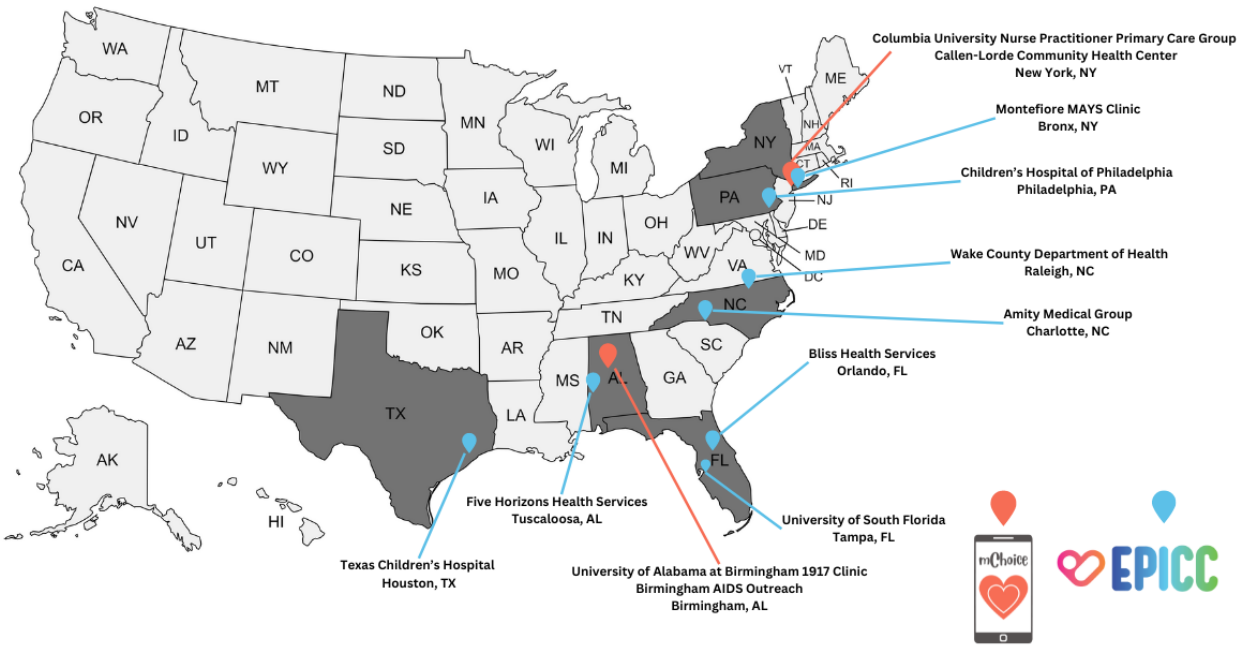

Table 1. Online PrEP[a] training module titles and topics used in EPICC[b] and mChoice Studies.

Module title	Topics covered
Module 1: Why Do We Need PrEP?	HIV epidemic in the United States, the EHE plan, PrEP update in the United States, and PrEP efficacy and effectiveness
Module 2: Who and Why for PrEP	PrEP guideline changes, PrEP screening, and HIV testing recommendations
Module 3: What Is PEP and Who Should Get It?	PEP screening, prescribing, and monitoring
Module 4: Considerations in Choosing Among Oral PrEP Options	Oral PrEP regimens, oral PrEP initiation and follow-up, 2-1-1 or on-demand PrEP, and oral PrEP side effects
Module 5: Considerations in Prescribing and Monitoring Injectable PrEP	Injectable PrEP initiation, follow-up, adherence, side effects, and future PrEP modalities
Module 6: Maximizing PrEP Adherence and Persistence	Adherence counseling components, PrEP implementation, and cost considerations

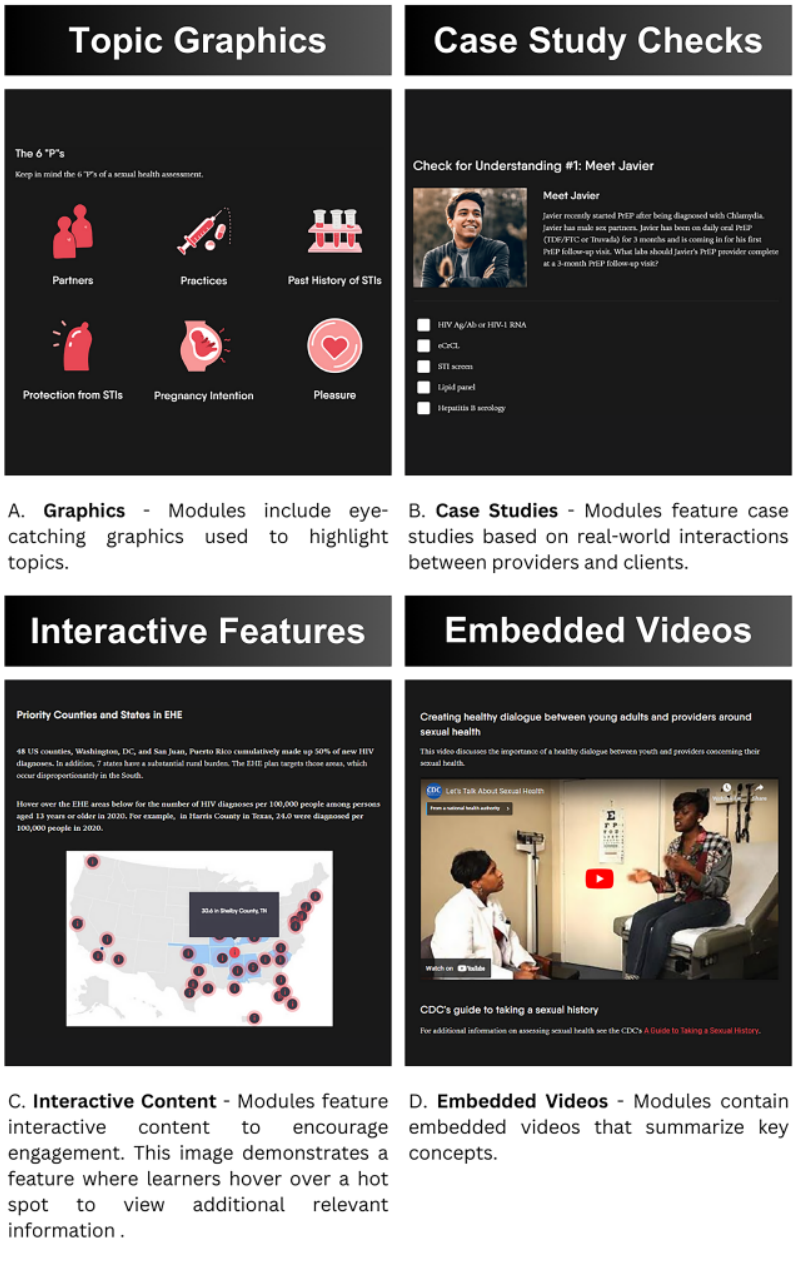
Figure 4. Screenshots and descriptions of interactive content within online PrEP modules used in EPICC and mChoice provider training.



A. **Graphics** - Modules include eye-catching graphics used to highlight topics.

B. **Case Studies** - Modules feature case studies based on real-world interactions between providers and clients.

C. **Interactive Content** - Modules feature interactive content to encourage engagement. This image demonstrates a feature where learners hover over a hot spot to view additional relevant information .

D. **Embedded Videos** - Modules contain embedded videos that summarize key concepts.

Longitudinal Cohort

Both EPICC and mChoice projects will enroll a cohort of 400 participants. Study participation will range from 12-18 months, depending on the study enrollment date. Eligibility criteria include (1) age 18-39 years, (2) the male sex, (3) ever had sex (as a top or a bottom, insertive or receptive) with a person who has a penis, (4) have an active prescription for PrEP (including both new prescriptions at baseline or refills), (5) receive care at 1 of the participating study sites, (6) provide a mailing address within the 50 states where packages can be received, (7) have daily smartphone access, and (8) be fluent in written and spoken English or Spanish. Cohort participants will be recruited by the clinic staff during scheduled visits, through study advertisements placed in clinic waiting rooms, or through study advertisements on social media platforms.

Each project team builds off prior work to adapt their unique digital health tools poised to support PrEP choice and ongoing adherence. The EPICC project builds from the HealthMpowerment (HMP) intervention. HMP is a theory-based status app designed to provide health and wellness information and resources relevant to young people via a mobile optimized platform. HMP was created based on the Integrated Behavioral Model [22-24]. HMP is flexible and easy to adapt for specific populations and health topics. The EPICC project's version of HMP includes resources most relevant for our study population. The mChoice app was created based on the Information System Research framework and builds on formative work to develop a PrEP adherence and monitoring app [25-27]. The mChoice app was built in collaboration with Compliance Meds Technologies (CMT) CleverCap. CMT is an mHealth technology solutions provider that develops adaptable technology to promote health. The CleverCap app is linked to a CleverCap device, which is an electronic pill bottle that records when the cap opens and closes and tracks medication adherence. The CleverCap app was customized to the needs of the mChoice project to support PrEP adherence among YMSM. It offers PrEP resources, such as 2 client-facing PrEP training modules created by the study team and a sexual activity log. It can be programmed for the use of participants who are taking any of the 3 PrEP regimens: oral (daily or event driven) or injectable. Table 2 lists the features of each project's mobile app.

Table 2. Description of EPICC[a] and mChoice digital health support tools.

Feature	EPICC	mChoice
Resources	Educational content across a range of health topics, as well as support for app engagement and behavior change through information and skill building	Participant-facing PrEP training modules, links to the CDC[b] website
Adherence support	Medication tracker to support oral, injectable, or event-driven PrEP adherence	Electronic adherence monitoring through the use of the CleverCap app and device
Sexual behavior tracking	Sexual activity log	Sexual activity log
Connection to care	"Ask the Expert" feature to allow providers to anonymously answer user questions and connect users to resources	Chat function to communicate with the study team
Engagement features	Gamification with badges and avatars earned for completing activities	Adherence statistics for participants taking oral daily PrEP
Integrations with test kits	Yes	N/A[c]

[b]CDC: Centers for Disease Control and Prevention.

[c]N/A: not applicable.

Cohort Procedures

Participants will complete a computer-assisted self-interview (CASI) every 3 months while in the study. Surveys will be hosted on REDCap. EPICC surveys will be distributed through emails and links available within the study app. mChoice surveys will be completed at study sites on a tablet. The surveys will address various topics related to PrEP care engagement, PrEP usage, and PrEP adherence, as well as sociodemographics and risk factors related to PrEP adherence (Table S1 in Multimedia Appendix 1) [7,28-38].

EPICC project participants will complete a home-based DBS collection kit every 6 months while in the study to assess for levels of tenofovir-diphosphate (TFV-DP) and emtricitabine-triphosphate (FTC-TP). Additionally, EPICC project participants can attend an optional virtual onboarding visit with a member of the study team to review key features of the study app and DBS collection instructions. mChoice project participants who report using PrEP containing TFV and FTC will provide a urine sample of 15-30 mL at each visit to measure adherence. After the visit, the staff will use the urine sample for a rapid strip test to interpret adherence results. The staff will upload a picture of the test results to REDCap to send to the lab so that they can perform quality control checks. Participants' urine samples will be used for 2 separate tests: one that measures TFV levels and another that measures FTC levels. Throughout the study period, participants (EPICC and mChoice) will be asked to track their PrEP adherence and sexual behavior in study mobile applications. Electronic health record (EHR) data (EPICC and mChoice Studies) will be collected every 6 months during the study period; variables will include PrEP prescription information, HIV testing, sexually transmitted infection (STI) testing, and results. Clinic site staff will complete medical record abstraction (MRA) using participants' EHRs

every 6 months while in the study. MRA will collect information about PrEP prescriptions, STI testing and results, and HIV testing and results. Table S1 in Multimedia Appendix 1 includes cohort measures.

A subset of EPICC project participants will also complete exit interviews. Questions will focus on understanding factors that influenced participants' selection of PrEP regimens, changes, or discontinuations; perceptions of the counseling they received by providers at PrEP initiation and follow-up; and the receipt of tools or materials that influenced their choice and feasibility/acceptability of the HMP app. The mChoice project team will similarly conduct in-depth interviews with a subset of participants following completion of the intervention to explore experiences with PrEP, reasons for PrEP choices, and impressions of the mChoice intervention.

Postcohort Provider Focus Group Discussions and Interviews

After the cohort is completed, the EPICC project team will conduct 6 virtual focus groups with PrEP providers, clinic staff, and study staff. The purpose of the focus groups will be to gather feedback on overall perceptions of the barriers and facilitators to education tool implementation within their clinical site. Prior to participating in the focus groups, participants will complete a survey that will collect their demographics, whether the provider can prescribe PrEP, and how long the provider has worked at their current clinic.

The mChoice project team will conduct in-depth interviews with participating providers following completion of the PrEP training modules and assessments. The research staff will ask participants about the implementation of the mChoice intervention, any long-term effects of the intervention, opinions of the provider training modules, and recommendations for future implementation of the mChoice intervention.

Primary Outcome Measures

The primary outcome for provider training is PrEP familiarity, PrEP beliefs, and intentions to use PrEP measured at pre- and posttraining. The primary outcome for the cohort is PrEP adherence. For the EPICC project, adherence outcomes will be measured by using blood and will be tailored for oral PrEP modality (daily or 2-1-1) and categorized as protective (1) or not protective (0). The protective level of PrEP in the blood is defined as ≥4 doses taken per week, and the not-protective level is defined as <4 doses taken per week. Adherence outcomes for participants on CAB-LA will be determined by the timely administration of injections. The timely administration of the second injection is defined as within +/–1 week of the target date and within +/–2 weeks of the target date for subsequent injections. For the mChoice project, adherence outcomes, as measured by using urine, will be assessed by testing TFV and FTC levels in urine specimens collected from participants who report daily use of PrEP containing TFV and FTC. The mChoice project will also measure adherence by electronic medication monitoring via the CleverCap device, EHR data, and self-report.

Secondary Outcome Measures

Secondary outcomes for provider training include the feasibility and acceptability of implementing provider training and barriers and facilitators impacting the implementation of new PrEP modalities in clinical practice measured through participant responses during the provider focus group discussions that will occur at the end of the cohort follow-up. The EPICC project cohort's secondary outcome is persistence measures and will be based on (1) the participant's self-report of currently taking PrEP (daily or 2-1-1) or having received the last shot of CAB-LA and (2) the participant having an active prescription for PrEP based on study records or drug levels associated with use within a 1-month window at 6 months, 12 months, and 18 months postenrollment. mChoice secondary outcomes will consist of sexual risk behaviors, HIV status, substance use, and outcomes by the initial PrEP regimen, as reported through follow-up assessments and EHR data.

Statistical Analysis

Specific statistical analyses will be performed for the different projects. Next, we describe the EPICC and mChoice project analysis plans separately.

The EPICC Project

Sample Size and Power Calculations

The sample size for this study was determined based on feasibility after considering the intended analyses and multiple parameter estimates. With 400 participants, the minimum detectable difference in the PrEP adherence and persistence rates was 5.6%, assuming 15% loss to follow-up and a reference rate of 20%, at 0.80 power with a 1-sided test and 0.05 type I error. For baseline to postintervention analyses, simulation-based results indicated the minimum detectable difference from a baseline rate of 20% was approximately 9% (odds ratio 1.6), assuming again 15% loss to follow-up, at 0.80 power with a 1-sided test and 0.05 type I error [39].

Analysis Plan

Baseline participant characteristics will be described for the entire sample and disaggregated by regimen, site/region, ethnicity, level of HIV risk perception, substance use, PrEP experience (naive vs familiar), partner relationship status, and the other variables of interest included in Table S1 in Multimedia Appendix 1.

To determine any differences in discontinuation and nonadherence, we will use Cox proportional hazards to analyze (1) time to first discontinuation and (2) time to first nonadherence by regimen using PrEP adherence measures. To incorporate observations after the first discontinuation or after the first nonadherence, including allowing for the possibility of restarting on PrEP after discontinuation and for periods of nonadherence followed by a period of adherence, we will use a multilevel survival model by including a frailty term in the model to allow analysis of recurrent events [40]. We will follow the same analytic strategy for other dichotomous primary and secondary effectiveness and implementation outcomes. For the composite measure of number of prescriptions (primary implementation outcome), we will fit a multilevel linear or a

generalized linear regression model, again using all the time point data available to assess the strength of the associations between the composite measure for the number of prescriptions and the predictor variables. To examine the trajectories of regimens, we will use generalized linear mixed models (GLMMs) and a survival model to assess the time to each regimen switch.

Provider Training

Mean scores for the pre- and postadministration of PrEP knowledge items, as well as the mean scores for motivational interviewing familiarity and comfort, will be evaluated for significance of difference using the nonparametric Wilcoxon signed-rank test for hypothesis testing of repeated measurements on a single sample [41].

The mChoice Project

Sample Size and Power Calculations

Sample size estimation was based on the number of individuals required in order to detect an odds ratio of 1.7 or greater, based on a previous intervention study [42], in the primary outcome measures (PrEP adherence and persistence) before and after the intervention. We used a GLMM [43] with 80% power and a 2-sided test of .05 significance. We estimated the power and sample size by simulating responses based on the following assumptions: 20% attrition postintervention follow-up, an intraclass correlation coefficient of 0.2 across sites, and correlations in the range of 0.3-0.6 of participants' outcomes at different time points [43]. With these conditions, a sample size of 400 was needed [43].

Primary Outcome

A GLMM, also called an individual growth model and a multilevel model, with an appropriate link function will be used to compare the pre- and postintervention difference for each outcome. The GLMM allows different trajectories for each participant, and this method is appropriate to compare outcome changes after the implementation of the intervention, with the control of baseline values. Analyses will be conducted for the full sample and by study location (New York City and Birmingham) separately [44].

Secondary Outcomes

Similar GLMMs will be used for analyzing secondary outcomes. We will conduct a multigroup comparison in pre- and postintervention differences (the difference-in-difference analysis) using a GLMM by adding the group variable and the group × intervention status interaction (pre- and postintervention) in the GLMM described before. Because the PrEP regimen cannot be randomized, we will use the propensity score method [45] to reduce the between-group bias. We will also examine factors that are associated with the length of time that participants take to change their regimens or associated with the instantaneous rate of change of regimen. Since we will know the date of change of the PrEP regimen (from the EHR data), we will apply a Cox proportion hazard ratio model with time-varying covariates (eg, sexual activity, insurance, side effect) to examine the time to change the regimen.

Provider Training

Mean scale scores for the pre- and postadministration of PrEP knowledge items, as well as the mean time with PrEP patients, will be evaluated for significance of differences using the nonparametric Wilcoxon signed-rank test for hypothesis testing of repeated measurements on a single sample [41]. Categorical data for assessing differences in the proportion of participants in agreement with individual items before and after participating in the knowledge module will be analyzed using the McNemar test of marginal homogeneity [41].

Results

The EPICC project formative work to develop evidence-based tools (Maragh-Bass et al, unpublished data, March 2025) was completed in April 2023 [17]. Provider training enrollment began in January 2024 and was completed in August 2024. Cohort enrollment began in April 2024. As of October 2024, 40 participants were enrolled in the EPICC project cohort. Cohort enrollment is expected to be completed in September 2025, with the final results anticipated in early 2027. Provider focus groups are expected to begin in April 2026, with the final results expected in early 2027.

The mChoice project formative work to develop and evaluate evidence-based tools was completed in January 2024 (Kay et al, unpublished data, March 2025) [18,46]. Provider training enrollment began in June 2024 and is ongoing. Cohort enrollment began in July 2024. As of October 2024, 18 participants were enrolled in the mChoice project cohort. Cohort enrollment is expected to be completed in July 2025. The final results are expected in late 2027.

Discussion

Overview

Posttraining, we anticipate providers will increase competence in using EBTs and providing PrEP support services. We also anticipate participants in the cohort will increase PrEP adherence and persistence. Given the changing PrEP landscape and the availability of new options and formulations, the implementation of provider education and tools to maximize uptake and adherence within their patient populations is needed. By delivering culturally competent and interactive provider training on PrEP options, the study will help providers counsel and guide participants on the effective and safe use of PrEP. The digital health tools created will support participant adherence and help them optimize the prevention benefits of their chosen PrEP regimen. Through the longitudinal, cohort design, the PrEP Choice study will provide real-world data about PrEP use that will be critical for informing future guidelines and tools.

Limitations

This research is limited in its design as a cohort study and not a randomized controlled trial. However, early work to harmonize measures and outcomes across the 2 projects is expected to allow for informative descriptions and the possibility for both pooled and separate analyses, as well as comparison across the entire study. Although multiple study sites across the United

States are included, PrEP Choice is not a nationally representative study and results will not be generalizable.

Conclusion

A multitude of efforts exist to make PrEP more available for people at risk for acquiring HIV infection, especially YMSM. Activities to increase PrEP uptake need to be accompanied by research that assesses its real-world use and identifies strategies to support and maximize its benefits. In addition to improving our understanding of how those at increased risk for acquiring HIV infection use PrEP, the PrEP Choice study will support the design and testing of informed interventions to support PrEP users' adherence and persistence, in addition to initiation.

Abstract

Background: *Pudilan Xiaoyan* oral liquid (PDL) is a proprietary Chinese medicine preparation widely used for upper respiratory tract infection, known for its significant therapeutic effects. However, the safety profiles reported in several observational studies vary, and these studies primarily focus on efficacy rather than specifically addressing safety concerns, thus representing inadequate safety monitoring.

Objective: This study aimed to investigate the incidence of adverse drug reactions (ADRs) associated with PDL and explore the factors contributing to these reactions.

Methods: The study is a prospective, observational, multicenter, hospital-based surveillance study. A total of 17 hospitals from China are involved. The study is expected to enroll a large sample of 10,000 patients aged between 18 and 80 years with upper respiratory tract infection who were prescribed PDL. The patients' data, including demographics, medical history, diagnostic information, medication details, adverse events, and laboratory test results, will be monitored. The occurrence of ADRs will be recorded. The primary outcome is the incidence of ADR. Secondary outcomes are the ratio of patients whose body temperature return to the normal range (cases of body temperature normalization and the duration for achieving normal body temperature within a 3-day period will be documented) and changes in liver and kidney function (occurrence of drug-induced liver injury and acute kidney injury). Descriptive analyses will be performed for the primary and secondary outcomes. A cohort, nested, case-control study design will be used. If one patient has an ADR, then 4 patients without ADRs will be matched as the control group according to gender, age within 5 years, drug batch, and other factors, at a ratio of 1∶4 to compare the symptoms related to ADRs. The differences of ADR incidence among the possible influencing factors will be compared separately to find the factors with large differences. Then, synthetic minority oversampling technique and group least absolute shrinkage and selection operator methods will be used to identify factors influencing the occurrence of ADRs. Finally, propensity scoring methods will be used to control for confounding variables. The progress of each subcenter will be closely monitored, and the incidence of ADR will be systematically calculated. Furthermore, the characteristics and influencing factors of ADR will be analyzed, along with an investigation into its geographical distribution.

Results: The study began on July 17, 2019. Due to the limited number of eligible patients, missed follow-ups, and the huge clinical burden caused by public health events in 2019, the final case will be enrolled on August 30, 2025.

Conclusions: This study will obtain safety results of PDL in the real world and provide guidance on the clinical safety of traditional Chinese medicine formulations.

Trial Registration: ClinicalTrials.gov NCT04031651; https://clinicaltrials.gov/study/NCT04031651

International Registered Report Identifier (IRRID): DERR1-10.2196/65789

KEYWORDS

Pudilan Xiaoyan oral liquid; PDL; upper respiratory tract infection; URTI; registry; adverse drug reaction

Introduction

Upper respiratory tract infection (URTI) involves inflammation of the respiratory mucosa from the nose to the lower respiratory tract; it causes localized symptoms that constitute several overlapping syndromes: pharyngitis, common cold, sinusitis, and bronchitis [1]. Bacterial or viral infections may be the cause of URTI, but antibiotics are recommended only for the former [1]. It is a self-limiting viral infection [2]. Currently, considering the treatment of symptoms for URTI and anti-infective therapy [3], the efficacy remains unsatisfactory with notable adverse reactions [4]. *Pudilan Xiaoyan* oral liquid (PDL) is a Chinese patent medicine, collected in the *Chinese Pharmacopoeia*. It has been widely used for URTI and has obtained good curative effect [5,6]. It contains drugs such as *Scutellaria baicalensis*, *Corydalis bungeana*, *Taraxacum mongolicum*, and *Isatis indigotica* [7]. All four herbs have the traditional Chinese medicine effects of removing heat and toxic materials, cooling blood, and reducing swelling. Besides, they also have anti-inflammatory, analgesic, antibacterial, and other biological effects [8]. Despite the efficacy of PDL, it is also necessary to monitor its safety.

