Abstract

Background: Many patients with nonmetastatic prostate cancer receive radiotherapy, which may be associated with acute cystitis, particularly if the volume of the urinary bladder is small. Three studies showed bladder volumes <200 ml or <180 ml to be associated with increased urinary toxicity. Therefore, it is important to maintain bladder volumes greater than 200 ml during as many radiation fractions as possible. Several studies investigated drinking protocols, where patients were asked to drink a certain amount of water prior to radiotherapy sessions. This may require considerable discipline from the patients, who are predominantly older adults. Adherence to a drinking protocol may be facilitated by a mobile app that reminds patients to drink water prior to each radiation session. This study investigates the effect of such an app on bladder filling status in patients with prostate cancer undergoing external beam radiotherapy (EBRT) alone.

Objective: The primary goal of this study is to evaluate the impact of an app that reminds patients irradiated for prostate cancer to drink 300 ml of water prior to each radiotherapy session on the number of fractions with bladder volumes <200 ml during the radiotherapy course.

Methods: This ongoing phase 2 aims to recruit 28 patients treated with EBRT alone for nonmetastatic prostate cancer. Radiotherapy will be administered using normo-fractionation, with doses ranging from 70 to 80 Gy in 35 to 40 fractions of 2 Gy, preferably with volumetric-modulated arc therapy (VMAT). Treatment volumes include the prostate with or without the seminal vesicles.

Results: Recruitment for this trial will start in March 2025 and is planned to be completed in October 2026. The study is scheduled to conclude in December 2026.

Conclusions: This trial is the first to evaluate the impact of a reminder app on the number of radiotherapy fractions with bladder volumes <200 ml in patients undergoing irradiation for localized prostate cancer.

prostate cancer; external beam radiation therapy; radiation toxicity; bladder filling; mobile app

Introduction

Prostate cancer is one of the most common solid malignancies worldwide [1]. Most patients with nonmetastatic disease receive either prostatectomy or radiotherapy. Radiotherapy is often performed with normo-fractionated (5 × 2 Gy per week) external beam radiotherapy (EBRT) alone or EBRT plus a high-dose-rate brachytherapy boost [2]. For normo-fractionated EBRT alone, the recommended total dose is between 74 and 80 Gy, corresponding to 37 to 40 fractions of 2 Gy [2]. Prostate cancer radiotherapy may be associated with significant acute urinary toxicity such as cystitis, particularly if the volume of the urinary bladder is small. A total of 3 studies showed that bladder volumes <200 ml or <180 ml, respectively, were associated with increased acute or late urinary toxicity [3-5]. In a retrospective study by Pisani et al [3], which included 280 patients treated with EBRT for prostate cancer, bladder filling (volumes <200 ml vs ≥200 ml) was an independent predictor of grade ≥2 acute urinary toxicity. A prospective study by Pinkawa et al [4] assessed the quality of life in 80 patients irradiated for prostate cancer at different time points. At follow-up between 6 and 10 weeks after radiotherapy, pain with urination was reported less frequently by patients with an initial bladder volume of ≥180 ml compared to <180 ml. In another prospective study from Germany, 193 patients received training via a biofeedback mechanism to achieve a bladder volume between 200 and 300 ml at each radiation session [5]. The results showed that reproducible bladder volumes >180 ml were associated with a significant decrease in grade ≥2 acute urinary toxicity. In another study, a planned bladder volume >200 ml and daily filling between 82% and 113% were associated with reduced intrafraction motion of the prostate [6]. Moreover, in the study by Smith et al [7], optimal bladder dose constraints were missed more frequently if the bladder volumes were <200 ml. Therefore, it is important to maintain bladder volumes >200 ml at as many radiation fractions as possible.

In a recent study by our group that investigated the bladder volumes at each of the first 35 radiation fractions in 72 patients receiving EBRT alone, the mean and median numbers of radiation fractions with bladder volumes <200 ml were 17.8 (SD 12) and 16.5 (IQR 7.5-29.5) fractions, respectively [8]. On the other hand, in a subgroup of 37 patients with a bladder volume of at least 200 ml before the start of the radiotherapy course, the mean and median numbers of radiation fraction with bladder volumes <200 ml were only 9.4 (SD 8.3) and 8 (IQR 2-16), respectively. The mean and median were significantly higher in the subgroup of 35 patients with bladder volumes <200 ml, at 26.7 (SD SD 8.5) and 30 (IQR 22-34), respectively. Therefore, there is a medical need for improvement, especially in the latter subgroup.

Several studies have investigated the role of drinking protocols [5-7,9-17]. Patients were asked to drink a certain amount of water prior to computed tomography (CT) simulation and radiotherapy sessions. In these studies, the amount of water ranged between 200 and 600 ml, and the time interval until the CT simulation or radiation session was between 30 and 60 minutes [5-7,9-17]. However, drinking a certain amount of water at a specific point in time may require considerable discipline from patients, who are predominantly older adults. These considerations led to the idea of developing a mobile app that reminds patients to drink a certain amount of water prior to each radiation session. The idea of testing a reminder app in this context was based on our experience with such an app during our previous Interreg project NorDigHealth [18,19].

This study investigates the number of radiation fractions with bladder volumes <200 ml in a prospective cohort of patients using a reminder app. Additionally, it evaluates whether the use of the reminder app significantly reduces the proportion of radiation fractions with bladder volumes <200 ml compared to a historical control group without app support. After several ethical discussions, we decided to compare the cohort of the single-arm phase 2 trial to an appropriate historical control group after careful matching rather than performing a randomized phase 3 trial. Since the responsible individuals at the contributing centers were confident that the reminder app would improve bladder filling in the phase 2 cohort, they deemed it unethical to withhold the app from approximately 50% of the patients participating in a randomized phase 3 trial. The main goal of this prospective phase 2 study is to evaluate the impact of a reminder app on the number of fractions with bladder volumes <200 ml during radiotherapy in patients irradiated for prostate cancer. The app reminds the patients to drink 300 ml of water 45 minutes prior to each radiotherapy session. The primary end point is the number of radiation fractions with bladder volumes <200 ml after 35 fractions of radiotherapy. Additionally, the following end points will be evaluated: (1) the number of radiation fractions with bladder volumes <200 ml at the end of radiotherapy, (2) patient satisfaction with the reminder app, and (3) the impact of the reminder app on the use of health technology.

Methods

Trial Design and Duration

This is a single-arm prospective study performed in 1 university hospital, 2 academic teaching hospitals, and 1 private practice. It will investigate the effect of a reminder app on the number of radiation fractions with bladder volumes <200 ml during a course of radiotherapy for the treatment of prostate cancer compared to a historical control group [8]. The control group is considered appropriate for comparison with this study cohort, as these patients were treated very recently (in 2022 or 2023)

with external beam radiotherapy alone in 3 of the 5 centers participating in this study. The control group underwent a cone beam computed tomography (CBCT) session prior to each radiation fraction, enabling bladder volume assessment with the same level of precision as in this study. To ensure comparability of the total number of fractions administered in the prospective study with those in the historical control group, the primary end point is restricted to the first 35 fractions administered. The recruitment of all 28 patients is planned to be completed within 20 months. The follow-up period will end directly after the radiotherapy course, which is scheduled to take 7 to 8 weeks. This equals a total running time of 22 months for the study. In accordance with the previous study assessing the number of radiation fractions with bladder volumes <200 ml during a course of radiotherapy for treating prostate cancer, the following characteristics will be recorded to allow adequate comparison with the historical control group: (1) bladder volume at CT simulation, (2) BMI, (3) age, (4) prostate volume prior to radiotherapy, (5) Karnofsky performance score, (6) risk group of prostate cancer, and (7) antihormonal therapy [8]. All patients in the phase 2 cohort and the historical control group must have a bladder volume <200 ml at CT simulation.

Patient Selection

This trial will be performed in patients with prostate cancer receiving definitive normo-fractionated radiotherapy. Patients will be adequately informed about their diagnosis and the nature, significance, and scope of the trial. Patients will only be included after completing the pretherapy evaluation, meeting all inclusion criteria, and not meeting any exclusion criteria (Textbox 1).

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria:

- Histologically proven prostate cancer
- Indication for definitive normo-fractionated radiotherapy
- Possession of and ability to use a smartphone
- Bladder volume at computed tomography (CT) simulation <200 ml
- Age ≥18 years
- Written informed consent
- Capacity of the patient to consent

Exclusion criteria:

- Radiotherapy of pelvic lymph nodes
- Expected noncompliance

Patient Interventions

For all patients, radiotherapy will be administered using normo-fractionation with 70 to 80 Gy in 35 to 40 fractions of 2 Gy, given 5 days per week (overall treatment time 7-8 weeks), preferably with volumetric-modulated arc therapy (VMAT) [2]. Treatment volumes include the prostate with or without the seminal vesicles.

Radiotherapy for prostate cancer may be associated with acute side effects, including dermatitis, cystitis, proctitis, diarrhea, and fatigue. If grade 3 toxicity occurs according to the Common Terminology Criteria for Adverse Events (CTCAE) version 5, radiotherapy may be delayed for a maximum of 7 days without consequences [20]. If it is delayed for more than 7 days, participation in the study will be terminated, and the coordinating investigator must be informed.

Patients may receive concurrent systemic agents as part of their anticancer treatment, regardless of their participation in this trial [2]. These agents will be indicated and prescribed by treating medical oncologists or urologists outside this trial.

The following parameters will be recorded prior to the start of radiotherapy: medical history including micturition disorders, medication including anticancer treatment, physical examination, age, body height and weight, Karnofsky performance score, bladder volume and prostate volume at CT simulation, tumor stage, histology, Gleason score, prostate-specific antigen, risk group, planned radiation dose and dose per fraction, number of fractions, radiation boost, treatment volume, radiation technique, experience with smartphones, and need for support regarding the use of the reminder app. Throughout the trial, bladder volumes will be assessed by staff members prior to the radiotherapy course (based on CT simulation) and before each radiation fraction using CBCT. Adverse events will be assessed on an ongoing basis according to CTCAE version 5 [20]. At the end of the radiotherapy course, patients will be asked to complete a questionnaire assessing their satisfaction with the reminder app and the impact of its use on their attitude toward health technology.

Safety Management

An adverse event is any event experienced by a patient or participant in a clinical trial that does not necessarily have a causal relationship with the treatment. It can include any adverse or inadvertent occurrence (including notable laboratory findings), symptom, or illness that occurs during the treatment period, regardless of whether there is a causal relationship. Existing illnesses that deteriorate during the trial should also be reported as adverse events. Events covered by the documentation for concomitant diseases and radiation-related

acute toxicities of Grade ≤2 do not have to be additionally documented as adverse events. Serious adverse events are those that fulfill one of the following criteria at any dose level: lethal, life-threatening, requiring hospitalization or extent of a hospital stay, permanent or significant disability, birth defects or malformations, any medically significant event, or any event necessitating surgery to prevent one of the aforementioned concomitant illnesses. Hospitalization should be defined as necessary for treating the adverse event. Hospital stays that are part of the treatment outlined in the protocol or due to a planned, elective operation are not classified as serious adverse events. Likewise, an elective hospitalization to facilitate the trial process does not count as a serious adverse event.

Sample Size Calculation

The primary goal of this study is to assess the impact of an app that reminds patients irradiated for prostate cancer to drink water before each radiotherapy session on the number of fractions with bladder volumes <200 ml during the radiotherapy course. This study also aims to demonstrate that this number is lower than without using an app (historical control group). To allow for a skewed distribution of the primary end point, the Wilcoxon-Mann-Whitney test will be applied for confirmatory statistical analysis. Sample size calculation is based on the article by Noether [21]. In the external historical control group consisting of 35 patients, the mean number of radiation fractions with bladder volumes less than 200 ml was 26.7 (SD 8.5), and the median number was 30 (IQR 22-34). A decrease in this mean value by roughly 30% (to 18.7 fractions) is considered clinically relevant. For illustrative purposes, translating this decrease into a nonparametric effect size framework (assuming normal distribution) leads to a probability of roughly 0.25 that the number of fractions <200 ml with the reminder app will be larger than without the app. Based on this effect size, a sample size of 25 patients in the prospective trial is required for comparison with the historical control group to ensure 90% power to reach statistical significance with a 2-sided Wilcoxon-Mann-Whitney U test and a 5% significance level. Assuming that roughly 10% of the enrolled patients will not be eligible for the primary analysis as they received less than 35 fractions, a total of 28 patients should be enrolled.

Statistical Analyses

All data recorded in the case report forms describing the study population, efficacy, safety, and quality of life will be analyzed descriptively. Categorical data will be presented in contingency tables with frequencies and percentages and 95% CIs. Continuous data will be summarized with at least the following: frequency (n), median, quartiles, mean, SD (standard error), minimum, and maximum. The number of participants with protocol deviations during the study and listings describing the deviations will be provided. Chi-square tests will be used to compare percentages in a 2 × 2 contingency table, replaced by the Fisher exact test if the expected frequency in at least 1 cell of the associated table is less than 5. Stratified 2 × 2 contingency tables will be analyzed using Cochran-Mantel-Haenszel tests. Logistic regression models serve as multivariable methods for binary end point data. A comparison of ordinal variables between treatment arms will be performed using the asymptotic Wilcoxon-Mann-Whitney test, replaced by its exact version in case of ordinal categories with a small number of categories and/or sparse data within categories. Any shift in the location of quantitative variables between study groups will be performed using the Wilcoxon-Mann-Whitney tests. All patients who start the radiotherapy and provide data on the primary end point will be analyzed (full analysis set). The data analysis will be performed according to the statistical analysis plan, which will be finalized prior to database lock and any statistical analysis.

The primary study end point is defined as the number of radiation fractions with bladder volumes less than 200 ml after 35 fractions of radiotherapy. Descriptive measures of location and dispersion will be used to describe the results of the prospective study. The impact of patient characteristics on the primary end point will be assessed by Wilcoxon 2-sample tests. These characteristics include age (<75 vs ≥75 years), Karnofsky performance score (70-80 vs 90-100), BMI (<30 vs ≥30=obesity), prostate volume prior to radiotherapy (<60 vs ≥60 mL), risk group of prostate cancer (low to intermediate vs high), and antihormonal therapy prior to and/or during the course of radiotherapy (no vs yes). For confirmatory analysis, the prospective study will be compared with the historical control group through a 2-sided Wilcoxon-Mann-Whitney 2-sample test and a significance level of 5%. A high degree of comparability is expected between the prospective trial cohort and the retrospective patient data set. However, potential heterogeneity among the study populations will be identified by comparing patient characteristics with Wilcoxon-Mann-Whitney tests. Homogeneity will be assumed if all resulting *P* values are above 20%. Any factor indicating a tendency toward heterogeneity (ie, *P*<.20) will be included in a multivariable count data Poisson regression model with the number of radiation fractions with bladder volumes <200 ml as a dependent variable and the respective factors and binary factor (prospective study vs historical control) as the independent variables. If there is evidence of overdispersion, the Poisson model will be replaced by a negative binomial model.

Additionally, secondary end points will be subjected to statistical analysis. Since no comparison with historical data is possible, these analyses will focus on descriptive statistical analysis only. Patient satisfaction results will be used to decide whether the app needs modifications. In the case of a dissatisfaction rate >20%, app modifications will be made. If the app has a dissatisfaction rate >40%, it will be considered not useful.

Ethical Considerations

The examinations to be carried out as part of this trial are all considered standard procedures. There are no additional laboratory investigations or X-rays to be done, or any other examinations that could be potentially burdensome for the patient. The trial protocol was approved by the ethics committee of the University of Lübeck, Germany (file 2024-519), and the trial has been registered at Clinicaltrials.gov (NCT06653751). Prior to inclusion in the trial, each patient will be fully informed about its contents and procedures. If the patient has received the necessary information and the investigator is sure that the patient has understood this information, they will be asked to provide their consent via signature. The patient will receive a

copy of their information and the signed informed consent forms. The investigator will also inform the patient that they have the right to withdraw consent to participate in the trial at any time and without providing any reasons. Patients will be informed that the data collected as part of the trial will be documented anonymously and then forwarded for scientific evaluation.

The trial will be conducted in accordance with the principles laid out in the Declaration of Helsinki. Data will be collected in accordance with the regulations set out in the Data Protection Act. All findings from the clinical trial will be stored on electronic data storage devices and treated with utmost confidentiality. Organizational measures have been taken to prevent the data from being sent to unauthorized people. Patients will only be identified via their individual patient numbers throughout the entire documentation and evaluation phase, and any identifiable data will not be used.

For the personal activation of the app for each study participant, Nextlabel OHG will receive the participant's e-mail address. To ensure the protection of all e-mail addresses, a contract has been signed between the Sponsor (University Medical Center Schleswig-Holstein) and Nextlabel OHG. The contract includes an approved data protection concept. Nextlabel will not have access to any patient data that are not pseudonymized. Amendments to the study protocol may only be implemented if approved by the responsible ethics committees. Only the coordinating principal investigator may carry out such changes. However, all coinvestigators will contact the coordinating principal investigator if modifications are deemed necessary. If any changes are made to the study protocol, all investigators will be informed after ethics committee approval, and the notice must be confirmed.

Data Management and Monitoring

All data relating to patients will be recorded pseudonymously. Each patient will be identifiable only by their unique patient number, date of birth, and sex. A patient identification list will only be kept in the relevant trial centers and will not be forwarded to the sponsor. Data collection will be done using the study-specific data documentation forms that must be filled in using a ballpoint pen. Fountain pens or pencils will not be used. If corrections need to be made, we will cross the error out once with a straight line, enter the correct information next to it, and note the date and/or reason for correction. Comments will be made if data fields cannot be filled in because of missing information. The forms will be filled in as soon as possible and submitted to the checker for review, signed, dated, and forwarded to the study management team.

The original versions of all key trial documents, including the documentation sheets, will be kept at the trial headquarters (ie, the sponsor responsible for the trial) for a minimum of 10 years after the final report.

The principal investigator/head of the trial center will keep all administrative documents (ie, written correspondence with the ethics committee, regulatory authorities, trial management, and trial headquarters), the patient identification list, the signed informed consent forms, copies of the documentation sheets, and general trial documentation (ie, protocol and amendments) for the aforementioned time period. Original patient data will also be kept for the length of time stipulated for the trial centers but not for less than 10 years.

Clinical on-site monitoring at the German sites will be conducted according to good clinical practices and written standard operating procedures to ensure the patients' rights and safety are upheld, along with the reliability of the trial results. For initiation, trial sites will be visited onsite by a clinical research associate. During the trial, sites will be visited at regular intervals depending on the recruitment rate and data quality. Informed consent and defined key data will be checked for all patients. Medical files will be screened for adverse and serious adverse events. Patients' questionnaires will be checked. All trial-specific monitoring activities will be defined before starting the trial and documented in writing (monitoring manual). The sites in other countries will be monitored according to the corresponding national regulations in their own responsibility. No regular audits are planned. However, to ensure the correct execution of the study, audits may be conducted if necessary. Because this study is not linked to the German Medicinal Products Act, no inspections of higher federal authorities are scheduled. A data monitoring committee is not required since patients in this trial will receive standard treatment.

Results

This phase 2 trial investigates the number of radiation fractions with bladder volumes <200 ml in a prospective cohort of patients using a reminder app. In addition, this study evaluates whether the use of the app leads to a significant reduction of the proportion of fractions with bladder volumes <200 ml when compared to a historical control group without app support. The reminder app was developed by the professional company Nextlabel OHG from Lübeck, Germany. It reminds the patients to drink 300 ml of water 45 minutes prior to each radiation session. The time to be reminded can be set by the patients for each radiation session to consider potential changes in schedule (eg, due to maintenance of the linear accelerator). The patients must confirm their water intake and receive a puzzle piece as a reward. Prior to its use in the REFILL-PAC (Reminder App to Optimize Bladder Filling During Radiotherapy for Patients With Prostate Cancer) trial, the app was tested by 30 healthy volunteers to assess its functionality and practicability and to identify and solve relevant issues prior to the start of the trial. Recruitment for this trial will start in March 2025 and is planned to be completed in October 2026. Termination of the entire study (28 patients) is scheduled for December 2026. The expected results will be available at the beginning of 2027. The REFILL-PAC trial did not receive any specific funding. It is part of the Interreg Deutschland-Danmark project Health Advancing Technologies for the Elderly (HeAT) funded by the European Regional Development Fund (01-1-23 2).

Discussion

Expected Results

It is expected that the use of the reminder app will reduce the mean number of radiation fractions with bladder volumes <200

ml by approximately 30% from 26.7 (of 35 fractions) found in the historical control group to 18.7 fractions in patients with a bladder volume <200 ml at CT simulation [8]. A sample size of 25 patients is required for the phase 2 cohort to achieve a power of 90% for statistical significance and a 5% significance level.

Study Limitations

Although appropriate matching will be conducted based on 7 patient- and tumor-related characteristics, the risk of a hidden selection bias cannot be entirely excluded due to the retrospective nature of the data obtained from the control group. Moreover, the fact that patients in the phase 2 cohort must possess a smartphone and be able to use the app may lead to a selection bias. These limitations must be considered when the results of the comparative part of this study will be available and distributed.

Comparison With Prior Work

Radiotherapy for prostate cancer may be associated with significant urinary toxicity such as cystitis, particularly if the volume of the urinary bladder is <200 ml at the time of irradiation. Findings from 3 previous studies highlight the importance of patients drinking a sufficient amount of water each day before irradiation to achieve a bladder volume of <180 ml or, preferably, ≥200 ml [3-5]. To ensure appropriate bladder filling, protocols asking the patients to drink water before CT simulation and/or each radiation fraction have been investigated [5,6,8-17]. In the corresponding studies, the amount of water ranged between 200 and 600 ml, with a waiting period of 30 to 60 minutes before CT simulation or the radiation. However, bladder volumes during the radiotherapy course varied considerably, and adherence to the drinking protocols was suboptimal. This raises the question of whether an app reminding patients before each radiation session of the required water intake could improve adherence to the prescribed drinking protocol.

Dissemination Plan

The coordinating principal investigator will work toward a comprehensive internal and external dissemination of the study results. The coordinating principal investigator, biostatisticians, and staff members of the center will prepare a report regardless of whether the study concludes as planned or is terminated early.

The scientific results will be published in an international, peer-reviewed journal. Additionally, the results will be presented at meetings and symposia. Reports and publications related to the study must be coordinated with the statistician to avoid misinterpretations. Conclusions must be statistically validated and approved by the statistician. The study acronym REFILL-PAC will be used in all publications.