In terms of safety, among the biological mechanisms of PDL, *S baicalensis*, *C bungeana*, *T mongolicum*, and *I indigotica* have been identified as herbs with low toxicity. The aforementioned drugs, however effective, are associated with gastrointestinal adverse reactions due to their bitter cold properties. Additionally, *S baicalensis* exhibits limited embryotoxicity and hepatotoxicity and can induce allergic reactions leading to vesicular eruptions [9]. *T mongolicum* primarily contributes to reversible toxicity targeting red blood cells [10], while *I indigotica* possesses nephrotoxic properties and may impose a burden on the urinary system with prolonged use [11]. The formulation of *C bungeana* contains certain hepatotoxic effects [12]. Therefore, it is necessary to investigate the safety of PDL since it is composed of the aforementioned herbal groups.

Monitoring the unintended effects of a drug (pharmacovigilance or drug safety) is crucial due to limited knowledge of rare or late-stage side effects upon market release of new drugs [13,14]. In recent years, numerous related studies have reported the clinical efficacy of PDL; however, there were few independent safety studies on it, most of which were small scale and exhibited significant variations in reported safety outcomes across different studies [15-18], resulting in inadequate understanding of its safety monitoring. In summary, published safety data on adverse effects of PDL therapy were insufficient, thereby impeding the use of standardized recommendations that are necessary for ensuring drug safety.

Although Chinese patent medicine generally exhibits a low incidence of adverse reactions, the evidence pyramid classification derived from effectiveness evaluations primarily considers randomized controlled trials as high-level evidence. However, this classification standard may not fully meet the evidence requirements for postmarketing drug safety evaluation due to limitations such as short intervention courses or small sample sizes, often resulting in an inability to detect ADRs and differences between groups. For the above reasons, this study intends to adopt a large-scale, multicenter, long-term, noninterventional, observational study design to comprehensively analyze and report on the occurrence of adverse events (AEs) [19].

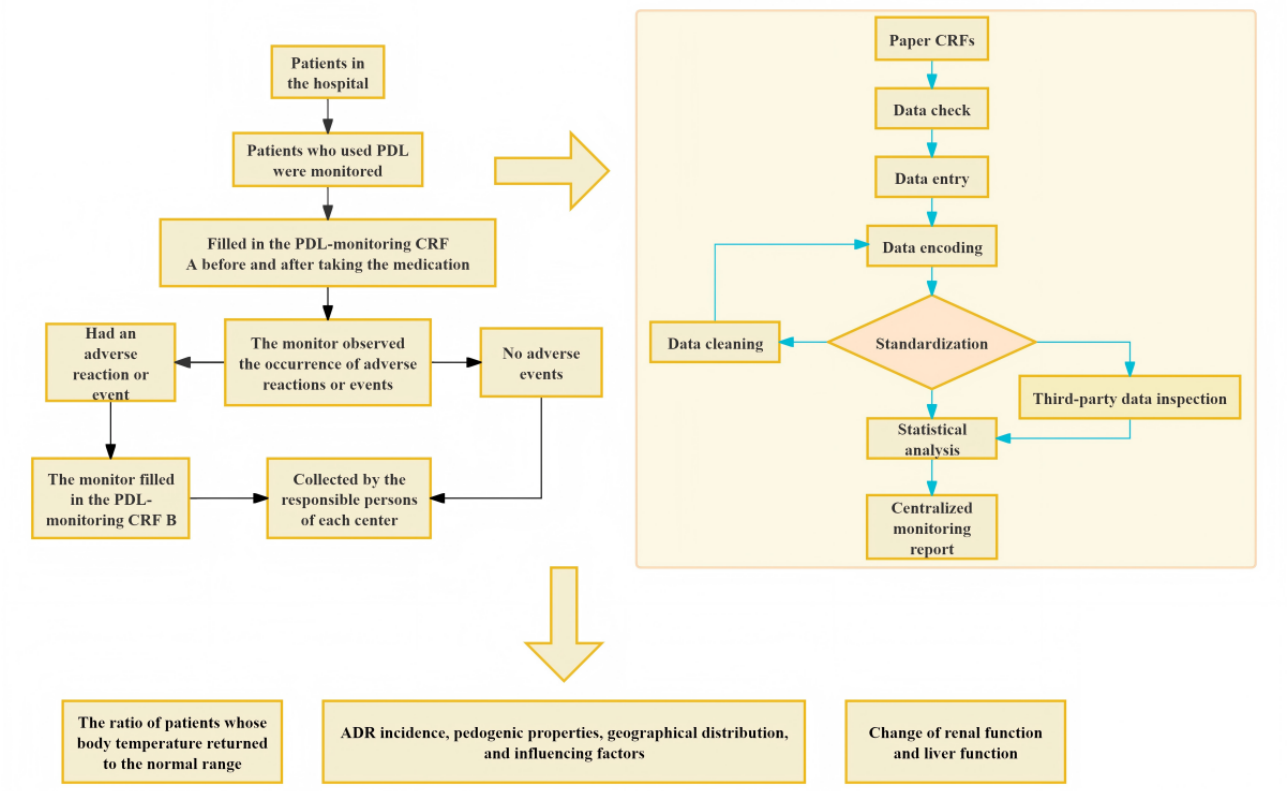
The mechanism of kidney metabolism and excretion of various drugs and toxins is an important cause of drug nephrotoxicity [20], while studies have shown that most of the AEs related to the urinary system were from treatment with PDL [21]. It can be seen that the kidney damage caused by PDL needs further investigation. As hepatic function plays an essential role in drug metabolism [22], clinical studies are necessary to determine the characteristics of PDL-related hepatotoxicity. Additionally, the influencing factors of other PDL-related adverse reactions are still unclear and may be related to the inherent characteristics of the drug itself, improper usage and dosage, improper combination, repeated administration, or use without indications, which need further investigation and study. Furthermore, a comprehensive study regarding the adverse effects associated with PDL use in patients is imperative to optimize the risk-benefit ratio and alleviate strain on limited health care resources.

Methods

Research Design

This is a prospective, observational, multicenter, hospital-intensive monitoring, and continuous registry study. We used the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) checklist when writing our report [23]. The study flowchart is shown in Figure 1.

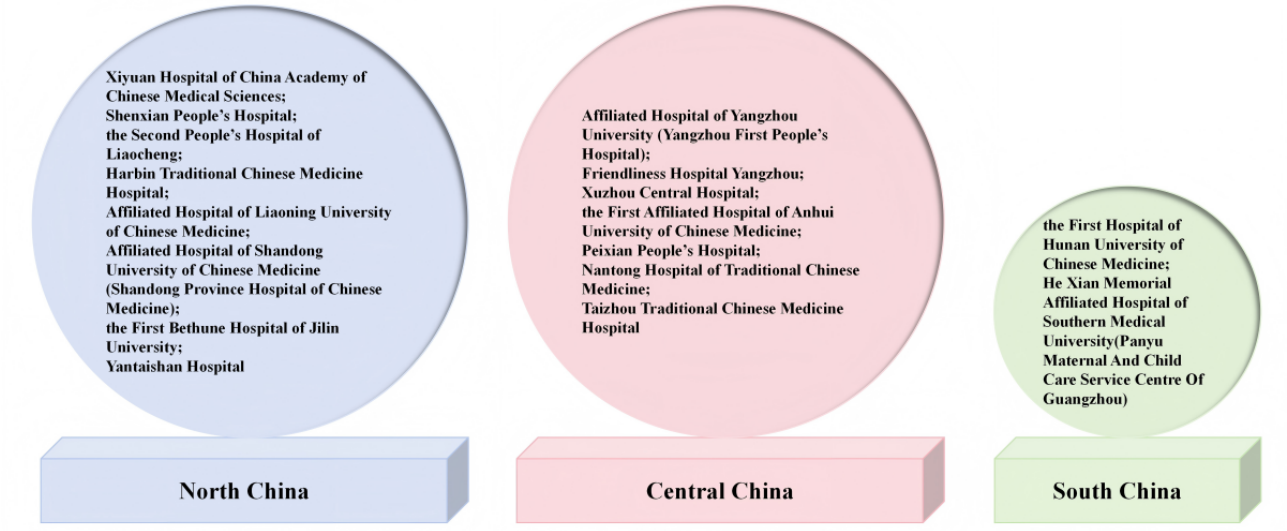
Figure 1. Study flowchart. ADR: adverse drug reaction; CRF:case report form; PDL: Pudilan xiaoyan oral liquid.



Organization

A total of 17 hospitals in China are involved in this study: Xiyuan Hospital of China Academy of Chinese Medical Sciences, the First Hospital of Hunan University of Chinese Medicine, Nantong Hospital of Traditional Chinese Medicine, Shenxian People's Hospital, the Second People's Hospital of Liaocheng, He Xian Memorial Affiliated Hospital of Southern Medical University(Panyu Maternal And Child Care Service Centre Of Guangzhou), Harbin Traditional Chinese Medicine Hospital, Affiliated Hospital of Yangzhou University (Yangzhou First People's Hospital), Friendliness Hospital Yangzhou, Xuzhou Central Hospital, Peixian People's Hospital, Affiliated Hospital of Liaoning University of Chinese Medicine, Affiliated Hospital of Shandong University of Chinese Medicine (Shandong Province Hospital of Chinese Medicine), the First Bethune Hospital of Jilin University, the First Affiliated Hospital of Anhui University of Chinese Medicine, Yantaishan Hospital, and Taizhou Traditional Chinese Medicine Hospital. Figure 2 shows their specific locations.

Figure 2. The geographical location of the 17 hospitals in China involved in this study.Light blue represents North China, light pink represents Central China and light green represents South China.



Sample Size

In accordance with the requirements of the *Guide to Key Drug Monitoring for Manufacturing Enterprises* [24], and referring to the 2013 *Technical Specifications for Intensive Hospital Safety Monitoring of Post-Marketing Chinese Medicine* [25], the "rule of threes" was used for sample size calculation, which states that "if no specific event is observed in X existing cases, there is a 95% likelihood that the occurrence rate of such an event is ≤3/X." Based on the detection rate of rare ADRs (1/10,000 to 1/1000), it is estimated that 3000 cases would need to be collected. However, due to the low probability of ADR occurrences investigated in this study, actual monitoring will be extended to 10,000 cases.

Monitoring Time and Follow-Up

Patients are monitored throughout the medication period in the hospital. The treatment duration of PDL for URTI ranges from 3 to 14 days. This study will include a follow-up period of 7 days after the completion of observation treatment [26], aiming to assess the drug's long-term efficacy and observe any delayed ADRs. The follow-up will be conducted either through face-to-face meetings or via telephone communication. We will use systematic methods and reminders to schedule appointments with patients.

Criteria

The inclusion and exclusion criteria are reported in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Patients with upper respiratory tract infection (URTI) who are administered

  Pudilan Xiaoyan

  oral liquid; the diagnostic criteria for URTI are based on the disease code J06.900 of the

  International Classification of Diseases, 11th Revision
- Aged between 18 and 80 years

Exclusion criteria

- Lactating women, pregnant women, those planning to become pregnant, patients with psychiatric conditions, and others

Instructions for Taking Medicine

In the respiratory and emergency departments of the hospitals under surveillance, the medication of PDL is observed for those aged 18-80 years who strictly follow the prescribing instructions: taking PDL 10 mL at a time, 3 times a day. During hospitalization, the patient must take PDL at least once. The patients will be visited and checked before and after taking the medicine.

Monitoring Content and Data Administration

Monitoring Patient Data, Demographic Information, Diagnosis, Complications, and Medication Information

A collaborative monitoring approach involving doctors, nurses, and pharmacists will be used in this study. They will receive relevant training in surveillance knowledge.

Basic Information Form for Administering PDL

The researchers will record the AE information collected during the study period into the safety monitoring case report form (CRF). All patients will be required to complete CRF A (PDL basic information form). If the monitored patient experiences an ADR or AE during the medication period, the monitor will need to fill out CRF B. We will check the monitoring data; enter, encode, standardize, and clean the data; and then conduct a third-party data inspection. Any discrepancies in the data will be addressed by two data administrators who will resolve them after independently verifying the original CRFs.

Interpretation of ADR Causality

In this study, AEs, ADRs, and serious ADRs will be judged according to the *Administrative Measures on Reporting and Monitoring for Adverse Drug Reaction* issued by the Ministry of Health in 2011 [27]. The evaluation of ADRs follows a 3-level decision-making process, comprising initial reporting by clinical practitioners, assessment by the Expert Committee for ADR Monitoring at the surveillance center, and final determination by panel of senior domestic experts. Based on established assessment criteria, the causal relationship between AEs and PDL will be evaluated according to five key parameters: (1) temporal plausibility, (2) consistency with known mechanisms of action or established adverse reaction profiles, (3) positive dechallenge response, (4) positive rechallenge response, and (5) exclusion of alternative explanations. The correlation between AE and PDL will be divided into six grades: positive, probable, possible, possibly unrelated, to be evaluated, and unable to be evaluated. Those judged to be the first three grades will be classified as ADRs, those judged to be "possibly unrelated" will be classified as AEs, and those judged as "to be evaluated" or "unable to be evaluated" should be rejudged in combination with the original monitoring data. We will conduct thorough evaluations to ultimately confirm the incidence of ADRs associated with PDL. This approach helps to minimize potential biases associated with patient self-reporting and variations in medical practices across different centers. The occurrence characteristics and processes of ADRs will be meticulously documented, with particular emphasis on the timing of ADR onset, the

implementation time of intervention measures for ADRs, and the termination time of ADRs.

Quality Control of ADRs

Each monitoring subcenter will formulate the first-level, quality-control rules and quality-control list according to the content of the monitoring program. The information system of each monitoring unit will be reviewed to ensure that the clinical study data are authentic and traceable. The implementation of the study will adhere to the research protocol and standard operating procedures in order to ensure the authenticity and reliability of the research data. The data collected are presented in Table 1.

[a]Patients are visited and examined before and after taking the medication.

[b]Expense category refers to the classification of expenses, such as out-of-pocket (self-funded) costs, expenses covered by medical insurance, and other payment types. It helps in understanding how different types of expenses are categorized based on their funding source or payment method.

[c]ECG: electrocardiogram.

Outcome Measures

Primary Outcome Measure: Incidence of ADRs

The incidence of ADRs is the primary outcome measure, and we will identify factors that contributed to the occurrence of ADRs. The incidence of ADR will be primarily categorized in accordance with the criteria proposed by the Committee of International Organization of Medical Sciences: very common (≥10%), common (1%-10%, including 1%), occasional (0.1%-1%, including 0.1%), rare (0.01%-0.1%, including 0.01%), and very rare (<0.01%) [28], as well as according to the classification of ADR symptoms by the World Health Organization (WHO) [29]. The WHO classification of organs and systems involved in ADRs will also be referenced [30]. The incidence characteristics and regional distribution will be subsequently analyzed, while concurrently investigating the influencing factors (Table 2).

Table 2. Centralized monitoring results of Pudilan Xiaoyan oral liquid in the registered hospitals.

Monitoring result	Description
Categorization	• The ADR[a] was categorized based on general, novel, and severe classifications • The classification was based on the organs and systems affected by the ADR • The symptoms of the ADR were classified
ADR incidence	• The specific event features of each ADR included the incidence rates of various categories and whether they are infrequent or exceptionally rare
Pedogenic properties	• Occurrence characteristics of ADRs specific to each category
Geographical distribution	• The distribution of ADRs is primarily observed in North China, Central China, South China • Each region exhibits distinct characteristics of ADRs
Influencing factors	• Days of medication, age, drug combination, etc

[a]ADR: adverse drug reaction.

Secondary Outcome Measures

The Ratio of Patients Whose Body Temperature Returned to the Normal Range

The cases of body temperature normalization and the duration for achieving normal body temperature within a 3-day period will be documented. The body temperature will be recorded prior to medication, on the first day after medication, and on the second and third days after medication. Daily measurements will be conducted by professional nurses using mercury thermometers. The time of normal body temperature restoration is defined as when the body temperature drops below 37.3 °C after the initial medication administration, with no recurrence observed within a 24-hour period. Thus, the ratio of normalization represented the percentage of cases in which individuals return to a normal body temperature within the total number of cases in the group.

Change in Liver Function

We will observe liver function in at least 3000 patients before and after medication. Liver function indexes will include alanine transaminase (ALT) and aspartate transaminase. To observe whether the above liver function indexes appear abnormal after medication, we will use the 2011 International Association for Severe Adverse Reactions–recommended biochemical diagnostic criteria for drug-induced liver injury [31]. Drug-induced liver injury is defined as meeting one of the following conditions:

1. ALT ≥5× upper limit of normal (ULN);
2. Alkaline phosphatase ≥2×ULN, especially with 5’-nucleotidase or γ-glutamyl transpeptidase elevation, excluding alkaline phosphatase elevation caused by other diseases; or
3. ALT ≥3×ULN and total bilirubin ≥2×ULN.

Change in Renal Function

We will observation renal function in at least 3000 patients before and after medication. The renal function indexes will include creatinine and blood urea nitrogen. To observe whether the above renal function indexes appear abnormal after medication, the diagnostic criteria for acute kidney injury will be defined based on the Kidney Disease: Improving Global Outcomes serum creatinine criteria [32] (at least 50% increase in creatinine within 7 days or a 26.5 μmol/L increase within 48 h).

The time frame for all four result items is 7 days (Table 2).

Statistical Analysis

Data review and cleaning work will take the paper monitoring form as the original record, delete redundant and repetitive parts, supplement missing data, modify wrong values, and report about abnormal values. The basic characteristics of the patients will be included. Descriptive analyses will be performed for the primary and secondary outcomes. SPSS Statistics 26 software (IBM Corp) will be used for descriptive analysis. Data conforming to a normal distribution will be described by means and SDs, and those conforming to a skewed distribution will be described by median, minimum, maximum, and IQR scores. Categorical data will be described by frequencies and percentages. A cohort, nested, case-control study will be used. If 1 patient has an ADR, then 4 patients without ADRs will be matched as the control group according to gender, age with 5 years, drug batch, and other factors, at a ratio of 1∶4 to compare the symptoms related to adverse reactions. In addition, the risk factors of adverse reactions will be analyzed. First, the differences of ADR incidence among the possible influencing factors will be compared separately to find the factors with large differences. Then, synthetic minority oversampling technique and group least absolute shrinkage and selection operator methods will be used to identify factors influencing the occurrence of ADRs, while propensity scoring methods will be used to control for confounding variables.

Ethical Considerations

This monitoring scheme is implemented after the approval of the Ethics Committee of Xiyuan Hospital of China Academy of Chinese Medical Sciences (ethics batch: 2019XL009-1). Patient data included in the analysis were approved by the institutional review committee of each participating agency. Informed patients in this study were exempt from signing the consent application. In addition, the data will be kept confidential, and the researchers who participate in the data

inquiry will need to submit the corresponding application, to ensure that no individual participant or user can be identified in any images in the paper or supplementary materials.

Results

The first case was included on July 17, 2019. Due to the limited number of eligible patients, missed follow-ups, and the huge clinical burden caused by public health events in 2019, the final case will be enrolled on August 30, 2025.

Discussion

Summary

The practice of traditional Chinese medicine in China spans over 2000 years and has consistently garnered high regard for its precise therapeutic efficacy, minimal adverse effects, and cost-effectiveness [33]. As a proprietary Chinese medicine preparation already on the market, PDL had outstanding efficacy in treating URTI [5]. The action mechanism of PDL has been extensively used in clinical practice. However, it is important to acknowledge that there are no completely safe drugs, and every drug administration carries inherent risks. Therefore, the objective of this study was to closely monitor the safety profile of PDL.

The therapeutic safety of PDL is currently being overlooked during the course of disease treatment. Early identification and a better understanding of its adverse reactions will enhance the drug safety profile of PDL and mitigate the therapeutic costs associated with such reactions.

This study is a continuous registry, hospital-intensive monitoring study. Hospital-intensive monitoring allows the evaluation of efficacy and safety in diverse populations under real-world conditions, including sensitive populations that may not be included in premarketing clinical trials, such as pregnant women, ethnic minority groups, older adult patients, children, patients with multiple comorbidities, and those taking multiple medications. The limitation of centralized monitoring in registry hospitals is that it may underestimate the impact of ADRs, as health care professionals may prioritize serious adverse reactions and overlook general adverse reactions. However, this study will implement a 3-level, quality-control approach, using a professional electronic data management system to mitigate missing and misreported data occurrences and ensure the validity and authenticity of the collected information [19].

There are numerous pathological conditions that contribute to drug-induced acute kidney injury, among which the nephrotoxicity of drugs stands as a preventable factor. Enhancing our comprehension of drug safety aids in mitigating the risk associated with drug-induced acute kidney injury. Furthermore, apart from the inherent nephrotoxicity of drugs themselves, administering potentially nephrotoxic medications in high doses or over prolonged treatment durations amplifies the likelihood of renal damage. Additionally, concomitant administration of multiple drugs can synergistically induce nephrotoxicity and consequently lead to kidney injury. Therefore, studying the kidney injury factors of PDL forms the basis for preventing adverse reactions. The Chinese medicine preparation PDL can also induce hepatotoxicity, leading to drug-induced liver damage, which may occur at both therapeutic and overdose doses. This can be attributed to either direct intrinsic hepatotoxicity of the drug or specific (unpredictable) liver toxicity [34], which needs to be further observed and explored.

The monitoring and evaluation of the safety of proprietary Chinese medicine preparations, along with the acquisition of authentic drug safety information, can complement drug instructions, promptly grasp the latest research advancements in related medications, guide their clinical application, and enhance the safety and efficacy of their clinical use.

Conclusions

This study will obtain the safety results of PDL in real-world, clinical applications. Furthermore, monitoring and evaluating the safety of proprietary Chinese medicine preparation is instrumental in providing further clinical guidance on drug use.

Acknowledgments

This trial is supported financially by the National Key R&D Program of China (2022YFC3502004), Funder National Natural Science Foundation of General Program (81973982), Seventh Batch of National Old Traditional Chinese Medicine Experts' Academic Experience Inheritance Project (Chinese Traditional Medicine Teaching Letter [2022] 76), and Fundamental Research Funds for the Central Public Welfare Research Institutes (ZYJGKX202407).

Data Availability

Since this is a protocol, data are not yet available, and information not included in this paper will be provided by the corresponding author upon completion of the trial.

Authors' Contributions

MW and LW prepared the study and the first version of the manuscript. RC participated in the design of the trial. FL collected the information needed for the performance of this trial in each center. ZW, XC, and YL performed a critical revision of the manuscript. YX and LW are responsible for all aspects of the study, including the preparation of the grant application, securing funding, data analysis, and interpretation and preparation of the final manuscript for publication. All of the authors discussed,

read, and revised the manuscript and gave final approval for the publication of this study protocol. The sponsor of this protocol is China Academy of Chinese Medical Sciences, and the responsible party is YX.

Conflicts of Interest

None declared.

Abstract

Background: Transgender women have few interventions to support their HIV prevention and treatment outcomes in South Africa. Further, increased focus should be on intervention development that will reduce HIV transmission within HIV-discordant partnerships, especially for transgender women who navigate gender, sexuality, and relationship stigma. The Speaking Out and Allying Relationships (SOAR) intervention has been developed for sexual minority men to address these outcomes in South Africa. It is a behavioral intervention that is delivered in groups via videoconference to develop coping skills to manage HIV-related stress, assist with disclosure to partners, and establish and maintain safer sex practices with partners. Tailoring SOAR may be feasible for transgender women to support their HIV care while reducing transmission within their relationships.

Objective: This study aims to (1) adapt SOAR for transgender women and test its usability, then (2) assess its feasibility.

Methods: To achieve aim 1, we will use a human-centered design approach to tailor the existing SOAR intervention for transgender women. Interviews and a survey will be administered to transgender women (N=15) to assess intervention preferences. Findings will be used to tailor content like roleplays, scenarios, and media to align with transgender women's lived experiences navigating HIV and relationships. Afterward, we will conduct a usability test with 7 (47%) of the 15 participants to determine intervention understanding and satisfaction. Participants will be transgender women living with HIV and in a relationship with a man who has unknown HIV status or is HIV-negative. All participants will be recruited using community-based approaches. In aim 2, we will examine SOAR feasibility using a 1-arm pilot study. Transgender women (N=20) will be recruited using aim 1 methods and eligibility criteria, with participants completing feasibility surveys and interviews, as well as behavioral and biomedical assessments.

Results: Intervention adaptation began in May 2023 with interviews. Feasibility pilot testing was conducted with 14 transgender women, with study completion in January 2025.

Conclusions: Transgender women need more intervention options that engage their relationships since these can present barriers to HIV treatment outcomes like hindering viral suppression in South Africa. Delivering an existing yet tailored intervention via videoconference expands its reach to transgender women and allows them to engage with others and learn new skills in a secure setting like their homes. SOAR has the potential to improve relationship dynamics and reduce violence, which will in turn enhance HIV treatment and prevention engagement.

Introduction

Background

HIV infections among transgender women are 2.2 higher than gay, bisexual, and other men who have sex with men in sub-Saharan Africa due to syndemics consisting of stigma and discrimination that perpetuate violence and victimization, limiting access to HIV prevention and treatment [1-4]. In South Africa, the HIV incidence for transgender women is 31 cases per 100-person years, with studies showing limited pre-exposure prophylaxis (PrEP) and antiretroviral therapy (ART) access and adherence. Based on other African studies, only an estimated 25% of transgender women are virally suppressed [5-7]. HIV prevalence among transgender women in South Africa mirrors the realities that they share with their peers in other Global South settings, with a 52% mean prevalence documented in 3 South African cities [8]. Transgender women's health and safety remain compromised in South Africa, inhibiting their ability to engage in HIV services to lower transmission risk and improve their overall wellness, and compounding these health outcomes are poor relationship dynamics.