Conclusion

This phase 2 trial is the first study that investigates the impact of a reminder app on the number of radiation fractions with bladder volumes less than 200 ml in patients treated with normo-fractionated radiotherapy alone for localized prostate cancer. The hypothesis is that using the app will significantly reduce the number of fractions below 200 ml compared to a historical control group of patients who underwent normo-fractionated radiotherapy without app support. If the reminder app proves effective, it may contribute to a decrease in urinary toxicity.

Acknowledgments

The REFILL-PAC (Reminder App to Optimize Bladder Filling During Radiotherapy for Patients With Prostate Cancer) trial is part of the Interreg Deutschland-Danmark project Health Advancing Technologies for the Elderly (HeAT), which is funded by the European Regional Development Fund (01-1-23 2). The trial sponsor is the University Medical Center Schleswig-Holstein, Germany. Neither the funding body nor the sponsor has any role in the study conception, data handling, or article writing.

Abstract

Background: Usability tests provide important insight into user preferences, functional issues, and differences between target groups for health interventions and products. However, there is limited guidance on how to adapt the usability testing approach for a youth audience, especially for digital health interventions.

Objective: This protocol paper outlines a novel approach for conducting usability tests with a diverse audience of youth, parents, and clinicians in the development of 2 digital health tools for the pediatric emergency department (ED) setting.

Methods: This paper outlines a protocol for usability testing as part of a broader study aimed at co-designing ED discharge communication tools with youth, parents, and clinicians. The broader study involved co-designing 2 digital tools: one for asthma and one for concussions. A multimethods approach to usability testing was used to assess the functionality of these tools through 2 rounds of testing. A mix of youth, parents, and ED clinicians were invited to participate in each round of usability testing. Participants were asked to provide feedback on the tools through quantitative surveys and open-ended qualitative questions. The usability testing approach was adapted to suit each target group, such as including a youth in the data collection process, to enhance the quality of the data. The severity of usability problems was analyzed following the first round of testing, and each tool was refined based on this feedback. The second round of usability tests involved collecting both qualitative and quantitative feedback on the revised tools.

Results: All usability data have been collected and are being analyzed. Outcomes will be disseminated through a subsequent publication. Results will include demographic characteristics from each user group from both rounds of testing, severity of usability scores, qualitative and quantitative feedback, and differences in test outcomes between each target group.

Conclusions: This paper provides novel guidance for conducting usability tests with youth participants when designing digital health tools. By using a comprehensive co-design and usability testing approach, we anticipate that final tools will be highly relevant to the end users and will lead to better uptake and patient outcomes when pilot-tested in future studies. The outlined approach may be adapted to different health care contexts for other youth participants. Further research should continue to explore ways to design usability tests that are suitable for youth audiences, as there is still a significant gap in the literature around this topic.

Introduction

The International Organization for Standardization describes usability as "the extent to which a system, product or service can be used by specified users to achieve specified goals with effectiveness, efficiency and satisfaction in a specified context of use" [1]. Usability testing is a method in which a product is evaluated by users as they perform tasks, and may include formative or summative testing [2]. Usability testing is considered a cornerstone of user-centered design, valuable for capturing user preferences, to identify any functional issues and determine differences between how certain demographic groups use a product or tool [3]. This information is helpful for both designers and researchers who want to ensure that a product suits the needs of the end user.

In the context of eHealth (ie, digital health tools and health information technologies), applying methods and approaches to usability testing could improve the design and implementation of new interventions. This includes digital tools such as mobile apps, kiosks, virtual care, and electronic health records [4]. The World Health Organization recognizes eHealth interventions as a global priority, as part of the 2020-2025 global strategy on digital health, to create more efficient and effective health care systems [5]. Despite this global health priority setting, it is unclear how often eHealth interventions undergo usability testing prior to implementation. One systematic review reported limited or poor-quality usability testing of electronic health records prior to implementation [6], while another review of 104 eHealth interventions reported that only 38% of them included an aspect of usability testing [4]. Often, eHealth researchers rely on industry-focused protocols, which may lack transferability to complex health care contexts. To evolve the rigor and field of usability testing in the development of eHealth interventions, more diverse testing protocols applied in specific health contexts (eg, emergency departments [EDs]), for specific populations (eg, youth, their caregivers, and clinicians), or for specific types of eHealth interventions (ie, websites versus kiosks) are needed.

Further, eHealth researchers should develop usability protocols that are developmentally appropriate for the target users (ie, age and condition) and relevant to the specific context (ie, hospital or outpatient clinic) where they may be deployed. A scoping review by Maramba et al [7] identified 133 studies where usability testing informed the development of eHealth interventions. However, no studies in the review reported on the usability testing of eHealth interventions in the ED setting, and despite 9 studies being related to child health [7], only 2 studies included youth (aged 14-21 years) as usability testing participants [8,9]. This represents a significant research-to-practice gap as youth and their parents (eg, parents, caregivers, and/or legal guardians) are typically early adopters of eHealth interventions, and their insights could benefit broader adoption. Health services researchers need guidance on how to conduct or adapt usability tests to ensure that end users are appropriately involved in design. The aim of this protocol paper is to describe a youth-, parent-, and clinician-focused approach to usability testing of 2 eHealth interventions for pediatric EDs. This paper will highlight key testing session logistics, considerations for test user eligibility, testing activities and scenarios, adaptations for youth test users, and approaches to synthesizing multimethods usability data.

Methods

Study Design

This protocol paper describes one component of the emergency department discharge communication strategies (EDUCATE) study, which aimed to evaluate a co-design method for discharge communication tools for use in the pediatric ED [10]. Based on methodological guidance from Barnum [2] and calls for a more comprehensive approach to usability testing, as reported in previous literature [6], a multimethods approach including quantitative (ie, surveys and severity scoring) and qualitative (ie, open-ended interviews) data was used. Using a multimethods approach allowed us to view usability data from different lenses, with count and frequency data from surveys and experiential data from qualitative sources. The protocol was designed to support remote synchronous usability testing. Remote, synchronous usability testing has previously been shown to be as effective as in-person usability testing for eHealth interventions among both adults and youth [11]. Formative usability testing was used, where tools were evaluated through 2 iterative cycles with a small number of participants [2] to identify any errors prior to implementation. The Template for Intervention Description and Replication (TIDieR) checklist was used to guide the reporting of this protocol paper [12] (Multimedia Appendix 1).

Ethical Considerations

The study received ethical approval from the institutional review board at IWK Health (#1024004). All participants provided written informed consent prior to each usability test. Additional consent was obtained from a research team member whose image is included in the study materials. Following each usability test, participants received a unique identifier, and their data remained anonymous and confidential. Upon completion of the usability test, all participants received a CAD $30 (US $20.96) gift voucher as a reimbursement for their time.

Tool Development

During the first phase of the EDUCATE study, 2 electronic discharge communication tools were co-designed by parents, youth, and ED clinicians (ie, nurses and physicians) [13]. A full description of the co-design process will be published in a future publication and is briefly described here. Two co-design teams were established, one for asthma and one for concussion, and met 8 times over a 2-year period between 2020 and 2022. Each co-design team worked together to develop an interactive web-based tool that would address a key discharge

communication issue for youth and families visiting the ED. One tool was co-designed to help parents and youth decide whether to visit the ED during an asthma attack, while the second tool was co-designed to help parents and youth navigate the postconcussion recovery journey after leaving the ED. Two user design experts integrated the co-design teams' ideas into 2 digital tools, which were then assessed for usability.

Usability Testing Steps

The usability testing process involved four steps, based on usability testing literature [2]: (1) defining the user profiles, (2) the think-aloud process, (3) task-based scenarios, and (4) refining and retesting. Each usability test was facilitated by a researcher trained in mixed and multimethods health services research (MS). Previous literature shows that usability tests often use one approach (ie, quantitative, qualitative, or heuristic methods) to collect usability data, but few use multiple methods [7]. Therefore, a combination of quantitative and qualitative methods was used to gather comprehensive usability data and to identify as many usability issues as possible. The usability tests included a combination of quantitative self-report survey questions, qualitative think-aloud processes, observations, and open-ended interview questions, and were planned to last approximately 60 minutes. This protocol paper focuses on the usability testing process, while more details on recruitment, study setting, and outcome data will be reported in a future publication. Table 1 and the following section describes each of the four usability steps in detail, including how each step was adapted for each target population (ie, youth, parents, and ED clinicians).

Table 1. Overview of the usability testing process including each step and corresponding component of the usability test.

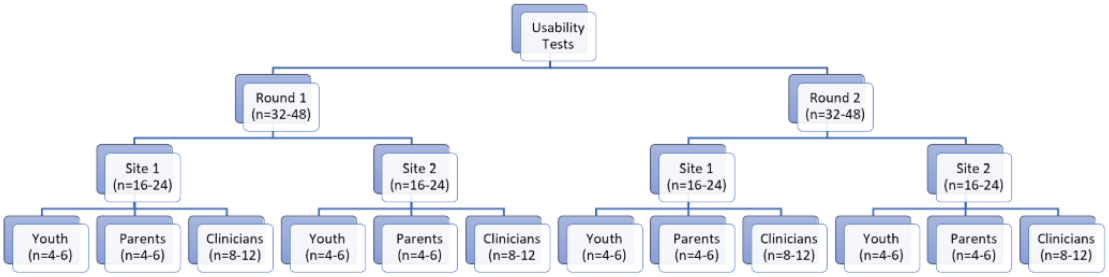
Step and item	Goal
Usability step 1: defining the user profiles	
Presession	
Screening questionnaire	• Determine eligibility for the usability test
Informed consent	• Gain written informed consent
Round 1 (total session time: 60 minutes)	
Opening script (5 minutes)	• Describe the study and provide an overview of tasks • Allow participants to ask questions
Demographic survey (5 minutes)	• Gather demographics, health care usage, and computer skills data
Usability step 2: think-aloud process—overview of the "think-aloud" process (5 minutes)	• Describe the think-aloud process • Go through 1 live example of the think-aloud process, using a familiar website (all participants) • Share a prerecorded video of the think-aloud process with a youth participant (youth participants only)
Usability step 3: task-based scenarios	
Task 1: first impressions (20 minutes)	• Gather initial thoughts about the tool • Complete a word desirability activity
Task 2: scenario-based activities (×2; 15 minutes)	• Gather qualitative and quantitative metrics related to specific tasks, designed to capture the main functions of the tool
Gibson survey (5 minutes)	• Gather additional quantitative usability testing data
Thank you and closing remarks (5 minutes)	• Thank participants for joining • Discuss compensation and next steps
Postsession	
Quantitative data analysis	• Gather time to complete tasks, number and frequency of errors, usability severity scores, and satisfaction data
Qualitative data analysis	• Gather qualitative feedback about usability issues and satisfaction with the tool
Usability step 4: refining and retesting	
Presession	
Screening questionnaire	• Determine eligibility for the usability test
Informed consent	• Gain digital e-consent
Round 2	
Demographic survey	• Gather demographic details about participants prior to testing
Posttask questionnaire	• Gather quantitative and qualitative usability and satisfaction data on a refined version of the tool through an asynchronous, remote usability test with a new group of end users

Step 1: Defining the User Profiles

Overview

Barnum [2] proposes that defining the user profile is an important first step in usability testing. As our tools were codeveloped by and for ED clinicians, parents, and youth, these 3 target groups were chosen as the user profiles. For this study, youth included any individual aged between 12 and 19 years who had visited the ED for either asthma or concussion in the past year. Parent users included any adult (>18 years) who visited the ED with their child for asthma or concussion presentations in the past year, and the clinician profile included any nurse or physician employed in a pediatric ED setting. Nielsen and Landauer [14] argue that 85% of usability issues could be identified with as few as 5 participants, and Barnum [2] proposes that formative usability testing is better suited to a smaller number of participants. Therefore, we aimed to include 2 to 3 participants from each user group (youth, parents, ED nurses, and ED physicians) for each tool across 2 study sites for a proposed sample of 16 to 24 participants from each site in each round of usability testing (Figure 1).

Figure 1. Overview of the expected number of usability testing participants to be recruited from each site for each round of testing for each tool.



Eligibility and Pretest Survey

To determine eligibility, a screening survey was administered to interested participants through the REDCap (Research Electronic Data Capture; Vanderbilt University) platform [15]. Since participants would be testing a digital tool, it was important to screen for health literacy level and access to a computer with audio/video capabilities. To assess health literacy level, the REDCap survey included branching so that parents would be directed to the METER health literacy test [16], which is shown to be a quick and valid measurement of health literacy level among adults. Youth were directed to the Health Literacy Assessment Tool 8 test [17], a quick, feasible and accurate health literacy assessment tool for youth [1]. Clinicians did not have to complete a health literacy test. The screening survey can be found in Multimedia Appendix 2. Participants provided written informed consent and agreed on a day and time to complete a test session with the facilitator (MS).

Test Session Setup

Participants joined the session remotely via the Zoom (Zoom Video Communications) using their own computer and webcam. The facilitator provided a brief overview of the study and allowed participants to ask questions to ensure that they understood the expectations of the usability test. The facilitator described that the aim of the usability test was to find problems with the tool and assured participants that their skills and abilities were not being evaluated. This was important to create a safe testing space, particularly for youth participants. Participants were then asked to complete a demographic questionnaire on REDCap prior to the start of the test. The facilitator shared a link to the survey and allowed the participant to complete the test in real time to ensure higher completion rate. Sessions were video recorded.

Step 2: the Think-Aloud Process

The think-aloud process involves participants talking through their thought process as they complete a task or solve a problem [18]. This approach is common in usability tests of eHealth interventions [6,7] and is valuable for understanding participants' decision-making processes rather than strictly observing their behaviors [19,20]. Following the completion of the demographic survey, and immediately prior to the start of the usability test, the facilitator explained to participants how to use a think-aloud approach during the usability test. A mock example was used, which involved navigating a popular Canadian departmental store's website so that test users could become familiar with the think-aloud process in a web-based environment they recognized. While it was important to demonstrate the think-aloud process with all participants, the co-design team suggested that a second think-aloud example featuring a youth should be modeled for youth participants prior to their usability test. Therefore, a youth member of the co-design team created a 1-minute video of themselves using the think-aloud process to find their way on a popular theme park's map (Figure 2). This was played for all youth participants prior to the start of the usability test. Examples of the think-aloud process were shared with the co-design teams and refined based on their feedback prior to starting the usability tests with participants.

Figure 2. A screen capture of the youth-led think-aloud example.

Step 3: Task-Based Scenarios

Overview

Once participants confirmed that they were comfortable with the think-aloud process, the facilitator started video-recording the usability testing session. The facilitator used a variety of techniques to fully evaluate the usability of the eHealth intervention by adapting traditional usability methods for the end user population (ie, youth, parents, or clinicians). Before sharing a link to the tool, the facilitator shared a link to a web-based Microsoft Word document to guide the user through tasks and included visual prompts to support the scenario-based exercises. This approach was used to eliminate the need for alternating screen sharing by the facilitator and participant and to reduce complexity in the remote testing environment [21]. Six documents were developed, based on the 6 unique user groups (ie, youth with asthma, their parents, and their clinicians; and youth with concussions, their parents, and their clinicians).

Task 1: First Impressions

The first task in the usability test was designed to gather participants' first impressions of the tool. This crucial step in usability testing can quickly determine whether users like or dislike a tool in about 80% of cases [2]. After opening the tool, users were invited to click around, using the think-aloud process to describe their initial reactions to the tool. The facilitator used open-ended prompts to encourage verbalizations of what the participant was thinking; these included the following: "What are your first impressions of the tool?" "What do you think the purpose of the tool is?" Participants were then asked to choose 5-10 words from an adapted list of 118 desirability reaction words of Benedeck and Miner [22]. For usability tests, the Nielsen Norman Group [23] suggests adapting the original list to include approximately 25 words that are appropriate for the user interface being evaluated, with at least 40% of chosen words having a negative connotation. This activity aimed to gather additional user satisfaction data while helping participants, particularly youth, feel more comfortable about sharing their honest thoughts about the tool. This approach has been successfully used in previous usability tests [24]. The list of desirability words can be found in Multimedia Appendix 3.

Task 2: Scenario-Based Questions

Next, participants were presented with a scenario relevant to their user identity (ie, youth, parent, or clinician) and medical condition (ie, asthma or concussion). Each scenario was designed by a research team member (MS) based on the user's persona, as outlined by Quesenbery and Brooks [25]. This involved crafting a situation with the user as the main character where they must achieve a specific goal by using the eHealth intervention being tested. The facilitator used a visual guide and a predetermined script to describe a scenario and then ask participants to complete 2 tasks. The tasks were designed to walk participants through key features of the tool so that additional navigation and usability errors could be easily identified. Participants were asked to use the think-aloud process to describe their thoughts and decisions as they completed each task. Participants were asked open-ended questions about the scenario-based activities, such as the following: "How did you find using the tool to complete that task?" "Is there anything you would change about the tool to make that task easier?" The user-specific tasks are outlined in Multimedia Appendix 4.

Global Feedback

Following the scenario-based tasks, participants were asked open-ended questions about the tool, such as the following: "Is there anything else you would change about the tool to make it better?" "On what device/format would you most likely use this tool if you were to use it in the future?" Quantitative data about

the functionality and satisfaction of the tool were captured through a REDCap survey, which was administered to participants at the end of the usability test. The facilitator shared a link to the survey using the chat feature of the web-based meeting platform and waited until participants completed the task in real time, to ensure a high completion rate. This posttest was adapted from a survey by Gibson et al [26], which is a validated tool for collecting patient and provider satisfaction data on educational resources. The survey by Gibson et al [26] aims to gather information on visual appeal, functionality, content, and intended use. Branching was used to direct participants to the correct survey in REDCap, as the youth survey also included a question to understand the impact of seeing a youth-led example of the think-aloud process. The posttest surveys adapted from Gibson et al [26] can be found in Multimedia Appendix 5 [26].

Step 4: Refining and Retesting

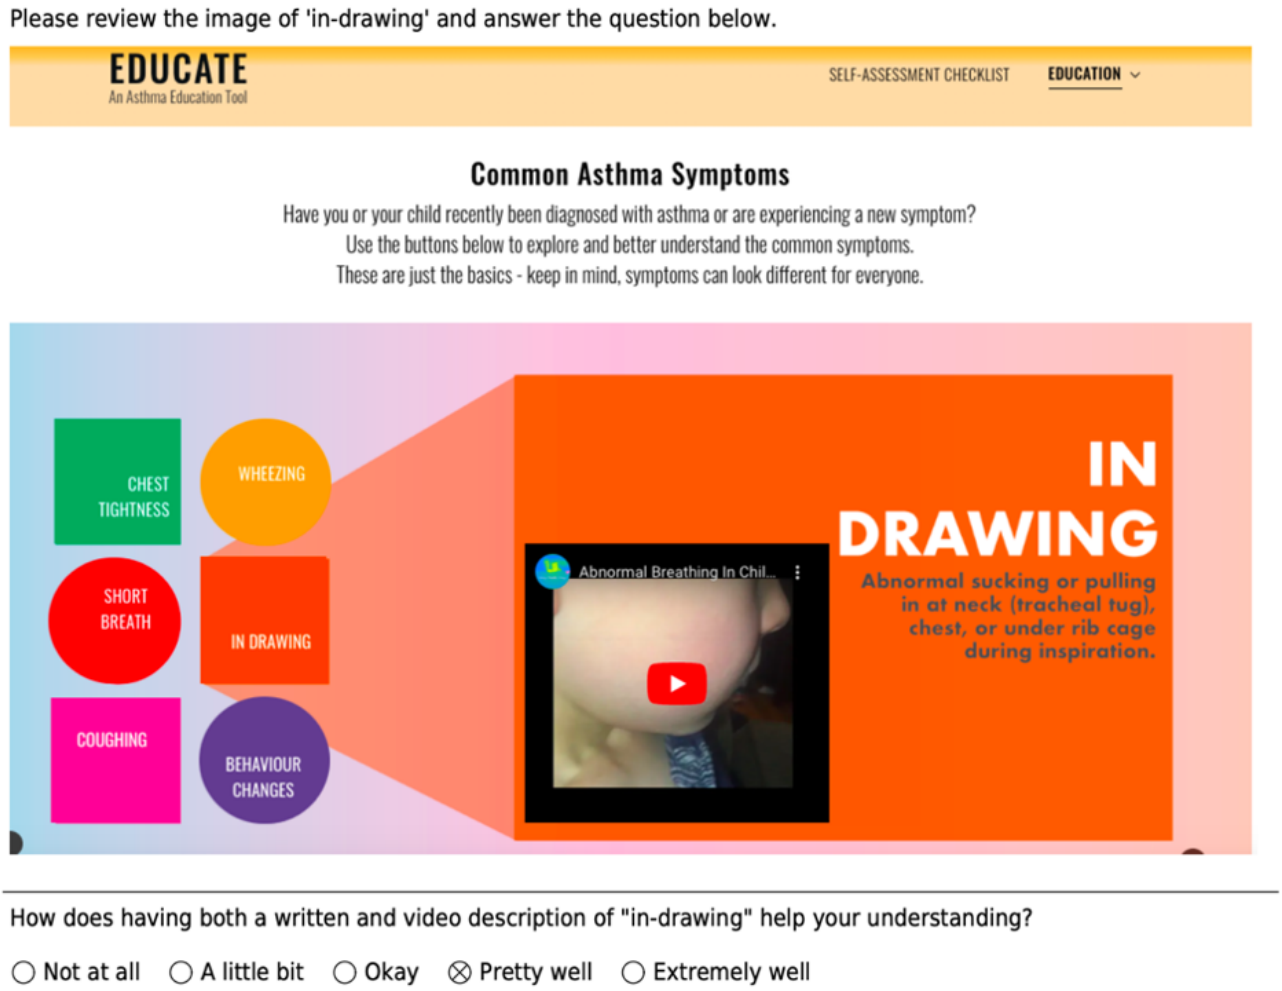
Following each usability testing session, the video recording was uploaded to a secure, password-protected internet server. Four coders (MS, JC, AG, LW) watched the videos and independently scored the usability issues using a combination of Nielsen's [27] scoring system and qualitative analysis. The Nielsen scoring system for severity of usability issues is based on a 5-point scale, ranging from 0 (no usability problem) to 4 (catastrophic usability problem) [27]. Nielsen [27] proposes 3 factors associated with a usability issue: frequency of the problem, impact of the problem, and persistence of the problem. If an eHealth intervention is evaluated to include only minor usability issues (score of 0-2), then the tool may be released without further refinement, while an eHealth intervention with major or catastrophic issues (score of 3-4) should undergo alterations before another round of testing and/or public release [27]. Each coder scored the recorded usability sessions using a deductive approach, following Nielson's [27] scoring system. A numerical value and descriptive details were entered into an Excel (Microsoft Corp) sheet to explain the reasoning underlying each score. Coders then met to discuss their scores and reach a consensus on final severity scores for each usability test.