Being in an unhealthy or imbalanced relationship for transgender women can lower their HIV testing behaviors and increase rates of condomless anal intercourse with partners to create trust and intimacy [9-13]. Fear of partner rejection or loss and intimate partner violence may lead transgender women to limit or halt ART use to conceal their serostatus from partners [14-16]. Further, studies increasingly show that transgender women experience negative outcomes of relationship stigma (when partners fear being romantically associated with someone who is stigmatized), which in turn has hindered their ability to discuss HIV treatment with them [15,17]. Although studies with transgender women in South Africa are limited, in the United States, relationship dynamics for transgender women influence HIV risk, in the same ways they do for cisgender women and sexual minority men [17-21]. Additional factors hindering HIV prevention and treatment discussions that transgender may have with a partner include living with them, drug use, alcohol use, education level, and low self-efficacy to use condoms [18]. In sum, cisheteronormative social structures and power dynamics have been shown to result in increased marginalization, increased susceptibility to intimate partner violence, and increased risk of mental issues among transgender women, all hindering HIV prevention and treatment [22-24].

Further, transgender women are less likely to disclose their HIV status to other transgender women and sexual minority men within their social networks, increasing social isolation [25-27]. Only after being out of care and developing AIDS-related illnesses do transgender women disclose their HIV status to an immediate family member in order to secure support for their treatment, but this disclosure does not extend to partners [25,27]. Given a history of HIV care marginalization and discrimination, transgender women often possess inaccurate knowledge and skills in discussing with partners how PrEP and ART adherence, including "undetectable is untransmissible" (U=U) messaging, can work together to reduce transmission and in turn support relationship health [14-16]. Thus, transgender women have ongoing HIV-related stress without the skills to manage this stress and their disclosure to partners and others for support.

The benefits of social and partner support are significant for transgender women. Studies show that transgender women in committed relationships are less likely to engage in HIV-related high-risk behaviors, with researchers suggesting that relationship stability and emotional support lead to more consistent condom use and improved HIV prevention and treatment overall [28-30]. Specifically, higher relationship satisfaction, trust, and commitment were protective factors against HIV transmission among transgender women [17,31]. Additionally, 1 randomized controlled trial found that a social support group intervention further reinforced relationship-related protective behaviors among transgender women [32]. Therefore, a relationship-focused HIV intervention may support treatment and prevention outcomes for transgender women and their partners while garnering the support of family members earlier in their treatment journey.

To address this gap in interventions for transgender women living with HIV in South Africa, the aim of our study is to tailor our existing intervention, Speaking Out and Allying Relationships (SOAR) intervention, with them and then conduct a 1-arm pilot study to assess intervention feasibility in Eastern Cape, South Africa. Specifically, we will tailor SOAR and assess usability for content understandability and satisfaction (aim 1), and then evaluate its feasibility to include retention and any changes in behavioral and biomedical measures (aim 2). We hypothesize that participants will find SOAR feasible, acceptable, and safe to inform a larger efficacy study.

Our SOAR intervention is based on Healthy Relationships (HR), a 5-session, group-based evidence-based intervention to develop individual HIV disclosure risk assessment and safer sexual behavior skills with partners that have demonstrated efficacy in these outcomes in a range of settings [33,34]. The core elements of SOAR are to: (1) develop coping skills to manage HIV-related stress and sexually risky situations; (2) enhance decision-making skills for HIV disclosure to partners; and (3) establish and maintain safer sex practices with partners. The HR intervention was identified based on our preliminary research with sexual minority men and transgender women in South Africa [35]. Additionally, through this preliminary research, we demonstrated that transgender women are willing to complete HIV-related group work and have an interest in mHealth tools, like videoconference modalities, to learn skills in HIV treatment management and disclosure for support

[36,37]. Moreover, harnessing high use rates of smartphones by transgender women for intervention delivery is feasible in South Africa [20,38]. Increased evidence shows that transgender women access web-based social networking sites and use SMS for social networking through mobile and smartphone technologies, creating the potential to tag on ART adherence interventions [39,40]. In our research, we found that HIV-positive sexual minority men and transgender women regularly use videoconferencing to support community networking across rural and urban settings, with 2-hour conversation events focused on HIV, sexuality, and gender [37]. Further, mHealth tools (SMS, chat rooms, and web-based video group interventions) for HIV prevention and treatment in South Africa are part of the national strategic plan [41]. As in the original HR, our SOAR intervention integrates media, scenarios, and roleplays for skill development, and these reflect the experience of South African sexual minority men living with HIV and in relationships. In addition to the standard 5 sessions, we include three 30-minute booster sessions to review action plans over 3 months.

Theoretical Framework

Social cognitive theory serves as the framework for the intervention, which posits that cognition, behavior, and environment interact and influence health outcomes, like HIV risk reduction, disclosure, prevention, and ART adherence. SOAR aims to enhance coping skills for HIV-related stress, self-regulation of disclosure to include risk assessment, treatment, and prevention, and build self-efficacy in healthy behaviors and communication within relationships. Further, the intervention will provide a platform for participants to strengthen coping skills that will support and empower gender affirmation within relationship dynamics that may be experiencing stigma or risk of violence, or desire for improved relationship communication. Within the social cognitive theory model, the intervention will incorporate components such as HIV risk reduction education, treatment education including U=U, HIV prevention strategies like PrEP, and gender affirmation within the context of HIV. Skill-building activities for HIV communication and disclosure risk assessment will be conducted in a confidential group setting. By helping individuals plan for safe sex and consider HIV communication and disclosure to partners, the intervention aims to support ART adherence, empower participants with a sense of agency, and reduce negative feelings associated with their HIV status and internalized HIV stigma.

Our proposed tailoring of SOAR for transgender women is based on high interest to participate among those who attended community outreach activities for recruitment of sexual minority men as part of the original intervention. If this tailoring shows promise of feasibility, then we will conduct a larger randomized controlled trial to assess efficacy and implementation with local agencies that service sexual and gender minority communities in South Africa.

Methods

Study Design Overview

The study will use a 2-fold approach, beginning with intervention tailoring and usability assessment (aim 1) and then a 1-arm pilot study of the intervention (aim 2) to evaluate feasibility. Prior to study initiation, a study coordinator will be hired and trained in study procedures and the SOAR intervention and its delivery approach. The coordinator will be a member of the sexual and gender minority community in Eastern Cape and have a history of HIV program work. Coordinator training will include a review of sexual and gender minority health with a focus on HIV treatment and prevention barriers and facilitators for transgender women, gender-affirming care such as hormone replacement therapy, and relationship dynamics influencing HIV care. Additionally, the coordinator will complete training in good clinical practice and ethics and study procedures including data collection. Finally, the coordinator will be trained in the SOAR intervention which will include both didactic and simulation sessions until competency has been achieved. The study coordinator will conduct all study procedures with mentoring provided by the research team.

Tailoring SOAR for Transgender Women

In aim 1, we will tailor SOAR by using a human-centered design approach. First, we will assess transgender women's preferences and confirm their relationship dynamics regarding HIV. Then, we will evaluate the functionality of the intervention in a videoconference format (Zoom, Qumu Corp), and usability by gauging participants' understanding and satisfaction with the SOAR intervention.

The study will be conducted in Buffalo City Municipality, Eastern Cape, South Africa. In this setting, there is a 46% HIV prevalence among transgender women who live in both urban and rural areas [8]. We will recruit transgender women (N=15) living with HIV and in a relationship for more than a month. Recruitment activities will be conducted by study staff at community events focused on transgender women and sexual and gender minorities. Study staff are members of the sexual and gender minority community and allies, and all completed LGBTQ competency training. Interested participants will be provided study explanation and invited to answer questions in the screening survey. Eligible participants will complete written informed consent in the language of their choosing (eg, isiXhosa, Afrikaans, English). The consent form will outline confidentiality and protections of participant information if they are interested in participating in the study. All participants will receive travel reimbursement and refreshments to complete study procedures.

Preference Assessment and Integration

To assess transgender women's preferences for the intervention, we will conduct in-depth interviews (IDIs). These interviews will delve into influences on HIV treatment including support and relationship dynamics, and gather feedback regarding various aspects of the intervention, including format and delivery. A semistructured question guide will ask questions in four domains: (1) HIV prevention and treatment knowledge;

(2) relationship scenarios involving HIV disclosure and support for role-play development; (3) videoconference delivery preferences; and (4) positive representation of transgender persons in media (web-based, television, and movies) to show during the sessions. Each interview will be 60 minutes long, conducted in the local language (isiXhosa), transcribed verbatim, and translated for analysis. Findings from the analysis will be used to tailor SOAR to the contextual factors influential in HIV treatment and status disclosure for transgender women and to ensure representation of their empowering voices in the roleplays and videos to support skill building.

Usability Testing

Usability testing will involve 2 tasks: pretesting and IDIs with participants. We will recruit 7 (50%) racially and relationship-length diverse transgender women participants from step 1 for pretesting. The pretesting phase will span 5 weeks, with 2-hour sessions each week. At week 8, 3 weeks after the last session, a group check-in session will be conducted via Zoom. Participants will receive SMS reminders for each session and the Zoom session link. All sessions will be completed together to foster positive group dynamics and will include a set of group rules for this purpose, and to protect the confidentiality of participants and their contributions during the sessions. The interventionist will monitor participant engagement throughout the pretesting and follow up with any missed sessions. Participants will provide their smartphone numbers for session reminders, self-assessment, action plans, and partner referrals delivered through Research Electronic Data Capture (REDCap; Vanderbilt University). The sessions and group check-in will be video-recorded for analysis, and participants will receive a data plan to facilitate their participation. After the pretesting phase, IDIs will be conducted with racially and relationship-length diverse participants over Zoom. The interviews will cover 6 usability domains for SOAR, including session functionality, timeliness and appropriateness, clarity of content delivery, document clarity and management, incomplete sessions, and technical transitions between sessions. The individual interviews in isiXhosa are expected to last approximately 50 minutes. Audio recordings of the interviews will be transcribed and translated into English for further analysis.

Data Analysis

To understand SOAR preferences and usability, interview transcripts will be cleaned and confirmed for accuracy before being uploaded into the qualitative data management program, Dedoose, where data will be coded and categorized [42,43]. First, the research team will separately analyze each transcript using predefined codes and open coding, and then discuss coding to confirm alignment and coding distinctions in order to clarify codes [16]. Second, using a thematic approach [44], researchers will analyze the coded transcripts to identify SOAR preferences and usability themes as an iterative process. An additional comparative analysis based on age was conducted to identify any distinctions [44-46]. These discrepancies will be resolved by agreement during research team discussions.

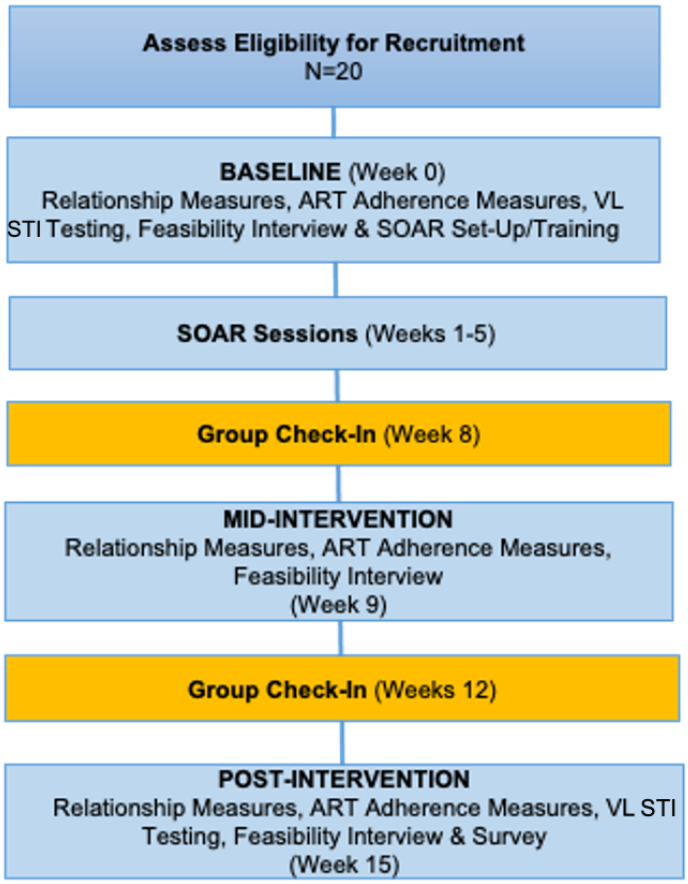
Evaluating the Feasibility of SOAR for Transgender Women

After SOAR has been tailored, in aim 2, we will conduct a pilot study of the intervention using a 1-arm design to determine feasibility, acceptability, willingness, and safety for transgender women (SOAR study design; Figure 1). Also, we will collect data on ART adherence (viral load) and relationship communication to establish a preliminary understanding of outcomes and implementation of measures in a larger study.

We will recruit transgender women (N=20) living with HIV and suboptimally adherent to ART (missed at 2 doses over 2 weeks), to complete the intervention. Additionally, participants must have been in a romantic relationship with a man for more than 1 month and live in Eastern Cape. For screening, participants will complete a rapid HIV viral load test to confirm HIV status.

There will be 5 participants per group for a total of 4 groups. All participants will be recruited and screened into the study by the trained study coordinator, and all recruitment activities will occur at transgender community–focused events. During the consent process, participants will be provided a general overview of the study and informed about the number of study sessions and expected behavioral and biomedical data collection procedures. As in aim 1, all participants will receive a travel reimbursement and refreshments.

Figure 1. SOAR study design. ART: antiretroviral therapy; SOAR: Speaking Out and Allying Relationships; STI: sexually transmitted infection; VL: HIV viral load.



Procedures

Overview

Once enrolled, participants will complete a behavioral survey on REDCap. These measures cover HIV, sexuality, relationship stigma and discrimination, communication in relationships, and HIV prevention and treatment behaviors [47-53]. They will also complete syphilis testing using a rapid diagnostic test (Abbott Determine Syphilis TP), blood draw for HIV viral load, and urine collection for *Chlamydia trachomatis* and *Neisseria gonorrhea* testing. All measures will be administered by study staff.

Afterward, participants will receive training in Zoom, and their smartphones will be assessed and set up for Zoom compatibility. Participants will be notified that they will receive an SMS reminder 12 hours before each session, and then 1 hour before each session, they will receive an SMS with the Zoom link for that session. Also, participants will be informed that during the intervention they will be asked to complete an action plan, and they will receive a partner referral letter via SMS or in paper form (their choice) at the start of the study and can request the letter throughout the study. The referral letter describes the availability of local HIV and mental health services. Each participant will be informed that they will complete 1 SOAR session per week for 5 weeks with 2 check-in sessions afterward.

Group Check-Ins

All participants will be invited to attend group check-ins (n=2) via Zoom. The check-in dates and times will be provided during the last session with connection details (eg, Zoom link) sent via SMS to their mobile devices. Participants will be informed that they will receive a reminder about each check-in session 12 hours before and then 1 hour beforehand.

Each session and group check-in will be conducted by the study coordinator and a research assistant who is trained in the intervention.

Retention Procedures

All participants will be given a card with the study phone number to contact the interventionist if their phone number changes or if they have technical difficulties during the session (the card will not contain information that identifies their participation in the study). The interventionist will phone participants after a missed study visit and SMS each participant monthly to confirm smartphone numbers to support retention.

Measures and Data Analysis

We will use the same measures as outlined in the parent study to include feasibility, behavioral outcomes for ART adherence and relationship communication, and HIV viral load.

Feasibility

The assessment of feasibility encompasses four domains: feasibility [54], acceptability [55], willingness [56], and safety

[57]. Feasibility pertains to the ability to successfully recruit and retain participants, as well as facilitate message exchange and engagement in group sessions [54]. Acceptability refers to participants' preferences and satisfaction with different components of the intervention [55]. Willingness relates to participants' interest in enrolling in a longer study and their likelihood of recommending the intervention to others [56]. Safety focuses on ensuring the confidentiality and security of participant data and communication both within and outside the intervention.[57]

We will assess feasibility using surveys and interviews. The Self-Intervention Evaluation Form and the Client Satisfaction Questionnaire will be administered to evaluate the acceptability [58,59]. A study-specific Likert scale survey will also be developed to assess feasibility, willingness, and safety [60]. This survey will gauge participants' perceived ability to exchange messages, participate in group sessions and check-ins (feasibility), their likelihood of enrolling in a longer study or referring other transgender women (willingness), their willingness to provide referral letters to partners, and their perception of the intervention's confidentiality and security (safety). Also, we will conduct 30-minute interviews with purposively all participants, and these will be conducted at baseline, midintervention, and postintervention [61]. Feasibility will be evaluated by examining participants' attitudes toward various aspects of the intervention, such as video-group interactions, referral letters, and their perceived changes in self-management of ART, HIV risk, and HIV disclosure [62]. Acceptability will be assessed by examining participants' preferences and satisfaction with specific intervention components and the intervention as a whole [62]. Willingness will be measured by assessing participants' willingness to use the intervention consistently from start to finish, their openness to using the intervention in different contexts, and their likelihood of recommending the intervention to others [62]. Safety will be examined by evaluating participants' perceived levels of discomfort with different intervention components and their perceptions of personal safety and the risk of unwanted disclosures [57].

Relationship, ART Adherence, and Biomedical Measures

In this study, we will assess the feasibility of collecting behavioral and biomedical measures and provide a preliminary understanding of outcomes. The SOAR intervention is designed to provide transgender women skills in assessing disclosure and related risks, and association communication skills to discuss HIV with partners. We will administer surveys for relationship satisfaction [63] and communication [64], HIV disclosure [65], and HIV treatment adherence [66] Also, we will assess HIV viral load using whole blood. All measures will be administered at baseline through follow-up.

All data will be analyzed using similar procedures as outlined in aim 1 of this study.

Participants

For both study aims, all transgender women will be over the age of 18 years, be in a relationship for more than a month, own a smartphone, be comfortable with group discussions about HIV, and be HIV-positive with confirmatory testing using OraQuick (OraSure Technologies) during screening. We will enroll with racial diversity to ensure the representation of multiple voices. Our relationship criteria require participants to have a self-reported romantic or emotionally connected partnership with another individual of any sex or gender, and partners must be either HIV-negative or of unknown status. Additionally, all participants need to live in Eastern Cape and suboptimally adhere to their HIV treatment [66].

Ethical Considerations

For this study, aim 1 procedures have been reviewed and approved by the University of Cape Town Review Board (FWA00001938) with reliance on the institutional review board at Arizona State University (STUDY00014539). For aim 2, the study procedures were reviewed and approved by the University of Pretoria Review Board (189/2022) with reliance on Arizona State University (16397). All participants completed written informed consent. All participants will complete written informed consent and will receive R150 (around US $10) as travel reimbursement for completing the study activities and an R150 (around US $10) data plan to support their session attendance. All data will be anonymized when reported.

Results

Staff hiring and intervention tailoring began in May 2023 and were completed in November 2023. During this time, interviews were completed and we identified preferences for the integration of gender-affirming care and South African transgender women's voices (eg, videos) into SOAR sessions. Feasibility pilot testing started in January 2024 and was completed in January 2025. At this time, there are 14 participants who have completed 1-5 SOAR sessions. Primary feasibility results will be used to inform further adaptation and a clinical trial.

Discussion

Expected Findings

The SOAR intervention for transgender women is responsive to South African clinical guidelines for HIV care and addresses barriers to HIV disclosure management and treatment with partners [67]. Specifically, recent clinical guidelines outline a recommendation to deploy mHealth tools for treatment support, as these may allow transgender women to navigate perceived and enacted stigma and discrimination more easily when seeking clinic care [15,16]. Given the established smartphone use in South Africa, and among transgender women, harnessing these tools in HIV interventions is feasible [68]. However, few mHealth HIV interventions have been designed and tested for transgender women [4].

SOAR leverages videoconferencing and group format for delivery. Both modes of delivery have been shown to be highly effective in other settings [69,70], and more research is needed to determine its feasibility with transgender women in South Africa. Further, SOAR has the potential to improve skill-building for HIV status disclosure management that may in turn garner needed support from partners and improve HIV treatment adherence. If partner disclosure and support are not

feasible, then SOAR provides participants with coping skills to manage HIV treatment and identification of other support systems for care.

Given that transgender women have some of the highest HIV incidence rates in South Africa and globally [4], it is imperative that we develop more intervention options based on their lived experiences. Integrating mHealth tools into these interventions can empower participants, as it allows them to control engagement based on their safety and needs. If SOAR is feasible as videoconference delivery for transgender women, then we will propose an efficacy study of the intervention to understand the impact on HIV viral load and quality of life. The intervention has the potential to build relationship skills around HIV treatment for transgender women and their partners who are consistently left behind in the HIV response.

Limitations

The one potential study limitation is smartphone ownership or access. Specifically, although smartphone use is high in South Africa, device costs may be prohibitive for some participants. To facilitate participation such that we have representation of transgender women across socioeconomic standing, we will provide smartphones for participants to borrow, or they may access a tablet with headphones at a community site to attend the sessions.

Acknowledgments

The authors would like to thank sexual and gender minority community organizations and leadership for supporting this study in Eastern Cape, South Africa. This study was funded by a supplemental grant to the parent study, National Institutes of Mental Health, R34MH125790.

Authors' Contributions

The study was conceptualized and designed by JD. CB completed data acquisition with data analysis and interpretation by JD, SN, CB, RPP, and LLAVDM. The writing was completed by JD, SN, and SPP with review and revision by JD, LLAVDM, SPP, RPP, CB, and SN. All authors approve and are accountable for the manuscript content.

Conflicts of Interest

None declared.

Abstract

Background: Low-dose computed tomography (LDCT) screening is promising for the early detection of lung cancer (LC) and the reduction of LC-related mortality. Despite the implementation of LC screening programs worldwide, recruitment is challenging. While recruitment for LC screening is based on physician referrals and mass advertising, novel recruitment strategies are needed to improve the enrollment of high-risk individuals into LC screening.

Objective: We aim to identify whether patients with LC can act as advocates to enroll their family members and close contacts into LC screening and whether this strategy increases screening uptake at the population level.

Methods: We designed a prospective cohort study comprising 2 cohorts constituted between June 2023 and January 2024 with a prospective follow-up of 18 months. Patients with LC (cohort 1) are approached at clinics of the McGill University Health Centre, educated on tools for communicating with family members and close contacts about the benefits of LC screening, and invited to refer their close ones. Referred individuals (cohort 2) are directed to this study's web-based questionnaire to assess their LC risk score with the PLCOm2012 (Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial) prediction model. Individuals meeting the eligibility criteria for LC screening (PLCOm2012 score ≥2% and aged 55-74 years) are directed toward the Quebec LC screening program. Data collected include sociodemographic characteristics, health literacy and smoking status (all participants), patient activation (cohort 1), perceived risk of LC, and generalized anxiety at baseline and at 28 days (cohort 2). LDCT completion within 18 months from referral is assessed from health records. Focus groups will identify the barriers and facilitators in the uptake of LC screening and preventative behaviors based on perceived genetic and clinical LC risks. The primary outcomes are the number of referred participants per survivor of LC and the mean risk of LC of the referred population based on PLCOm2012 scores. The secondary outcomes are the proportion of (1) participants eligible for LC screening; (2) participants eligible for screening who complete LDCT screening within 18 months of referral from a survivor of LC; (3) participants showing interest in genetic testing to inform LC risk; and (4) participants showing interest in a smoking cessation program. Multivariable logistic regression will identify the predictive factors of being referred for LC screening. PLCOm2012 scores will be compared for referred participants and controls from the provincial LC screening program.

Results: Overall, 25 survivors of LC and 84 close contacts were enrolled from June 2023 to January 2024, with followed up through July 2025. The results are expected by the end of 2025.

Conclusions: We describe an approach to LC screening referral, leveraging patients with LC as advocates to increase screening awareness and uptake among their family and peers.

Introduction

Background

Almost three-quarters of lung cancers (LCs) are diagnosed at stages III and IV with poor overall survival [1,2]. LC remains the cancer with the highest mortality rate, with high rates of comorbidities also [3,4]. The projected increase of LC burden in Canada calls for improving its early detection and preventative strategies [5]. Low-dose computed tomography (LDCT) screening of high-risk individuals is promising for early detection and reduction of LC-related mortality [6]. With more than 50,000 high-risk individuals enrolled, the pioneering National Lung Screening Trial has shown a 20% reduction in LC-related mortality with LDCT screening compared to standard chest radiography [7]. Evidence supporting this screening strategy was further supported by the NELSON (Nederlands-Leuvens Longkanker Screenings Onderzoek Trial), Pan-Canadian Early Detection of Lung Cancer Study, and UK Lung Cancer Screening Trial [8,9], leading to recommendations for screening high-risk individuals and the implementation of LC screening programs in North America and Europe [10].