In conjunction with Nielson's [27] severity scoring step, each reviewer made notes about users' open-ended responses or comments during the usability session. For example, if users described their dislike of a certain feature of the eHealth intervention, the reviewer documented this during the qualitative analysis. Directed content analysis was used to understand the qualitative data and identify the most reported user issues [28]. This type of qualitative analysis allows for a deeper interpretation of qualitative data, often informed by a theory or previous research, and allows for the quantification of the data [28]. In this study, the quantitative findings informed the qualitative data analysis and allowed researchers to calculate the number of user issues with additional context. Following qualitative analysis and severity scoring of each usability test, a description of the most severe usability issues and a list of proposed changes was sent to the design team. The developers then refined the tools by addressing severe usability issues and the most common cosmetic concerns.

The refined tools were brought to each co-design team for further input before undergoing a second round of usability testing with another sample of target users. As the first round aimed to identify catastrophic usability issues, the second round was intended to identify additional, minor issues. This second round of usability testing involved a modified, remote, asynchronous approach to capture any additional usability issues in the tools. As the first round aimed to identify catastrophic usability issues, the second round was intended to identify additional minor issues. Therefore, a modified approach was used to quickly gather usability information without placing unnecessary burden on participants. To capture remote usability data, images and video clips were embedded in a new REDCap survey to demonstrate the main functions and features of the tools (Figure 3). Participants then completed posttask questionnaires using a Likert scale, informed by Nielson's [27] methods, with additional free-text boxes to capture qualitative data. Basic demographic questions were also included in the survey.

The final version of each tool was then presented to the co-design team members for their thoughts. Each team made final decisions about what refinements should be incorporated into each tool, signaling the end of the usability testing process.

Figure 3. Example of an embedded video clip, along with posttask questions from the asthma tool.



Results

The first round of usability testing was conducted between December 2021 and July 2022, while the second round of testing was conducted between November 2022 and March 2023. Data analysis of round 1 took place in July and August 2022 and informed the second round of testing. The final results from both rounds of usability testing will be shared in a future publication. Outcome data will include an overview of severity of usability scores from round 1, qualitative feedback on tool usability and satisfaction from rounds 1 and 2 of testing, and demographic details about study participants. Details about the changes made between rounds 1 and 2 of usability testing will also be presented and may include changes such as button size or location, colors, and new navigation pathways. We will describe any observations related to user characteristics and feedback and identify opportunities for future usability testing and implementation.

Discussion

Anticipated Findings

This paper addresses an important gap in the academic usability literature by detailing a co-designed approach to usability testing that was adapted for youth, parents, and clinicians. In particular, this paper describes multiple adaptations that were made to the testing procedures to address developmental stages and comfort levels of youth participants. These adaptations included modeling the think-aloud technique by other youth, allowing for a test-and-try before initiating the recording, screening for the appropriate level of health literacy so participants would be able to complete tasks, using multiple methods for soliciting feedback (self-report survey, observation, and interviews) so participants had varied opportunities to express opinions and suggestions, keeping testing sessions brief and accessible offsite (ie, via Zoom), keeping the sessions short (<60 minutes), using branching logic in data collection methods so participants only accessed information relevant to them, and including less cognitively demanding activities (eg, word desirability activity) to solicit feedback. By applying these approaches to usability testing, it is anticipated that the feedback will be highly relevant, leading to a more user-centered product. We expect that the first round of usability testing will lead to several changes to the tools, while the second round may result in fewer or more minor changes. By using a co-design approach and bringing the usability feedback to each co-design team for further consideration, the next step of piloting the 2 tools in ED settings will lead to positive uptake and outcomes. Previous studies have indicated the benefits of using a co-design approach to engage more end users [29]. However, few usability studies tend to include the youth perspective, even when they are the target

audience [7]; hence, we expect this paper to be a significant and beneficial contribution to the usability literature.

Strengths and Limitations

While this paper provides a comprehensive overview of an approach to usability testing for youth, there are several limitations to consider. Due to the remote nature of the usability tests, participants require internet and computer access. Further, among individuals who do complete a remote usability test, the differences in home environments and technical equipment may affect the quality of the testing process [21]. Future work may focus on offering technical support or request a specific technology setup, as these concerns may have limited participation for some individuals, particularly those from lower socioeconomic backgrounds. Additionally, while it is not a requirement to speak English as a first language to participate in the study, the digital tools were only designed in English, and therefore non–English speakers may be unable to complete the usability tests. Although a small sample of participants is needed to identify most usability issues, a small sample may reduce the generalizability of the findings, which may be seen as a limitation. We have future research planned to mitigate both of these concerns by co-designing multilingual digital tools with broader populations to ensure that the specific needs of clinicians, parents, and youth from varied backgrounds are met. Finally, while the findings of the usability tests may not be generalizable to a non-ED health care context or for individuals presenting with medical conditions apart from concussion and asthma, the techniques used to engage youth may be applied to any usability testing setting.

Key Recommendations and Conclusion

Youth provide valuable perspectives into eHealth intervention designs and therefore should be included in the usability process; however, there is a significant gap in the literature around usability testing with youth in health services. Therefore, researchers may find the methods used in this paper helpful for guiding usability tests with youth participants in other health care contexts. Further outcome data are needed to determine what works well in youth-based usability studies, some of which will be shared through a future publication presenting the outcomes of the detailed approach.

Acknowledgments

We would like to acknowledge the members of each co-design team who designed the digital health tools assessed through usability testing.

Data Availability

The datasets generated during this study are not publicly available because the results have not yet been analyzed but are available from the corresponding author on reasonable request.

Abstract

Background: Cognitive impairments are a key aspect of schizophrenia spectrum disorders (SSDs), significantly affecting clinical and functional outcomes. The COVID-19 pandemic has heightened concerns about mental health services and cognitive stimulation opportunities. Despite evidence-based interventions like action-based cognitive remediation (ABCR) and metacognitive training (MCT), a research-to-practice gap exists in their application across mental health settings.

Objective: The iCogCA study aims to address this gap by implementing digital ABCR and MCT through a national Canadian collaborative effort using digital psychological interventions to enhance cognitive health in SSDs.

Methods: The study involves 5 Canadian sites, with mental health care practitioners trained digitally through the E-Cog platform, which was developed by our research group. Over 2.5 years, participants with SSDs will undergo pre- and postintervention assessments for clinical symptoms, cognition, and functioning. Each site will run groups annually for both ABCR and MCT, totaling ~390 participants. A nonrandomized concurrent controlled design will assess effectiveness design, in which one intervention (eg, ABCR) acts as the active control for the other (eg, MCT) and vice versa, comparing cognitive and clinical outcomes between the interventions using generalized linear mixed effect modeling. Implementation strategy evaluation will consider the digital

platform's efficacy for mental health care practitioners' training, contextual factors influencing implementation, and sustainability, using descriptive statistics for quantitative data and thematic analysis for qualitative data.

Results: A pilot pragmatic trial has been conducted previously at the Montreal site, evaluating 3 early implementation outcomes: acceptability, feasibility, and engagement. Patient and therapist acceptability was deemed as high and feasible (21/28, 75% of recruited service users completed therapy, rated feasible by therapists). Technology did not appear to significantly impede program participation. Therapist-rated levels of engagement were also satisfactory. In the ongoing study, recruitment is underway (114 participants recruited as of winter 2024), and intervention groups have been conducted at all sites, with therapists receiving training via the E-Cog learning platform (32 enrolled as of winter 2024).

Conclusions: At least 3 significant innovations will stem from this project. First, this national effort represents a catalyst for the use of digital technologies to increase the adoption of evidence-based interventions and will provide important results on the effectiveness of digitally delivered ABCR and MCT. Second, the results of the implementation component of this study will generate the expertise needed to inform the implementation of similar initiatives. Third, the proposed study will introduce and validate our platform to train and supervise mental health care practitioners to deliver these interventions, which will then be made accessible to the broader mental health community.

schizophrenia spectrum disorders; digital technology; cognitive health; cognitive remediation; metacognitive training; schizophrenia; digital group interventions

Introduction

Background

Schizophrenia and related psychoses present debilitating challenges, imposing an enormous burden on individuals, families, and communities [1,2] and are characterized by symptom recurrence, social deterioration, and cognitive impairments [3-8]. Most affected individuals experience persistent positive (eg, hallucinations and delusions) and negative symptoms (eg, amotivation, avolition, and reduced expressivity), alongside notable cognitive challenges like difficulties in verbal memory, executive functions, and attention. In addition to these impairments are cognitive distortions [9], affecting reasoning and information processing and, collectively, represent a core feature of schizophrenia, impacting clinical and functional recovery [10-13]. Thus, addressing overall cognitive health in schizophrenia is crucial. Over the past 25 years, advancements in psychological interventions, including cognitive remediation (CR) and metacognitive training (MCT), have shown promise for the treatment of schizophrenia spectrum disorders (SSDs). Both CR and MCT have been found to enhance cognitive functioning and decrease cognitive biases [14,15].

Cognitive Health Interventions in Schizophrenia: State of the Evidence and Delivery Format

Meta-analyses affirm the effectiveness of CR in enhancing cognition [14,16,17] and MCT in addressing cognitive biases [15,18]. Notably, various mental health practitioners with an understanding of cognitive processes can be trained to provide these interventions, providing flexibility in service delivery [19-21]. Delivered in a group format, these interventions enable practitioners to reach multiple service users simultaneously [20]. Research indicates the feasibility of using technology for remote cognitive assessment and psychological interventions, as individuals with psychosis express interest and willingness to engage with digital mental health services [22-24] and find this mode of communication more satisfying and less challenging than observed in the general population [25].

Preliminary Work on Remote Delivery of Cognitive Health Interventions

Our preliminary work investigated the remote delivery of action-based cognitive remediation (ABCR) and MCT [26]. ABCR is a distinct form of CR, which integrates the traditional cognitive training techniques of CR with simulated workplace scenarios and goal setting [27]. This work involved evaluating 3 crucial early implementation outcomes: acceptability, appropriateness, and feasibility for both patients and therapists. Across 6 cohorts (3 ABCR and 3 MCT) conducted within Montreal, patients expressed high acceptability, with overall satisfaction for expectations and perception of progress. The interventions demonstrated feasibility; 36 participants completed therapy, attending an average of 10 MCT sessions and 12 ABCR sessions.

Using recently developed measures [28], therapists also reported excellent acceptability, appropriateness, and feasibility of the interventions [26]. Several facilitators and barriers to delivering these digital interventions were also identified. Barriers comprised patients' clinical status (eg, more severe symptomatology and medication side effects), interaction issues (eg, lack of involvement and decreased accountability), technological challenges (eg, access to devices and the internet), program elements (eg, language options), and scheduling conflicts. On the other hand, facilitators included patients' motivation to learn, therapist characteristics (eg, warmth and proper training), financial support for internet connectivity, program support (eg, education on interventions and ice breakers), and logistical adjustments (eg, offering evening sessions and forming smaller groups).

Objectives

Having established the acceptability, appropriateness, and feasibility of our digital interventions that collectively represent the early stages of implementation, the next step is to examine how the proposed digital strategies promote the uptake of these interventions across mental health care settings. A major challenge with evidence-based psychosocial interventions is that very few are subsequently tested in effectiveness or implementation trials and thus have little impact on population health [29]. The field of implementation science has emerged over the last 20 years, promoting strategies to adopt and integrate evidence-based interventions and change practice patterns within specific settings. Implementation frameworks, such as the Consolidated Framework for Implementation Research (CFIR) [30], provide the roadmap and tools to achieve this. To test this implementation strategy, we propose a study spanning 5 different mental health care sites across Canada. In collaboration with partners and knowledge users, we will conduct a hybrid effectiveness-implementation trial and create a bilingual digital learning platform (English and French) to ensure the long-term use of these digital interventions nationwide. The first objective of this study is to investigate the clinical effectiveness of the digital modality of ABCR and MCT. The second objective of the study is to investigate the implementation strategy involving (1) the contextual factors influencing the digital delivery of cognitive health interventions [31], (2) the effectiveness of a digital learning platform (E-Cog) to train mental health practitioners, and (3) the sustainability of the maintenance of these interventions within current clinical settings.

Methods

Study Design

A hybrid effectiveness-implementation trial [32-34] relying on digital technology will be used. The effectiveness component involves assessing the outcomes of these interventions, while the implementation component focuses on conducting the research in a way that emulates the naturalistic clinical setting. This design is ideal for transferring evidence-based behavioral interventions into real care environments [32-35], as it confirms clinical effectiveness while targeting necessary procedures to deliver and sustain such interventions in real-world care settings. A nonrandomized concurrent controlled design will be used to assess clinical effectiveness where one intervention acts as the active control for the other. The nonrandomized concurrent controlled design was selected, as it eases access to the preferred intervention by service users, overcoming the challenges of randomizing participants in real care settings and facilitating recruitment.

Study Setting

This study takes place across 5 sites providing care to those with psychotic disorders across Canada. These sites include the Centre intégré universitaire de santé et de services sociaux (CIUSSS) de l'Ouest-de l'Ile de Montréal, Royal Ottawa Health Care Group, Kingston Health Sciences Centre, Ontario Shores Centre for Mental Health Sciences in Toronto, and Vancouver Coastal Health. We will recruit 390 service users across the 5 sites.

Selection Criteria

Inclusion criteria include 18 years of age or older; diagnosis of affective or nonaffective psychosis or related disorder; followed and treated by a clinician at one of the services mentioned earlier; considered symptomatically stable and capable of using the digital platforms and participating in intervention groups, as judged by their primary clinicians; access to a private space to ensure group confidentiality; and provision of emergency contact and consent to allow researchers to contact their clinician or emergency services in the event of an emergency during study procedures. Most criteria are present for the safety of the group and participants. Exclusion criteria include intellectual disability, hospitalization at the time of recruitment, inability to speak or read English or French, and high suicide risk as per evaluation. We will recruit 4-6 mental health practitioners per site who will complete training on the E-Cog training platform to deliver the 2 cognitive health interventions. Practitioners will be eligible if they have a background in psychology, social work, nursing, or any other health-related training.

Recruitment

Recruitment for this study uses a multimodal communication strategy designed to effectively reach potential participants. This strategy includes displaying informational flyers on hospital television screens, distributing email newsletters to health care employees, and presenting intervention details to case managers to facilitate referrals. Additionally, recruitment materials will be posted in clinic waiting rooms. n example of the recruitment pamphlet is provided in Multimedia Appendix 1. Health care team members can refer eligible participants or obtain consent for the research team to make direct contact. Participants are permitted to be engaged in other psychological or psychosocial interventions while participating in our study. Data on whether they are currently receiving other interventions will be collected.

Ethical Considerations

This study has been approved by the respective research ethics boards (REBs) of the 5 mental health sites and their partner institutions. The study will be conducted in Montreal (CIUSSS de l'Ouest-de l'Ile de Montréal; REB 2023-561) [36], Ottawa (Royal Ottawa Health Care Group; REB 2022034) [37], Kingston (Kingston Health Sciences Center; REB 6037321) [38], Toronto (Ontario Shores Centre for Mental Health Sciences; REB 38116) [39], and Vancouver (Vancouver Coastal Health; REB H22-02300) [40]. The research adheres to the principles outlined in the Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans and complies with Canadian legal requirements for scientific research involving human participants, including the Privacy Act and applicable clinical trial regulations [41]. Participants provide informed consent through a comprehensive process that includes a detailed explanation of the study's objectives, procedures, potential risks and benefits, and their rights as research participants, in accordance with the Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans guidelines. This process will involve both written documentation and verbal discussion, and participants will be informed of their right to withdraw from the study at any time without consequence to their ongoing care. Particular attention will be given to ensure

an understanding of these processes among individuals with SSDs. All collected data will be deidentified using unique participant codes, with personal identifiers stored separately in encrypted files accessible only to authorized research personnel. In terms of compensation, participants will receive monetary remuneration for each completed assessment measure, with a standardized gift card amount of US $18 per assessment session or focus group. This compensation structure ensures fair and consistent reimbursement for participants' time and effort while maintaining ethical standards for human participant research. The compensation details will be clearly communicated to participants during the informed consent process to ensure transparency and avoid undue influence on participation decisions.

Measures

To assess the effectiveness of the 2 digital cognitive health interventions (objective 1), primary outcomes will encompass quantitative measures of cognitive function for ABCR and cognitive biases for MCT. These outcomes were selected in alignment with the primary targets for each intervention and primary outcomes assessed in the past ABCR and MCT studies. To capture the full extent of these outcomes, both objective and self-report measures were selected. The collection of these primary outcomes will be prioritized. Secondary outcomes for both interventions will include clinical and functional measures. Propensity score matching will consider background characteristics such as sociodemographic variables, illness duration, medication dosage, length and nature of prior treatment, and subjective reports of cognitive capacity and biases. To promote data quality, research staff will partake in centralized interrater reliability sessions every 6 months. To evaluate the implementation strategy (objective 2), a combination of quantitative and qualitative data will be gathered. Refer to Table 1 for a breakdown of the data types to be collected, organized by objectives, time points, and stakeholders.

Table 1. Summary of the type of data to be collected as a function of objectives, time points, and stakeholders.

Objectives or data type and measures	Measurement time points	Stakeholder groups
1. Effectiveness (quantitative)		
Cognitive tests or tasks: • Brief version of the CANTAB[a] computerized battery (Intra-Extra Dimensional Set Shift, Stocking of Cambridge, and Spatial Working Memory)[b] [42] • Wechsler Memory Scale (Logical Memory Subscale)[b] [43] • Cognitive bias against disconfirmatory evidence story[b] [44] • Jumping to conclusions (Beads)[b] [45]	• Preintervention • Postintervention • 3-month follow-up	Service users
Subjective cognition: • Subjective Scale to Investigate Cognition in Schizophrenia (Brief)[b] [46] • Cognitive Motivation Scaleb [47] • Davos Assessment of Cognitive Biases Scale[b] [48]		
Symptoms: • Positive and Negative Syndrome Scale-6 [49] • Brief Negative Symptom Scale [50] • Psychotic Symptom Rating Scales [51]		
Psychosocial: • Self-Esteem Rating Scale—Short Form [52] • Overall Emotional and Social Loneliness Scale [53] • Short Warwick-Edinburg Mental Well-Being Scale [54] • Questionnaire About the Process of Recovery [55] • Basic Psychological Need Satisfaction and Frustration Scale [56] • Autonomous-Controlled Motivation for Intervention Questionnaire [57] • Personal and Social Performance [58]		
Intervention: • Health Care Climate Questionnaire [59] • Autonomous-Controlled Motivation for Intervention Questionnaire [57] • MMI[c] Cognitive Training Questionnaire [60] • Satisfaction With Therapy (STQ[d]) [61] • Time spent on cognitive drill exercises (ABCR[e]) • Last log in (iCog platform)	• Midintervention	Service users
2. Implementation (quantitative and qualitative)		
Evaluation of E-Cog platform: • Number of practitioners invited to participate in the E-Cog training • Number of practitioners agreeing to participate in E-Cog training • Reasons for nonparticipation or participation • Number of practitioners not agreeing to participate in E-Cog training • Total number of attendees participating in all of the training modules • Total number of attendees per session or module • Semistructured interview (health care practitioners)	• Preintervention • During intervention	Health care practitioners and service users
Evaluation of factors influencing the implementation of the 2 digital interventions: • E-Therapy Attitudes and Process Questionnaire—Therapist Version [62] • Semistructured interview (service users and health care practitioners)	• Postintervention (8-12 and 24-30 months after the 2 interventions are implemented)	Health care practitioners and service users
Sustainability: • Program Sustainability Assessment Tool [63] • Monitoring of the intervention offer after an effectiveness trial at each site	• Postintervention	Health care practitioners and service users

[a]CANTAB: Cambridge Neuropsychological Test Automated Battery.

[b]Denotes primary outcomes in the study.

[c]MMI: MUSIC Model of Academic Motivation Inventory.

[d]STQ: Satisfaction Therapy Questionnaire.

[e]ABCR: action-based cognitive remediation.

Cognitive Health Interventions

Interventions will be delivered through a secure videoconference platform. Network-connected tablets will be provided as necessary for the trial duration. ABCR [27,64] sessions consist of computer-based cognitive training activities (Brain Training Pro; 60%), teaching of problem-solving strategies (20%), and transfer activities (20%). Transfer activities include discussing and role-playing how cognitive skills are applied in everyday life and teaching potential strategies for overcoming cognitive challenges. ABCR targets include processing speed, attention, memory, executive functions, and social cognition, which are all commonly impaired in psychosis [12]. ABCR will be delivered in 16 sessions lasting 1.5 hours each over an 8-week period. MCT targets cognitive biases and errors in judgment underlying delusions using the theoretical foundations of cognitive behavioral therapy [65]. Sessions consist of discussions and activities aimed at increasing participants' awareness of distortions and expanding their current problem-solving strategies. MCT will be delivered in 12 sessions lasting 45-60 minutes each over 6 weeks.

Both interventions will be offered at all sites. Depending on the site, interventions will either be offered concurrently or in sequence. Intervention group allocation follows a personalized, participant-centered approach. Potential participants will meet individually with the research coordinator at their site, who will provide a comprehensive overview of both interventions. Together, they will collaboratively determine which intervention best aligns with the participant's personal goals and preferences. To maximize participant benefit and engagement, individuals will have the opportunity to complete the alternative intervention after finishing their initial chosen intervention. This flexible approach ensures that participants can potentially benefit from both interventions.

To improve adherence, participants will be contacted prior to each session with reminders. If participants miss several sessions in a row, therapists or a research assistant will contact them to confirm their interest in continuing the intervention and discuss any barriers to their participation. If any adverse reactions occur during the trial, participant involvement in our study may be discontinued after a discussion with the research team. Finally, to improve and track treatment adherence, sessions will be audio recorded, and 2 sessions from each of the ABCR and MCT groups will be randomly selected for review by 2 experienced facilitators using the treatment integrity assessment tool.

Training Platform

E-Cog training platform [66] is a digital platform providing training certifications for ABCR and MCT interventions developed by our group following the analyze, design, develop, implement, and evaluate model for the design of digital learning platforms [67]. Each training certification includes three training modules: (1) impact of cognitive impairments in psychosis and an introduction to remediation strategies (2 hours), (2) technological tools for digital mental health (1 hour), and (3) theoretical foundations and practical delivery of ABCR (~9 hours) or MCT (~12 hours). After obtaining the training certification, mental health practitioners participate in weekly supervision by a dedicated experienced trainer using a secure videoconferencing software. Screenshots from the training platform can be found in the multimedia appendices (Multimedia Appendices 2-4).