The efficiency of LC screening programs relies on the optimization of the risk-benefit ratio and ensuring high participation rates within individuals with a higher risk of LC. Efforts to improve screening uptake within these groups are necessary as the preliminary uptake rates from pilot programs in the United States, Canada, and Europe were suboptimal, with only 4% to 13% of eligible individuals enrolling in LC screening [11,12]. Recent scoping reviews identified the barriers to LC screening uptake, with the most important barriers being the lack of awareness of screening programs, perceived smoking-related stigma, socioeconomic difficulties, and fear of receiving a cancer diagnosis. Furthermore, individuals facing these barriers have concomitantly higher risk of LC [13,14]. For example, in Canada, the highest rates of LC are clustered among individuals living in rural areas with lower socioeconomic status, who also have lower access to screening programs for those geographical and socioeconomic reasons [15,16]. Strategies to reach those most socially disadvantaged groups are thus imperative to guarantee the efficiency of LC screening.

Survivors of LC are empowered with valuable knowledge on their disease's trajectory, from diagnosis to treatment. By sharing their stories within their communities, they can empower other individuals in similar health states. Due to a combination of both genetic and shared risk factors such as smoking or exposure to radon, individuals with a first-degree relative with a history of LC have a 2- to 3-fold higher risk of LC compared to the general population [17]. In a qualitative study, among individuals eligible for LDCT screening per the US Preventative Services Task Force, Roth et al [18] demonstrated that having friends or family members being treated for LC was a major motivator for being screened themselves.

So far, no previous studies have examined the impact of using survivors of LC as sources of education and referral for peers and family members who may be eligible for screening. We hypothesize that survivors of LC would be willing to refer family members or peers to LC screening, leading to a positive impact on the uptake of both the preventative and screening behaviors of the referred population. This study thus aims to determine the feasibility and acceptability of referral to LC screening through patients with LC referring their close ones to LC screening and to assess the early impact of this novel recruitment strategy on the uptake of LC screening and the patients' outcomes.

Objectives

We aim (1) to examine if patients with LC are willing to refer family members or close contacts to LC screening and if referral is associated with increased patient activation; (2) to examine if targeted enrollment of family members or close contacts of patients with LC for LC screening leads to increased engagement of individuals at higher risk of LC compared to referral through usual care; and (3) to examine the barriers and facilitators on the uptake of preventative strategies and LC screening, based on perceived genetic and clinical LC risks.

Methods

Study Design

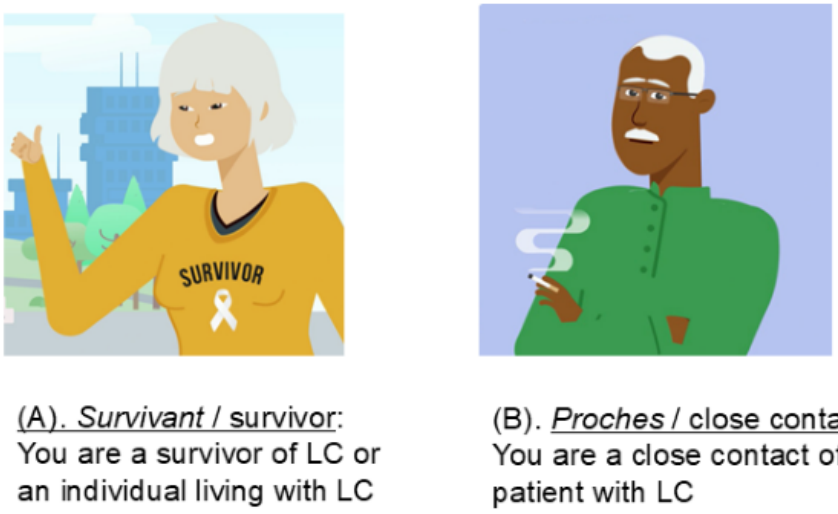
This is a prospective cohort study of 2 separate cohorts.

Participants Eligibility and Recruitment

Cohort 1

The first cohort includes biopsy-proven patients with LC aged older than 18 years at various stages in their disease trajectory, including those undergoing clinical surveillance. Participants in cohort 1 are recruited into this study either through discussion with trained research staff approaching them in the clinical settings or through posters or pamphlets available for viewing in the waiting areas of the clinics. The clinical settings where participants are recruited include the thoracic surgery clinic, pulmonary oncology clinic, pulmonary procedural suites, and chemotherapy infusion centers located at the McGill University Health Centre, one of the largest university hospitals in Montreal, Canada. Recruitment discussions and materials invite these patients to access this study's website [19]. The web page section directed at participants in cohort 1 (Figure 1A) includes educational material on the rationale for LC screening and the methods on how to approach and discuss LC screening with peers and family members.

Figure 1. Screenshot of the web page for survivors of lung cancer and their close contacts. LC: lung cancer.



Patients interested can consent and enroll through this study's website using digital or paper forms. Participants are invited to provide contact information (email or phone number) for the close ones they wish to refer for inclusion in the second cohort of our study. They are also advised to inform their close contacts that they shared their details with the research team and that their informed consent will be mandatory before participation.

Cohort 2

The second cohort includes participants being referred for inclusion into our study by the participants of cohort 1. Referred participants should be aged older than 18 years. Individuals with a personal history of LC are excluded. Referred participants are contacted by our research team through emails, phone calls, or through a recruitment pamphlet mailed for those without internet access. Participants are encouraged to access our study's website [19]. The web page section directed at cohort 2 (Figure 1B) provides general information on LC, its epidemiology, information on LC screening programs and the risk-based eligibility, and information on risk mitigation strategies such as smoking cessation and home radon testing. The enrollment of referred participants is also carried out with a submittable digital form available on this study's website. Participants lacking the digital literacy to enroll by themselves are contacted by the research team to enroll over the phone or through mailed material.

Once enrolled, participants have their 6-year risk of LC estimated with the PLCOm2012 (Prostate, Lung, Colorectal and Ovarian Cancer Screening Trial) risk model [20]. The risk prediction PLCOm2012 model has been extensively validated in previous studies [21,22]. The PLCOm2012 model has also shown adequate properties to discriminate patients with LC in a large cohort of Quebec smokers [23]. Moreover, data from the International Lung Screening Trial have shown that the PLCOm2012 model was more efficient compared to the US Preventative Services Task Force 2013 criteria to identify high-risk individuals to enroll into LC screening programs [24]. Participants who meet the eligibility criteria for the provincial LC screening program (ie, aged between 55 and 74 years and PLCOm2012 score ≥2%) are directed toward the provincial LC screening program to complete LDCT.

Website and Educational Material

This study's website [19] and educational material were developed based on 3 main pillars: accessibility, comprehensibility, and inclusivity. First, we succinctly presented information to account for the health literacy level of the targeted population. Individuals at high risk of LC and with lower education levels are significantly less likely to enroll for LC screening and engage in harm-reduction programs [25], underlining the importance of presenting information comprehensible for all. This study's website content was developed in collaboration with current patients with LC with written material created to be comprehensible at a 5th-grade reading level and above. Second, audiovisual contents are more easily comprehensible and with lower decisional conflict when used as a patient decision aid compared to information presented in textual format [26]. The audiovisual format is also more inclusive of participants with very low literacy. In collaboration with the digital media company Tactica Interactive [27], videos were produced to include the textual information of the website in audiovisual format. Lastly, for participants interested in enrolling in this study but lacking the digital literacy to enroll by themselves, information is provided on this study's website to contact this study's research staff (email address and telephone number).

Outcomes

The primary and secondary outcomes are summarized in Table 1.

Table 1. Study outcomes.

Outcomes	Methods
Primary outcomes	
Number of referred participants per individuals with LC[a] (survivors of LC)	• Questionnaire: cohort 1
Mean risk of LC in the referred population	• Questionnaire: cohort 2 • PLCOm2012 model
Secondary outcomes	
Proportion of participants eligible for the Quebec provincial LC screening program	• Questionnaire: cohort 2 • PLCOm2012 model
Proportion of participants eligible for screening who complete LDCT[b] screening within 18 months from referral	• Provincial health data
Proportion of participants who demonstrate interest in undergoing genetic testing to inform their LC risk	• Questionnaire: cohort 2
Proportion of individuals who demonstrate interest in a smoking cessation program among referred participants who are current smokers	• Questionnaire: cohort 2
Barriers and facilitators in the uptake of LC screening and preventative strategies, based on perceived LC risk	• Focus groups: cohort 1 and cohort 2
Number of visitors on the study's website for referred participants	• Google analytics data

[a]LC: lung cancer.

[b]LDCT: low-dose chest tomography.

Data Collection

Overview

Data are collected using the REDCap (Research Electronic Data Capture; Vanderbilt University) platform [28]. Participants are sent links to complete the web-based questionnaires.

Baseline data collected for all participants include sociodemographic characteristics (age, sex, education level, and ethnicity), health literacy, and smoking status. Health literacy is assessed with the 3-item Brief Health Literacy Screen [29] questions: "How often do you have someone help you read hospital materials?" "How confident are you filling out medical forms by yourself?" and "How often do you have problems learning about your condition because of difficulty understanding written information?" rated on 5-point Likert scales.

Cohort 1

For participants with LC (cohort 1), the phase of LC trajectory (investigative, treatment, or surveillance), tumor stage, performance status (as defined per Eastern Cooperative Oncology Group performance status grading), and their relationship to the referred participants are collected. The degree of self-empowerment they experienced by referring peers and family members for LC screening is assessed using the 13-item Patient Activation Measure (PAM) questionnaire [30]. The 13-item PAM questionnaire is a validated instrument to measure patient knowledge, skills, beliefs, and confidence for self-managing health. Patient activation stands as an important pillar of patient-centered care [31], and evidence has shown that being engaged and active in one's own care is linked to better outcomes [32]. For each participant with LC, the number of unique web page visits is quantified using Google Analytics, and the number of referrals per participant with LC is collected. For participants who refer family members only, supplementary questions are asked to explore the potential barriers: "I don't feel comfortable speaking with friends or close contacts about their health"; "I did not want my friends or close contact who smoke or used to smoke feel judged about their smoking"; "I did not want my friends to worry about their risk of LC"; "Speaking about LC screening and/or LC in general brings up negative emotions for me"; "I don't see or speak with my friends or close contacts very often"; and "This study did not help me feel more comfortable discussing the potential benefits of LC screening."

Cohort 2

For referred participants (cohort 2), the web-based questionnaire collects their known personal history of chronic obstructive pulmonary disease, prior exposure to radon or asbestos, smoking habits, and nicotine dependence using the Fagerström Tolerance questionnaire [33]. Data are used to calculate their PLCOm2012 six-year LC risk. The perceived risk of developing LC is assessed by asking "Compared with others your age, what do you think your chances are of being diagnosed with LC during your lifetime?" rated on a 5-point Likert scale. We also assess whether referred participants believe their risk is high or low due to genetics or smoking exposure and which they think is more important in increasing their lifetime LC risk. Generalized anxiety is assessed at baseline using the General Anxiety Disorder 7-item questionnaire (GAD-7) [34], and a question asks if they believe their anxiety is associated with their perceived risk of LC. We repeat the GAD-7 at 28 days after enrollment to assess the impact of the LC screening risk assessment on anxiety levels. Patients will be asked to give their

consent to access their provincial health records within the 18 months following their enrollment in this study. Extracted data will consist of whether these participants underwent LC screening via LDCT within 18 months after enrollment. No data about the results of the LDCT imaging will be extracted.

Both Cohorts

Focus groups are conducted to explore the perceptions of LC risk (perceptions of genetic risk based on polygenic scores vs perceptions of clinical risk based on PLCOm2012 scores) and their associations with engagement in LC screening and preventative behaviors (such as smoking cessation, radon measurement, and remediation). Qualitative questionnaires and clinical scenarios are presented to this study's participants of both cohorts to explore these themes and elucidate the most prevalent barriers and facilitators toward engagement in preventative behaviors and screening programs. Focus groups will be audio visually recorded and transcribed in verbatims.

Statistical Analysis

Quantitative Analysis

Participants with LC who refer at least one peer for participation will be compared to those who did not refer a peer for participation. To identify the predictive factors of referral, multivariable logistic regression will be used, adjusting for age, sex, educational attainment, health literacy, PAM score, and phase of LC trajectory. The dependent variable in the logistic regression will be referral by patients with LC. Using logistic regression, we will also examine if increased patient with LC activation is associated with increased odds of referral. Chi-square tests and 2-tailed *t* tests will be used for comparisons of categorical and continuous variables.

Referred participants who are eligible for LC screening will be considered as cases. A control group will be selected from patients who were either self-referred or referred by their primary care physician to the Quebec LC screening program and matched by age (1:1). To determine if participants in cohort 2 have a higher risk of LC than the controls, the mean PLCOm2012 scores will be compared using 2-tailed *t* tests in our cohort and in the Quebec LC screening program. The predictive factors of being eligible for LC screening and whether being referred by survivors of LC is associated with increased odds of being eligible will be examined using multivariable logistic regression. We will account for clustering among individuals referred by the same family member using a random effect model.

Spearman coefficients will be calculated to assess the correlations between the actual risk and the perceived risk of LC. Kruskal-Wallis tests will be used to compare actual and perceived risks of LC with different levels of anxiety. Odds ratios and their 95% CIs will be reported. All statistical analyses will be conducted using R (version 4.2.0; R Foundation for Statistical Computing).

Qualitative Analysis

Focus groups consisting of both cohorts will be conducted. For referred participants, the association between their perceived risk of LC based on both their genetic perceptions of risk and their actual clinical risk of LC and undertaking preventative behaviors and screening will be explored.

First, focus groups consisting of both cohorts will be audiovisually recorded and transcribed in verbatims. Responses will be labeled with descriptive codes by 2 independent analysts using NVivo (Lumivero). Interrater agreement and κ coefficients will be calculated to assess intercoder reliability and consensus reached through comparison and discussion within the panel group. The second stage will involve constant comparison, where codes and their content are compared across interviews to discern common and divergent themes. In the final stage, the data will be organized by searching for patterns, variations, and relationships between themes to characterize the entire dataset.

Sample Size

Preliminary data from the provincial LC screening program indicate that 40% of patients either referred to the program by their primary care physician or via self-referral meet the eligibility criteria for LC screening. The McGill University Health Centre receives approximately 800 new patients with LC annually, and the provincial LC screening program receives around 100 referrals each month. With a sample size of 194 referred participants, we will be able to detect a 20% difference in the rates of referral, with a power of 80% and an α value of .05.

Ethical Considerations

This study has been approved by the McGill University Health Centre's Research Ethics Board (MP-37-2023-9041). All participants will provide their informed consent before participation and will be informed that they can withdraw from this study at any time. Informed consent is obtained in either the English or French language through (1) internet-based web forms, (2) phone calls with trained research staff, or (3) completing consent forms in person when approached in one of this study's clinics. To ensure participants fully understand this study's goals when they enroll, three simple comprehension questions are asked being: (1) if this study involves medications (false), (2) if participants will be asked to complete questionnaires (true), and (3) whether they will be asked to refer family and friends (true). If participants have any questions or concerns regarding this study, they can contact our research team via telephone or email at any time (contact information is available on this study's website, pamphlets, and posters).

The REDCap platform used to collect data conforms to the General Data Protection Regulation and Canadian privacy legal and security standards. Access to the REDCap platform is secured with private log-ins and 2-factor authentication. The REDCap database is securely hosted on the Research Institute of the McGill University Health Centre server. No information will be released to unauthorized third parties without prior written approval of the participant except as necessary for monitoring by public health authorities or our institutional research board. Participants will not receive compensation for their enrollment in this study. Those participating in focus groups will be reimbursed on an hourly basis by the Research Institute of the McGill University Health Centre.

Results

Enrollment in the cohorts was conducted from June 2023 to January 2024, with participants being followed up through July 2025. Overall, we have enrolled 25 survivors of LC who have referred 84 of their close contacts to this study. The results of this study are expected to be reported at the end of 2025 through publications in peer-reviewed journals and presentations at relevant national and international conferences.

Discussion

Principal Findings

This paper describes the protocol of a pilot study examining the acceptability, feasibility, and impact of an innovative strategy of referral using patients with LC as advocates to increase the uptake of LC screening among individuals with high risks of LC. Increasing the uptake of LC screening for high-risk individuals is crucial as early detection of LC with LDCT has proved effective in reducing LC-related mortality by 20% and all-cause mortality by 7% [9]. LC screening with LDCT presents unique barriers that hamper the implementation and efficiency of these programs at the population level. In our study, survivors of LC receive education aimed at increasing awareness and enrollment in LC screening programs. We postulate that encouraging survivors of LC to empower and refer their close ones can not only have a positive effect on uptake rates for LC screening but can also improve patient activation and the psychosocial and clinical outcomes of patients with LC themselves.

LC is clustered among individuals with lower socioeconomic status who often also reside in rural areas [15,16,35,36]. The low screening uptake within these subpopulations has been well-established through prior LC screening programs [37]. Determining eligibility for screening is unique to LC screening and requires more extensive shared decision-making discussions between provider and patient compared to other cancer screening programs. As a result, primary care physicians need to dedicate a significant portion of a clinical visit to an LC screening discussion, which can be time-consuming. These subpopulations often face limited access to health care services while concomitantly having a high burden of clinical comorbidities. Thus, health care visits are both limited in frequency and in time as the other comorbidities may require further investigation. A recent study has shown that 67% of primary care physicians would not engage in LC screening discussions if they expected that the discussion would exceed 8 minutes [38]. Placing the referral burden entirely on primary care physicians appears to be unrealistic. These subpopulations with a higher risk of LC may benefit from this approach of encouraging survivors of LC to raise awareness within their social networks and reduce the burden placed on the providers servicing these groups.

As opposed to other cancer screening programs, such as those for breast, colon, and cervical cancers, there is a robust causal association between LC and “self-inflicted” behaviors in individuals at high risk [39]. This perceived smoking-related stigma has a negative psychosocial impact on high-risk patients, leading to self-blame, guilt, and hesitance in discussing their risk of LC with health care professionals and peers [40]. Smoking-related stigma impacts the patient-provider relationships as patients who smoke tobacco are often hesitant to provide an accurate disclosure of their smoking status to their provider and often demonstrate avoidance to discuss topics such as smoking cessation and investigations for ongoing respiratory symptoms. Prior evidence has also consistently shown that this smoking-related stigma leads to delays in seeking medical evaluation when experiencing the presenting symptoms of LC and limits patient involvement in treatment and survivorship care [41]. In turn, this smoking-related perceived stigma leads to hesitancy in seeking enrollment into LC screening programs. Ali et al [42] explored the barriers among high-risk individuals from enrolling in the UK Lung Cancer Screening Trial and determined that current smokers were significantly less likely to enroll in LC screening than exsmokers or never smokers. Compared to nonsmokers, current smokers were more fatalistic and less likely to consider LDCT for LC screening and also less likely to believe early detection would improve their chances of survival [43]. When exploring methods to mitigate the burden of smoking-related stigma, it emerges that current smokers experience the most empathy and can express their emotions more comfortably within support groups made up of other current smokers with similar “lived experiences” [44]. Using preexisting relationships as a forum for open communication and advocacy can therefore be fruitful. Perceived risk of LC can be an important motivator to help balance the negative effects of both practical and emotional barriers and engage in LC screening programs. Interestingly, the perceived risk of LC was positively correlated to the estimated risk of LC in participants from the Pan-Canadian Early Detection of Lung Cancer Study [45]. Furthermore, the perceived risk assessment of LC was associated with higher self-referrals, implying that encouraging individuals to both acknowledge and assess their own perceived risk of LC can be a significant motivator to enroll in screening programs. Using preexisting interpersonal relationships between survivors of LC and close contacts can be fruitful in establishing a forum of open communication to share lived experiences.

This study also aims to show that empowering survivors of LC to engage and motivate close contacts in LC screening and harm-reduction initiatives may have a positive impact on their own clinical outcomes and survivorship. In a recent qualitative study among survivors of LC, the concept of “passing it on”—referring to survivors’ experience with becoming and acting as educators for others—was identified as an important way to address their personal perception of the stigma of LC [46]. Survivors of LC placed significant value on the need to share their stories with their communities, to help family members learn about LC and navigate the health care system. In engaging in a conversation with close contacts regarding LC, they can express how the disease impacted their own well-being from the psychosocial stressors it placed on their mental health, the consequences on their interpersonal relationships, or the physical problems they face daily. Expressing these emotions to their social network may help them feel heard and understood, and in turn, their social network may be more aware and caring of the survivor’s well-being and needs.

Limitations

This study should be interpreted considering the following limitations. First, the recruitment is conducted in clinical settings based on patients receiving in-person care, either through approaching patients with LC directly or via self-referral to our study's website after viewing study-related posters or pamphlets in the waiting areas of clinics. Patients who receive telemedicine follow-up care (such as teleconsultations with health providers and real-time counseling) are then less likely to enroll in this study. This recruitment strategy may introduce a selection bias with a selection of participants in better health states who can participate in this study, living closer to this study's urban health care center, or with a larger social network that supports them in their travel to this study's site. However, this bias appears limited as telehealth for LC care remains marginal at our institution, as also stated in a review of telehealth in LC during the COVID-19 pandemic [47].

Second, when potential participants are approached in person or view our study's recruitment material in the clinics, those accompanying them are exposed to the same discussion and material. Therefore, the referred cohort may be biased to preferentially include the first-degree relatives of survivors of LC as these are the close contacts most likely to accompany patients to their clinical appointments. Friends or more distant relatives of survivors of LC may ultimately be underrepresented in the referred cohort.

To finish, this study is conducted among a cohort of residents in Quebec, where public health care expenses are covered for citizens. The generalizability of the results is limited to similar populations and health care systems, and caution is needed when generalizing results to other Canadian provinces or countries.

Future Directions

Primary care health providers and mass advertising are the current methods of recruitment to LC screening programs. In Canada and the United States, most participants who are eligible for LC screening are being referred to screening programs by a health provider. Barriers related to health care services access then limit the uptake of LC screening, notably in Canada, where approximately 15% of patients are unattached to a regular primary care provider [48]. This lack of providers per population is even worse in Quebec and is expected to worsen with the current population ageing. Developing new strategies to identify and enroll high-risk individuals into LC screening programs is crucial to ensure the success of implementing those programs and, in the end, to improve the patients' outcomes.

Conclusion

Early diagnosis of LC can improve survival rates, and strategies are needed to engage high-risk individuals in LC screening. We believe that patient advocacy has an important value and could be harnessed to identify high-risk individuals to participate in LC screening. Patients with LC have a unique role to play as advocates, and by sharing their lived experience, they could improve the motivation and engagement in LC screening and preventative strategies for their close ones. This study will provide evidence on the feasibility, acceptability, and early impact of this novel referral strategy. The results will be of interest for public health programs and policies, as well as for clinicians, patients facing LC, and their close ones.

Abstract

Background: Diabetes distress (DD) is a common emotional response to living with diabetes. If not addressed, DD can have negative impacts on diabetes management, including the progression to mental health conditions such as depression and anxiety. Routine screening and treatment for DD is recommended, with primary care being an ideal setting given that the majority of people with diabetes receive their diabetes care from primary care providers. However, consistent screening of DD does not routinely occur in primary care settings. Research is needed to understand how to effectively and feasibly integrate DD screening and treatment into routine diabetes care.

Objective: This study aims to (1) design and implement individualized technology-supported DD workflows, (2) evaluate the primary outcome of determining the acceptability and feasibility of integrating technology-based workflows to provide treatment for DD, and (3) evaluate the secondary outcomes of changes in DD, depression, and anxiety (baseline, 3 months, and 6 months) in patients receiving screening and personalized treatment.

Methods: In total, 30 English and Spanish-speaking primary care patients with either type 1 or type 2 diabetes will receive screening for DD during clinical visits and subsequent support from an artificial intelligence (AI)–based health care chatbot with interactive tailored messaging. In addition, the use of electronic consultation with a specialist or referral to a behavioral health provider could occur depending on the severity and source of DD. The use of electronic consultations allows providers convenient and timely asynchronous access to a range of specialty care providers. Health outcomes will be measured through changes in validated screening measures for DD, depression, and anxiety. Digital outcomes will be measured through surveys assessing user experience with technology and system usability, and by system performance data. Qualitative data on acceptability and satisfaction with the clinical workflows and technological interventions will be collected through interviews with patients and clinical providers. Descriptive statistics will summarize quantitative outcome measures and responses to closed-ended survey items, and rapid thematic and content analysis will be conducted on open-ended survey and interview data.

Results: Workflows for screening and treating DD have been approved and clinical staff have received training on the process. Electronic surveys for screening measure collection have been created. Data from visit screeners will be entered into the electronic medical record during the medical appointment. Recruitment will begin late June-July 2024.

Conclusions: This study is expected to demonstrate the feasibility and acceptability of integrating individualized workflows for DD into primary care. Improving clinical and digital interventions for addressing DD in primary care can provide alternative

care options for busy clinical providers. This study is intended to deliver whole-person diabetes care to people with diabetes within a primary care setting.