Involvement of Individuals With Lived Experience

Peer support workers have been involved at different stages of the project. The pilot study, which informed this study, involved 2 peer support workers in the project committee. In this study, our peer support worker has been providing continuous consultation, which has led to changes throughout the study (eg, adapting intervention materials). Our peer support worker will also be involved in the intervention groups and will be coconducting the service user qualitative interviews.

Statistical Analysis

Power

Monte Carlo simulations computed in R (R Foundation for Statistical Computing) were used to estimate the required sample size for our proposed models. Our analyses, based on simulated data, suggest that a total sample size of 300 provides enough statistical power (up to 90%) to detect anticipated effect sizes on primary outcomes of cognitive capacity and cognitive bias based on values from our group and those reported in the literature (CR: d=0.50 and MCT: g=0.27) [9,20,27,31]. The attrition rate for our digital groups has been approximately 20%; we will nonetheless conservatively adjust for an attrition rate of 30%. When considering the propensity score, this results in a requirement of 390 participants. Comparable studies using the same interventions and statistical methods in in-person settings have included similar sample sizes as those proposed at our individual sites [68,69]. Further, this sample size will allow us to detect anticipated effect sizes on secondary outcomes related to symptomatology (CR: d=0.28 and MCT: g=0.38) [70,71] and functioning (CR: d=0.36-0.51 and MCT: d=0.37) [31,71,72]. We also anticipate that the proposed sample size will be adequate to explore sex- and gender-related differences using subgroup analyses of 2 (male and female) and 4 (men, women, nonbinary, and other) groups, respectively.

Data Analysis

Data related to the analysis of objective 1, focusing on clinical effectiveness, will be compared between both interventions. Primary and secondary outcomes will be compared between the 2 interventions, using one as the active control for the other. First, propensity score matching will be used to identify a subset of participants who will comprise the active control group that is equivalent to the intervention group on background variables (sociodemographic variables, illness duration, medication dosage, length and nature of prior treatment as well as subjective reports of cognitive capacity and cognitive biases). Then, Z-standardized outcome data will be compared between the groups with generalized linear mixed effect modeling techniques using R software. Factors of interest will include fixed time (pre, post, and follow-up), fixed treatment (ABCR and MCT), fixed time and treatment interaction (time*treatment), random site (CIUSSS de l'Ouest-de l'Ile de Montréal, the Royal's Institute in Ottawa, Kingston Health Sciences Centre, Ontario Shores Centre for Mental Health Sciences in Toronto, and Vancouver Coastal Health), random intercepts (participants'

ID), and random slopes (participant*time). Age, illness duration, medication dosage, length, and nature of prior psychological treatment will also be included as fixed covariates. This procedure will be done twice, with the active control group subset using propensity score matching. This approach ensures that participants are not counted twice and is an integral part of the propensity score matching procedure. Statistically, performing the procedure twice helps to validate the robustness of the matching process without introducing bias, as each participant is only included once in each comparison. Specifically, the procedure will be as follows: (1) ABCR as the intervention and MCT as the active control and (2) MCT as the intervention and ABCR as the active control. Missing data pattern will be assessed for whether it is missing completely at random, missing at random, or not at random [73]. If data are missing at random, multiple imputation will be applied [74]; if data are missing not at random, then the robustness of the primary analyses will be evaluated through sensitivity analyses.

Analyses for all implementation objectives will be executed using descriptive statistics for quantitative data and thematic analysis for qualitative data, following Braun and Clarke's [75] interpretive descriptive approach. This method emphasizes the researcher's active role in the analytical process, allowing for a nuanced understanding of themes such as facilitators and barriers to implementation, identified from CFIR semistructured interviews. Investigator triangulation will be used, with 3 independent raters conducting iterative qualitative analyses until a consensus (≥80%) is reached. A convergent quantitative-qualitative mixed methods design [76] will facilitate a comprehensive comparison of results from quantitative and qualitative analyses, aiming to develop a holistic understanding of factors influencing implementation. Side-by-side comparison tables will support this analytical process and engage implementation teams in interpretation. To ensure reflexivity, member checks will be conducted with participants to validate findings, ensuring that their perspectives and interpretations are accurately represented and that any potential biases in the researcher's analysis are addressed. This methodological framework is designed to uphold rigorous standards in qualitative research while ensuring that the findings are credible, dependable, and relevant to broader contexts. All qualitative analyses will be done using NVivo (version 15; Lumivero).

Results

A pilot pragmatic trial [26] has been conducted previously at the Montreal site, where 6 cohorts (3 ABCR and 3 MCT) were run, evaluating 3 early implementation outcomes: acceptability, feasibility, and engagement. Of the 28 participants attending at least 1 session, 21 completed more than half of the sessions. All completers reported a positive experience with therapy, 2 of 3 were not bothered by the remote setting, and 16 trusted the confidentiality of the information shared. Technology did not appear to significantly impede program participation. Therapist-rated levels of engagement were also satisfactory [26].

This study was approved by the institutional review board by September 2023. From September 2022 to January 2023 staff training was conducted across all 5 sites. Intervention materials including intervention manuals and digital portals began in June 2022 and continued until November 2023. Therapist training began on the E-Cog learning platform in April 2023 and is ongoing. All sites began recruitment in 2023 and have run cohorts of MCT and ABCR in their respective regions. Quantitative data collection occurs prior to and following the intervention group and is ongoing, qualitative data collection for implementation assessment began in summer 2024 and is ongoing. As of winter 2024, a total of 114 participants have been recruited and 32 therapists are enrolled in the E-Cog training platform with 25 therapists having completed the training. The updated project timeline can be accessed for those who create free accounts on the iCogCA Hub web page [77].

Discussion

Overview

This study aims to address the crucial clinical needs of individuals with SSD by evaluating the feasibility and effectiveness of delivering cognitive health interventions through a digital platform. We hypothesize that these interventions will yield positive outcomes in terms of accessibility, engagement, symptom reduction, and cognitive functioning.

Principal Findings and Comparison to Prior Work

The objectives of this study are 2-fold, focusing on both service users and mental health care providers. The first objective aims to assess the effectiveness of digital cognitive health interventions in enhancing accessibility and engagement for individuals with SSD. If proven effective, these interventions may provide an evidence-based framework for other service providers providing care for individuals with psychotic disorders and could be adapted for other populations receiving mental health services where these interventions show similar efficacy (eg, mood disorders) [78,79]. Objective 2 aims to identify facilitators and barriers to digital delivery and a digital training platform for clinicians. We anticipate that this study will introduce and validate our platform to train and supervise mental health care practitioners to deliver these interventions, which will then be made accessible to the broader mental health community. Further, these findings will furnish crucial information for the implementation of digital health technologies to improve access to psychosocial therapies for optimized care. These findings will be used to guide the implementation of similar projects across Canada. Notably, New York State has already fully integrated CR into its psychiatric care systems [80], and parallel efforts are underway in Australia [81] and the United Kingdom [82]. Collaborating with a National Steering and Implementation Committee, we will test our set of tools based on the CFIR and make them accessible to the mental health community. Site-specific implementation committees, which include patient partners, will assist with the local implementation of our cognitive health interventions.

Strengths and Limitations

This proposed national collaborative effort serves as a catalyst for leveraging digital technology to enhance the adoption of evidence-based psychosocial interventions. This study has

several strengths. The first is the implementation across multiple Canadian sites, which enhances the generalizability of our findings. Second, we also aim to engage a broad pool of participants, both service users and mental health practitioners, by using digital technology to provide the intervention and training. Encouragingly, previous studies have demonstrated that a significant portion of those with severe mental illnesses appear to have the required technological access and ability to join, participate, and benefit from digital services [83,84]. We have also a planned comprehensive collection of quantitative and qualitative data. Our data collection plan involves service users and mental health practitioners at multiple time points, allowing us to answer our research questions in a multifaceted manner. Finally, we have engaged with diverse stakeholders throughout various stages of the study, including those with lived experiences, clinicians, researchers, and managers.

Some limitations of our study include the nonrandomized concurrent controlled design, which raises concerns about potential group differences. However, we will address this by statistically controlling for measurable background characteristics. Second, although we aim to engage a broader population by providing services using a digital format, we acknowledge that there could be variability to technology access. We have planned to provide tablets and internet to service users without access to technology. For service users or health care providers unfamiliar with technology, we will also offer orientation sessions to help them become comfortable with the digital format. Next, the recruitment of therapists within a research setting may not reflect therapists involved in nonresearch settings. In addition, although we have taken great care in selecting instruments that have been validated in our population and available in both English and French, some limitations may still exist with the instruments chosen. For instance, ceiling effects have been observed in the Cambridge Neuropsychological Test Automated Battery cognitive test. Finally, there may exist differences across 5 sites in training experiences and implementation fidelity. We plan to attend to this by standardizing training and fidelity checks conducted across all sites.

Conclusions

In summary, this project aims to address pressing clinical needs related to cognitive impairments and biases in SSDs. By leveraging digital technologies, it aims to facilitate the adoption of evidence-based interventions within clinical settings, support future implementation of similar initiatives, and validate an adaptable platform designed for widespread use.

Acknowledgments

The authors would like to thank the study staff, community and clinical partners, and study participants who support this work. SG and GS are supported by a Chercheur Boursier Junior 1 from the Fonds de Recherche du Québec en Santé. ML is supported by a James McGill Professorship from McGill University. ET receives postdoctoral fellowship funding from the Canadian Institutes of Health Research (#171198). The authors thank the following people for their support with this project: Shalini Lal, Michael Bodnar, Deji Ayonrinde, Alexandra Baines, Ridha Joober, Tania Lecomte, Jai Shah, Nicola Wright, David Attwood, Patricia Debergue, Alonso Montoya, Tim Pauley, and Phil Tibbo. This research was undertaken thanks in part to funding from the Canada First Research Excellence Fund awarded through the Healthy Brains, Healthy Lives initiative at McGill University and by a Canadian Institutes of Health Research Project (grant #180501).

Data Availability

The datasets generated or analyzed during this study are not publicly available due to ongoing data collection but are available from the corresponding author on reasonable request.

Authors' Contributions

CA-Y and HT were responsible for writing the original draft and conducting investigations. They will also handle future formal analysis. MB, SG, KML, ET, and GS developed the conceptual framework and methodologies and participated in writing and reviewing the manuscript. AES contributed to the visualization and also engaged in manuscript review and editing. CRB, MM, SM, MP, and TSW contributed to conceptualization and methodology, provided resources, and reviewed and edited the manuscript. ML played a multifaceted role including conceptualization, methodology development, drafting and reviewing the manuscript, as well as overseeing the project administration and securing funding. DR-C was involved in conceptualization, methodology development, writing the original draft, and reviewing the manuscript, in addition to supervising the entire project. All authors reviewed the final manuscript.

Conflicts of Interest

This project is carried out in collaboration with the company SBT, which provides licenses for the Happy Neuron platform. ML reports grants from Roche Canada, grants from Otsuka Lundbeck Alliance, and personal fees from Boehringer Ingelheim, Janssen, Lundbeck Canada, and Otsuka Canada outside the submitted work. SG has received financial compensation for consulting services from Boehringer Ingelheim outside the submitted work. MB has received consulting fees from Boehringer Ingelheim. KML reports consulting fees from Otsuka Canada, Lundbeck Canada, and Boehringer Ingelheim. SM has received consultant fees from

Boehringer and ROVI and is developer of metacognitive training. DR-C reports consultations fees from Otsuka Canada Pharmaceutical, outside the submitted work. All other authors declare no conflicts of interest.

Abstract

Background: An individual education plan (IEP) is a key element in the support of the schooling of children with special educational needs or disabilities. The IEP process requires effective communication and strong partnership between families, school staff, and health care practitioners. However, these stakeholders often report their collaboration as limited and difficult to maintain, leading to difficulties in implementing and monitoring the child's IEP.

Objective: This paper aims to describe the study protocol used to evaluate a technological tool (CoEd application) aiming at fostering communication and collaboration between family, school, and health care in the context of inclusive education.

Methods: This protocol describes a longitudinal, nonrandomized controlled trial, with baseline, 3 month, and 6-month follow-up assessments. The intervention consisted of using the web-based CoEd application for 3 months to 6 months. This application is composed of a child's file in which stakeholders of the support team can share information about the child's profile, skills, aids and adaptations, and daily events. The control group is asked to function as usual to support the child in inclusive settings. To be eligible, a support team must be composed of at least two stakeholders, including at least one of the parents. Additionally, the pupil had to be aged between 10 years and 16 years, enrolled in secondary school, be taught in mainstream settings, and have an established or ongoing diagnosis of autism spectrum disorder, attention-deficit/hyperactivity disorder, or intellectual disability (IQ<70). Primary outcome measures cover stakeholders' relationships, self-efficacy, and attitudes toward inclusive education, while secondary outcome measures are related to stakeholders' burden and quality of life, as well as children's school well-being and quality of life. We plan to analyze data using ANCOVA to investigate pre-post and group effects, with a technological skills questionnaire as the covariate.

Results: After screening for eligibility, 157 participants were recruited in 37 support teams, composed of at least one parent and one professional (school, health care). In September 2023, after the baseline assessment, the remaining 127 participants were allocated to the CoEd intervention (13 teams; n=82) or control condition (11 teams; n=45).

Conclusions: We expect that the CoEd application will improve the quality of interpersonal relationships in children's IEP teams (research question [RQ]1), will show benefits for the child (RQ2), and improve the well-being of the child and the stakeholders (RQ3). Thanks to the participatory design, we also expect that the CoEd application will elicit a good user experience (RQ4). The results from this study could have several implications for educational technology research, as it is the first to investigate the impacts of a technological tool on co-educational processes.

Introduction

Background

There is a growing body of literature on the benefits of using educational technologies to support children with special educational needs or disabilities (SEND) and, notably, those due to neurodevelopmental disorders (NDD; eg, [1-4]). Most of these technologies target students as their primary users, forgetting the social environment that has to work together to support the children in their educational project. This study aims to conduct a field study to assess the effectiveness of an interactive web application (namely, the CoEd application) for fostering collaboration between family, school, and health care practitioners.

In several countries, a key element in the support of the child's schooling is the individual education plan (IEP), which defines their needs and gathers information on aids and adaptations that can be implemented to help them attain their full potential. IEP structures differ by country, but the core process emphasizes a robust partnership among families, school staff, and health care professionals, with regular meetings and a deep understanding of the child's profile and progress [5,6]. Effective communication between teachers and parents is universally recognized as a cornerstone of a child's education [6,7]. The ability of parents to share pertinent information about their child's disabilities, strengths, and weaknesses significantly enhances educators' awareness and enables them to tailor their pedagogical approaches [8]. Furthermore, parental involvement in the educational process has far-reaching implications, encompassing the holistic development and well-being of children with SEND. It serves as the bedrock for fostering a culture of productive family-school collaboration and cultivating a supportive school environment [9,10]. For students grappling with complex disorders such as autism spectrum disorder (ASD), the synergy of collaboration between parents and educators paves the way for improved academic performance, smoother integration, and enhanced social adaptation [11]. In a broader context, collaboration between parents and educators emerges as a catalyst for positive outcomes, benefiting students across the spectrum of educational needs [12]. Despite all of this, studies on the IEP process consistently underscore the pronounced discord between stakeholders' aspirations for effective teamwork and the actual communication and collaboration practices in place [12-17]. This paradox is particularly evident in the experiences of parents, teachers, and educators who frequently encounter obstacles ranging from resource constraints to training deficits, communication impediments, intercoordination challenges, and intricate administrative processes [12,18-22]. These challenges are not unique to inclusive education of children with NDD and extend to other areas such as patient care [23,24].

Within the continuum of collaborative practices in inclusive education, 3 progressive levels can be delineated: cooperation, coordination, and collaboration [25]. As elucidated by Larivée et al [26], elevation in the school-family-community collaboration level correlates with mutual recognition of expertise, bidirectional communication, shared responsibilities, and the spirit of reciprocity.

Several theoretical models of collaborative practices within the framework of IEPs have been proposed. These models may pivot around the child, exemplified by the "Whole School, Whole Community, Whole Child" model [27,28], or emphasize the dynamics of partnerships between stakeholders, as exemplified by the Sunshine model [29]. Other models are grounded in the objectives of IEPs, as demonstrated by polycentric approaches based on the child's life project [30]. Additionally, some models embrace a multidimensional perspective typified by the Holistic School Care Coordination System Model [31,32].

The proliferation of these models underscores the pivotal role of educational systems in facilitating interactions between educators and families. This entails the provision of guidelines and recommendations for effective collaboration, alongside the allocation of critical resources encompassing time, physical infrastructure, and financial support [19,20]. Among the envisaged solutions, harnessing digital technologies emerges as a promising avenue to support continuous communication for efficient stakeholder collaboration [33,34].

Prior Work

Maintaining communication and collaboration within the extended team for IEPs is challenging due to various communication channels like emails and phone calls. Despite digital advancements, tools often prioritize one-to-one communication over team-based sharing. Additionally, the lack of trackability in one-to-one exchanges hampers information flow within the team. To the best of our knowledge, very few digital tools are designed to help stakeholders with team-based information sharing, communication, and collaboration in the follow-up of the IEP and of the child's schooling and development [35]. Many proposed devices in this field lack maturity, either due to an inadequate design that does not consider user needs, resulting in usability issues, or because participatory design methods were used without subsequent effectiveness studies conducted to standard methodological levels for producing evidence (for a review, see [35]). An example of that is illustrated by the CoEd application, which provides a web application with functionalities aiming at fostering information sharing, communication, and collaboration in IEP and with the support team [36]. Through participatory methods, the CoEd application was designed based on stakeholders' needs and iterative design steps for eliciting good

user experience, usability, and utility (see [36] for the design process).

Aims

We propose to conduct a field study aiming to evaluate the impact of using the CoEd web application on 3 outcomes. First, we hypothesized that the CoEd application will improve communication and relationships between stakeholders (family, school, and health care practitioners), as well as their attitudes toward school inclusion, and increase each stakeholder's perceived self-efficacy (research question [RQ]1). Second, we hypothesized a beneficial effect of using CoEd on the child in terms of behavioral or academic functioning (RQ2). Third, we expect that using CoEd results in a better quality of life for both the stakeholders and the children (RQ3). Finally, as it is crucial when evaluating technology to verify that it is both effective and usable [37], we added measures related to the user experience of participants. Thanks to the participatory design, we expected that the CoEd application will elicit a good user experience (RQ4).

The paper follows the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) guidelines for reporting study protocols [38]. The SPIRIT checklist for this paper is provided in Multimedia Appendix 1.

Methods

Ethical Considerations

The ethics committee (Comité Opérationnel d'Évaluation des Risques Légaux et Éthiques [COERLE]) of the French National Institute of Informatics and Mathematics (Inria) approved the study protocol (application number 2022-08).

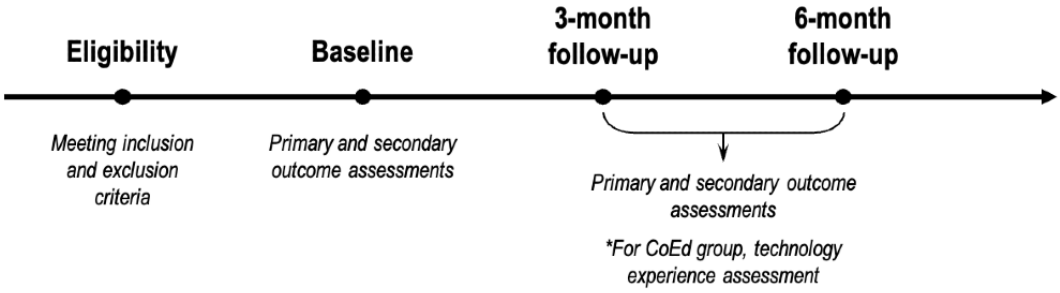
As the study protocol implies the management of health-related data, the CoEd app is hosted and managed on a secured server at Inria as if CoEd's data are medical data, in respect of the General Data Protection Regulation (GDPR). Additionally, the study protocol and data management processes were approved by the National Commission of Informatics and Liberty and by the Inria Security Homologation committee (application number 13953). All participants were informed about the study and gave written informed consent.

Study Overview

We designed a longitudinal, nonrandomized controlled trial to evaluate the impact of the CoEd application developed by our team [36]. We enrolled teams monitoring the school or social inclusion of secondary school pupils with NDD (between 10 years and 16 years old). These teams were recruited throughout France via email communication with schools, school districts, special education advisors, academic inspectors specializing in Special Education, and associations supporting families of children with NDD. Field partners of the project, namely the Nouvelle-Aquitaine academy, Autism Resources Center, and Association pour la Réadaptation et l'Intégration, were also engaged in the recruitment process and encouraged participation in their networks. We also put out calls for participants on digital social networks. Parents, teachers, and health care professionals were asked to complete a questionnaire to check the inclusion criteria. When the participant and child were eligible, all the members of the follow-up team were contacted, and the study was presented to them. Once participation was confirmed, individual participants received a consent form. They were given a week to return the completed form, with researchers available to address any questions during this period.

Whether they were in the control or experimental condition, they had to complete a baseline assessment and a 3-month follow-up assessment, and if they were willing to continue participating, they would complete a 6-month follow-up assessment (Figure 1).

Figure 1. Timeline of the field study according to the group conditions and the number of school terms (3 months for each term) for study participation.



Eligibility Criteria

To participate, a support team had to consist of at least two stakeholders, including at least one of the parents. Additionally, the pupil had to be aged between 10 years and 16 years, enrolled in secondary school, be taught in mainstream settings, and have a diagnosis of ASD, attention-deficit/hyperactivity disorder, or intellectual disability (IQ<70). The pupil needed either an established diagnosis or to be undergoing a multidisciplinary intervention for diagnosis.

Allocation and Blinding

In this quasi-experimental trial, the group allocation was not randomized. Group allocation was carried out as participants were recruited according to eligibility criteria, taking care to balance groups in terms of team size. A nonrandomized procedure was chosen because we recruited participants as volunteers arose who had a complete team. As the control group did not use the CoEd application and functioned as usual whereas the experimental group was asked to use the CoEd application and needed secure access to the web-based application, it was not possible to conduct a double-blind study.

Outcome Measures

Selection of Outcome Measures

Outcome measures were chosen from the researchers' hypotheses and participatory decision-making. In 2 focus groups, parents, teachers, and health care professionals discussed the CoEd application's potential impact and evaluation criteria (Multimedia Appendix 2). Participants reviewed preselected indicators and suggested new measures, especially concerning quality of life and caregiver burden, for the field study. As a result, the primary outcomes include 3 main dimensions (ie, stakeholders' relationships, perceived individual efficacy, and attitudes toward school inclusion). To this end, parents, teachers, and health care professionals completed a series of common or specific questionnaires (Table 1). The secondary outcomes include measures for stakeholders (burden and quality of life) and for the children (quality of life, school well-being, and school inclusion perception; Table 1). Additionally, a measurement of technology experience that covers technology skills and CoEd experience was included for the intervention group (Table 1). Although some questionnaires had a validated French version, others did not. In the latter case, as we are French native speakers, we translated them in collaboration with native English speakers. The scales used are presented in Table 1.