Introduction

Backgrounds

In the United States, diabetes is the eighth leading cause of death [1], with an estimated 38 million people living with diabetes [1]. This chronic condition requires consistent care for effective management to help avoid poor health outcomes [2]. In fact, it is estimated that people with diabetes spend over 8000 hours per year managing their diabetes outside of medical settings [3]. Diabetes distress (DD) is the disruptive and demanding emotional response to these daily demands of living with diabetes [4]. This emotional burden associated with diabetes is pervasive, with one in 4 people experiencing severe DD [4]. DD is associated with negative impacts on engagement in self-care and self-management behaviors, medication adherence, and exacerbation of mental health conditions [5].

Accordingly, the American Diabetes Association recommends that diabetes care be delivered by an interdisciplinary team with a person-centered approach [6] and that it includes regular screening for and monitoring of DD in routine diabetes care for people with diabetes with treatment for DD to be provided by practitioners with specific training to address DD [5]. In addition, a recent white paper by the National Committee for Quality Assurance suggested having a variety of pathways to tailor DD treatment for individuals who screen positive for DD by involving relevant health care professionals and care modalities [7]. Yet, in everyday clinical settings, DD is infrequently identified and only a small number of people with diabetes are asked about how diabetes affects their life by their health care professionals [8]. As primary care is where most people receive their diabetes care, it is a crucial setting within which to assess and address DD [9,10]. However, there remains a lack of consistent screening for DD within primary care, which likely contributes to the emotional burden of diabetes going undetected and untreated [4,11]. Thus, even though DD is highly prevalent and there exist well-validated measures to assess for DD, there is a significant knowledge gap in best practices for implementing DD screening and treatment interventions systematically in primary care. Intervention studies specifically aimed to treat DD have largely been conducted in specialty care settings and not in primary care [5]. Further, among health care providers there remain a lack of awareness of DD and a shortage of trained health care providers who feel adequately equipped to assess for DD and intervene when a patient is experiencing DD [12]. Consequently, there is a clear need to develop scalable and feasible workflows and interventions that can be easily incorporated into primary care settings. Implementing assessment and treatment for DD is a crucial part of incorporating the psychological and emotional aspects of living with diabetes into routine diabetes care. It is part of intentionally incorporating the often-forgotten about psychological and emotional aspects of diabetes care that comprise whole-person care.

Clinical decision support systems (CDSS) have proven effective in prompting providers to deliver recommended care [13]. In general, CDSS improves health care delivery through the use of technology to enhance clinical decision-making, sometimes even using data and observations that are normally unobtainable by providers alone [14]. Clinical decision support technology leverages electronic health records (EHRs), medical knowledge databases, and algorithms to provide patient-specific recommendations, thus enabling providers to make more informed decisions [15]. Benefits can include a reduction in medical errors, enhanced patient safety, improved decision-making, and scalability [15]. The recent integration of artificial intelligence (AI) into health care technology has led to the classification of CDSS as either knowledge-based systems using traditional technology frameworks, or nonknowledge-based systems to indicate the use of AI to transform data into information for the user [16]. Recent reviews of studies that focus on the implementation of nonknowledge-based CDSS in diabetes care have demonstrated significant improvements in patients' blood glucose, blood pressure, and lipid profiles in 71%, 67%, and 38% of the studies, respectively [16]. Technology-based referrals to specialty care electronic consultation (eConsults) have been shown to successfully augment and support care provided in the primary care setting without requiring patients to leave their medical home. Curated health chatbots are an interactive, patient-focused approach to providing patients with important information in an empathic manner at the time of need and point of inquiry, without requiring appointments or waiting for return calls from highly burdened health care professionals. While CDSS can promote diabetes care by facilitating patient self-management, it is hoped that further emerging technology will allow for more efficient and effective management for many people living with diabetes [16].

Research examining the treatment of DD indicates that when DD is specifically targeted that it can be improved, which is important given that DD is known to worsen over time if it is not addressed [17]. eHealth interventions providing support for DD have shown promising results. For instance, a systematic review and meta-analysis concluded that eHealth interventions were effective at significantly reducing DD and that these reductions occurred across a range of different eHealth interventions (eg, telehealth, web-based, and mobile health) [18]. While the eHealth interventions were found to reduce DD, the authors of the meta-analysis indicate the results be

interpreted with caution because of the low number of studies included in the review [18]. Additional research delivering DD interventions through flexible and affordable eHealth avenues requires further exploration. This study is intended to build upon previous research suggesting that digital interventions could provide an avenue for treating DD.

Objective and Aims

The primary objective of this study is to assess the feasibility and accessibility of using health IT integrated into primary care workflows to improve screening and treatment for DD. This project will examine the technical and operational feasibility, patient and provider experience, and behavioral health outcomes of a new technology-supported workflow to conduct screening for DD and provide follow-up treatment by a multidisciplinary team in a primary care setting.

The aims of this pilot study are to (1) design and implement individualized technology-supported DD workflows, (2) evaluate the acceptability and integration of technology-based workflows to provide treatment for DD, and (3) evaluate the change in DD (baseline, 3 months, and 6 months) in patients receiving screening and personalized treatment for it. Symptoms of anxiety and depression will also be evaluated. The primary outcome of this study is to determine the feasibility and acceptability of integrating individualized workflows for DD into primary care.

Methods

Intervention Implementation Process

Preimplementation

The principal investigator (PI) conducted a 1-hour practice-level training session for clinical team members including primary care practitioners, medical assistants, administrative staff, and behavioral health providers. The training topics included an orientation to DD, person-first language when working with people with diabetes, a review of the DD screeners, and a brief introduction on how to support patients experiencing DD. This training was informed by expertise from clinical experts on DD. The training also reviewed the clinical workflow for this study and provided the opportunity for staff and providers to ask questions about the protocol.

Implementation

Patients will complete informed consent to participate in the research study. After being consented, they will attend a scheduled diabetes-specific visit with their primary care physician (PCP). The workflow for the diabetes-specific visit is presented in Figure 1. At clinic check-in, front desk staff or a medical assistant (MA) will provide the patient with the appropriate assessment to complete based on their diagnosis, either the Type 1 Diabetes Distress Assessment System (T1-DDAS) [19] or the Type 2 Diabetes Distress Assessment System (T2-DDAS) [20]. Clinic staff will also provide the patient with the Patient Health Questionnaire-9 (PHQ-9) [21] to assess for symptoms of depression and the Generalized Anxiety Disorder-7 Scale (GAD-7) [22] to assess for symptoms of anxiety. The PHQ-9 and GAD-7 questionnaires are already part of the rooming process and thus not an addition to the established workflow. During the visit rooming process, the MA will enter the results of the screeners (eg, PHQ-9, GAD-7, T1-DDAS, or T2-DDAS) into the flowsheets in the EHR. The EHR used in this study is Epic. Refer to Table 1 for measure descriptions.

Figure 1. Primary care diabetes distress screening and treatment workflow. AI: artificial intelligence; eConsult: electronic consultation; MA: medical assistant; PCP: primary care physician.

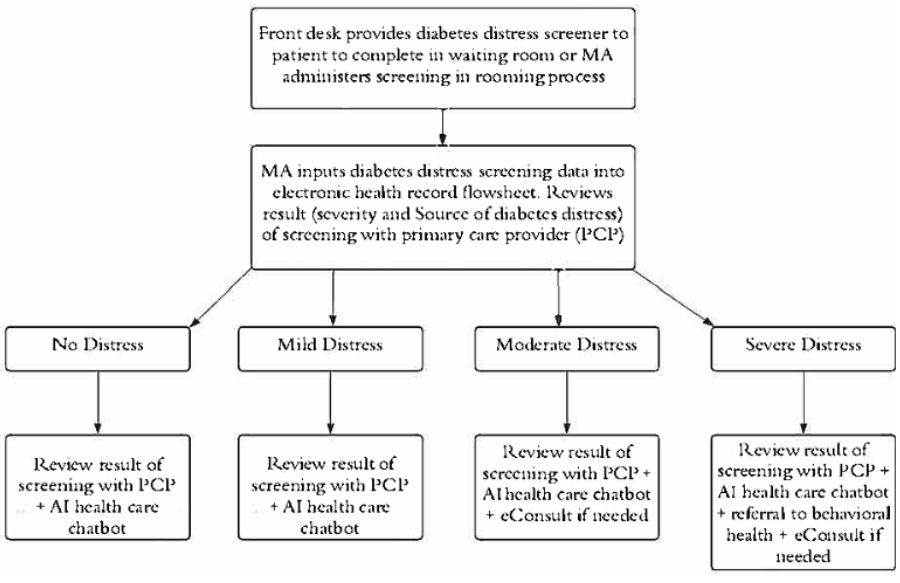

Table 1. Diabetes distress pilot study measures.

Measure	Description	Collection time points
T1-DDAS[a] [19]	• 30 items; 5-point Likert scale. • Assesses the emotional impact of living with type 1 diabetes. Determines the severity and Source of DD[b]. The sources of DD indicate which aspects of living with type 1 diabetes are creating challenges. • The T1-DDAS was validated with adults with type 1 diabetes and has adequate internal consistency on the Core Scale (α=0.95) and Source Scales (α range=0.53-0.88).	• Baseline (at initial clinic visit) • 3 months post screening • 6 months post screening
T2-DDAS[c] [20]	• 29 items; 5-point Likert scale. • Assesses the emotional impact of living with type 2 diabetes. Determines the severity and source of DD. The Sources of DD indicate which aspects of living with type 2 diabetes are creating challenges. • The T2-DDAS was validated on people with type 2 diabetes including both insulin and noninsulin users. Adequate reliability for the Core scale was demonstrated by alpha statistics for noninsulin users (α=0.94) and insulin users (α=0.95). The Core Scale has statistically significant construct validity with the 7 Source Scale criterion variables (all, P<.001).	• Baseline (at initial clinic visit) • 3 months post screening • 6 months post screening
PHQ-9[d] [21]	• 9 items; 4-point Likert scale. • Brief screener assessing symptoms of depression. Amongst a primary care population, the internal reliability was excellent (Cronbach α=0.89) [21]. • The PHQ-8[e] omits question 9 on the PHQ-9, which asks respondents about thoughts of self-harm or death.	• Baseline (at initial clinic visit) • 3 months post screening • 6 months post screening
GAD-7[f] [22]	• 7 items; 4-point Likert scale. • Brief screener assessing symptoms of anxiety. The reliability of the weighted scoring of the items on the GAD-7 has been estimated at 0.91 with internal consistency estimated at 0.92.	• Baseline (at initial clinic visit) • 3 months post screening • 6 months post screening
UMUX-lite[g] [23]	• 2 items; 7-point Likert scale. • Brief measure assessing participant's experience of technology (ie, AI[h] chatbot). Internal reliability estimates for the UMUX-lite range from 0.81-0.87).	• 3 months post screening
System Usability Scale [24]	• 10 items; 5-point Likert scale. • Brief measure assessing the usability of the technology (ie, AI chatbot). Research demonstrates an average reliability using coefficient alpha to be 0.91. Concurrent validity ratings range from 0.22 to 0.96.	• 3 months post screening
Technology Use Assessment [25]	• A 12-item survey assessing user's comfort with and routine use of technology in daily life.	• Baseline (at initial clinic visit) • 3 months post screening
Practice demographics	• Clinic data (ie, number of patients with diabetes, clinical staff, and roles).	• Baseline
AI Chatbot System Performance Metrics	• Engagement and operational metrics recording during the period of system use.	• 3 months post screening
eConsult[i] System Performance Metrics	• Operational metrics recorded during system use from study-specific standardized templates, including the number of patients receiving eConsults, which specialists were eConsulted, what were the consult questions, the time to respond by the specialist, and did the patient follow up with the specialist if referred.	• 3 months post screening • 6 months post screening
Patient demographics	• Includes age, race, ethnicity, gender, sexual orientation, health care insurance type, and comorbid medical diagnoses if applicable.	• Baseline
Qualitative data-clinical staff	• Semistructured interview and survey questions. • Questions assessing experience implementing new workflows and screening patients for DD from clinical staff. A trained qualitative researcher will conduct interviews over the phone or video call according to the semistructured interview guide.	• 3 months post screening

Measure	Description	Collection time points
Qualitative data-patients	• Semistructured interview and survey questions. • Questions assessing participants' experience of being screened for DD, using an AI chatbot, and being referred to targeted providers using eConsults. A trained qualitative researcher will conduct interviews over the phone or video call according to the semistructured interview guide.	• 3 months post screening
Diabetes Distress Provider Time Survey	• Survey form tracking the types of tasks and amount of time spent on tasks related to workflow.	• Primary care physician completes following each participant encounter.

[a]T1-DDAS: Type 1 Diabetes Distress Assessment System.

[b]DD: diabetes distress.

[c]T2-DDAS: Type 2 Diabetes Distress Assessment System.

[d]PHQ-9: Patient Health Questionnaire-9.

[e]PHQ-8: Patient Health Questionnaire-8.

[f]GAD-7: Generalized Anxiety Disorder-7 Scale.

[g]UMUX-lite: Usability Metric for User Experience-lite.

[h]AI: artificial intelligence.

[i]eConsult: electronic consultation.

If there is a negative screen on the T1-DDAS or T2-DDAS, the MA will communicate this to the PCP. The PCP will then provide validation and encouragement based on the skills they learned in the team training. The patient and provider will then collaboratively determine which aspects of DD the patient would like to start to receive information and guidance on from the AI chatbot. Even though the patient is not currently experiencing DD, it is theorized that receiving coping skills and other information from the chatbot will help mitigate future distress. The PCP will send these identified areas through the EHR to the research team so they can send push notification from the AI chatbot to the patient's cell phone in these specific areas.

If there is a positive screen on the T1-DDAS or T2-DDAS, the MA will communicate the severity and source of DD to the PCP. On the T1-DDAS there are 10 sources of distress including financial worries, interpersonal challenges, management difficulties, shame, hypoglycemia concerns, health care quality, lack of diabetes resources, technology challenges, burden to others, and worries about complications [19]. The T2-DDAS indicates specific areas or sources of distress that people with type 2 diabetes may experience [20]. On the T2-DDAS there are 7 sources of distress including hypoglycemia, long-term health, health care provider, interpersonal issues, shame or stigma, health care access, and management demands [20]. The research team has developed specific content areas for sources of distress for both the T1-DDAS and T2-DDAS meant to provide targeted and individualized material to support the needs of patients delivered through the AI chatbot. The study design for levels of DD is the same for type 1 and type 2 diabetes. There are three levels of distress on the T1-DDAS and T2-DDAS: (1) little or no distress, (2) moderate, and (3) high. The levels and source of distress will guide clinical decision-making and intervention pathways that are selected. For each level of distress, the PCP will provide validation and support to patients based on skills they learned during the team training. For little to no distress on the T1-DDAS or T2-DDAS, the PCP will discuss the top 3 sources of distress with the patient and the patient will then obtain a push notification on their cell phone from the AI chatbot on these specific areas. For moderate levels of DD on the T1-DDAS or T2-DDAS, the provider will discuss the main sources of distress with the patient and determine if an eConsult or referral might be indicated based on the needs of the patient in addition to the AI chatbot. An eConsult to the following specialists can include endocrinology, clinical pharmacy, social work or care management, diabetes education, and behavioral health. All these specialty providers are available in the primary care practice where this study will occur. For high levels of DD on the T1-DDAS or T2-DDAS, the PCP will collaboratively determine which areas of distress would be more relevant for the patient to receive from the AI chatbot and determine if an eConsult to any of the above-stated specialties would be indicated and then subsequently discuss and provide a referral to behavioral health if needed. Integrating eConsults into the treatment process allows the PCP to ask a specific clinically oriented question about their patient and obtain an asynchronous response from the specialist. Thus, allowing for shared care decisions between the PCP and specialist without having to refer the patient to an in-person appointment and leading to a possible delay in care [26].

AI Chatbot Intervention

All patient participants, regardless of whether they have DD or the severity of the DD, will be enrolled to receive text messages from the AI chatbot. The AI chatbot will provide education on DD, normalization of DD, suggestions for solution-focused coping strategies, and information provision on patient resources and support. For patients not reporting symptoms of DD, chatbot messaging will be seen as a preventative measure to provide information and build awareness of DD should this arise in the future. For patients reporting DD, the AI chatbot will be seen as a resource to provide suggestions for coping strategies connecting to local support resources and psychoeducational material. Following a collaborative discussion with their PCP on the sources of DD that they would like to receive support on, they will obtain a push notification with the top 3 identified areas of distress. Following this initial conversation, the AI

chatbot will deliver a 12-week curriculum on topics specifically related to DD and the sources of DD (for either the T1-DDAS or T2-DDAS). Participants will receive 3 scheduled text messages on the curriculum content per week throughout the 12 weeks to their cell phone. In between scheduled messages, participants can initiate interaction with the AI chatbot through the text message chain if they choose. Development of the AI chatbot content was overseen and reviewed by DD expert consultants. Participants will not receive messages on topics unrelated to DD or content that was not developed and approved by the study team. In other words, participants will not receive content that is generated by the system or off-topic.

The technology will facilitate error-free delivery of messages via text to user cell phones using an AI chatbot that deploys natural language processing for highly precise communications. We will maximize chatbot precision so that users are more often sent a response from our system that matches the intent of their query. Specifically, we have developed and categorized anticipated "intents"—that is, the specific topics we believe people want to learn or ask about DD and self-management, along with 25-50 variations on ways to ask each question. Question variations allow the system to have enough initial data to learn how to interpret user questions, tolerate misspellings, and recognize the underlying intent of each question. When the system cannot match a response to the question intent, it reverts to a fixed choice (called a "pick list") of responses, for example, "I think you are asking about one of these topics: (1) Cost of diabetes medicine, (2) Cost of treatment, (3) Where to find medications near me. Please type the number corresponding to the topic you wish to explore or try your question again." We rely on data augmentation techniques to create and continuously update a robust library of questions and question variations that the system draws on to generate precise and consistent responses to user queries. We do this through "lemmatization" and "stemming," both processes that group the different inflected forms and stems of a word so they can be analyzed as a single item (eg, runs, run, and running are all forms of the word "run" and thus "run" is the lemma, or root, for all these words). After doing this preprocess work on our prototype dataset, we use Multinomial Naïve Bayes, Linear SVC, and multiclass regression algorithms to anticipate prediction accuracy in correctly matching a response to a question.

eConsult Intervention

The EHR-embedded eConsult system provides a streamlined and timely consultative process that has been shown to improve the quadruple aim-related outcomes and to enhance communication and coordination of care between primary care providers and specialists regarding specific patient areas of concern [27]. The PCP sends a focused question with relevant subjective and objective patient information to a specialist through the eConsult system. The specialist then reviews pertinent information from the EHR and responds to the PCP with guidance and care support with recommendations regarding diagnosis, treatment, and follow-up plans.

Following the patient-specific interaction with the PCP in the diabetes-specific visit, an eConsult with different specialties (indicated above) will be placed through the EHR. The eConsult system is already an established part of routine clinical care since it is embedded in the EHR. eConsults will be used to assist with clinical decision-making and obtaining specialized knowledge and support from various health care professionals based on the specific source of DD. If the patient requires additional support, the eConsult system will allow for a conversion to an in-person or telemedicine visit with the needed specialty.

Poststudy Intervention

Poststudy time point 1 (3 months following initial screening): the research assistant (RA) will send patients a link to complete the screening measures through the patient portal. The screening measures completed at 3 months post screening will assess for DD, symptoms of depression and anxiety, and technology use (refer to Table 1). Outside the clinical setting, the PHQ-8 will be administered instead of the PHQ-9 [28]. The technology measures include the Usability Metric for User Experience-lite (UMUX-lite) [23], System Usability Scale (SUS) [24], technology use assessment, AI chatbot system performance metrics, and eConsult system performance metrics. Qualitative data will be collected at 3 months post screening. Table 1 includes the measures and time points for data collection. The RA will call each patient to conduct a semistructured interview and ask survey questions if patients have not completed surveys electronically within 1 week. The qualitative interview will include questions about participating in screening for DD, experience with the AI health care chatbot and being referred to specialty providers through eConsults. Further, the RA will obtain qualitative data through semistructured interviews and survey questions with 6 clinical staff and both primary care providers who participated in the study. The questions for health care staff or providers will assess their time spent and experience implementing workflows that screen for DD and offer treatment options through provider support, AI health care chatbot, and eConsults.

Poststudy time point 2 (6 months following initial clinic visit): the RA will send patients a link to complete the screening measures through the patient portal at the 6-month time point. The screening measures completed at the 6-month time point are included in Table 1. If patients do not complete the surveys electronically within 1 week, the RA will call to follow up and administer surveys via phone.

Study Design

We propose a pilot clinical trial to be conducted at a suburban multidisciplinary family medicine practice in an academic medical setting. The study is designed to provide feasibility and acceptability data for the development of DD-based screening and treatment using digital and clinical interventions.

Participants

Up to 30 adult English- or Spanish-speaking patient participants with a diagnosis of type 1 diabetes or type 2 diabetes who receive their diabetes care from 2 PCPs at the primary care practice will be enrolled in the study. For Spanish-speaking participants, Qualified medical interpreters are used for translation services that are provided at no cost at the clinic. Qualified medical interpreters are part of routine medical

services. A sample size of 30 is the minimum generally recommended if the underlying population is expected to have a normal distribution [29]. It is also double the minimum recommended number of persons to be included in human factors and usability testing for medical devices, which allows for loss to follow-up or nonparticipation by some individuals in data collection activities [30].

Clinic staff engaged in the new workflows for DD will also be invited to participate in surveys and interviews about their experience with the technology-supported intervention following the completion of the study. Inclusion and exclusion criteria are mentioned in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Age at time of consent 18-89 years;
- Diagnosed with type 1 or type 2 diabetes;
- Patient at the primary care clinic;
- Able to understand English or Spanish;
- Willing and able to sign the informed consent form;
- Willing to be contacted by the study team through the patient portal, phone, or text to complete study measures;
- Ability to reliably send and receive text messages.

Exclusion criteria

- Participation in another study that might interfere with participation in this study;
- Unable to follow the study procedures for the duration of the study or is deemed unacceptable to participate in the study per principal investigator judgment;
- Participant or participant's immediate family member is an employee of the health care chatbot company providing services for the study;
- Planning to move in the next 6 months;
- Planning to change primary care practices in the next 6 months.

Data Collection and Outcome Measures

Both qualitative and quantitative methods will be used to assess study outcomes at the patient level, practice level, and technology system level. Patient-level health outcomes include DD, depression, and anxiety measured at baseline, 3 months, and 6 months using the T1-DDAS or T2-DDAS, PHQ-8, and GAD-7. The T1-DDAS was selected to be used in this study because it is the most updated and comprehensive assessment tool for determining DD in people with type 1 diabetes. The T2-DDAS was used as a measure because it is the most comprehensive and contemporary survey tool to determine DD among people with type 2 diabetes. The PHQ-9 and GAD-7 are commonly used brief screeners in primary care [21,22]. User experience with technology will be assessed through the administration of the UMUX-lite at 3 months, the SUS at 3 months, and a technology use assessment at baseline and 3 months. The SUS is widely adopted as a reliable measure of usability across technology types and in a variety of populations. The UMUX-lite represents a user experience-focused usability measure that has proven to correlate well with the SUS in overall usability and is appropriate for use with health technologies. The technology use assessment was previously developed by a member of the research team for use in discerning technology adoption and use patterns with primary care patients [25]. In addition, qualitative data from interviews and responses to open-ended survey items will be collected from practice staff, PCPs, and patients to determine the acceptability and feasibility of implementing screening and technology-supported treatment for DD. Interviews will be conducted by a trained qualitative analyst according to a semistructured interview guide, recorded and transcribed using artificially intelligent transcription software (Otter.ai), with human adjudication of transcripts to avoid error (refer to Multimedia Appendices 1 and 2 for interview guides). Positive experiences with the digital interventions will be determined by participant responses to the qualitative interview questions. Further, PCPs will complete the DD Provider Time Survey to track activities and time spent on workflow tasks. Acceptability with the eConsults will be evaluated by standard data collection protocols in the EHR. eConsult data will capture the patient-specific inquiries and requests from PCPs and responses given by specialists. AI chatbot performance data will be collected from the chatbot system and used to evaluate engagement with the AI chatbot according to the People at the Center for Mobile Application Design framework [31]. Table 1 lists the measures to be collected for this study in detail.

A number of the validated measures have existing published versions in both English and Spanish including the T1-DDAS, T2-DDAS, PHQ-8, and GAD-7. For outcomes measures including the UMUX-lite, SUS, and the technology use assessment that did not have an available version in Spanish, we had a system-verified language translator assist in translating these materials from English into Spanish.

Data Analysis

Quantitative Data Analysis

The study team will use standard statistical packages (eg, R [R Foundation for Statistical Computing]) to conduct data analysis. Descriptive statistics (means, SD, frequency distributions, and proportions) will be used to summarize baseline patient characteristics, clinical and behavioral outcomes, and other quantitative outcome measures and responses to closed-ended survey items. As a feasibility study, it is not powered for inferential analyses or power analyses, but the results are expected to inform future work. Based on results from similar studies, a 60% (18/30) threshold will be used to determine technical and operational feasibility and user acceptability, that is, 60% (18/30) of participants remain engaged with the technology solutions throughout the duration of the study, and 60% (18/30) of participants report positive experiences and satisfaction levels with the program overall [32]. The study has been planned to minimize the amount of missing data overall and thus anticipates the use of maximum likelihood methods to estimate missing values for statistical analysis. We will use this data to calculate an effect size to power a larger study.