Table 1. Description of the assessment batteries to address the targeted (primary and secondary) outcomes and technology experience of participants.

[c]Intervention group only.

Primary Outcomes

Perception of Stakeholders' Relationships

Parents and teachers completed the Parent-Teacher Relationship Scale [39], which consists of a 24-item questionnaire measured on a 5-point Likert scale (1=strongly disagree to 5=strongly agree) assessing the 2 dimensions joining and communication-to-other, including their feeling of affiliation and support; the dependability and availability of both parties; shared expectations; and beliefs about the child and each other, their communication, and their sharing of information and emotions. To assess the relationship with medical-social professionals, the Helping Alliance Questionnaire [40] was completed by parents, teachers, and health care practitioners. The Helping Alliance Questionnaire initially evaluated the therapeutic alliance through the 2 dimensions perceived helpfulness and collaboration, but it was adapted to the purpose of the study. Two versions were used: a 13-item parent form and an 11-item professional form, both using a 6-point Likert scale (1=totally disagree to 5=totally agree).

Perceived Individual Efficacy

The feeling of self-determination was measured using the French version of the Basic Psychological Need Satisfaction and Frustration Scale [41], which assesses satisfaction and frustration with the 3 basic psychological needs: competence, affiliation, and autonomy. This 24-item scale using a 5-point Likert scale (1=Completely False to 5=Completely True) provides a proxy of general individual efficacy. A version of the Goal Attainment Scale [42] adapted by our team was proposed. Initially, parents and professionals were asked to independently specify 2 to 5 school, social, or behavioral goals for the young individual, along with their current level, desired level, difficulty, and importance. At the end of the experimentation, the goal was recalled, and the adults were asked to assess the level of goal attainment. This adapted version of the Goal Attainment Scale provides a probe of (individual) educational efficacy.

Attitudes Toward Inclusive Education

The parents' attitudes toward inclusive education was measured using the Attitudes Toward Inclusion/Mainstream scale [43]. This questionnaire, consisting of 18 items that are rated on a 5-point Likert scale (1=strongly agree to 5=strongly disagree), assesses the overall attitude of parents toward the inclusion of students with disabilities in mainstream schools, including 4 dimensions (benefits factor, satisfaction with special education, teacher ability and inclusion support, child rights). The Multidimensional Attitudes Towards Inclusive Education Scale [44] was selected to evaluate teachers' attitudes toward the inclusion of students with disabilities in mainstream schools. It consists of 18 items assessed using a 6-point Likert scale (1=strongly disagree to 6=strongly agree) and measuring 3 dimensions (cognitive, affective, behavioral).

Secondary Outcomes

Perception of Caregiver Burden

Parents and professionals completed the Zarit Burden Inventory Short Form [45,46], which consists of 12 items assessing the individual perception of their burden. Each item is scored between 1 point and 5 points (1=never to 5=almost always), and the total score is the sum of all item scores. The higher the score is, the higher the burden is, with the following cut-offs: no to mild burden (0-10), mild to moderate burden (10-20), and high burden (>20). For parents, the assessment was completed with the Caregiver Strain Questionnaire [47] to evaluate the familial burden through 21 items using a 5-point Likert scale (1=not at all to 5=very much) and 3 dimensions (objective burden, internalized subjective burden, and externalized subjective burden). The Caregiver Strain Questionnaire has been specifically validated with families of children with disabilities, including NDD or ASD. For professionals, the level of burnout was assessed using the French version of the Maslach Burnout Inventory [48], a 22-item scale using a 7-point Likert scale (1=never to 7=every day) that evaluates emotional exhaustion, depersonalization in relationships with others, and a sense of reduced personal accomplishment in one's work.

Stakeholders' Quality of Life

Parents and professionals completed the WHOQOL-BREF [49], a 26-item scale using a 5-point Likert scale (1=Very Low, Very Dissatisfied, Not at all, Very Difficult, Never to 5=Very High, Very Satisfied, Extremely, Very Easily, All the Time) recommended by the World Health Organization to assess individuals' quality of life based on 4 dimensions (physical health, psychological health, social relationships, environment). The quality of life of the family was assessed using the Beach Center Family Quality of Life scale [50], adapted into French by Rivard et al [51]. This scale, consisting of 25 items using a 5-point Likert scale (1=Slightly Important, Very Dissatisfied to 5=Very Important, Very Satisfied), measures 5 dimensions of family quality of life: family interactions, parenting, emotional well-being, physical and material well-being, and disability-related support.

Child's Quality of Life

The pupil's quality of life was assessed using the Pediatric Quality of Life Inventory [52]. The Pediatric Quality of Life Inventory is composed of 23 items using a 5-point Likert scale (0=never to 4=almost always) assessing children's physical, emotional, social, and school functioning through self-report (completed by children) and proxy report (completed by parents).

Child's Perception of School Life

The student's sense of school inclusion was evaluated using the single-item inclusion scale by Aron et al [53], which measures 7 levels of the sense of inclusion and has been adapted to assess the sense of inclusion in both the school and peer group contexts. School satisfaction was evaluated using an 8-item subscale that uses a 7-point Likert scale (1=strongly disagree to 7=strongly agree) derived from the French adaptation of the Multidimensional Students' Life Satisfaction Scale [54,55].

Measurement of Technology Experience (Experimental Group Only)

To assess the potential effect of prior technology skills on the use of CoEd, parents and professionals completed the Computer Usage Questionnaire [56] that consists of a self-reported measure of 18 questions asking for the frequency (5-point scale

ranging from never to very often) of different computer activities and software usage.

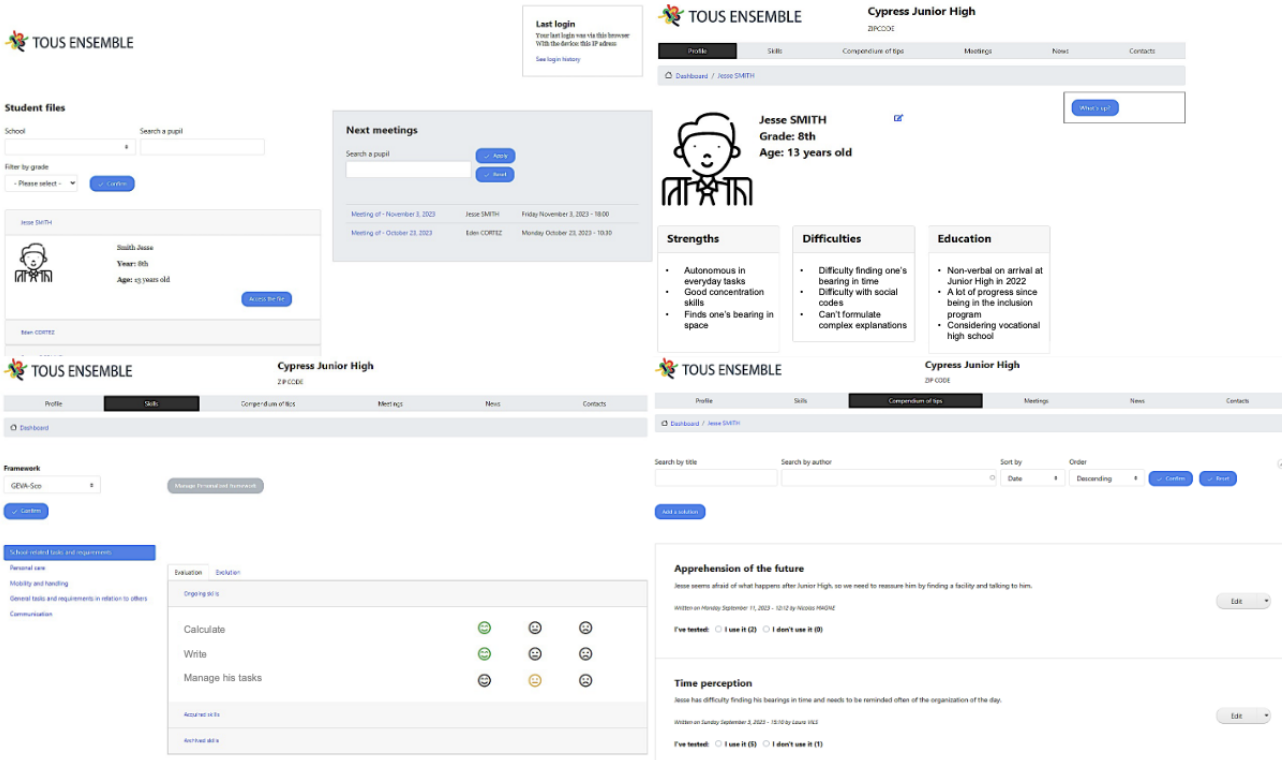
To address the specific user experience with the CoEd application, the User Experience Questionnaire short form [57] was selected as the measurement. It uses a 7-point Likert scale (–3=fully agree with negative term to +3=fully agree with positive term) of subjective perceptions of users in terms of both the hedonic and pragmatic dimensions toward a given product and according to a benchmark for digital products. The Technology-based Experience of Need Satisfaction-Interface [58] is related to the self-determination theory framework for assessment and uses a 5-point Likert scale (1=Do Not Agree to 5=Strongly Agree) to assess basic psychological need (autonomy, competence, relatedness) satisfaction through the interaction with the interface or system. Satisfaction of these needs is arguably associated with sustained engagement with a technology.

Complementary to the subjective measures, direct measures of CoEd use and usage are collected through active interactions (log data) with this web application, in particular the number of times the app was opened and the number of exchanged posts (Table 1).

Presentation of the CoEd Technology

Specific to the French school context, the CoEd application (Figure 2) is accessible through a web browser and allows users to view and edit one or multiple student files. Users need to be registered by the administrator and can log in with an email and password. Roles—parent, teacher, or external professional—are assigned during registration, offering equal file access rights. A designated moderator role, open to any team member by consensus, is suggested for content moderation.

Figure 2. Screenshots of different tabs from the CoEd app.



Once logged in, the user can access the student's file, which consists of 6 tabs: profile, skills, meetings, compendium of tips, news, contacts.

As an identity card, the profile provides key main information to know about the child. A “What’s up?” block allows users to be informed of new content in the folder.

The skills section allows users to review the child’s skill assessment. Two skill referentials are provided: (1) a formal IEP evaluation (ie, Geva-Sco scale for French IEP) and (2) a custom skill referential, where users can determine the categories and skills they wish to assess according to the child’s profile.

The meetings tab allows user awareness of past and upcoming meetings about the child. This section also provides an interface to automatically generate reports about past meetings in PDF format, which are accessible by all users.

On the compendium of tips tab, users can share tips, aids, and adjustments that they successfully used with the child in particular situations. They can receive feedback from the other team members.

The news section is dedicated to punctual and rapid information sharing, such as daily events or feedback and particular events.

On the contacts tab, all team members related to the child’s folder are identified, including their role in the team and contact information.

Procedure

When the participants were assigned to the CoEd intervention condition, the researchers created the child's page and the users' logins on the CoEd application. The participants may provide initial general information to be put on the child's page by the researchers. At the beginning of the study and after collecting baseline measures, the participants of the CoEd intervention condition received a user manual and video tutorials to help them handle the application, and additional training could be provided by the researchers if needed. Once the study began, the participants were asked to use the application at least once a week but were free to use it as often as they wanted.

The participants from the control group did not receive any intervention and were asked to function as usual.

All questionnaires were administered through online forms. Every participant received an identification number, which was used to anonymize the data collected. At the date of measurement (baseline, 3-month follow-up, 6-month follow-up), participants were instructed by mail to complete the questionnaires. The data collection was monitored by the researchers, and the participants who did not answer were reminded once a week by mail or phone. If participants remained unreachable for more than 6 weeks, they were labeled as "lost" and excluded from the trial.

The data collected through forms and the CoEd application were stored on a secure server at the Inria research center and anonymized using participants' identification numbers. Only researchers working on the project are authorized to consult the collected data.

Statistical Analysis

Power

We did not find previous studies assessing the impact of a digital device on IEP teams' relationships and communication in order to perform a power analysis. However, some behavioral interventions with the same target were published and reported moderate effect sizes. Thus, we based our power analysis on an effect size of d=0.600.

Planned Statistical Analyses

We plan to conduct pre-post mean comparison analysis on primary (RQ1) and secondary outcomes (RQ2 and RQ3) to assess within and between-team effects of the intervention. We will conduct within-team analyses using 1-way ANCOVA to compare pre and postintervention differences separately for each team's experimental and control groups. This approach helps identify specific changes within teams and assesses differential effects between groups. Additionally, a between-team analysis will treat all participants as a single population, using repeated-measures ANCOVAs or linear regression analyses to examine the overall intervention effect across teams. This global analysis disregards team distinctions to assess the intervention's overall impact. In addition, using ANCOVA will allow us to control for potential bias coming from the variability in technological skills (Computer Usage Questionnaire; see Table 1) as well as any variable that may compromise the homogeneity across groups. Missing data will result in the exclusion of related observations, and dropouts will be monitored to explore the reasons.

By combining these methods, we aim to provide a comprehensive evaluation of the psychological intervention's effectiveness, considering both within-team variation and overall effects.

To assess the user experience (RQ4), only the participants of the CoEd intervention condition answered the user experience questionnaire. These data will be analyzed through descriptive statistics and compared with questionnaire-related benchmarks.

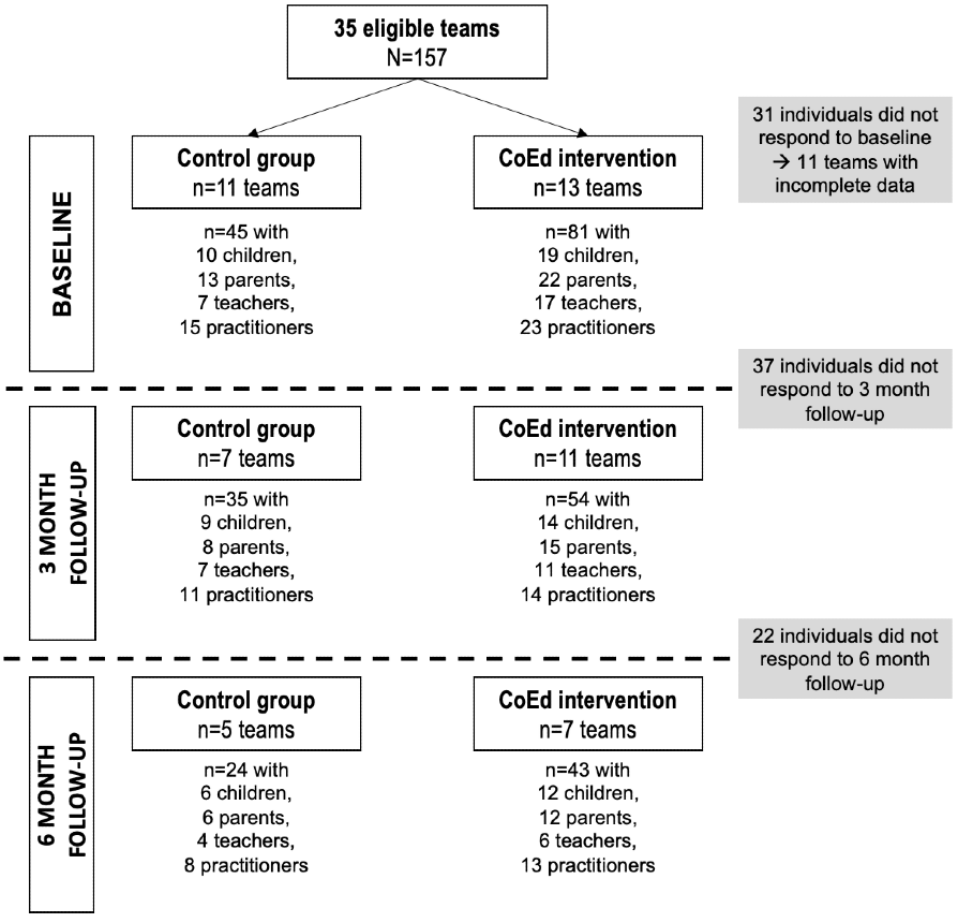
Results

The study was funded in 2021 with public funds from Conseil Régional d'Aquitaine and the Fondation International pour la Recherche Appliquée au Handicap (FIRAH), Klesia, and Comité National Coordination Action Handicap (CCAH).

Figure 3 shows the flowchart of the recruitment process. We initially recruited 37 eligible teams who were allocated to either the experimental or control group, which resulted in a sample size of 157 participants (2-7 people per team). At baseline, 31 individuals did not complete the questionnaires, leading to the exclusion of 11 teams due to incomplete data. In September 2023, the recruitment ended with 13 teams participating in the experimental condition (n=82) and 11 teams in the control condition (n=45). The experimental group is larger than the control group due to the nature of our action-research approach. Participants and partners expressed a strong preference for being included in the intervention to benefit from the CoEd app, viewing control group assignment negatively. To address this while maintaining rigorous assessment, we included more participants in the experimental group, ensuring sufficient data for analysis and respecting the ethical considerations of action research.

At the end of data collection (June 2024), a total of 59 individuals had dropped out: They stopped responding to the questionnaires and did not reply to our follow-up attempts. Consequently, there were 89 remaining participants at the 3-month follow-up and 67 participants at the 6-month follow-up. Data cleaning and analysis began in March 2025, and results are expected by June 2025. We anticipate that the findings may be ready for publication by the end of 2025, although this timeline remains provisional.

Figure 3. Flowchart of participant recruitment.



Discussion

Expected Results and Comparison With Prior Work

This research protocol was developed to empirically evaluate the impact of a digital technology solution on collaborative relationships among stakeholders in inclusive education. Conducting a field study with a quasi-experimental protocol will provide true empirical support of the technology's utility and effectiveness for fostering stakeholder collaboration. Through the targeted primary outcomes, we particularly expect an improvement in the quality of interpersonal relationships as well as more congruent cross-stakeholder attitudes toward school inclusion while empowering each stakeholder in their capabilities to achieve their own goals as educator and to support child in their IEP (RQ1). We also expect a beneficial effect of using the CoEd application on child-related outcomes (RQ2) and on the quality of life of stakeholders and children (RQ3).

Meyer et al [35] identified 6 digital projects and a strategy using an existing social network, all at different development stages. Of these projects, 3 used participatory design, 4 conducted needs analyses, and 3 were field-tested. However, none included a control group nor aimed to evaluate the impact on school inclusion, IEPs, stakeholder interactions, or health and well-being dimensions. From this review, it becomes evident that conducting quasi-experimental field studies and involving a substantial number of educational teams and various stakeholders will be an essential contribution. Building on this, our protocol seeks to provide robust evidence for a digital co-education tool designed with user-centered design methods and approaching a gold standard methodology.

Strengths and Limitations

The CoEd application has already completed all the design and user testing in order to reach the step of empirical evidence thanks to this study (see [36] for the design study). Furthermore, our field study included evaluations that cover more broadly other critical indicators for co-educators, such as their mental health using the burden and quality of life assessments. There is strong evidence of the great influence of perceived self-efficacy on a person's well-being [59,60]. Hence, we will be able to explore the links between the primary outcomes (interpersonal relationships, attitudes toward school inclusion, and self-efficacy) and some health measures. For the children, the collaboration benefits from technology could promote, by the bounds effect, their sense of school inclusion, school-life satisfaction, and overall well-being through an effect on parent-teacher relationships and collaboration between stakeholders [6,7,61-63]. This technology could also facilitate the implementation of IEPs by leveraging each stakeholder's expertise [6,8] and, as a result, increasing the educational achievement (academic and social objectives) for each child.

Additionally, the log data from the CoEd application will provide insights on its actual usage across time and the targeted primary outcomes. For instance, RQs could address the traditional dilemma between quality and quantity of exchanged

information, or content analyses could even document interpersonal tensions and their potential relation with a degraded partnership in the team and vice versa.

For the intervention group using the CoEd application, we are collecting data on usability, technology acceptance, and usage factors. This assessment is of great importance in studies examining the impacts of technology-based interventions, as usability and effectiveness are intrinsically related, and is part of most studies evaluating this kind of intervention [37].

These secondary indicators address the needs of project stakeholders (inclusive school policymakers, school organizations, teachers, practitioners, parents, and children with SEND) for successful participatory achievements and pave the way for innovative research, such as exploring relationships between CoEd acceptance and effectiveness in inclusive school environments. Most of the participants of this study are people who did not participate in the design steps of the project. Therefore, the bias from "being both designer and evaluator" is limited, and the results from this study will provide insight on the efficacy of using a citizen science approach in the domain of inclusive education. This study combines a traditional top-down approach (ie, expectations relative to specific primary criteria for a prescriptive purpose) with a bottom-up approach driven by the field expertise of the main stakeholders of school inclusion. As a reminder, the study outcomes have been cobuilt thanks to focus group methods involving actual stakeholders as well as researchers in the field (see Multimedia Appendix 2 for details about the focus group sessions). This citizen science approach (albeit risky) contributes to bridging science and practice, facilitating rapid societal impact, and emerging new research issues [64,65]. The results from this study could also contribute to documenting the effectiveness of citizen science and participatory design methods in designing innovative technologies tailored to the specific needs of people, especially in health and disability domains [24,65,66].