Qualitative Data Analysis

This study's acceptance is determined by patient and health care provider user experience through interviews, clinical team member feedback, and responses to user experience surveys. An overall positive rating on tailored survey items or positive themes identified from qualitative data represents acceptability for this study. The program will be deemed acceptable among participants overall if 60% (18/30) or more of participants report positive ratings and themes. Qualitative analysis of open-ended survey data and interview data will be conducted using rapid thematic and content analysis to assess user experience by identifying and exploring common topics and themes that emerge from participants' responses. The rapid analysis will be informed by the Consolidated Framework for Implementation Research and will use a dual-read approach and matrix classification method with 2 reviewers, who will discuss classification decisions to achieve consensus [33]. Enough participants are included in the planned sample size to ensure qualitative analyses will reach thematic saturation overall.

Ethical Considerations

Approval and Study Consent

This study has been approved by the Colorado Multiple Institutional Review Board (protocol #24-0186). The PI and primary care providers will assemble a patient list from the Diabetes Registry in the EHR and send this to the RA. The RA will outreach to potential participants via the patient portal in the electronic medical record, by email, and by phone using scripted language to invite patients to participate. As part of enrollment, the patient will opt-in to receive text messages from the AI chatbot. If a patient declines to participate, this will be documented for evaluation purposes so that the same patient is not reapproached in association with a future scheduled clinic visit. If the patient expresses interest in participating, the research team will complete informed consent and study enrollment before a future clinic visit. As part of the consent process, patients will agree to a chart audit by the research assistant within 4 weeks of their initial visit to ensure all initial measures are completed.

Safety and Potential Risks

The procedures used in the proposed research study pose no greater than minimal risks to patients and practices involved in the study. The AI chatbot is a nongenerative system meaning that it does not independently develop content. The primary clinical team has generated the content and reviewed it with expert consultants on DD. Further, no Protected Health Information is requested from patient participants or sent from the AI chatbot. The AI chatbot operates on HIPAA (Health Insurance Portability and Accountability Act)-compliant infrastructure under a business associate agreement between the health care system where this study is taking place and the AI chatbot company. During the course of this study, patients could experience worsening of their symptoms of DD as a result of interacting with the AI chatbot and discussing the emotional and psychological aspects of diabetes with their medical provider. However, we do not expect that these are likely risks for patients participating in the study in part because messages provided by the chatbot have been prewritten and approved by clinicians and the chatbot is not using in-the-moment generative AI technologies to respond, such that it cannot create separate content or go off-script. If these concerns arise through a review of messages and chatbot interactions or as reported by patients, the PI will review and refer as appropriate to other health care providers for follow-up. The clinic where this study will take place has fully staffed behavioral health providers integrated into the practice who will be available to discuss any concerns that providers and patients may experience.

Compensation

Patient participants will receive a small financial incentive at 2 separate time points. They will receive two US $25 gift cards (totaling US $50). The first US $25 gift card will be given after enrollment in the study and completing the first set of surveys. The second US $25 gift card will be given after completing the 3-month postscreening questionnaires. Providers will receive no direct financial incentive. The primary care clinic where this study will take place will receive a financial incentive for participating in and attending the team training.

Results

Implementation Status

The PI met with clinic leadership to describe the project and obtained buy-in from the team. Workflows were developed that outline study design and patient flow (refer to Figure 1). The PI conducted a team training with the clinic where this study will take place as well as met with the PCPs that will be participating in this study to provide education and training on DD, an overview of validated measures for DD (eg, T1-DDAS and T2-DDAS) and conversational tools that can be used to support people with diabetes and DD.

T1-DDAS and T2-DDAS scoring were incorporated into the EHR through an EHR build. The PI collaborated with the EHR administrative team on requesting the 2 DD measures be

incorporated into the EHR. This was done during the annual optimization and training period, namely the Epic Sprint program [34]. This program is intended to improve the users' experience of the EHR and assist with updates and requests. The DD measures were built into the EHR as flowsheets so that data could be entered and scored in the EHR.

Chatbot content specific to DD was developed with assistance from 2 leading diabetes psychologists with expertise in DD. The AI chatbot was field tested by the primary research team and the project was reviewed with patients with diabetes through a patient advisory committee including 8 members and feedback was incorporated in refinements of the chatbot content. Key feedback that was incorporated included the frequency of chatbot messages and the time of day that chatbot messages would be sent. The primary research team field-tested the chatbot by sending and receiving text messages to their cellular phones and documented any errors, challenges, or missing content that they experienced. This information was reviewed and discussed with the chatbot vendor and incorporated into the chatbot analytics and content library. The field testing and feedback process was repeated twice.

Recruitment Status

Patient recruitment is anticipated to begin during late June-July 2024. Recruitment will likely take place through January 2025.

Data Collection Timeline

We anticipate that data collection will be completed by July 2025.

Research Status

Institutional review board approval was obtained on March 15, 2024. We have signed contracts with RAs that will be performing the duties of providing outreach to eligible patients, obtaining informed consent from patient participants, and administering screening tools at the 3-month postscreening and 6-month postscreening time points. In addition, RAs will ensure that data collection from patient screeners is complete and documented appropriately. Following 3 months post screening, research assistants will conduct the semistructured interviews and administer the survey questions to both patients and clinical staff. At the 6-month study time point, the primary team will send the remaining screeners to patient-participants. The primary research team has been meeting weekly since November 2023 to develop the research plan and discuss project tasks.

Technology Status

Licensing agreements and institutional risk assessment approval for the AI chatbot were obtained before patient recruitment. The AI chatbot was initially beta-tested by the primary research team and patients with diabetes to determine if messages could be delivered on a schedule and if the system could get replies back. The beta test revealed that additional content related to suicidality and "hating having diabetes" was needed, more training on the model to correctly match intents to the content library was needed, and that more of the intents had existing content in the chatbot library but that improving the link to these was still needed. The clinical research team developed content related to suicidality including providing crisis resources and directions to seek emergency services if needed. The introductory chatbot disclosure message was reviewed and indicated that the chatbot is not a replacement for medical treatment and to contact 911 for medical emergencies. Before the study launch, the primary research team retested the chatbot system to ensure that the updates had been completed.

eConsults are an active clinical care option for PCPs at our institution, fully integrated into the EHR and in use by over 28 specialties [35]. As a result, they are a readily usable aspect of this study. For our study, specialists available by eConsults will include behavioral health, social work, care management, diabetes education, pharmacy, and endocrinology.

T1-DDAS and T2-DDAS were created and incorporated into the EHR as flowsheets. The PHQ-9 and GAD-7 are already embedded in the EHR. The results of the DD screeners will be able to be pulled into visit documentation, facilitating care coordination with eConsulted providers. In addition, flowsheet data can be tracked over time and will be easily accessible for providers to review during and after patient visits.

The chatbot performance metrics will be monitored throughout the course of this study and evaluation of the chatbot functionality is part of the feasibility. The study team will monitor for communication failures and in the event of longer-term impact will contact participants directly.

Funding Status

Funding for this study was secured from the Peer Mentored Care Collaborative in January 2024. The duration of the funding was 1 year.

Discussion

Expected Findings

This pilot study is expected to demonstrate the acceptability and feasibility of implementing screening and treatment for DD in a primary care clinic. Through this study, workflows will be developed and implemented to screen for DD at a diabetes-specific visit. Following screening for DD, patients will engage in a clinical conversation with their PCP about the results of the screening measure. A tiered approach will be used to determine the type of intervention that is suggested to the patient. All patients (regardless of DD screening result) will receive access to the AI chatbot. Patients might also receive an eConsult with another health care specialist (eg, social work, clinical pharmacy, care management, behavioral health, endocrinology, and diabetes educator) to support the specific Source of DD. If levels of DD are in the high range, patients may also receive a referral to a behavioral health provider.

We anticipate that the use of technological interventions such as the AI chatbot and eConsults will be experienced positively by participants. It is expected that participants will view the AI chatbot as beneficial to their diabetes care and will find it easy to use. The semistructured interviews will specifically request feedback on participant experience using the AI chatbot. The use of eConsults will allow PCPs to increase collaborative communication among the interdisciplinary team and provide participants with additional specialty services if needed. Having

increased coordination among their primary care team will likely be seen as beneficial and helpful to participants. Existing research indicates that specifically targeting DD for intervention has positive benefits on the severity of distress [17]. Further, eHealth interventions for DD have been shown to be effective for improving diabetes-related distress [18].

This study is expected to increase provider and staff awareness and knowledge of screening for and intervening with DD through team and provider training. The training will provide opportunities for learning important psychological and emotional aspects of patients with diabetes that often go overlooked in clinical care. Clinical conversations focusing on the emotional side of living with diabetes are expected to be a new experience for patients in this study. While this might be a new type of clinical interaction, obtaining validation, normalization, reassurance, and empathy from their medical provider will likely be seen as a helpful and rewarding experience. Living with diabetes is a challenging undertaking that under the best of situations requires nuanced interventions from providers and constant attention and monitoring on behalf of patients and their caregivers. Having a supportive environment to discuss challenging lived experiences is intended to improve the emotional burden of diabetes. This finding is anticipated given that emerging evidence suggests that how health care members speak to people with diabetes can impact the development or exacerbation of DD [12].

Even though DD has become increasingly viewed as an important aspect of diabetes care, there remains limited data on treatment approaches. Current literature points to the importance of addressing DD but interventions specifically focused on DD are needed [36]. Most studies do not examine DD as a primary outcome but deliver interventions focused on managing diabetes more broadly [36,37]. This study will provide interventions that are meant to target DD specifically. The primary research team intends to continue pursuing funding opportunities to conduct larger studies in DD assessment and treatment in primary care settings. Future research would expand the assessment and treatment of DD to entire practices involving the whole care team to provide consistency in whole-person diabetes care delivery.

DD significantly impacts clinical, behavioral, and psychosocial outcomes in people living with diabetes. The majority of people with diabetes receive their diabetes care in primary care. However, assessment and treating DD do not routinely occur in primary care settings. The use of several interventions, including supportive dialogue with PCPs, an AI chatbot, and eConsults, will assist in delivering individualized treatment and support for DD without contributing to increased workload for primary care practices. Learning how to provide screening and treatment for DD in primary care settings is crucial to improving the care of people living with diabetes. Health care systems should cultivate environments that promote open discussions about emotional health. This may include training staff to establish a welcoming atmosphere, integrating whole-person considerations into standard assessments, and ensuring that patients feel at ease when sharing their experiences. Embedding the assessment and treatment for DD within primary care workflows is intended to invite providers and patients to consider the broader impact of living with diabetes.

Limitations and Challenges

Given the current state of rapid evolution for AI technologies and associated policies governing AI use in practice, obtaining institutional approval to use AI chatbot technology as part of patient care requires an extensive review process. While health care technology continues to be seen as a scalable and feasible form of care delivery, administrative barriers can make implementation and usage challenging. Overcoming some of these barriers will likely contribute to increased uptake of technology.

Potential barriers to the implementation of new interventions into primary care practices can include lack of leadership buy-in, lack of communication regarding the rationale for the intervention to all practice staff and providers, and workflow barriers. We have thoughtfully approached each of these barriers through our preimplementation work highlighted above, including practice-level training. The PI also met with clinic and health system leadership before the start of the study to secure support for the project. In addition, the study was designed to seamlessly integrate into already existing practice workflows that were being used for depression and anxiety screening. The integration of DD measures into the EHR was intended to further reduce implementation barriers.

Potential barriers to implementing our protocol in other primary care settings include differing resources. Access to eConsults is not universal and alternative protocols would need to be developed depending on practice settings. Furthermore, not all clinics have integrated behavioral health teams easily accessible. It is likely that providers and staff in other primary care settings may also require training on the diagnosis of DD given its emerging status within the spectrum of care for patients with diabetes. The results of this study could help inform what resources (eg, personnel and training) would be needed to successfully integrate DD assessment and treatment into diverse primary care practices.

A potential limitation of eConsult use is the increased, noncompensated workload on primary care providers, who must act on the e-consultant's recommendations for each patient. Primary care is a fast-paced setting that is often stretched for resources, staffing, and time. Further, primary care is a diverse setting with varied access and structures to care delivery. Consequently, it is unlikely that a single approach or method of care is appropriate in all primary care settings. With significant variability in primary care, interventions need to have adequate flexibility to have a chance to be incorporated successfully into this care environment. Feasibility studies offer an opportunity to determine if interventions can be flexibly disseminated into primary care in a scalable fashion. For the AI chatbot, we anticipate a limitation to be the imperfect matching of responses to participant questions. We are mitigating this limitation by setting expectations upfront with participants and using the dataset to iteratively improve chatbot responses over time with use. We chose this curated content route versus an open generative AI approach to minimize potential risks from chatbot hallucination or inaccurate responses.

Given that this is a feasibility study with a small sample size, and we are not powered for inferential analyses, the results of this study will not be generalizable. However, the results of this study will be used as preliminary data for a larger trial.

Conclusions

Creating and disseminating workflows for screening and treating DD in primary care is an important component for delivering whole-person diabetes care. The use of an AI chatbot to deliver individualized treatment and support for DD and eConsults providing additional specialty support are expected to help increase support and treatment for DD without contributing to an increased workload for primary care practices. This study is intended to help us begin to understand how to implement DD screening and treatment in primary care settings in a scalable and real-world manner.

Acknowledgments

The authors thank the Peer Mentored Care Collaborative within the University of Colorado School of Medicine for funding this research, and the Primary Care Diabetes Lab Patient Advisory Council for their review and insights provided. We would like to thank our expert consultants, Lawrence Fisher PhD, ABPP, and Danielle Hessler PhD. This manuscript is original work and is not under review for any other publication.

Data Availability

Data sharing is not applicable to this article as no datasets were generated or analyzed during this study.

Authors' Contributions

MK, TKO, and SLM conceptualized the study. EK and JFG were involved in the dissemination of the project. DS and JFT supervised the project and provided feedback. AS assisted with a literature search and adding content to the manuscript. MK drafted the manuscript and designed the figure and table. All authors reviewed and approved the final version of the manuscript.

Conflicts of Interest

TKO has received funding through the University of Colorado for work related to diabetes technology but has no COI related to DD, eConsults, or the use of an AI chatbot. SK has received research money for diabetes technology but no COI regarding diabetes distress.

Abstract

Background: Current treatments for schizophrenia and other psychotic disorders have limited efficacy, with high rates of nonresponse to “gold standard” treatments. New approaches are therefore urgently required.

Objective: The aims of this pilot study are to investigate the feasibility, acceptability, safety, and usability of Hybrid treatment (primary aim); and to explore Hybrid’s treatment efficacy and engagement of treatment targets (secondary aim). The primary aim will be assessed via face-to-face user experience surveys on a (self-assessed) 5-point Likert scale (and qualitative open-ended questions) examining: (1) acceptability, (2) helpfulness, (3) engagement, and (4) perceived safety. We will also examine consent and completion rates, and the number of sessions attended. Our threshold for moving on to efficacy trials will be at least 70% of our participants to rate 3 and above (which corresponds to agree or strongly agree) that the intervention package was acceptable, feasible, and safe. The secondary aims will be assessed by observing whether individuals achieve self-directed modulation of high-β neurophysiological activity (neural target) and progression upwards through the VR-based exposure hierarchy (psychological target), and by assessing symptom change scores. This study developed a new treatment approach for auditory verbal hallucinations, a major symptom of psychotic disorders, that integrates advances in psychological therapy (cognitive behavioral therapy for psychosis), technology (virtual reality, VR), and neuroscience (electroencephalography-based neurofeedback).

Methods: Hybrid takes a “symptom capture” approach using individually tailored VR-based exposure exercises. Participants (N=10) will receive the intervention package weekly over 12 face-to-face sessions. Here, participants will be progressively exposed to symptom triggers and develop methods of downregulating neural activity associated with these symptoms (neurofeedback component) while concurrently receiving clinician-delivered cognitive behavioral therapy for psychosis.

Results: As of February 2025, Hybrid has commenced (unblinded) recruitment activities from Orygen clinical services in Northwestern Melbourne, Australia. A total of 75 individuals have been approached and 64 individuals have been prescreened (41 individuals were deemed eligible, 15 individuals were ineligible, and 8 individuals declined or did not respond to contact attempts) and 5 individuals have been included in the study. Of the 5 individuals who have commenced the Hybrid treatment, 4 are actively engaged in the program and 1 individual has withdrawn. We expect recruitment to conclude in July 2025 and for the results to be published in 2026.

Conclusions: The Hybrid study is piloting a novel approach that has the potential to address the shortcomings of current treatments for psychotic symptoms. If there is favorable evidence for the acceptability, feasibility, safety and usability of Hybrid, the study team will move on to efficacy trials.

Introduction

Overview

Psychosis is the distinguishing feature of schizophrenia spectrum disorders and a frequent manifestation of mood and substance use disorders [1]. It is characterized by alterations in thoughts and perceptions, often taking the form of positive symptoms such as delusions, hallucinations [2], and disorganized thinking [3], as well as negative symptoms such as blunted affect, poverty of speech, and withdrawal from social and occupational activities [4]. First episode psychosis (FEP) onset most commonly occurs in late adolescence and early adulthood [5], with auditory verbal hallucinations (AVHs) being the most prevalent type of positive symptom reported in this clinical population (≈80%) [6,7]. AVHs are typically characterized by hearing voices that are perceived as distinct from the person's own thoughts. Such experiences are often a cause of significant distress and disruption to daily functioning [8], making AVHs an important target for treatment. Furthermore, evidence supports the benefits of early intervention following the first onset of psychotic symptoms with the duration of untreated psychosis (ie, the time between first psychotic symptoms to antipsychotic treatment) consistently predicting poorer long-term outcomes in longitudinal studies [9,10].

Current Treatments for Psychosis

Current treatment recommendations for psychosis include antipsychotic medications, psychosocial support, and psychological treatment, specifically, cognitive behavioral therapy for psychosis (CBTp) [11-13]. Unfortunately, all currently available treatments are only moderately effective. First, the efficacy of antipsychotic medication for the treatment of positive symptoms of psychosis is not optimal. For example, while commonly prescribed antipsychotics can be significantly more effective than placebo, these medications are accompanied by side effects such as weight gain, sedation, and extrapyramidal symptoms which lead to high incidences of patient nonadherence [2]. A 2019 meta-analysis including 16 randomized controlled trials of antipsychotics and >6200 patients with schizophrenia found that 38% (n=2364) of patients met the criteria for nonresponse and two-thirds showed only "minimal improvement" [14]. Second, the effect sizes for psychological treatments, such as CBTp, tend to be small (≈0.4) and limited in long-term efficacy [2]. Both pharmacological and psychological interventions have higher rates of nonresponse [14] and disengagement [15] in patients with earlier onset of illness highlighting the importance of targeting FEP populations and developing effective and reliable treatments for early intervention. New treatment development, both pharmacological and psychological, is therefore urgently required.

"Cold Cognitions"

One of the limitations of psychological therapies such as CBTp may be that they tend to rely on abstract self-reflection (or "cold cognitions") which can be detached from the actual in vivo experience of symptoms (or "hot cognitions") [16]. This limitation may be particularly relevant for young people in the early stages of psychotic disorder, many of whom find it challenging to engage in this form of self-reflective therapy [17]. Borrowing from the "symptom capture" approach used in other mental disorders, the effectiveness of CBTp may be improved if it is applied while the symptom is actively occurring [18] and collaboratively addressing the symptom that has been activated. The benefit of actively eliciting "hot" cognitions has been demonstrated in the treatment of anxiety disorders and obsessive-compulsive disorder (OCD) [19]. In these disorders, "exposure and response prevention" (ERP) is a key feature of gold-standard psychological treatment [20]. This therapeutic approach involves actively eliciting a degree of anxiety by exposing the patient to symptom triggers and addressing the cognitive and behavioral reactions together with the therapist. Once a degree of mastery and tolerance has been achieved over a low-level, anxiety-inducing trigger, the patient and therapist collaboratively proceed to higher levels of an exposure hierarchy.

Virtual Reality

One advance in technology that may help anchor treatment to the in vivo experience of symptoms is virtual reality (VR). VR

is an interactive computer-generated experience in which the user wears a headset that immerses them in a simulated environment. The VR system is able to create sensory illusions that mimic reality and elicit brain and behavioral responses that parallel those that occur in the real world [21]. VR environments have been found to be useful in the treatment of mental disorders such as social anxiety (for review see Chard and van Zalk [22]), phobias (for review see Kothgassner et al [23]), posttraumatic stress disorder (PTSD; for review see Maples-Keller et al [24]), and as a treatment of psychotic symptoms such as paranoia [25] (see Valmaggia et al [26] for review). Similar to cognitive behavioral therapy (CBT) for anxiety and OCD, this therapeutic technique is founded on exposure principles, where a person is presented with feared, anxiety-provoking, or symptom-inducing stimuli in a graded manner within a controlled environment to enable them to gradually develop strategies to cope when triggers arise in the course of daily life. VR studies for PTSD have found that immersion (ie, a subjective sense of presence in the VR environment) and personalization of the VR environment (ie, tailoring the VR environment to the person's specific and idiosyncratic triggers) may lead to better outcomes, as therapy is more likely to generalize to real-world situations [27]. Indeed, a meta-analysis of VR-assisted exposure therapy for anxiety disorders showed a large overall effect size for VR exposure therapy compared with (mostly waitlist) control conditions (Cohen *d*=1.11, SE 0.15, 95% CI 0.82-1.39) [28]. Furthermore, research on the use of VR for psychosis treatment has indicated the approach can be feasible, acceptable, and effective for improving some symptoms including positive symptoms such as paranoia and hallucinations [29].

For the specific treatment of AVHs, the small number of VR trials to date have all involved avatar therapy, a related approach that involves the creation of a computerized, audio-visual avatar that mimics the hallucinated voices normally experienced by participants, either on a computer screen [30] or using a head-mounted display [31,32]. During these sessions, the participant is supported by the therapist to engage in a dialogue with the created personalized avatar and to develop strategies to respond to the voices. At the same time, the avatar voice and expressions are gradually adjusted from their normal content/tone (eg, abusive) to be friendly and supportive, controlled by the therapist [33]. A 2020 meta-analysis showed favorable results for avatar therapy in patients with schizophrenia compared with supportive counseling on measures of mental state, level of insight, and quality of life [34]. However, while avatar therapy involves artificially recreating an analog AVH experience, the use of the VR environment to elicit symptoms naturally (as is used in traditional ERP treatments) has not yet been explored.

Neurofeedback

Another technological advance, neurofeedback, has proven useful in the treatment of a number of disorders and has shown promising results for psychotic symptoms [35,36]. Neurofeedback is a technique in which individuals use a brain-computer interface to control their own brain activity by receiving real-time feedback on their neural activity. Neurofeedback has most commonly been provided via electroencephalography (EEG) or real-time functional magnetic resonance imaging (rtfMRI). In an example of EEG neurofeedback, individuals receive real-time information on their brain activity, often presented as a bar graph, where the height of the bar represents the power of oscillatory activity in a given frequency band (eg, α or β) measured in terms of power (ie, amplitude squared). This visual display allows participants to try to gain control over their brain activity by manipulating the visual feedback. Participants are typically provided with directions or mental techniques to control their brain activity, are encouraged to apply and adapt their own strategies, and to use the visual feedback display as a guide [37].

The ability of healthy individuals to manipulate their neural activity using neurofeedback has repeatedly been demonstrated [38-40] and is suggested to have positive impacts on cognitive and emotional domains, including the improvement of working memory [40], intelligence [38], and identification of emotional prosody [41]. This has led to neurofeedback's clinical application to a range of psychiatric or neurological disorders, with meta-analyses reporting benefits for attention deficit hyperactivity disorder [42], depression [43], PTSD [44], subclinical OCD [45], and epilepsy [46]. The findings in patients with medication-resistant epilepsy are particularly striking, with neurofeedback demonstrating efficacy in averting seizures once patients learn to anticipate their onset, and with a transfer effect evident even years later [42,46].

The use of neurofeedback in psychotic disorders is increasing in popularity, with a small number of studies published to date (for review see [36]). All studies have found that patients with schizophrenia were able to self-regulate their neural activity, although evidence for a transfer effect (that is, the ability of participants to employ the strategies they have learned during neurofeedback to control their neural activity in the absence of neurofeedback) has yet to be clearly demonstrated. A particularly promising study using rtfMRI indicated a transfer effect for patients with schizophrenia with treatment-refractory AVH after a 2-week training period [47]. Interestingly, the posttraining increase in functional connectivity between brain regions associated with AVH (the left superior temporal gyrus and inferior prefrontal gyrus) was associated with a reduction in AVH symptoms over the training period. As Nan et al [48], recently concluded, "these positive outcomes suggest that such intensive neurofeedback training may provide new insight into the treatment of schizophrenia and thus deserves further study to fully examine its scope."