From our combined approaches, the study consortium encountered a few issues that reinforced the study-related challenges, especially with children with SEND and with a technology-based intervention. First, major challenges were related to the quasi-experimental study design in which the CoEd intervention condition is compared with a control condition where there are fewer teams. We paid great attention to matching the 2 groups with respect to the factors known for influencing the primary outcomes as well as possible. These factors include the size of the team, demographic factors, and the SEND of the child. Nonetheless, we are aware that such a matching method does not neutralize possible biases related to differences in the group size. We plan to explore the impact of any variable that is not matched between groups to investigate its impact on the intervention's effect. A second study challenge was the great variability in the participants' technological skills in the CoEd condition. Indeed, computer skills and prior experience with technology will necessarily influence the experience with using a digital tool and, in turn, modulate the intervention's effects. We set up a standardized training phase for the use of CoEd application according to training use scenarios and provided both written and video tutorials to help people handle the CoEd application. In addition, the questionnaire on technological skills will be used as a covariable to explore the impact of this interindividual variability on the intervention's effects. Another study challenge was associated with the increasing digitalization of schools, whether in teaching, student support, or parental involvement. Since the COVID-19 pandemic, this digitalization has significantly increased, especially in the field of education [67]. However, the extensive digitalization during the COVID-19 pandemic brought issues related to digital anxiety and data protection [68], increased screen time, and the effects on well-being and interpersonal relationships [69-71]. In this project, these themes were central during design and development steps, as it involved processing data concerning children with NDD. This point was addressed during the participatory design steps and proved to be a very important one for future users [36]. During the development steps, we made data security a priority, so that users can use the system with complete confidence (compliance with regulations, security certification). Finally, the last challenge our research had to confront was related to the context of digital development in France. The French government has introduced a new digital tool to bridge the gap between decision-making bodies for educational obligations and resources allocated for the implementation of an IEP and schools. This deployment has led teachers to increase digital data input on academic difficulties and IEP accommodations. However, this deployment has caused confusion with CoEd and could lead some teachers to limit their participation, as some data would need to be entered both in CoEd and the governmental digital tool. However, there are important differences between the CoEd application and the governmental tool: The latter is more oriented toward archiving aims and digitalization of the IEP, while the CoEd application promotes free sharing of experiential knowledge from each stakeholder, which indirectly contributes to IEP implementation and follow-up. In addition, the CoEd application allows stakeholders to communicate with each other about daily events, which is not covered by the governmental tool. In this context, the CoEd application can be viewed as an aid for following IEP objectives and to better support the use of the governmental app through complementary features.

Despite all these challenges, the outcomes of the CoEd study will yield significant insights on the benefits of a digital collaborative tool for teaching students with SEND. It will also yield some insights on the communication factors influencing the health of stakeholders and children. The study will also inform the feasibility of technology-based personalization of IEP and will likely teach some useful lessons for future technology-based field studies regarding empowering stakeholders to teach children with SEND.

Dissemination Plan

Results from our study will be disseminated via scientific publications and conferences. In addition, as we previously included decision-makers of the French public policy of inclusive schooling in the CoEd design phases, we made sure that the solution is ethically, technologically, and financially sustainable in the public services. This will provide a solid foundation for a business model in case there is a startup to market the technology.

A second perspective is to explore the feasibility of disseminating the CoEd application outside of the French frontiers, by scaling up in other countries. However, there are cultural and structural differences between countries, particularly regarding inclusive education. This international dissemination will necessitate an additional needs analysis and adaptations to the application for the specific context of other countries [72]. A first step will be to explore the feasibility of disseminating the application in French-speaking countries with a similar cultural background (eg, Belgium), thereafter moving to wider internationalization with other European countries. This internationalization strategy is certainly ambitious and will necessitate a new needs analysis and adaptations of the CoEd application.

Conclusion and Future Directions

Although further research is needed, the findings of the CoEd project will provide the first real evidence-based study in the field of educational technology for social environments supporting children with SEND with their IEPs.

To move the robustness of the evidence forward, it will be necessary to consider conducting a trial using strict randomized controlled trial methods. In the same vein, the question of a large-scale intervention exists. As also mentioned, our ecosystemic and participatory approach has led us to work directly with the key stakeholders in inclusive education in order to both design an upstream CoEd application and evaluate it downstream. Consequently, a scaling up in other countries for the evaluation of the CoEd application will be required for better proof of the interest for an interactive web application for a co-education process.

Acknowledgments

We would like to thank all the members of this project: first, the participants and second, all the professionals linked to the project (eg, engineers, technicians, techno-clinicians) as well as the structures and organizations that allowed the project to be conducted (French School Academy of Bordeaux-New Aquitania in France) and Aurélien Dumez, Computer Security Officer and Engineer at the Inria (National French Institute of Informatics and Mathematics) center of the University of Bordeaux who supervised all the computer development required for the CoEd solution and notably its conformity to General Data Protection Regulation (GDPR) and European standards for ethical research with a digital tool.

The study benefited from several funding sources, primarily the Inria, public funds of Conseil Régional d'Aquitaine (grant number: AAPR2021-2020-11922210; principal investigators [PIs]: HS and CM), Fondation international pour la Recherche appliquée au Handicap (FIRAH; PI: HS), Klesia, and Comité national Coordination Action Handica (CCAH). These funding sources had no role in the design of this study and will not have any role during its execution, analyses, interpretation of the data, or decision to submit results**.**

Data Availability

Upon study completion, the data sets generated during or analyzed during this study will be available from the corresponding author on reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: Locomotive syndrome (LS) is a condition in which muscle weakness and reduced motor function due to musculoskeletal disorders cause reduced mobility and physical function. In Japan, musculoskeletal disorders are the most frequent reason for requiring home support or nursing care, and the prevention and amelioration of LS are thus being emphasized. However, it is difficult for older people to make a habit of exercise therapy, which is the mainstay of LS treatment. We investigated whether digital therapy could (1) lead to behavioral change in older people and (2) prevent or improve LS in older people.

Objective: We sought to determine whether digital therapeutics (DTx) are useful for the prevention and amelioration of LS in older people, and we assessed the effects of DTx on the participants' exercise awareness and motor function.

Methods: We conducted a multicenter, prospective, longitudinal, nonrandomized, single-group study of Japanese adults aged ≥40 years who were eligible for LS checks. Each participant underwent an 8-week locomotion training (LT) intervention, and their subjective and objective motor abilities and motor awareness were objectively assessed at the following time points: baseline (before the start of the DTx), interim (4 weeks after the start of the DTx), and end (8 weeks after the start of the DTx). We evaluated the participants' objective motor function using the timed up and go (TUG) test, and we compare the results using a 3-way ANOVA with the TUG test at the 3 evaluation time points as the dependent variable. The results of the 25-question Geriatric Locomotive Function Scale, which is a subjective measure of motor function, and the results of the Behavioural Regulation in Exercise Questionnaire 3, which assesses motor awareness, were also evaluated using an ANOVA in the same way as the TUG test. The significance level was set at .05 / 3 = .0167 after Bonferroni correction.

Results: As of April 2025, this study had enrolled 47 participants, and complete data had been gathered from 45 participants for the proposed analysis. Study participation was ongoing as of April 2025.

Conclusions: The study cohort will be used as a basis for further observational and intervention studies. This research could lead to more efficient use of medical resources and a reduction in financial and medical burdens on individuals and the economy, and it could support the prevention and amelioration of LS and the establishment of exercise habits among older people.

Introduction

Background and Rationale

The Japanese Orthopaedic Association (JOA) issued its first guidelines regarding locomotive syndrome (LS) in 2007 [1]. Locomotive syndrome refers to a condition in which a musculoskeletal disorder results in muscle weakness and motor weakness, leading to reduced mobility and physical function [1]. The development of LS causes a decline in healthy life expectancy and can lead to individuals becoming bedridden and requiring long-term care [2]. In Japan, motor system disorders are the most frequent reason for requiring assistance at home or nursing care, accounting for 24.8% of all cases [3]. The JOA recommends the early detection of motor function decline by conducting LS checks (LSCs), in part to prevent the future need for assistance or care [4]. The JOA also advocates locomotion training (LT), which involves standing on one leg and squatting, to prevent and ameliorate LS [5].

Guidelines for assessing the risk of LS were developed in 2015 [6]; these defined stage 1 LS as the early stage of motor decline and stage 2 LS as advanced motor decline. In 2020, stage 3 LS was added, defined as a state of progressive decline in mobility and difficulty in social participation [7]. The risk of developing LS is assessed based on three items: (1) a stand-up test, (2) a 2-step test, and (3) the 25-question Geriatric Locomotive Function Scale (GLFS-25) [5].

Japan has one of the world's most prominent aging populations, and the burden of health care for the oldest segment of Japan's population on the country's insurance system continues to increase [8]. It is also necessary to consider how to make the most effective use of limited medical resources. The prevention and amelioration of LS are considered important as countermeasures against motor system disorders. Exercises such as LT are effective for preventing and ameliorating LS [5], but it is difficult for many older adults to start or continue an exercise routine. As one solution, we advocate an approach to the prevention and improvement of LS in older people based on using technological devices to promote behavioral change.

Technology is used in the medical field for electronic medical records, telemedicine, and surgical robots; in addition to this, mobile devices are used for medical procedures and support, which is called mobile health (mHealth) [9]. Digital therapeutics (DTx) are an area of mHealth that is receiving particular attention [10]. A variety of apps have been approved by insurance as DTx, including diabetes and hypertension self-management apps and smoking cessation support apps [11-13]. However, DTx for musculoskeletal diseases have not been approved for insurance coverage. Although some apps have functions such as step counting and exercise management, they are not scientifically supported. We have created a smartphone app for older people who have no exercise habits and whose physical functions have declined. The smartphone app has functions that support the implementation of 2 types of LT, using video and audio, and when participants carry out LT, the implementation status is recorded not only on the target person's smartphone, but also on the health care provider's smartphone. The advantage of this system is that health care providers can check the progress of LT remotely, and the patient can feel that they are exercising with the support of health care providers. We are conducting this study to determine whether the use of DTx can lead to behavioral change in older people and prevent or improve LS.

Objectives

The study's primary aim is to determine whether the use of a smartphone app (ie, DTx) can prevent or ameliorate LS in older people: the outcomes are exercise awareness as assessed by the Behavioural Regulation in Exercise Questionnaire 3 (BREQ-3) and motor function as assessed by the GLFS-25 and timed up and go (TUG) test. In this study, participants who were unable to perform the stand-up test or 2-step test due to hip or knee pain were excluded from the measurement items. The research questions are as follows: (1) Can older people use DTx to proactively change their exercise habits with the help of their health care providers? (2) Are changes in exercise habits in older people associated with changes in motor awareness and function?

Our main and secondary study hypotheses are that (1) continued LT with DTx will prevent or improve LS in older adults and (2) well-established exercise habits will improve these individuals' motor awareness and function.

Methods

Participants and Study Setting

We plan to recruit a minimum of 50 participants aged ≥40 years who are eligible for LSCs [14] at any of 3 general hospitals (Bange-Kosei General Hospital, Southern Tohoku General Hospital, and Minami-Soma City General Hospital) that perform orthopedic surgery. The target minimum numbers of participants is 25 at Bange-Kosei General Hospital, 15 at Southern Tohoku General Hospital, and 10 at Minami-Soma City General Hospital. The overall recruitment target is based on the minimum sample size necessary to complete the intended analysis, taking omissions into account.

The study's inclusion criteria are as follows: participants aged ≥40 years who generally have lower-extremity muscle weakness [15] and who have visited 1 of the 3 abovementioned hospitals for an LSC, which are scored as follows: 1 point if the individual cannot put on a sock on one foot; 2 points if they stumble in their house; 3 points if they need a handrail to climb stairs; 4 points if they have difficulty using a vacuum cleaner at home; 5 points if they have difficulty carrying parcels weighing >2 kg; 6 points if they have difficulty walking continuously for >15 minutes; and 7 points if they cannot cross a crosswalk with a green light. Additional inclusion criteria are scoring ≥3 points on the Mini-Cog cognitive functional assessment [16,17], having access to the smartphone app, and being able to provide informed consent for study participation. The exclusion criterion was difficulty using smartphone apps due to cognitive decline or visual or hearing impairment.

Study Design

This trial is a multicenter, prospective, longitudinal, nonrandomized, single-group study of Japanese adults aged ≥40

years with applicable LSC results. The design includes 3 evaluation time points: baseline (0 weeks, ie, before the initiation of DTx), an interim evaluation (4 weeks after DTx initiation), and a final evaluation (8 weeks after DTx initiation).

An investigation of DTx that was designed to reduce anxiety about recurrence in postoperative breast cancer patients included a baseline assessment before the DTx intervention, an interim assessment after 4 weeks of intervention, and a final assessment after 8 weeks of intervention [18]. Previous studies have shown that 6 weeks of balance exercise intervention and 2 months of body weight–bearing exercise can improve lower limb muscle strength, balance ability, and walking speed in older people [19,20]. We and other research groups thus consider 4-week and 8-week postintervention assessment time points as appropriate for this type of study.

We registered the trial with the University Hospital Medical Information Network Clinical Trials Registry (UMIN000053922; receipt number R000061550). The date of approval was March 22, 2024.

Procedures

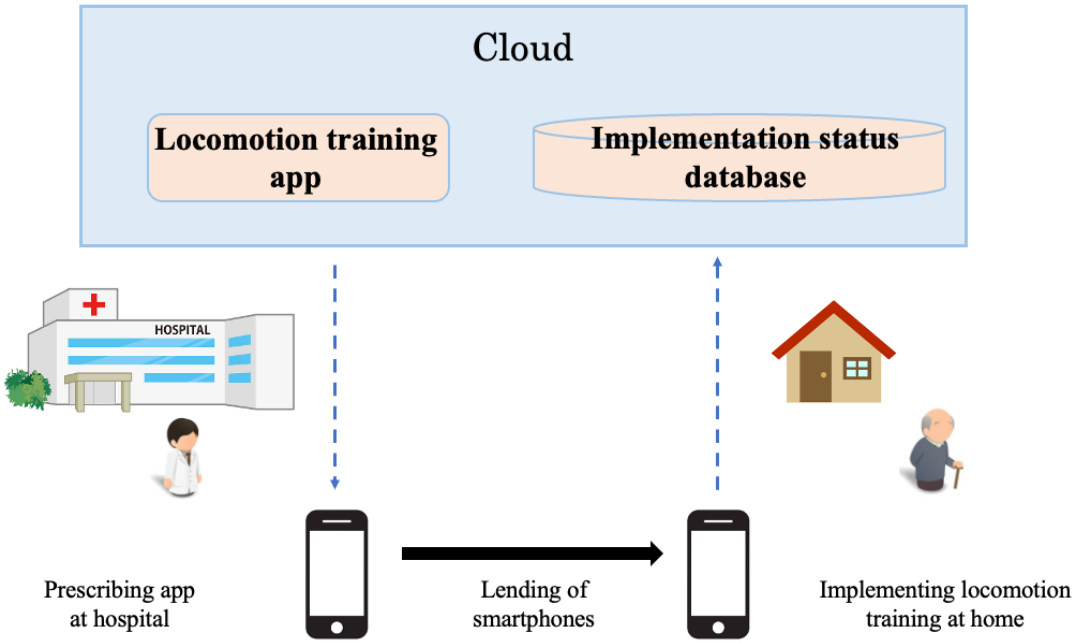
Recruitment

Participants will be recruited from among patients attending the collaborating hospitals. All 3 recruitment sites follow the same recruitment plan. Recruitment will continue until the target number of cases is achieved, with a 1-year time limit. At the end of a regular outpatient clinic session, a participant who meets all of the eligibility criteria and wishes to participate in the study will be provided with a description of the study, a questionnaire, and an evaluation sheet, and they will be asked to give their written informed consent to participate in the study. The need for follow-up and written consent for future contact will also be explained. The candidate participants are also informed that they can withdraw their consent or participation at any time if they so desire.

Intervention

The smartphone app used in this study is a newly prototyped app developed for this research study. We will provide smartphones equipped with a communication environment and downloaded apps in advance, which will be lent to the participants (Figure 1). The participants will be instructed to refrain from using the smartphone for any purpose other than use of the relevant smartphone app.

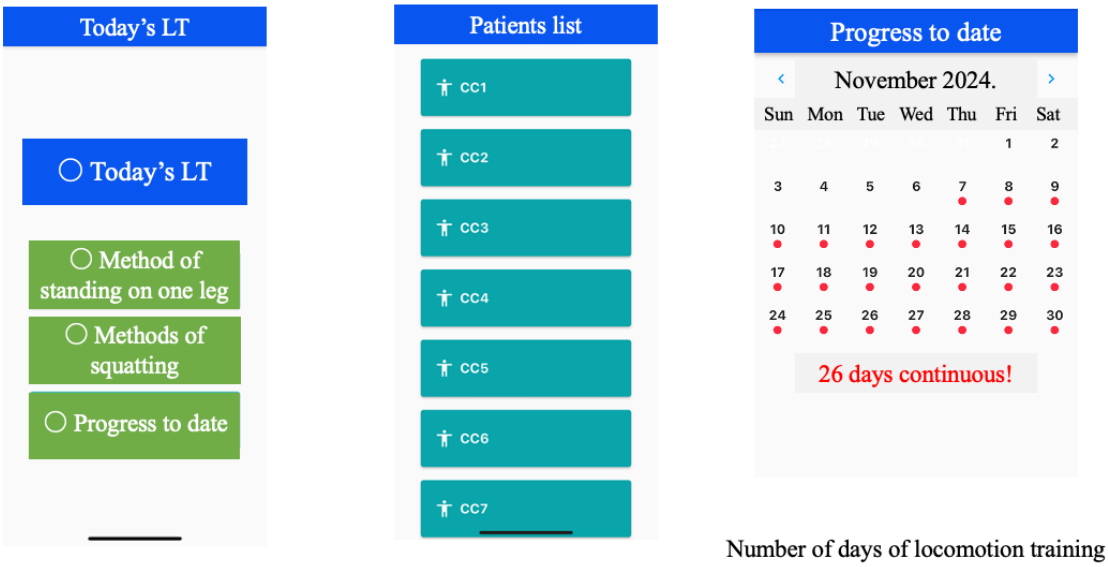
Figure 1. Implementation schema for the locomotive training (LT) app used in this study. The physician in charge will provide a smartphone onto which the LT app has been downloaded to the patient. The patients perform the LT at home, and the app's implementation data are stored in the database and saved in the cloud. Through the cloud, the physician can check the participant's LT implementation remotely.



Each participant will be scheduled for LT intervention every day for 8 weeks. The LT application is simple to use and is set up so that by touching the screen, a voice announcement is played and the user can perform 2 LT programs: the 1-leg stand program and the squat program. A single LT session consists of a program of 60 seconds of standing on one leg and 5 squats, with each exercise repeated 3 times. For participants with weak legs and backs who find it difficult to do the regular LT, it is recommended that they stand on one leg while supporting their body with their hands and fingers on a desk, or that they sit on a chair and stand up by putting their hands on a desk instead of doing squats. In addition, for participants with particularly weak legs and backs, each LT repetition could also be reduced to 1 time instead of 3 times [5]. Sustainable goals are set for each

individual for LT continuity. After completion of the LT, the participant touches the screen to check the record of the LT, not only on the participant's but also on his or her physician's smartphone (Figure 2).

Figure 2. Screenshots of the app used in this study. The app for patients has a simple design to help them perform the locomotive training (LT). The app for physicians allows them to check a patient's LT status based on the ID for that patient. The number of days with LT is displayed on the same screen for both the patient and the physician.



Outcomes

Timeline

The timetable of enrollment, interventions, and assessments is displayed in Table 1, including the quantitative self-reported outcomes and TUG results at the baseline, interim, and final evaluations. Demographic and clinical information will be obtained from the participants' electronic medical records at baseline and will include their date of birth, gender, BMI, medical history, and disease or diseases causing LS.

Patient background	✓		
Timed up and go test	✓	✓	✓
25-question Geriatric Locomotive Function Scale	✓	✓	✓
Behavioural Regulation in Exercise Questionnaire 3	✓	✓	✓
Days with locomotion training		✓	✓

[a]DTx: digital therapeutics.

Primary Outcome

The primary outcome is TUG test values before and after the DTx intervention. The TUG test is widely used in clinical practice as an outcome measure to assess mobility, fall risk, and dynamic balance in adults, and it can assess objective mobility [21,22]. Furthermore, previous research has shown that patients with LS have significantly longer TUG times than control groups [23]. In patients with rheumatoid arthritis, TUG values are significantly shortened and physical function is improved by continuing LT [24]. We determined that TUG is a useful indicator of the effects of LT for participants with LS.

Secondary Outcomes

Secondary outcomes are the participants' GFLS-25 and BREQ-3 scores. The GFLS-25 is a self-report questionnaire used to assess difficulties and impairments in daily activities related to LS and can be used to assess subjective mobility [5-7]. The BREQ-3 assesses motivation for exercise with 18 questions in 6 areas: intrinsic motivation, integrative adjustment, identification adjustment, incorporative adjustment, external adjustment, and demotivation [25]. The BREQ-3 is used in this study to assess changes in attitudes toward exercise before and after the DTx intervention.

Other Clinical Outcomes

We will evaluate the numbers of days LT was performed at 4 weeks and 8 weeks after the intervention, as recorded in the smartphone app.

Statistical Methods and Sample Size

The primary outcome of this study, TUG test values, will be measured repeatedly in the same participants at 0 weeks before the DTx intervention and 4 and 8 weeks after the intervention. These data will be compared with an ANOVA, with the TUG score as the dependent variable. The secondary outcomes, GLFS-25 and BREQ-3 scores obtained at the 3 time points, will also be compared with an ANOVA. The significance level will be set at .05 / 3 = .0167 with Bonferroni correction.

The minimal clinically important difference in the TUG test for patients with degenerative disc disease has been reported to be 3.4 (SD 5.0) [26]. Considering this finding, we set the minimal clinically important difference at 3 for this investigation. The required sample size was calculated using G*power (Heinrich-Heine-Universität Düsseldorf) [27]. We selected the corresponding *t* test, and we calculated the effect size as 0.6 based on a mean difference of 3.0 and an SD of difference of 5.0. Assuming that α is .05 and power $(1 - \beta)$ is .80, the required sample size was estimated to be 24. We set the target number of cases for this study at 50, taking into account that the SD might be smaller than in previous studies, some participants might drop out, and other factors.

Randomization and Blinding

This is a nonrandomized (unblinded) study and will use a single group. All participants will serve as their own controls; data from all participants before the DTx intervention will be used and compared with the data from after the DTx intervention. The planned statistical methods will add strength to the study's conclusions.

Data Monitoring and Adverse Event Reporting

The risk of adverse events from participation in DTx is very low. We are thus not establishing a data monitoring committee, and no interim analyses are planned to identify risks.

The principal investigator will (1) report the progress of the study without delay to the ethics review committee on an annual basis, (2) monitor adverse events related to the procedures and group program, and (3) discuss any necessary protocol amendments. If a member of the research team becomes aware of the occurrence of a serious adverse event, they will promptly report it to the research director, who will promptly report it to the principal investigator. If the principal investigator determines that the serious adverse event was unanticipated and is unable to be ruled out as being causally related to this study, he will promptly report it to the head of the research institution.

Ethical Considerations

The Fukushima Medical University Ethics Review Committee provided ethical approval for this study (REC 2023-196). All study methods follow the relevant guidelines and regulations, and written informed consent will be obtained from participants. The study's main results will be published in a peer-reviewed scientific journal and submitted for presentation at clinical and scientific meetings and conferences. The principal investigator will oversee the publication and presentation of the study results, including the determination of authorship. Participants will be asked if they would like to be informed about the study's main results, and those who express interest and provide contact information will be provided this information as soon as it becomes available. Data will be deidentified and participant information will be protected. Although no monetary rewards or other compensation will be provided to those participating in the research, in the event of an adverse event, we will respond promptly and provide compensation while consulting with the ethics committee.

Participants' data will be entered into a password-protected electronic file that will be kept on a secure computer by the principal investigator. Coding sheets with identifiable participant information will be stored on a secure computer as password-protected electronic files. Hard copies of consent forms and research documents will be stored in a locked filing cabinet at the research site.

Results

Trial enrollment began in April 2024 and will initially continue until at least April 2025. As of April 2025, 47 had participants agreed to be evaluated, 47 participants had completed the interim evaluation, and there were complete data sets from 45 participants for the proposed analysis. The data analysis has not yet been conducted.

Discussion

To our knowledge, this is the first trial to evaluate the effectiveness of DTx in preventing and ameliorating LS and changing the exercise behavior of older people. Although it is limited by its single-group design, the study has the strength that it evaluates the effectiveness of DTx in routine practice. External validity is also strengthened by the that fact that the practice sites are spread across 3 general hospitals and target communities with different sociodemographic characteristics.

A randomized design was not feasible, as the intervention is offered in routine practice [28], thus limiting causal conclusions. However, a randomized control study of approximately 200 participants per group in collaboration with local authorities has been proposed to strengthen this study. This is intended to improve the quality of the study by assessing in greater detail the impact of DTx on behavioral change and the prevention and amelioration of LS in older adults.

We are concerned that participants with low exercise awareness and low technology literacy may have difficulty participating in this study. However, for patients who are highly conscious of exercise but find it difficult to continue exercising on their own, or who are anxious about the content of the exercise, an advantage of the study is that they can exercise according to a set protocol with the cooperation of health care providers.

Notably, DTx enables the online assessment of the participants' engagement in LT and facilitates feedback in routine practice.

DTx is less burdensome for medical practitioners and more motivating for the participants as it creates an environment in which the participant is continuously supported by a physician. This research promises not only to lead to more efficient use of health care resources and reduced human and financial burdens, it may also lay the groundwork for more rapid implementation of DTx in real-world clinical practice, depending on the results. Nevertheless, a randomized controlled study based on our results will be required in order for DTx to gain insurance coverage in Japan, which calls for adequate funding and the cooperation of local authorities. If successful, the study will support the prevention and amelioration of LS and the establishment of better exercise habits among older adults.

Acknowledgments

We thank the hospital department heads for collecting the patient data and the study participants for their time and effort. This study is funded by a grant from the Japanese Orthopaedic Association (JOA-Subsidized Science Project Research 2022-1).

Data Availability

The datasets generated during and analyzed in this study will be made available from the corresponding author on reasonable request.

Authors' Contributions

TS and YM developed the evaluation method, participated in the study’s conception and design, obtained ethical approval, and wrote the manuscript. Both authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Cancer is a leading cause of global mortality, accounting for nearly 10 million deaths in 2020. This is projected to increase by more than 60% by 2040, particularly in low- and middle-income countries. Yet, palliative and psychosocial oncology care is very limited in these countries.

Objective: This study describes a protocol for the development, implementation, and evaluation of a psychosocial oncology and palliative care course on Cameroonian practicing nurses' knowledge, self-perceived competence, and confidence in palliative and psychosocial oncology care provision for patients with cancer.

Methods: A single group pre-posttest design, incorporating both quantitative and qualitative methods will be used. First, a psychosocial oncology and palliative care course for practicing nurses in Cameroon will be developed. This course will then be implemented with 50 practicing nurses purposefully selected from 2 oncology units in the Littoral region and 4 hospitals in the Southwest region of Cameroon. Finally, to assess the impact of the training program we will undertake a pre and posttest survey of nurses' palliative and psychosocial oncology competences, a pre and post training audit of patients' nursing records to examine nurses' practice of palliative and psychosocial oncology care and undertake a critical-incident interview of nurses' transfer of learning to practice. Descriptive and inferential statistics will be used to analysis quantitative data, while qualitative data will be analyzed using the framework approach.

Results: This study was funded in September 2023. The training program development was initiated in March 2024 and completed in June 2024. Baseline data collection commenced in May 2024 and as of September 2024, we had collected data from 300 patient record. Training implementation is planned for October-December 2024, and post intervention data will be started in October 2024 and continue till April 2025. Data analysis will commence in October 2024 and we aim to publish study findings in peer review journals by November 2025.

Conclusions: This study will improve our understanding of Cameroonian nurses' palliative and psychosocial oncology competency gaps. It will result in the development of a palliative care and psychosocial oncology course and in the training of 50 nurses in psychosocial oncology and palliative care in Cameroon. This study will inform strategies for future psychosocial oncology and palliative care training initiatives in Cameroon and other low- and middle-income countries.

Introduction

The global need for palliative and psychosocial oncology care continues to grow with the increasing prevalence of life-limiting conditions such as cancer [1,2]. In 2020, there were 19.3 million new cancer diagnoses and close to 10 million cancer-related deaths worldwide. As high as 1.9 million of these deaths occurred in low- and middle-income countries (LMICs) [3]. The number of people requiring palliative care globally has increased significantly in the last 2 decades, from 20 million in 2014 [4] to 56.8 million in 2020 [5]. Unfortunately, LMICs, especially those in sub-Saharan Africa, who have little or no psychosocial oncology and palliative care services harbor up to 80% of this global need [1,6-8]. The limited palliative and psychosocial oncology services in these countries has been associated with barriers such as the lack of competent health care providers with palliative and psychosocial oncology skills, the nonintegration of palliative and psychosocial care in the existing health care system [7,8], the lack of policies to support effective palliative and psychosocial care provision [7,9], and the presence of legislation that limits opioid prescription resulting in poor pain relief, among others [10]. There is therefore a need for strategies to overcome these barriers and facilitate the integration of palliative and psychosocial oncology care into the national health care systems in LMICs [7,11]. Providing educational opportunities to enhance the skills of health care providers in palliative and psychosocial oncology care is one important strategy to ensure that patients have early access to these essential health care services [5,6,12].

Patients and their families who receive a cancer diagnosis experience a high prevalence of pain, emotional, spiritual, and psychosocial distress [9]. The provision of palliative and psychosocial oncology care to these patients and their families will help prevent and relieve these problems [1,6,9] and is cost effective [13]. This is therefore priceless in LMICs where there are limited health care resources, and the cost of care is mostly borne by patients and their families who lack the needed financial resources [13].

With the increasing incidence of cancer in Africa, oncology capacity building opportunities are needed to enhance health care provider's competences and possibly ensure adequate management of patients and their families [14]. Palliative and psychosocial care are important components of quality cancer care that reduces distress, anxiety, and depression and improves patients' quality of life and survival [6]. However, it requires close monitoring and presence, which may not be feasible for an already overloaded oncologists [15]. Thus, nurses are in an ideal position to provide palliative and psychosocial care to patients with cancer, particularly in Africa, with huge shortage of oncologists and physicians [16]. Nurse-led palliative and psychosocial have been shown to improve access to palliative and psychosocial care for patients with cancer in resource limited settings [15,17].

The Need for Palliative and Psychosocial Oncology Care in Cameroon

In Cameroon, there is an upsurge of noncommunicable chronic disease morbidity and mortality [18]. Although cancer is likely underreported, there were approximately 19,564 new cancer diagnoses and 12,798 cancer deaths in Cameroon in 2022 [19]. Similar to most sub-Saharan African countries access to cancer care in Cameroon is limited, although cancer is a leading cause of premature death in the country [20]. There are 3 main cancer centers situated in 2 regions of the country, serving patients from all 10 regions of the national territory [21-23]. The majority of patients visiting these centers present with advanced cancer diagnoses due to delays in access to screening, diagnosis, and treatment [23]. With the limited number of oncology centers and specialists in the country, patients with cancer are often admitted in secondary level hospitals found in each of the 10 regions. Thus, patients with cancer are often cared for by nononcology professionals, particularly nurses. The Cameroon ministry of Public Health has developed a national cancer control plan to increase the number of cancer cases detected and treated early [23]. Thus, the need for strategies to promote early and timely access to psychosocial and palliative care. A study in Cameroon on psychosocial distress and quality of life of patients with cancer [22] found that majority of patients (n=83, 69.2%) presented with clinically significant distress. Financial difficulties, fatigue, transportation issues, and difficulties with work or school were the most reported problems. Up to half of the participants had moderate to severe anxiety and depression symptoms. The quality of life was fair, and there was a statistically significant negative relationship between psychosocial distress and quality of life of patients. These patients however lack access to much needed palliative and psychosocial care.

Palliative care was started in Cameroon in 2003 by the Cameroon Baptist Convention Health Services [24]. The literature reports the lack of a palliative care policy framework in the national cancer control plan [8,23], and limited accessibility to palliative care drugs, especially morphine [25]. These represent a huge gap in access to cancer care and is therefore a significant burden on the population. Training nurses to provide palliative and psychosocial oncology care to patients with cancer in Cameroon can improve access to care, patient experiences and quality of life. A few studies in Cameroon suggested that nurses lack knowledge about palliative care and have negative attitudes toward care of the dying [26,27]. However, there has not been any palliative and psychosocial oncology care training targeting practicing nurses in Cameroon.

Study Aim

The overall aim of this proposed study is to develop, implement, and evaluate the impact of a psychosocial oncology and palliative care course on Cameroonian practicing nurses' knowledge, and self-perceived competence and confidence in palliative and psychosocial oncology care provision for patients with cancer, using Kirkpatrick's framework [28] for training

program evaluation. Our specific aims are to develop a psychosocial oncology and palliative care training program for nurses in Cameroon, to implement the training program with 50 nurses who provide care to patients with cancer in selected health care facilities in the Littoral and South-West regions of Cameroon, to assess the impact of the training program on nurses' psychosocial oncology and palliative care knowledge and self-perceived competence and confidence in psychosocial and palliative care provision for patients with cancer after program completion, to assess the strengths and weaknesses of this training program and identify possible implementation challenges to inform future psychosocial oncology and palliative care curriculum initiatives in Cameroon, and to assess nurses' transfer of their learning from this training program in the care of patients with cancer and perceived impact on patient outcome.

Methods

Design and Methods

A single group pre-posttest intervention design will be used in this study and will incorporate both quantitative and qualitative methods of data collection and analysis. The study will be conducted in 3 phases: course development; course implementation, and course evaluation (Table 1). The Kirkpatrick's framework for training program evaluation will be used to evaluate the psychosocial oncology and palliative care training program. The Kirkpatrick's framework is selected for its unique focus on evaluating the outcomes of interventions beyond learners' satisfaction. It consists of four hierarchical evaluation levels including reaction, learning, behavior, and results. Patients and the public will not be involved in the design, or conduct, or reporting, or dissemination plans of the research.

Table 1. Summary of the phases of the study.

Study phase and objective	Activities
Phase 1: Develop a psychosocial oncology and palliative care course for nurses	• Engage nurse educators, palliative care experts and oncologist as course development team • Develop course through Delphi method • Inform course development with content from the psychosocial care competencies framework for nurses in Africa [6], the international psycho-oncology society's core curriculum [29] and a palliative care course for preregistration nurse training in Cameroon [26]
Phase 2: Course implementation	• Recruit nurses who care for patients with cancer in 6 hospitals from 2 Cameroonian regions • Deliver the course to 50 nurses over a 4 days duration through theoretical lessons and a practical session
Phase 3: Course evaluation	• Undertake a pre- and post-training assessment of nurses' palliative care knowledge, self-perceived competence and confidence in palliative care provision, and nurses' psychosocial oncology care competencies • Conduct a pretraining audit of nursing records of 300 hospitalized patients with cancer to assess nurses' baseline practice of palliative and psychosocial oncology care • Administer an end of course survey to evaluate the strengths and weaknesses of the course • After 6 months of training, undertake a posttraining audit of nursing records of 300 hospitalized patients with cancer nursing records to assess change in nurses' practice • After 6 months of training, conduct critical incident interviews with 18 nurses to assess transfer of their learning to practice

Settings and Sample

The study will be conducted in 6 health care facilities in the South-West and Littoral regions. This will include 2 oncology units in Douala in the Littoral region and 4 health care facilities in Fako in the South-West region. Patients in the Southwest region of Cameroon who receive a suspected diagnosis of cancer are referred to an oncology center in Douala, the neighboring town in the Littoral region. Thus, they travel long distances to access oncology care. Secondary level hospitals located in the Southwest region provide some consultation by a visiting oncologist. There are few health care providers in the Southwest region with palliative care training [30] and we do not know of any training in psychosocial oncology for nurses in Cameroon. A purposive sample of 50 nurses who work in hospital units that provide care to patients with cancer in the study hospitals from the oncology, medical, surgical, and intensive care units will be recruited, 9 nurses from each study site in the Southwest region and 7 nurses each from the oncology units in the 2 sites in the Littoral region. In a similar study in this setting [31], a power calculation showed that using a P value of .05 to determine a statistically significant result, 50 participants were required to give 98% power to find a significant difference in palliative care knowledge. In Cameroon, we have an estimate of 1 nurse per 1000 population [32]. In most secondary and tertiary level hospitals, there are about 10 nurses working in each of the targeted units. Thus, 50 nurses will be selected from an approximate population of about 220 nurses. Nurses who have worked in either the oncology, medical, surgical, or intensive care unit for at least 6 months will included in the study. We consider that 6 months of work in any of these units will allow the nurse to have encountered several patients with cancer and gathered relevant knowledge of their needs from which we can learn during the course and to which they can compare their post training competencies. The nurses have to provide consent and agree to participate during the entire training duration.

Participant Recruitment Strategy

Permission to conduct the study has been obtained from the directors and supervisors of nursing services of the study hospitals. We are requesting assistance from the general supervisors of nursing services in each study site to identify nurses who meet the inclusion criteria of the study. Interested nurses will register for the training by completing an application form. Selected participants will be contacted to complete the course registration process and consent. All participants will provide consent to participate. Personal identifiers, will only be collected to match pretest and post questionnaires. The questionnaires will be anonymized by coding and removal of any personal identifiers.

Data Collection

All data collection activities will be undertaken by trained research assistants (RAs), under the supervision of the principal investigators. We will train the RAs on how to use the survey instruments and how to conduct the individual critical incident interviews. We will undertake a mock data collection and role play of interviews with the RAs during the training, to ascertain they can undertake the exercise. The principal investigators will undertake validation checks of the data to ensure that data is precise, accurate and complete.

Study Activities and Data Collection Methods by Aim

Study Aim 1: Develop a Psychosocial Oncology and Palliative Care Training Program

We will develop a psychosocial oncology and palliative care training program for Cameroonian practicing nurses using the psychosocial care competencies framework for nurses in Africa [6], the International Psycho-Oncology Society's (IPOS) core curriculum [29] and the palliative care course developed for preregistration nurse training in Cameroon [26,27]. At the outset of the study, we will establish a curriculum development committee consisting of 3 members including an oncologists, a palliative care nurse, and psycho-oncologist. The research team will work with the curriculum committee to contextualize the competency framework and IPOS core curriculum for use in the training of nurses in Cameroon. This will be done in collaboration with the psychosocial oncology society of Ghana [7]. We will work virtually via email exchanges, using the Delphi strategy [33] and will organize 2 Zoom (Zoom Video Communications) meetings to finalize and validate the training program.

Study Aim 2: Implement the Training With Nurses

The training will be organized at the conference room of participating hospitals to facilitate nurses' participation. Thus, 6 training sessions will be implemented with participants in the 6 study sites. Each training session will last 4 days. Day 1 and 2 will entail classroom training sessions; day 3 will be clinical case studies and scenarios through role playing under the supervision of a palliative care nurse, oncologist, and clinical psychologist and day 4 will be experience sharing, action plan development, and training evaluation. The classroom sessions will include interactive lectures assisted by PowerPoint (Microsoft) presentations, pictures and videos, presentation of case studies, sharing of personal experiences and group discussions of concepts and experiences. An international facilitator will be invited to take part in the training and give an opportunity for others to present virtually during the training. For the clinical case studies and scenarios, participants will be shared in groups of 5 to work on different clinical case studies and scenarios followed by sharing feedback with the entire team. A similar approach has been used and shown to be an effective strategy in the training of nurses in psychosocial oncology [34]. Participants will be provided with printed copies of the palliative care toolkit by Lavy and Woodridge [35]. In addition, they will be provided with links to online resources including the free online resources by IPOS.

Aim 3: Assess the Impact of the Training Program on Nurses' Psychosocial Oncology and Palliative Care Competences

A pretest and posttest survey will be used to assess the impact of the course on nurses' psychosocial oncology and palliative care knowledge and self-perceived competence and confidence in psychosocial and palliative care provision. An advantage of a pretest and posttest assessment is that it can be used to enhance understanding of what change, particularly in factual knowledge or skill sets that could be credited to a training program. All 50 study participants will receive a paper-based pretest evaluation to determine their baseline psychosocial oncology and palliative care knowledge, and self-perceived competence and confidence in psychosocial and palliative care provision. The paper-based assessment will take place at the hospital on the first day of training. Posttest data will be collected on the last day of the training. A questionnaire has been collated and comprises of 3 subscales to collect the pretest and posttest data. These subscales include a researcher developed demographic information subscale, the Palliative Care Quiz for Nursing [36], Perceived Palliative Care Self-efficacy Questionnaire [37], and the psychosocial oncology knowledge subscales [34]. The demographic questionnaire will collect information on participants' characteristics including nurses' qualification, hospital and unit of work, gender, religious affiliation, and previous education about palliative care and psychosocial oncology. The validated Palliative Care Quiz for Nursing will be used to assess change in nurses' palliative care knowledge, the Perceived Palliative Care Self-efficacy Questionnaire will be used to assess self-perceived competence and confidence in palliative care provision. These instruments have adequate psychometric property and have been used to assess student nurses' palliative care competencies in the study setting. For the assessment of psychosocial oncology competences, we have adapted the instruments used in the study by Mahendran et al [34] in Singapore.

Aim 4: Assess the Strengths and Weaknesses of This Training Program

A course evaluation survey will be administered to participants to explore their experiences of the course, their perspective of its strengths and weaknesses, and their plans for transfer of their knowledge and skills from this course to practice, in the care of patients with cancer. This will include both close-ended and open-ended questions to give nurses the opportunity to expand

on their responses and provide all relevant information as they deem necessary. This survey instrument is under development by the team and will be administered by research assistants on the last day of each training session.

Aim 5: Assess Nurses' Transfer of Their Learning From This Training in the Care of Patients With Cancer

Individual critical incident in-depth interviews will be conducted with nurses to explore the transfer of their learning to practice, its perceived benefits to patients and implementation challenges. A random sampling technique will be used to invite 3 nurses from each study site for this interview. Thus, a total of 18 nurses will be interviewed. These interviews will be organized at month 6 following completion of the training for each hospital. An interview guide will be used and it is envisaged that the interviews will last for 1 hour and will be tape recorded. In addition, a pre- and posttraining audit of patient files will be carried out to assess the number of patients with cancer that nurses assessed for psychosocial distress and coping, depression, anxiety, and palliative care, the number they plan psychosocial nursing and palliative care interventions (cognitive behavioral therapy) for and the number that nurses referred or suggest referral to specialist mental health and palliative care services or psycho-oncologists. The pretraining audit will be conducted at baseline, using a checklist. We will select files of the 50 most recently discharged patients with cancer or patients who died during hospitalization from each study site. Thus, a total of 300 hospital files will be studied from the 6 sites. Six months after training implementation in each site, we will undertake the posttraining audit. We will randomly select 50 files of patients with cancer currently receiving or who received nursing care from trained nurses. In total we will study 600 files, 300 from baseline and 300 post training.

Data Analysis

We will evaluate changes in mean scores from pretest to posttest to assess the impact of the course on nurses' psychosocial oncology and palliative care knowledge, and self-perceived competence and confidence in psychosocial oncology and palliative care provision. A paired *t* test, will be used to calculate the change in nurses' psychosocial oncology and palliative care knowledge from pretest scores to posttest scores, and to examine the significance of this change. The between and within group variations of the pretest and the posttest scores in psychosocial oncology and palliative care knowledge before and after the training program will be assessed using ANOVA. The McNemars test will be used to assess changes from the pretest to the posttest in nurses' self-perceived competence and confidence in psychosocial and palliative care provision. Descriptive statistics (close ended responses) and content analysis strategy (open-ended responses) will be used to analyze data on nurses' evaluation of the benefits of the course on their psychosocial oncology and palliative care competencies, their experiences of the course and its strengths and weaknesses, and how they were able to use them in practice.

A framework analysis [38] will be used to analyze critical incidents where nurses implemented their learning in practice and their perspective of how that benefited the patients with cancer in their care. Themes will be used to describe these experiences. Finally, a content analysis of the change in nurses' practice in terms of the number and content of patients' assessment for psychosocial distress, depression, anxiety, and palliative care, the number of patients with psychosocial and palliative care nursing care plans and the number that were referred to specialist mental health or palliative care services by nurses before and after the training. All project team members, RAs, and program coordinator will be involved in data collection and analysis.

Ethical Considerations

Ethical approval for this study has been obtained through the University of Buea institutional review board (Ref-2023/2165-10/UB/SG/IRB/FHS). Participants will receive an information sheet regarding the study and will provide written consent for the study. Participation in the study will be voluntary and participants will also have the freedom to leave the study at any time without giving a reason to the study team. Data will be anonymized to ensure and no identifiable information will be stored. No compensation will be provided to research participants.

Results

This study was funded in September 2023. The training program development was initiated in March 2024 and completed in June 2024. We engaged 12 cancer care, psychosocial oncology and palliative care experts, and nurse educators in Cameroon (n=7), the United Kingdom (n=2), Ghana (n=1), Indonesia (n=1), and the United States (n=1) in a 3-round Delphi process for the development of a bespoke palliative care and psychosocial oncology training program. As of August 30, 2024, we had obtained administrative authorization from all participating hospitals. The collection of baseline data on nurses' practice of psychosocial oncology and palliative care as documented in the nursing records of patients with cancer was commenced in May 2024. As of September 19, 2024, we had completed an audit of the records of 300 hospitalized patients with cancer from all study sites. The implementation of the training program is planned for October-December 2024. Following course implementation, posttest data will be started in October 2024 and continue till April 2025. Data analysis will commence in October 2024 and will continue until June 2025. We aim to present study findings at national and international palliative care and psychosocial oncology conferences and publish papers in peer review journals by November 2025.