While rtfMRI-based neurofeedback (like that used in the aforementioned study) can be costly and uncomfortable (due to the space restrictions), EEG-based neurofeedback offers the benefits of portability, cost-effectiveness, and higher patient acceptability. EEG has the further advantage of capturing oscillatory dynamics associated with neural functioning, which cannot be detected using functional MRI owing to the slow temporal latency of the hemodynamic response [49,50]. For patients with FEP, studies on EEG frequency bands (α: 8 to 12 Hz; β: 13 to 30 Hz; θ: 4 to 7 Hz; δ: 0.5 to 4 Hz; low γ: 30 to 50 Hz; and high γ: 50 to 90 Hz) have reported several abnormalities across all 6 bands [51]. Oscillations in the high β band range (approximately 18-30 Hz) are associated with autonomic nervous system hyperarousal and anxiety, which are recognized

as one of the most common subjective features of AVH [52,53]. Previous studies have found that reducing high β band activity (and hyperarousal) is associated with a decrease in psychotic symptoms in patients with schizophrenia, including AVH [48,54,55]. Thus, the use of EEG-based neurofeedback targeting high β band activity represents an important target for the treatment of AVH.

The Hybrid Study

This study, Hybrid, will investigate the potential of a novel treatment approach to AVH in young people with FEP that, if successful, could be incorporated into an individual's broader health care program. Our integrative model combines psychological therapy (CBTp), new immersive technologies (VR), and neuroscience (neurofeedback) in an individualized symptom capture (or ERP) treatment approach. The term "Hybrid" is used to reflect the integrated approach of treatment where each element has been selected to strengthen the effectiveness of the treatment regime as a whole.

A pilot study is required to investigate the following aims: (1) to determine whether Hybrid is feasible, acceptable, and safe; (2) to examine participants' experience of the intervention package and whether it can be modified to increase probability of clinical utility; (3) to explore if there is a signal of clinical benefit in response to Hybrid treatment; and (4) to examine whether Hybrid engages specific neural (modulating high β band activity) and psychological (moving up a symptom-eliciting exposure hierarchy) targets (proof of concept). Hybrid will be an unblinded, single-arm intervention study.

Methods

Participants

Ten participants with a diagnosed FEP will be recruited via telephone from Orygen's Early Psychosis Prevention and Intervention Centre, headspace youth mental health services, and the Orygen Clinical Trials Unit database which serve the Northern and Western suburbs of Melbourne, Australia. Help-seeking participants with FEP from the community will also be recruited. Recruitment will involve phone calls, email, and SMS contact with potential participants. Participants will receive a manually initiated reminder SMS or phone call the day before participation sent by the study clinician or research assistant.

Inclusion Criteria

The inclusion criteria are as follows:

- Aged 15-26 years inclusive.
- Sufficient fluency in English to engage in psychological therapy with an English-speaking therapist, and to understand the study assessments.
- Ability to give informed consent and adhere to study procedures. Parental or guardian consent will be obtained for participants younger than 18 years.
- Psychotic threshold AVH in lifetime as measured by the Comprehensive Assessment of At Risk Mental States (5 or 6 on the severity and ≥4 on frequency for longer than 1 week [56]).
- A rating in the past year of ≥1 on the Psychotic Symptom Rating Scales hallucinations scale [57], corresponding to voices occurring at least once/week. The purpose of this is to ensure that participants with reasonably frequent hallucinations are included in the study, as the experience of symptoms during Hybrid sessions will optimize the study's test of outcomes of interest.

Exclusion Criteria

The exclusion criteria are as follows:

- Documented history of head injury, seizures, or other significant neurological illness.
- Documented history of intellectual disability.
- Visual impairment precluding the ability to view VR scenarios.

Ethical Considerations

Ethics approval for Hybrid has been obtained from The Royal Melbourne Health Human Research Ethics Committee (number 2022.116). This study has ethics approval via the Melbourne Health Human Research Ethics Committee (HREC/76936/MH-2022) for research involving humans and access to patient medical records and information. Participants (or their caregiver/guardian if younger than 18 years) must provide informed consent to participate in the Hybrid treatment. Participants are free to withdraw at any time, with the knowledge that doing so has no impact on their routine treatment. All data from the study is deidentified and only the study investigators have access to this information. This means that each participant's data will have a unique code which only the study team members will have access to. Each participant will be reimbursed AUD $50 (US $31.72) per research interview visit as well as AUD $20 (US $12.69) per EEG recording session.

Data Management and Imputation Strategy

To address attrition or missing values, we will code these as "N/A." The current follow-up protocol is designed to maximize data collection; however, if the missing data are substantial, we will apply multiple imputation methods.

Key Components of the Hybrid Treatment Model

Psychological Therapy

The CBTp approach used in Hybrid relies on hierarchical exposure principles in order to trigger cognitive and affective reactions that occur while experiencing symptoms, that is, "hot cognitions" during symptom activation [58]. As outlined above, this approach may maximize the impact of psychological therapy, as has been observed in other disorders.

Virtual Reality

The VR paradigm that will be used to elicit AVH is inspired by Stinson et al [59] who used a real-world setting comprising computer-generated characters of both sexes and several ethnicities and background sounds simulating the environment. Our VR approach is based on the CBTp framework, beginning with developing a shared understanding (functional analysis) between the participant and therapist of the antecedents of

hallucinatory episodes (eg, presence of other people and lack of meaningful activity) and habitual responses to them (eg, talking back to voices, avoidance). The participant and therapist will then select a template scenario from preexisting VR environments (eg, supermarket and bedroom) developed in consultation with a small group of current and previous service users. Various aspects of the VR environment will be modified to personalize it for the antecedents the individual has identified and to create a hierarchy of symptom-provoking situations. These will include such aspects as the number of people present, proximity and gaze intensity of people, context (interpersonal interaction, indoors, outdoors, time of day or night), sounds, and the presence or absence of "safety strategies" to manage symptoms (eg, mobile phone). For each participant, there will be 5 scaled variants of the personalized scene graded on a 0-100 scale of subjective distress (ranging between 0 and 20 [low], 21 and 40 [moderate], 41 and 60 [high], 61 and 80 [very high], and 81 and 100 [severe]). There are a number of benefits of the VR approach. (1) It provides a controlled environment that can be stopped at any moment, which is not always feasible in real-life exposure settings. (2) It can be designed in a manner that is highly personalized to the individual, which may maximize therapeutic potential. (3) It is a treatment approach that may be particularly suited to young people, given its engaging and interactive nature. (4) It is becoming increasingly feasible for translation into clinical services, given the dramatic reduction in the cost of VR equipment and the fact that VR devices are becoming increasingly portable.

Neurofeedback

EEG will be used to provide real-time neurofeedback to participants while experiencing AVH.

EEG will be acquired using the Muse Headband 2 attached to the Oculus Rift S VR headset. The Muse Headband 2 acquires EEG via 4 electrodes placed over the prefrontal (forehead) and temporal-parietal areas of the brain (electrodes AF7, AF8, TP9, TP10 in the traditional 10-20 electrode system) and collects data at a sampling rate of 500 Hz (with a fifth reference electrode in the position of FPz). The Muse device has been shown to yield frequency-based components of the EEG signal comparable to the research-grade EEG system Biosemi Active Two with the additional benefit of live-streaming capabilities and neurofeedback integration [60]. In Hybrid, the neural target will be the neurophysiological activity associated with autonomic nervous system hyperarousal, specifically, power in the high β range (18-30 Hz) as discussed above (see below for further details).

Intervention Design

Hybrid consists of a Preparation phase (face-to-face, approximately 2 weeks) followed by an implementation phase (12 weekly face-to-face sessions based on previous VR study designs [31,61-63]). Figure 1 shows a visual representation of the Hybrid intervention design and Figure 2 presents the schedule of assessments.

Figure 1. Hybrid design. CBT: cognitive behavioral therapy; VR: virtual reality.

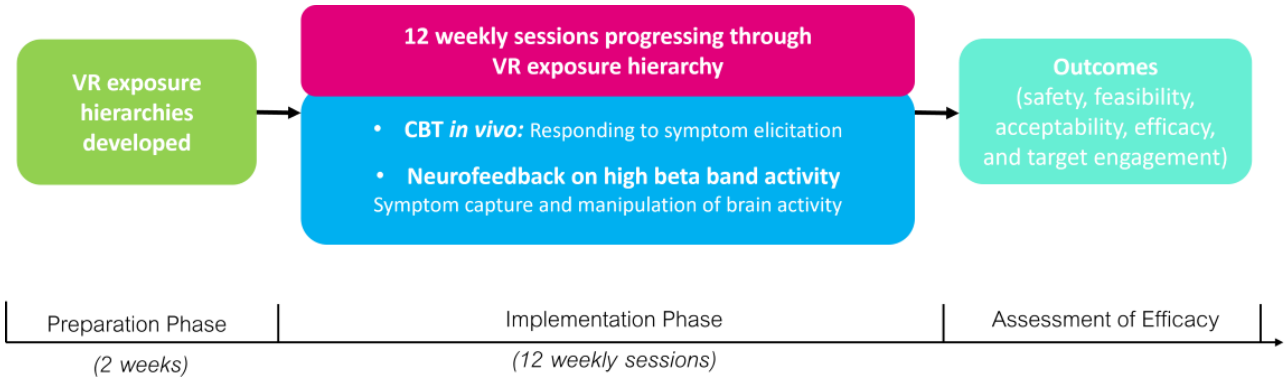

Figure 2. Hybrid schedule of assessments. BPRS: Brief Psychiatric Rating Scale; CAARMS: Comprehensive Assessment of At Risk Mental States; PANSS: Positive and Negative Syndrome Scale; PSAI: Pilot Study Assessment Instrument; PSYRATS: Psychotic Symptom Rating Scales; SCID-V: Structured Clinical Interview for the DSM-V; SOFAS: Social and Occupational Functioning Assessment Scale.

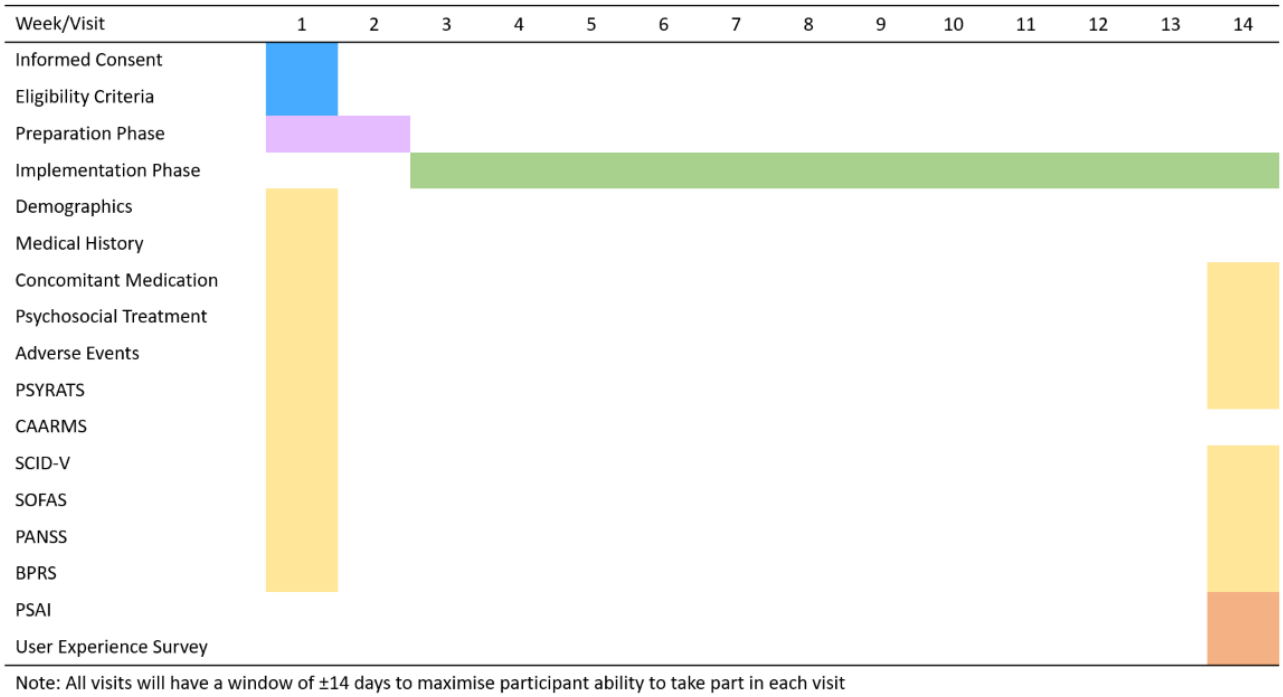
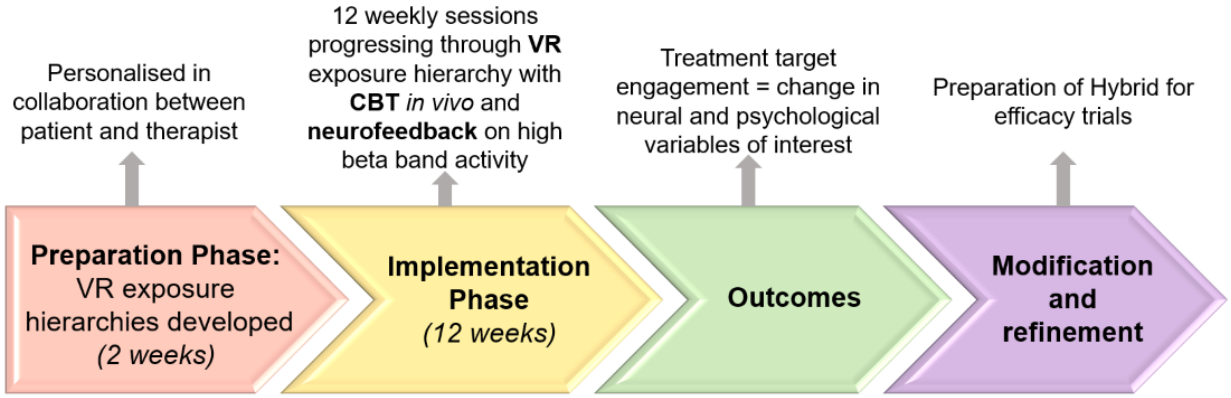


Preparation Phase (Weeks 1-2) Development of the VR Exposure Environment

The preparation of the VR exposure hierarchy will be embedded within a CBT framework by using an adaptation of the standard CBT for voices approach [64]. As mentioned above, the participant and therapist will develop a hierarchy of VR environments personalized for the antecedents identified as symptom-provoking. An example of a VR exposure hierarchy is provided in Figure 3. In developing this hierarchy, the participants will rate the degree of subjective immersion ("presence") they felt in the VR environment using the Immersive Technology Centre-Sense of Presence Inventory [65], a widely used measure in this field. VR environments will only be used if they are rated as inspiring at least "moderate presence," as this has been found to increase therapeutic effectiveness [27]. Once the VR exposure hierarchies have been developed, participants will commence the implementation phase.

Figure 3. Hybrid VR exposure hierarchy example: Shopping Centre template. Example of VR hierarchy exposure levels (left) based on the shopping center template. The participant is exposed to the exposure environments via the VR headset while concurrently speaking with their therapist (cognitive behavioral therapy for psychosis) and receiving neurofeedback of high β band activity via a visual display of a thermometer (right). VR: virtual reality.



#	Exposure Level	Subjective Distress	VR Environment
5	81-100	Maximum	Crowded shopping center, critical gazes, indistinct noises
4	61-80	Very High	Crowded shopping center, people passing by, looking occasionally
3	41-60	High	Interaction with cashier at checkout, people heard in the distance
2	21-40	Moderate	Walking in supermarket aisles, passing people, supermarket music playing
1	0-20	Low	Leaving shopping center, in car park, nobody around

Implementation Phase (Weeks 3-14)

The implementation phase will consist of weekly sessions delivered over a 12-week period (SD 14 days, Figure 2) and consists of the following two components: (1) CBT in vivo (in response to the VR exposure) and (2) neurofeedback simultaneously presented to the participant via the VR device. The VR apps and sessions can only be accessed by the clinician and administered in person. During these weekly sessions, the therapist will be able to view the VR scenario (via an external monitor) and the neurofeedback thermometer, hear the auditory input, and provide guided assistance to the individual.

Cognitive Behavioral Therapy in Vivo (in Response to VR Exposure)

The participant will start at the lowest level of their exposure hierarchy and progressively work up the hierarchy over the course of the sessions. The standard approach in ERP interventions will be adopted, which is to achieve a reduction in subjective units of distress to 30/100 before progressing to the next step in the hierarchy. While the participant is exposed to the symptom-eliciting VR scenario, they will engage in CBTp with their therapist (the participant will be wearing "open backed" headphones, allowing them to hear the therapist as well as sounds coming from the VR environment). The CBT will be standard, manualized CBT for voices [64,66,67] dealing with the "hot" cognition reactions elicited by the VR scenario. Key elements include reassurance regarding lack of threat, challenging appraisals of AVH (eg, their perceived power, threat, or dominance; reducing submissive or reactive behaviors), actively responding to AVH, and developing a sense of control over AVH by attempting to delay or reduce their volume or distract from them with a variety of strategies (eg, humming and visualization). Sessions will last 30-45 minutes and will be stopped at any point if requested by the participant.

Neurofeedback Simultaneously Presented to Participant Via the VR Device

While the participant is being exposed to the VR scenarios and engaging in CBT with a therapist, they will receive visual neurofeedback of electrophysiological activity (power) in the high β band (18-30 Hz) range as measured via EEG. The neurofeedback will be provided to the participant via a single visual image of a thermometer in the corner of the VR scene (ranging from 0 to 100 "degrees"). The temperature of this thermometer is based on the individual's "baseline" neural activity within the high β band range which is measured at the start of each session prior to entering the VR scenario. The thermometer will increase in "temperature" if high β band power increases. The therapist will inform participants that this thermometer is a visual representation of their current stress levels which will give them a real-time objective indication of how their brains are reacting to the Hybrid therapy. Participants will be instructed to keep their eyes open (so as to remain exposed to the VR scenarios) and to keep the thermometer below the 50-degree reading (ie, "half way"; regulating their neural activity in the desired direction) as an additional motivating goal. In keeping with other neurofeedback studies [18], they will be instructed to devise their own strategy for modulating this neural activity but will be informed that they can discuss different strategies with their therapist. If the thermometer measurement is maintained in the lower half ≥50% of the session time, participants will be made aware of the success of their

efforts as positive reinforcement at the end of each of their weekly sessions.

Integration of Multiple Technologies in One Innovative Treatment Package

Combining the treatment components in Hybrid will engage multiple treatment targets and possible pathogenic mechanisms (psychological, neurophysiological, and neurobiological) simultaneously. There is also likely to be a synergistic effect through the interaction of the individual treatment components that will make the package more than the sum of its parts. To illustrate, the real-time neurofeedback provided to participants and therapists in response to the VR exposure exercises will feed into the content of the CBT therapy, because the participant and therapist will be able to discuss the direct impact the exposure exercises are having in an immediate, non-retrospective fashion. This preserves the benefits of dealing with "hot" cognitive and affective reactions. In turn, the CBT will assist the young person in developing strategies for modulating their neural activity in response to the VR exposure exercises. Moreover, the neurofeedback will dynamically reinforce and boost the effect of CBT via participants being able to see in real time that the CBT is helping change their brain activity. This will create a salient and durable learning experience, contributing to a "real world" transfer effect and motivating the use of CBT skills in the absence of neurofeedback. This tridirectional impact of the treatment components—the way the individual items work together—will amplify their individual contribution to therapeutic gain.

Measures

Primary Outcomes

Feasibility and Acceptability of the Hybrid Model

A Pilot Study Assessment Instrument developed by Orygen researchers based on the user experience approach will assess (1) acceptability, (2) helpfulness, (3) engagement, and (4) perceived safety. Items are rated on a self-assessed 5-point Likert scale. Acceptability and feasibility will also be determined by assessing consent and completion rates, the number of sessions attended, the number of dropouts, and completion rates of measures. A high rate of elicited AVH is required to facilitate "hot" cognitions so that the symptoms are targeted directly rather than through abstract self-reflection.

Safety of the Hybrid Model

Safety will be assessed by recording adverse events or serious adverse events.

Usability of the Hybrid Model

Assessing the experience and usability of the VR environments was conducted using the user experience survey, a specifically adapted 18-item questionnaire from other Orygen VR studies for this study. This measure will be completed at the end of the Hybrid intervention (week 14 of the study). At this point, participants will also complete a semistructured interview about their experience of the intervention and suggestions for modifications to the treatment package.

Threshold of the Hybrid Model

Our decision to move on to efficacy trials will be based on the user experience survey, which uses a 5-point Likert scale. We will require at least 70% of our participants to rate 3 and above (which corresponds to agree or strongly agree) that the intervention package was acceptable, feasible, and safe.

Secondary Outcomes

Auditory Verbal Hallucinations

The hallucinations scale of the Psychotic Symptom Rating Scales will be used to assess changes in AVH severity, frequency, and distress.

General Psychopathology

The Brief Psychiatric Rating Scale [68], Structured Clinical Interview for the *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders* [Fifth Edition]) [69], Social and Occupational Functioning Assessment Scale (SOFAS) [70], and the Positive and Negative Syndrome Scale (PANSS) [71] will be used to assess change in general psychopathology and symptoms.

Psychological Treatment Target

The highest level in exposure hierarchies was achieved in each session. For each participant, the final target score of each of these measures will be the average over the 12 implementation phase sessions.

Neuropsychological Treatment Target

This will be operationalized as the difference (ie, change) between the first half and the second half of the VR exposure exercises in average power of high β band activity. A mean score will be used for analysis and will be given by the average change in ratings over the sessions attended.

Planned Analyses

As this study is a pilot study designed to generate initial data to guide future research, a power calculation has not been conducted. A sample size of 10 participants is consistent with similar proof-of-concept and pilot studies [44,48].

Primary Analyses

Means and SDs of acceptability, feasibility, safety, and usability measures and the percentage of participants showing different levels of ratings on the Pilot Study Assessment Instrument will be reported. Thematic analysis of the semistructured interviews will also be conducted. The number of adverse events and serious adverse events will be reported and reviewed.

Secondary Analyses

Clinical Efficacy

Effect sizes, paired *t* tests and Wilcoxon analysis of clinical rating changes before and after the intervention will be computed, which will inform future efficacy trials.

Target Scores

Means, SDs, and 95% CIs of neural (average β band power) and psychological (exposure hierarchy level) target scores will be reported. The magnitude of the changes in both scores will reflect the degree of target engagement achieved. A mean score

will be used for analysis and will be given by the average change over the first half (mean of weeks 3 to 8) and second half (mean of weeks 9 to 14) of the sessions attended.

Further Analyses

Whether greater engagement of neural and psychological targets is associated with greater change in clinical measures will also be explored. This finding would indicate a treatment mechanism that could be systematically tested in future studies.

Results

As of February 2025, Hybrid has commenced (unblinded) recruitment activities from Orygen clinical services in Northwestern Melbourne, Australia. A total of 75 individuals have been approached and 64 individuals have been prescreened (41 individuals deemed eligible, 15 individuals ineligible, and 8 individuals declined or did not respond to contact attempts). Of the 41 individuals who were prescreened as eligible, 9 individuals consented (16 individuals declined and 8 individuals did not respond) and 5 individuals have been included in the study. Of the 5 individuals who have commenced the Hybrid treatment, 4 individuals are actively engaged in the program and 1 individual has withdrawn. The demographic information for these 5 participants are as follows: aged 21 to 27 (mean 24, SD 2) years; 5 male sex at birth consisting of gender identity of 2 cisgender males, 1 transgender male, 1 nonbinary, and 1 questioning their gender. We expect recruitment to conclude in July 2025 and for the results to be published in 2026.

Discussion

Anticipated Findings

Hybrid introduces a new treatment approach that integrates CBTp with VR and neurofeedback. This integration of treatment components may augment each individual element in such a way that it maximizes the impact of each individual component. We anticipate that this will produce durable skill-building and a "real world" transfer effect that motivates the use of Hybrid strategies in everyday life. In addition, individuals should see a reduction in AVH distress, severity, and frequency as evidenced by symptom change scores at the end of the treatment package.

We predict that Hybrid will be successful in achieving this based on the fact that the treatment package will be as follows. (1) Engaging and acceptable: previous studies have shown that young people in the early stages of psychosis find neurophysiological assessments highly acceptable and the neurofeedback and VR components of Hybrid leverage "gamification" [72,73] (ie, using game design and mechanics to encourage active participation) in the treatment of mental disorders. (2) Easily implementable given the increasingly affordable and portable nature of the tools used in the Hybrid intervention (EEG and VR). (3) Empowering: young people develop self-directed control over their symptoms, as opposed to being an "object" of treatment, which is often how other treatment approaches, such as pharmacotherapy, are experienced [74]. As has been recognized [75] previously, neurofeedback can be a means of "taking back control" of the brain by promoting strategies to manage symptoms that come "from the inside" and can be used at any point in the course of everyday life. (4) Focused on individual symptoms rather than diagnostic categories. This is in keeping with the current trend in psychiatric research away from disorder-bound approaches toward transdiagnostic and symptom-based risk factors [76,77]. Therefore, Hybrid could represent a breakthrough in clinical research for effective treatments for psychosis and, if successful, would significantly improve clinical outcomes in young people with AVH.

In terms of study limitations, we highlight that our use of the PANSS and SOFAS as measures of symptoms and functioning may be suboptimal for fine-grained assessment of symptomatology (such as for the negative symptoms) and function. We note that the main aim of this study is to assess the feasibility and acceptability of the Hybrid treatment and we plan to include additional, more fine-grained measures in future studies. We chose to use the PANSS and SOFAS based on many previous studies in early psychosis populations using these measures and increasing our comparability to previous research [70,71]. Second, our clinical assessments are structured to minimize the burden on the individual, therefore, certain features which may be of significance (eg, past history of trauma or eating disorders) were not assessed, but may affect responsiveness to the Hybrid treatment. In subsequent trials, a more thorough assessment of psychopathology may be included to address this. Finally, by virtue of design, we cannot make inferences about any other symptoms associated with psychosis (eg, paranoia and disorganized thinking) as we were targeting AVH in these efficacy trials. Future studies could expand to target other psychotic symptoms.

Conclusion

This pilot study aims to demonstrate the safety, feasibility, and acceptability, as well as establish proof of concept for Hybrid treatment. This initial study will provide valuable information as to whether the Hybrid treatment protocol could be modified and whether moving on to efficacy trials is indicated.

Acknowledgments

We would like to thank Tamar Wong for his significant contribution to the VR component of the Hybrid study. We also extend our gratitude to Hybrid research participants. The study is funded by an NHMRC Investigator Grant (2026484) awarded to BN.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

JS contributed to writing the original draft, project administration, conceptualization, supervision, and investigation. ER was responsible for reviewing and editing the manuscript. MA-J, IB, ID, SL, JL, NT, AT, GW, and SW were involved in conceptualization, with IB also contributing to manuscript review and editing. LB and JL provided supervision. ID contributed to the methodology. CE and BM handled project administration, with BM also involved in investigation and manuscript review. HPY conducted a formal analysis. BN contributed to conceptualization, manuscript review, and editing, and secured funding.

Conflicts of Interest

None declared.

Abstract

Background: Relisten is an artificial intelligence (AI)–based software developed by Recog Analytics that improves patient care by facilitating more natural interactions between health care professionals and patients. This tool extracts relevant information from recorded conversations, structuring it in the medical record, and sending it to the Health Information System after the professional's approval. This approach allows professionals to focus on the patient without the need to perform clinical documentation tasks.

Objective: This study aims to evaluate patient-reported satisfaction and perceived quality of care, assess health care professionals' satisfaction with the care provided, and measure the time spent on entering records into the electronic medical record using this AI-powered solution.

Methods: This proof-of-concept (PoC) study is conducted as a multicenter trial with the participation of several health care professionals (nurses and physicians) in primary care centers (CAPs). The key outcome measures include (1) patient-reported quality of care (evaluated through anonymous surveys), (2) health care professionals' satisfaction with the care provided (assessed through surveys and structured interviews), and (3) time saved on clinical documentation (determined by comparing the time spent manually writing notes versus reviewing and correcting AI-generated notes). Statistical analyses will be performed for each

objective, using independent sample comparison tests according to normality evaluated with the Kolmogorov-Smirnov test and Lilliefors correction. Stratified statistical tests will also be performed to consider the variance between professionals.

Results: The protocol has been developed using the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) checklist. Recruitment began in July 2024, and as of November 2024, a total of 318 patients have been enrolled. Recruitment is expected to be completed by March 2025. Data analysis will take place between April and May 2025, with results expected to be published in June 2025.

Conclusions: We expect an improvement in the perceived quality of care reported by patients and a significant reduction in the time spent taking clinical notes, with a saving of at least 30 seconds per visit. Although a high quality of the notes generated is expected, it is uncertain whether a significant improvement over the control group, which is already expected to have high-quality notes, will be demonstrated.

Introduction

Background

In the medical field, medical record writing is an essential task that requires time and accuracy on the part of health care professionals. The medical record, which includes the patient's medical history, any symptoms they have had, treatments performed, and other relevant details, is a critical component in making appropriate medical decisions and ongoing patient follow-up [1].

In the modern health care context, there has been a transition to the digitization of these records, giving rise to the concept of the electronic medical record (EMR). An EMR is the electronic representation of a patient's medical record, created and maintained by health care professionals. This digital approach has not only revolutionized the way medical information is stored and accessed but has also improved the efficiency of medical care by facilitating the retrieval of relevant data at the point of care [2,3]. EMRs provide a centralized platform for medical information management, allowing for more accurate tracking and more coordinated care [4].

Traditionally, health care professionals have spent a significant amount of time writing medical records [5], which can affect the efficiency and quality of care they provide. This manual task is not only time-consuming but can also lead to documentation errors, omissions, or inconsistencies in the information recorded. A descriptive study published in the *Annals of Internal Medicine* in 2020 conducted a detailed assessment of the amount of time doctors spent using EMRs during outpatient visits. In this study, which included comparisons of 1482 doctors, it was found that doctors were actively using EMRs for 43% of the total time they were online [6]. It has also been shown that all this can contribute to an increase in burnout among professionals [7,8].

In recent years, the field of artificial intelligence (AI) has experienced significant advances in natural language processing and speech recognition [9,10]. These advances have enabled the creation of automated tools and systems that can accurately and efficiently transform speech into text. In the health care setting, this technology has the potential to streamline and improve the writing of medical records, freeing up time for professionals to focus on direct patient care [11,12]. However, this technology was necessary but not sufficient, and it was not until the advent of generative AI that a key part of the process could be completed to obtain sufficient quality for practical use [13,14].

Another important aspect is the issue of data privacy and security [15]. The implementation of AI systems in clinical practice must comply with strict regulations regarding the protection of patient health data. This includes ensuring the security of data transmission and storage, as well as compliance with data privacy regulations, and the General Data Protection Regulation [16]. In the case of AI use, these requirements must go further, given the additional risks of training models with data in health care, which in the worst cases can result in data hacking or the inclusion of strong biases in the algorithms [17,18].

Several companies and academic institutions have developed prototypes and pilot systems for the automated writing of medical records from the doctor-patient conversation in English (Nuance DAX, Amazon HealthScribe). These tools use advanced algorithms and AI models trained on large amounts of clinical data to extract and record relevant information [19].

Relisten

In this context, the Spanish company Recog Analytics has developed Relisten [20], an automated clinical note-writing system designed to handle real-world consultations, supporting multiple languages and offering integration with EMRs.

Through a natural conversation between the health care professional and the patient, this AI-powered tool uses recordings to extract relevant fields corresponding to key sections of the medical history in a structured way and then send them to the Health Information System (after correction and approval by the health care professional). A detailed description of the algorithm's architecture can be found in

Multimedia Appendix 1, providing technical insights into its design and functionality.

Methods

Study Objectives

This study has the following objectives: (1) to evaluate the perceived quality of care reported by patients with the use of an AI-powered solution in the consultation, measured through anonymous satisfaction questionnaires at the end of each consultation (Multimedia Appendix 2); (2) to assess the satisfaction of health care personnel with the care provided in consultations, measured using an anonymous satisfaction survey at the end of the study (Multimedia Appendix 3) and a structured interview; and (3) to assess the time spent by health care personnel on entering records in the EMR, measured by statistical tests comparing consultations with and without the tool.

Overview, Design, and Hypotheses of Study

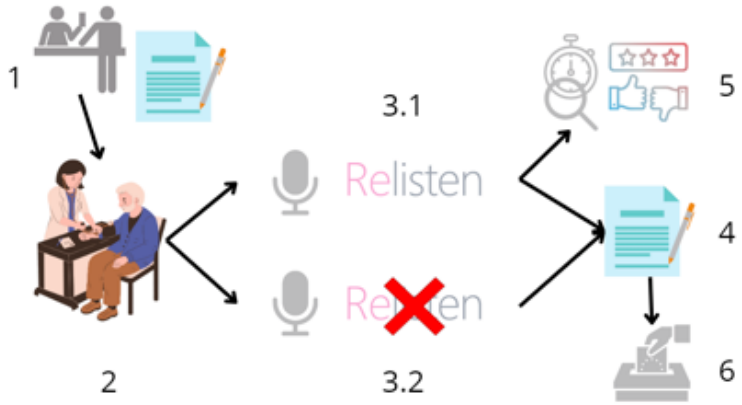
A proof-of-concept (PoC) analysis will be carried out in the context of a multicenter study, where several health professionals (nurses and physicians) from different primary care centers (CAPs) will use the AI-powered tool in consultations (under informed consent of the patient) and will survey patients and the professionals themselves.

The project is structured in three main phases: (1) preparation: this includes the demonstration and initial training of the participating professionals, the preparation of the technological infrastructure (microphones), and the coordination for carrying out the surveys, with an approximate duration of 2 weeks; (2) development: this consists of the use of an AI-powered solution during consultations, as well as data collection, including audios, clinical notes, and survey results, lasting approximately 20 weeks; and (3) data analysis and presentation of results: this phase involves the processing and analysis of the data collected, followed by the presentation of the results obtained, and lasts approximately 2 weeks.

The measurement of the objectives will be carried out using the following methods: (1) perceived quality of care as reported by patients using an anonymous patient survey after each consultation, in a patient-blinded study (patients are not told beforehand whether the AI-powered tool has been used in the consultation; this fact is outlined by a graphic mark in the surveys in which the tool has been used); (2) satisfaction of health care personnel: an anonymous survey will be conducted at the end of the study. This will qualitatively evaluate the tool's impact on consultations, focusing on aspects such as its general usefulness, ease of use, the quality of notes generated, its perceived ability to improve attention during consultations, and the extent to which it saves time. In addition, the study will incorporate structured interviews with primary care health care professionals (nurses and physicians) to explore their experiences with the tool in depth. The interviews will include questions about the above concepts, as well as at least an additional request to the health care professional to identify limitations and improvements to the tool. (3) Time spent entering information into the EMR. To determine the magnitude of savings, 2 measurements taken during the PoC will be compared: the time the health care professional spends typing in the consultation and the time the health care professional spends reviewing and correcting notes generated by the AI-powered tool.

Figure 1 facilitates the visualization of the development of the study in consultations.

Figure 1. Steps involved in the study workflow.



The steps mentioned in Figure 1 include:

1. Patient consent at reception: the patient arrives at the CAP and is attended to at the reception desk, where he or she is given the information sheet and the informed consent form, which he/she will return signed if he/she agrees to participate in the study.
2. Consultation begins: the patient arrives for consultation and the doctor confirms their participation.
3. (3.1) Use of Relisten: the consultation is carried out, alternating between consecutive patients (simple randomization). Recording and using the AI-powered tool to provide full patient care. In this mode, the health professional does not take notes during the consultation and proceeds to step 5.
4. (3.2) Standard documentation: recording it and writing it at the same time in the electronic record as usual. In this mode the AI-powered tool is only used as a consultation recorder to calculate the typing time of the health care professional, using these consultations as a control group.

5. Note review or writing: the doctor hands the survey to the patient and says goodbye.
6. Satisfaction surveys: the doctor reviews the notes generated by the AI-powered tool, recording the time required for that task directly on the tool's website, copies and pastes them into the electronic record, and rates the notes generated by the tool for that consultation.
7. Anonymous survey submission: the patient deposits the completed survey anonymously in the box provided.

The study team hypothesizes that the use of an AI-powered tool improves the perceived quality of care by allowing health care professionals to spend more time interacting directly with patients and less time on clinical documentation. This translates into more patient-centered care and a measurable improvement in both patient and staff satisfaction.

Setting of the Study

The study population will be made up of patients who are visited in person at CAPs in Catalonia, both in emergency and control consultations, whose professionals (nurses and physicians) participate in the study. The participating primary care centers are CAP Amposta, CAP Centelles, CAP Artés, CAP Sallent, CAP Súria, and the Consorci d'Atenció Primària de Salut Barcelona Esquerra.

Given the nature of the tool and its applicability to most of the practice settings, there will be no previous selection of patients, but any patient who comes for consultation with the professionals participating in the study will be eligible.

Participants eligible for inclusion in the study must have provided written informed consent, be involved in face-to-face medical or nursing consultations conducted in Catalan or Spanish, and be aged 18 years or older.

Participants will be excluded from the study if they are unable to understand the nature of the study, lack fluency in Catalan or Spanish, do not provide consent to be recorded, or if any technical issues, such as internet service downtime, compromise the recording process.

The study included patients in unscheduled visits (emergency), first visits (with history taking), and follow-up for chronic disease.

The SPIRIT guidelines were followed when designing the research (Multimedia Appendix 4) [21].

Sample Size and Randomization

To calculate the sample size, the 2 objectives that require such calculation are considered:

1. For the patient satisfaction surveys, proposed on a Likert scale from 1 to 5, we are faced with the problem of comparing independent samples. Assuming normality in the difference of the samples (a hypothesis that will be verified during the statistical tests), the formula for the determination of the required sample size is the following:

Where Z_α and Z_β represent the Z-table values for confidence level and test power, respectively, sigma is the SD of the (estimated) differences, and d is the effect size to be measured. For this study, standard values for α=.05 (95% confidence) and β=.8 (80% test strength) are selected, σ=1 is estimated as an extreme case to ensure that the results will be statistically significant, and d=0.25, as the minimum improvement we want to demonstrate. The result is n=395.21 for each group, so we set the number of patients to be analyzed to 400 with the AI-powered tool and 400 without the tool.
2. For time-saving, applying a similar procedure with the same standard values, σ=90 seconds and d=30 seconds, we obtain n=111.15 for each group, so we set the number of consultations to be analyzed to 120 with the AI-powered tool and 120 without the tool.

Since the groups are the same and there is no interconnection between the measurement of both objectives, it is possible to use the same consultations for both, and therefore the total number of patients required will be the larger of the two above, resulting in n=800 (400 patients with the AI-powered tool and 400 without the tool). The randomization was carried out in a simple format, given the sufficient sample size and the fact that the aim is to validate the hypotheses at a general level, although for information purposes the study also shows intermediate results stratified by type of consultation (first or follow-up) or by a health professional.

Data Collection

The data collection process involves the following:

1. Satisfaction surveys completed by patients at the end of the consultation (with the AI-powered tool as a test and without the tool as a control). The survey will be given to the patient on paper by the health professional inside the doctor's office at the end of the visit. They will be collected anonymously in a box upon exiting the office, in a visible and accessible place. This involves single-blinded data collection (the patient does not know whether the AI-powered tool is being used, although the health care professional does). These questionnaires will be available in Catalan and Spanish.
2. Quality surveys at the end of each consultation by health care professionals, on a scale of 0-10 with the possibility of including open-ended comments, will be carried out directly through the AI-powered tool's digital platform. These questionnaires will be available in Catalan and Spanish.
3. Satisfaction surveys completed by health care professionals at the end of the study, as well as interviews to better understand the impact and limitations in a qualitative manner.
4. Recordings of conversations between the patient and health care professional (Recog will delete the recordings at the end of the study).

These items align with study objectives and are detailed in the Multimedia Appendices 2 and 3.

Qualitative data will be collected using open-ended survey surveys for patients and health care professionals and structured interviews with professionals. These data will be analyzed using thematic analysis.

The study variables are mentioned in Textbox 1.

Textbox 1. Study variables.

Independent variables

- Indicator of whether the artificial intelligence (AI)–powered solution has been used in the consultation (no typing during the consultation; yes or no)
- Identifier of the health care professional involved (user code stored in the AI-powered tool)

Dependent variables

- Results for each survey question, on a scale of 1-5.
- Time saved during consultations is measured by comparing the writing time in the 2 scenarios: one where doctors manually write notes during the consultation (non–AI-powered audios) and another where they review and correct notes generated by the AI-powered tool. For the non–AI-powered audios, investigators listen to the recordings and measure the exact time the professional spends writing. In AI-assisted consultations, the doctors use the platform to time their note corrections. By comparing these two measurements, the study aims to quantify the time-savings offered by the AI-powered tool, with each recording being analyzed individually for accuracy. This has been chosen because other forms of measurement (such as automatically measuring silences) may introduce greater biases (silences due to circumstances other than note taking) than human interpretation. Although logically it is not a perfect measure either, the savings impact is expected to be sufficiently significant for these random errors to have a very small impact in relative terms.

  In addition, health care professionals are asked to include, through the AI-powered tool's digital platform, possibly relevant comments about the consultation they have just carried out, such as when a consultation has been carried out in multiple languages, with one participant speaking in Spanish and another in Catalan.

Statistical Analysis

The main hypotheses of the study focus on evaluating the reported quality of care and saving time in the writing of clinical notes. To assess the improvement in reported quality of care, the normality of the sample will be checked using the Kolmogorov-Smirnov test with Lilliefors correction. Student *t* test for independent samples will be applied in the case of normality, or an equivalent nonparametric test otherwise. Key survey items, including patient-reported satisfaction with time spent, the attention received, and perceived care quality, as well as health care professional satisfaction with reduced administrative burden, ease of use, and note quality, will be analyzed to test for significant differences.

In terms of time savings, 2 aspects will be measured separately: the relative time (in percentage) that the professional spends writing notes during the consultation without using the AI-powered solution, and the relative time that the doctor spends reviewing the notes generated by the tool. Similarly, the normality of the sample will be checked using the Kolmogorov-Smirnov test with Lilliefors correction, and the Student *t* test or its nonparametric equivalent will be applied as appropriate.

Since the sample is not randomized, a sensitivity analysis will be conducted to account for potential selection bias. All statistical analyses will be performed using RStudio, considering a confidence level of 95% and a statistical power of 80%.

Confidentiality

In this study, confidentiality will be rigorously protected by several procedures. The patient surveys, which will be conducted anonymously upon exiting the consultation, will be transcribed by the Recog staff into a Microsoft Excel file for subsequent analysis, without any identifying data. The audios collected during the consultations will be automatically stored in the AI-powered tool platform, guaranteeing their security by storing them in the S3 (Simple Storage Service) service of Amazon Web Services, with controlled access, encryption, and without identifiers that allow patients to be identified. The professionals' comments will be stored in Amazon Web Services DynamoDB tables, also with controlled access, thus ensuring the confidentiality of all the information collected.

In no case is the objective of the study to train the algorithm with the data obtained, since the algorithm is already trained. The models applied are speech-to-text models, originally trained on multilingual datasets [22] and a large language model trained on generic datasets in multiple languages, public and private, not specified by the model developer. Notes are written in the project and no medical analysis is being performed by AI. The initial tests have shown the correct capability of the complete software for this task, which we seek to validate more extensively with this project. The initial stages of the algorithm use machine learning techniques, such as advanced speech-to-text models for transcription. The subsequent steps, including structuring the extracted information into relevant clinical fields, rely on a combination of rule-based processes, predefined templates, and generative AI models.

Ethical Considerations

This study was approved by the University Institute for Primary Care Research Jordi Gol Health Care Ethics Committee (Code 3/286-P). The research adhered to institutional guidelines for studies involving human subjects, including those requiring the recording of patient interactions and subsequent analysis. Written informed consent will be obtained from all participants before their inclusion in the study. Participation was entirely voluntary. No monetary or material compensation was provided to participants. All participants will complete a written informed consent. Upon arrival at the CAP, the Admissions administration staff will offer the patient the chance to participate in the study. The participant will be given the information sheet attached to the informed consent form, where he or she will be informed

about the purpose of the study and the handling of the data. If the patient authorizes his or her participation, he or she must complete and sign the informed consent form and give it to the clinical professional with whom the consultation is to take place.

Results

This study was preregistered on ClinicalTrials.org. Recruitment began in July 2024, and as of November 2024, a total of 318 patients have been enrolled at participating CAPs. The recruitment process is proceeding more slowly than expected and to ensure sufficient sample size the recruitment period has been extended until March 2025. This adjustment enables comprehensive data collection without compromising the study's objectives.

Discussion

Principal Findings

The implementation of AI-based technologies in health care has been a topic of growing interest in the last decade. These technologies promise to improve the efficiency and quality of health care, but their adoption depends largely on empirical evidence to support their benefits.

This study seeks to contribute to that evidence base by evaluating a specific tool that has the potential to alleviate one of the main sources of administrative burden for health care professionals: the writing of clinical notes. By freeing up time that would otherwise be spent on administrative tasks, an AI-powered tool could enable health care professionals to focus more on direct patient care, thereby improving the quality of care.

The results of the project will serve to validate the usefulness of an AI-powered solution in daily practice, from the perspectives of improving the perceived quality of care and saving professionals' time, which could amount to more than an hour a day that could be invested in attending to more patients, promoting adherence with the same patients, or other value-added tasks.

If the result of the study is favorable, the tool is technically prepared to be integrated with IT systems, is scalable to thousands of queries in parallel and has been designed from the ground up with absolute priority to data security and privacy (the tool deletes queries minutes after processing to avoid being a target for cyberattacks; it is not a database, just a processor). It is therefore considered that its implementation may be feasible, the first step being to validate its capabilities in this study.

While our study is one of the first to evaluate the use of an automated clinical note-writing system based on AI algorithms in day-to-day clinical consultations in primary care, previous research has explored similar technologies in other medical specialties. For example, a 2024 study assessed the accuracy of AI-generated clinical notes using ChatGPT-4 (OpenAI), finding that such tools can produce notes comparable in quality to those taken by physicians [23]. In another study, the Permanente Medical Group (United States) implemented AI scribes for more than 10,000 physicians and found that this technology reduced documentation time, improved doctor-patient interactions, and achieved high satisfaction among both patients and physicians [24].

Limitations of the Study

One of the main limitations of this study is that the sample is not randomized, which may introduce selection bias. To address this, a sensitivity analysis will be performed to ensure that any potential bias is minimized. Related to the sample size, while substantial for a PoC study with 800 participants, may still be considered relatively small.

Another important limitation is the variability introduced by the participation of different health professionals, who can generate a significant variance in the results obtained, both in patient satisfaction and in the time saved in the consultation. Although patients were blinded to the use of the tool, their reported satisfaction may still be influenced by other factors such as the health care professional's behavior or consultation dynamics. To mitigate this effect, it has been decided to involve a reasonable number of professionals, seeking a balance between reducing variance and avoiding an excessive burden on participants, although this will still be a limiting factor.

Another possible bias is in the measurement of time saved. This is calculated as the difference between the time spent on a consultation without the AI-powered tool to write the notes and the time needed to review the notes generated by the tool in another consultation. However, there will always be an inherent bias, as it is not possible to reproduce the same consultation exactly, and the professional's previous knowledge may influence how quick they are in carrying it out. In addition, the measurement of the time the professional spends writing may not be completely accurate. In addition, while we assess the time spent on writing clinical notes, another potential limitation lies in the time spent reviewing the notes generated by the tool. This measurement may be influenced by external factors, such as interruptions (eg, being called to the door, receiving phone calls, etc), which could result in prolonged review times without the actual time being spent on reviewing the notes. The start and end points of the review period are based on when the professional clicks "start review" and "finish review," but interruptions could lead to inaccurate time recordings. In addition, another limitation is the risk that doctors rely too much on AI-generated notes without thoroughly reviewing them, which could lead to inaccuracies. Although doctors are instructed to verify the notes as soon as possible following the consultation to avoid this, individual differences in review diligence could have an impact on the results. Despite these challenges, an analysis of these errors has been performed and it has been concluded that their impact will be significantly lower than the effects that are intended to be measured, so the results, with the proposed sample, can be considered valid. However, if any extreme values are identified during the analysis, they will be excluded.

Conclusion

We anticipate that patients participating in the study will perceive an improvement in the quality of care they receive and

that there will be a significant reduction in the time spent taking clinical notes. Although we expect the generated notes to be of high quality, it remains uncertain whether a significant improvement over the control group, which is already expected to have high-quality notes, will be demonstrated. Ultimately, this proof-of-concept study seeks to explore the potential benefits of integrating AI in primary care settings.

Acknowledgments

We thank all the primary care centers that participated in this study, as well as the health care professionals and patients who volunteered. We would also like to thank the Recog Analytics technical team for their ongoing support during the development and implementation of Relisten. This project has had no external funding except for the development of the tool by the company Recog Analytics.

Data Availability

The datasets used and/or analyzed during the current study will be available from the corresponding author on reasonable request.

Authors' Contributions

JV-A, CA, and DHH made significant contributions to the methodology, investigation, and writing (original draft and review & editing of the work). They also supervised and validated the project. AC, ES-F, MLB, CFP, IM, RA, OC, RF, JA, CM, MMM, MG, and SN critically reviewed the manuscript, ensuring accuracy, clarity, and intellectual rigor, and approved the final version for publication, participating in writing and validation. AG coordinated and supervised the project, critically reviewing the intellectual content, approving the final published version, and participated in project administration and supervision.

Conflicts of Interest

CA, DHH, and ACC are employees of Recog Analytics, the company that developed Relisten. While the study was funded by Recog Analytics, to minimize potential bias, the analysis of the results will be conducted independently by authors not affiliated with the company. We have a collaboration agreement with Recog Analytics for this research project. This agreement ensures compliance with data privacy regulations, prohibits fine-tuning of the algorithm using study data, and mandates the deletion of all temporary data immediately after processing. The tool is used solely for research purposes and its inclusion in this study is based on its potential to support primary care professionals by reducing administrative burden and improving workflow efficiency.