Discussion

Expected Project Outcomes

This protocol provides details of the steps for the development, implementation and assessment of the impact of a psychosocial oncology, and palliative care training program on Cameroonian nurses' palliative care and psychosocial oncology knowledge, self-perceived competencies, and practice. In this study, we are developing a palliative and psychosocial oncology course for nurses in Cameroon. We will pilot it with 50 nurses working in 6 hospitals in the southwest and littoral regions of Cameroon. We envisage that this training program will improve

participating nurses' palliative care knowledge and self-perceived competence and confidence in psychosocial and palliative care provision for patients with cancer. The implementation of this training program will enhance our understanding of the components and strategies for an effective palliative care and psychosocial oncology training program for nurses in Cameroon. We also hope that study findings will support future psychosocial oncology and palliative care training initiatives in Cameroon and similar contexts.

The field of psychosocial oncology is still developing in Africa [39] and therefore, initiatives to enhance health care providers' competences in this practice area are crucial especially in sub-Saharan Africa. Given the limited numbers of oncologist, psycho-oncologist, mental health experts and palliative care physicians and nurses in Cameroon, it is important to train registered nurses, who make the most of the health care workforce in Cameroon to provide palliative and psychosocial oncology care to patients with cancer and their families. This project builds on previously successful educational initiatives in palliative care for nursing students in Cameroon to enhance care of patients with life-limiting illnesses including patients with cancer [26,27]. Training nurses in palliative care and psychosocial oncology in other contexts have yielded positive impacts in terms of improvements in their knowledge and skills in palliative and psychosocial oncology care provision, with positive patient outcomes [15,34,40,41]. Similar outcomes are anticipated for this training in Cameroon.

Similar to this study, most studies have used both validated instruments such as the Palliative Care Quiz for nurses, and nonvalidated self-reported tools to evaluate the effective of training programs [15,40,41]. However, the use of self-reported tools is limited, with the possibility of recall bias, and social desirability bias [42]. Participating nurses may not recall past practices and may also tend to please the researcher and answer questions in ways they consider right rather than giving a true self-assessment of their competencies. Furthermore, nurses could overrate or underrate their competencies, resulting in a response shift bias [43].

The Kirkpatrick's model of training program evaluation used in this study provides us with a logical structure and process to measure participants' learning, satisfaction and transfer of learning to practice. It will provide us with an understanding of the specific areas for improvement within this training program, based on its strengths and weakness, thus informing program enhancement [44]. We aim to disseminate our study's findings in a peer reviewed journal and local and international conferences. In addition, during program implementation we will engagement with general supervisors of nursing services, nurse educators, and other health care professions education stakeholders in Cameroon. This has the potential to inform nursing education reforms and drive the long-term goal of curriculum revision to include palliative care and psychosocial oncology in the training programs of health professionals in Cameroon.

Acknowledgments

We thank the participating study sites for granting access to the institution for this study. This work was supported with grant funding from Pfizer Global Medical Grants (76387581).

Data Availability

The datasets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

All authors contributed to the conceptualization, writing-review and editing, and approval of the submitted manuscript and will be accountable for its contents. NB and TN performed supervision. NB, TN, and BA performed data curation. NB, TN, BA, EVA, EME, NE, and ASA performed investigation and methodology. NB, TN, and BA handled project administration, managed resource and software and conducted validation. NB wrote the original draft.

Conflicts of Interest

None declared.

Abstract

Background: Diabetes affects half of the patients with cystic fibrosis who are aged 30 years and older. Diabetes progresses asymptomatically over a long period of time. Two treatment options are possible: start insulin as soon as cystic fibrosis diagnosis is made with the additional constraints of cystic fibrosis or wait while monitoring the patient's clinical condition and start insulin when diabetes symptoms develop and therefore later. This situation is particularly well suited to shared decision-making (SDM) between the physician (health care team) and patient/relatives.

Objective: The aim of this study was to perform qualitative and quantitative analyses for evaluating the outcomes and experience of SDM implementation between the physician/health care team trained for SDM and patients/their relatives for cystic fibrosis–related diabetes.

Methods: A quasi-experimental with a comparison study will be developed. Three cystic fibrosis reference centers (CFRCs) will be trained in SDM by using a web-based training, including a validated decision aid and coaching for physicians and the medical team. Two control CFRCs will maintain their usual practices. A qualitative analysis through observation of consultations, individual semistructured interviews with patients, and focus groups in CFRCs will be conducted based on a thematic content analysis. Questionnaires related to decision-making and experience of decision-making with and without SDM implementation will be administered to patients and physicians.

Results: Forty patients will be included (8 patients in each center), that is, 60 consultation observations (2 consultations per patient in the intervention groups given the modalities of the SDM process) will be conducted in 2025. Eight focus groups will be conducted in the 5 centers (2 groups in each intervention CFRC and 1 group in each control CFRC). This qualitative corpus plus responses to the patient and physician questionnaires will make it possible to know whether the practice of SDM in CFRCs is increased by an implementation strategy and to analyze the experience of patients and their relatives regarding decision-making modalities. Analysis of the outcomes and experience of the implementation of SDM are of importance to identify the facilitators and barriers to SDM from patients' and CFRCs' point of views.

Conclusions: Our study will give us keys to adapt, improve, and disseminate SDM more widely in the context of cystic fibrosis therapy. SDM could thus be used in routine clinical practice in CFRCs at the national level.

KEYWORDS

shared decision-making; implementation; training; decision aid; cystic fibrosis

Introduction

Background

Many patients want to play an active role in their own care [1], and many health care professionals want the same for their patients [2]. Shared decision-making (SDM) in the physician-patient encounter is one way of meeting this wish. In SDM, "the information exchange is 2 ways […]. The defining characteristic of deliberation […] is its interactional nature (ie, between the physician and the patient or potential others), and both parties work toward reaching an agreement and both parties have an investment in the ultimate decision made" [3].

SDM often relies on information and decision support tools (decision aids), which provide written support for exchanges. Decision aids are increasingly digitalized and adapted to patients' health literacy levels [4]. They present management options with their benefits and risks, informing patients and enabling them to participate in the decision-making process if they wish so. They can be used both during and outside the consultation. For several years now, national and international health care policies have been encouraging the implementation of SDM for reasons ranging from ethical imperatives [5] to the reduction of unjustified variations in clinical practice [6]. However, despite the legal framework encouraging SDM in several countries (France [7], Germany [8], United Kingdom [9], United States [10]), the implementation of SDM in clinical practice is not yet widespread [11]. SDM research has focused on physician- or patient-mediated interventions to promote SDM [12]. Légaré et al [13] in their Cochrane review showed that a combination of both physician- and patient-mediated interventions is more likely to be successful. With regard to physician-mediated interventions, SDM training can teach health care professionals to involve patients in the decision-making process. A number of studies have shown the positive effects of training programs, such as improving physicians' SDM skills and increasing patient participation and satisfaction [14,15]. Joseph-Williams et al [16] in their systematic review also showed that patients want to be informed so that they can play an active role in decision-making. Patient-initiated interventions can also enhance the patient's ability to participate in the decision-making process. Patients who have learned to use tools that encourage them to ask questions to health care professionals participate more actively [17,18]. Finally, decision aids are a means of increasing SDM. The Cochrane systematic review by Stacey et al [4] based on 105 randomized controlled trials showed the beneficial effects of decision aids in improving doctor-patient communication (without increasing patient anxiety), improving patient knowledge, respecting patient rights, increasing physician and patient satisfaction, improving the quality of care, as well as reducing the decision-making conflict.

In 2017, we developed a decision aid based on the Ottawa Personal Decision Aid Guide [19] and the International Patient Decision Aid Standards Collaboration criteria [20] on the theme of cystic fibrosis–related diabetes treatment. Psychometric tests performed at the cystic fibrosis reference center (CFRC) in Lyon showed that the tool was valid and reliable [21]. In recent years, initiatives have been developing to implement SDM in routine clinical practice. Elwyn et al [22] in their systematic review of studies of decision support interventions concluded that the majority of studies do not base their design on an implementation theory or model. Although their review focused on the routine implementation of decision support interventions to promote SDM, there are other strategies for implementing SDM. For example, a large-scale, multicomponent SDM implementation program involving training of health care professionals in SDM and decision aids has been performed within the National Health Service in the United Kingdom (Making Good Decisions in Collaboration [MAGIC] Program). It showed that successful implementation of SDM in routine clinical practice (primary care, urology, obstetrics, oncology) was based on considering stakeholder attitudes, involving all stakeholders at an early stage and analyzing barriers and facilitators [23]. Such an approach is in line with the recommendations for implementation research developed by Grol and Grimshaw [24].

According to us, SDM seems to be particularly relevant in cystic fibrosis, where there are complex treatment options with variable short, medium, and long-term side effects, and where the disease and its treatments have a high impact on the patient's quality of life. This genetic disease affects almost 7000 people in France [25] and requires lifelong multidisciplinary care. From the moment of diagnosis, patients are regularly monitored in CFRCs. As a result, the doctor, the multidisciplinary team, and the patient/relatives have often known each other for a long time, forging a strong relationship based on mutual understanding and confidence.

A patient's quality of life is severely impaired by pulmonary exacerbations and regular digestive disorders. The patient's care load is considerable, combining daily respiratory physiotherapy, daily aerosol therapy, and multi-daily drug treatments. The social constraints (follow-up appointments every 3 months, daily medication intake, diet) associated with the disease and its treatment are considerable [26]. In addition, complications arise during the course of the disease such as diabetes. After the age of 30 years, half of all patients develop diabetes [27,28].

Diabetes adds significant morbidity [28,29]. Cystic fibrosis–related diabetes is quite specific, differing from type 1 diabetes and type 2 diabetes. It has the particularity of being asymptomatic for a long time, with normal fasting blood glucose levels. For this reason, international recommendations suggest annual screening for diabetes from the age of 10 years, with an oral glucose tolerance test [30]. If diabetes is confirmed by the results of the oral glucose tolerance test, the question arises of how to treat it with insulin. If the patient's clinical condition is stable and the fasting blood glucose level is normal, there are 2 possible treatment options: start insulin as soon as the diagnosis is made or defer initiation of insulin therapy and reserve it for cases where the patient is experiencing impaired respiratory function, increased frequency of exacerbations, or weight loss. Each of these options is complemented by the appropriate dietary and exercise measures generally recommended for all patients with cystic fibrosis. To our knowledge, very little work has been done on SDM in cystic fibrosis [31] and none on SDM for the treatment of cystic fibrosis–related diabetes.

Research Assumption

We hypothesize that the practice of SDM by CFRC health care teams for the decision to treat cystic fibrosis–related diabetes will be favored by the implementation of an SDM intervention based on e-learning training integrating an information and decision support tool and coaching for physicians and the medical team.

Aims

Primary Objective

The primary objective is to evaluate the pilot implementation of an SDM intervention, that is, the adoption of SDM between the health care professional and the patient with cystic fibrosis–related diabetes among patients managed in centers receiving the intervention compared with patients managed according to the usual decision-making practice in control centers. SDM is a decision-making process in which the health care professional (plus medical team) and the patient (plus his/her relatives) exchange information on treatment options and then reach a common agreement on the decision to take. It is based on an information and decision support tool used during the consultation. The SDM intervention evaluated comprises 5 components.

1. Web-based SDM training (e-learning) for the entire CFRC medical team
2. Individual coaching for physicians and medical team
3. SDM implementation: (1) consultation 1, including patient activation and delivery of the information and decision support tool to the patient; (2) consultation 2 on discussion and decision-making; and (3) between the 2 consultations, the patient has a cooling-off period of 8-15 days, wherein the physician discusses the content of the consultation with the CFRC team
4. Link with institutional patient engagement initiatives
5. Integration of SDM into CFRC multidisciplinary concertation meetings

Secondary Objectives

The secondary objectives were to evaluate the effects of SDM on patients' level of knowledge of management options with benefits and risks, anxiety, and decisional conflict compared with patients managed in centers without intervention and to evaluate the effects of SDM on the physician-patient relationship in terms of information and decision-making.

In Intervention Centers

The objectives were as follows.

1. To evaluate the implementation of the SDM approach.
2. To evaluate the experience of the implementation of SDM regarding the treatment of diabetes in patients with cystic fibrosis. For patients: observations of SDM consultations, individual semistructured interviews based on an interview guide containing key items relating to information and participation in decision-making (barriers, helps) based on our previous work in the field, and questionnaires (9-item Shared Decision-Making Questionnaire [SDM-Q-9], CollaboRATE, knowledge, State-Trait Anxiety Inventory, SURE [Sure of myself, Understand information, Risk-benefit ratio, Encouragement] questionnaire). For health care professionals: focus groups with CFRC teams held at the start of the intervention and afterwards in each CFRC in the intervention group.
3. To identify the individual and organizational factors that influence the implementation of SDM in the treatment of diabetes in patients with cystic fibrosis by health care professionals: focus groups with CFRC teams, semistructured interviews with patients, and exchanges with institutional decision makers such as quality services.

In Control Centers

The objective is to describe the process and experience of making decisions about diabetes treatment. For patients with cystic fibrosis, in usual practice, the objective is to conduct observations of consultations dedicated to the discussion of insulin therapy, individual semistructured interviews, and questionnaires. For CFRC health care professionals, the objective is to conduct focus groups with teams from each CFRC (focus groups held once in each CFRC during the course of the study).

Methods

Ethics Approval

This study has been approved by the Scientific and Ethical Committee of the Hospices Civils de Lyon University Hospital on the data study (outside the Jardé law; MR004-ID 21_356).

Design and Setting of the Study

Based on our previous work on SDM in cystic fibrosis [21] and the Consolidated Framework for Implementation Research of Damschroder et al [32], this quasi-experimental here-elsewhere study compares the populations of 3 centers receiving the intervention with those of 2 centers not receiving it (controls). The 5 centers will be studied simultaneously to reduce the risk of contamination of the control group. The evaluation will

follow a mixed methods approach, combining qualitative methods (consultations observations, individual semistructured interviews with patients, and focus groups with health care professionals) with quantitative methods (self-administered questionnaires). A convergent mixed methods approach will be used, with concomitant data collection, separate analysis, and subsequent linking of results. This study conforms to the StaRi (Standards for Reporting Implementation Studies) checklist (Multimedia Appendix 1).

Characteristics of the Participants

Patient Inclusion Criteria

The patient inclusion criteria were as follows: (1) older than 18 years, with cystic fibrosis, followed up in one of the 5 CFRCs; (2) be able to understand French; (3) have an oral glucose tolerance test at the stage of diabetes or with a blood glucose Holter considered by the clinician to be pathological, justifying possible insulin initiation; (4) have normal fasting blood sugar levels; (5) stable clinical pulmonary and nutritional status, enabling the 2 treatment options to be considered; and (6) having received the information and not exercised their right to object.

Patient Exclusion Criteria

Patients who had undergone a transplant and those receiving insulin therapy were excluded.

Inclusion Criteria for Health Care Professionals

Medical and paramedical professionals working in the adult CFRC (physicians, nurses, dietitians, psychologists, physiotherapists, etc) who have not exercised their right to object were included.

Description of Intervention and Comparisons

SDM Implementation Program

This program was divided into several parts and as already mentioned, theoretically based on the Consolidated Framework for Implementation Research [21] and on existing literature on the implementation of SDM [13], structured into 5 components (A to E) focusing on health care professionals and patients.

Component A: Health Care Professionals' SDM Training in the 3 CFRCs

A 2-hour e-learning course will be the common core of the training. It comprises 7 modules: (1) training objectives; (2) review of national and international literature on SDM; (3) understanding SDM; (4) cystic fibrosis–related diabetes; (5) developing an information and decision support tool; (6) communicate benefits and risks to the patient; and (7) encourage active patient participation by means of a video of 2 simulated consultations with a doctor from the CFRC in Lyon and a patient who volunteered to take part in the project since its inception: one consultation leading to a shared decision to start insulin now and the other to start later. The e-learning will be supplemented by a presentation by one of the researchers specialized in SDM at the 3 CFRCs to answer questions/comments from the teams.

Component B: Individual Coaching for Physicians and Medical Team After e-Learning

This will be performed by the SDM methodologist to improve physicians' adoption of SDM practice. In line with research on this method [33], coaching will be provided verbally. The SDM methodologist will observe 1 or 2 consultations in each of the CFRCs, providing both oral and written feedback. Her feedback will be standardized across the 3 CFRCs on the 3 essential components of SDM (bilateral information/deliberation/common agreement on the decision taken).

Component C: Implementing SDM in 6 Steps

The 6 steps are as follows.

1. Initial consultation with the patient to discuss diabetes treatment options, detailing the benefits and risks of each option. The physician and patient inform each other, discuss throughout the consultation with the help of the information and decision support tool, elicit their preferences, and work toward reaching an agreement on the decision to take.
2. Patient activation strategy: this patient-mediated method is based on the "Ask 3 questions" tool used in international SDM implementation studies [20]. It consists of short questions that patients can ask their doctor to enable them to participate more fully in decision-making if they so wish (ask 3 questions: what are my options? what are the possible benefits and harms of those options? how likely are the benefits and harms of each option to occur?) [20]. This tool is displayed in the waiting room before the consultation.
3. The physician gives the patient a paper version of the information and decision support tool [21].
4. The physician presents the exchanges with the patient to the CFRC team trained in SDM to obtain their feedbacks.
5. A cooling-off period of 8-15 days is required before the second consultation. During this period, the patient can discuss with his or her family, general practitioner, or any other health care professional outside the CFRC as well as with the CFRC team, and can call, based on the information and decision support tool, if he or she so wishes.
6. A second consultation takes place after this period of reflection to make the decision (in this case, to take insulin now or later). Several attitudes are possible: clear patient preference for one option, patient decides alone, refusal by the patient to choose an option, or the physician decides on the basis of the therapeutic thesaurus. It should be noted, however, that this is not the paternalistic model, as far as it is the patient who, after being informed, asks the doctor to decide; thereafter, they come to a common agreement on the decision taken (decision taken together), resulting in SDM.

Component D: Link With Institutional Initiatives to Promote Patient Involvement

This will be performed by means of a short questionnaire describing the current situation on the topic. At the start of the study, this questionnaire will be supplemented by a phone interview with the hospital quality manager or referent. As CFRC teams are integrated into university hospitals that implement patient engagement initiatives, it will be important

to collaborate with their management teams to work together on integrating the SDM approach into these hospitals.

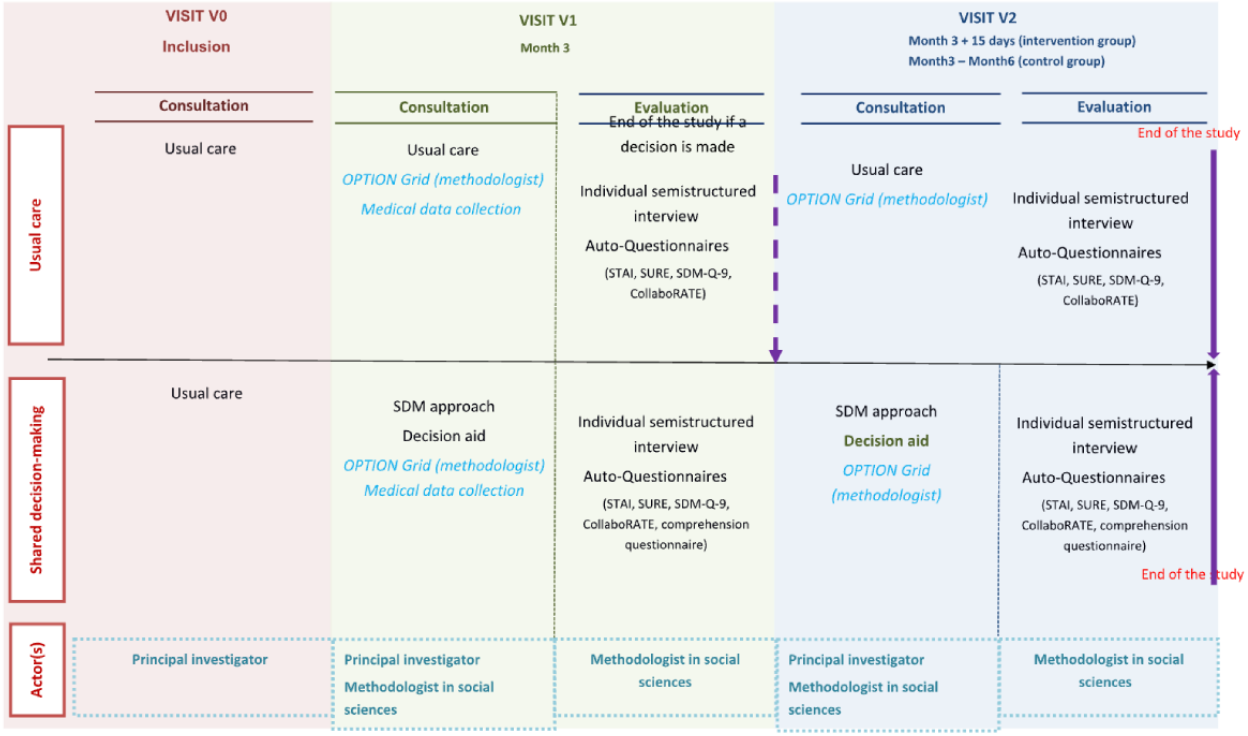
Component E: Integrating SDM Into CFRC Multidisciplinary Concertation Meetings

In order to best integrate SDM into the 3 CFRCs in the intervention group, we will organize in 2025 and in 2026 a meeting in each of the CFRCs to see how to integrate SDM into the recommendations for practice in multidisciplinary concertation meetings, and we will consider the organizational and practice specificities of each of these 3 CFRCs.

Standard Care

Insulin therapy decisions are made according to the usual practice defined in each CFRC, with decision-making procedures specific to each center and each CFRC physician/dietitian/nutritionist/team. The decision-making process generally involves 2 consultations (Figure 1).

Figure 1. FORAIDMUCO study protocol. SDM: shared decision-making; SDM-Q-9: 9-item Shared Decision-Making Questionnaire; STAI: State-Trait Anxiety Inventory; SURE: Sure of myself, Understand information, Risk-benefit ratio, Encouragement; OPTION: Observing Patient Involvement in Shared Decision Making.



Outcomes and Measures

The outcomes are measured using the following measures.

1. Adoption or nonadoption of SDM: SDM-Q-9 [34,35], CollaboRATE questionnaire [36], OPTION (Observing Patient Involvement in Shared Decision Making) questionnaire [37,38]
2. Level of patient knowledge: knowledge questionnaire developed by the authors on the basis of their previous work [39] and the literature since no validated knowledge questionnaire exists
3. Patient anxiety level: Spielberger State-Trait Anxiety Inventory [40]
4. Patients' level of decisional conflict: SURE questionnaire [41]
5. Patients' experience of information and decision-making procedures and more specifically of SDM implementation
6. Individual and organizational factors influencing SDM implementation

Inclusion Visit (V0)

When the patient comes to the CFRC following orally induced hyperglycemia, the physician will check the patient's eligibility criteria. During this visit, the physician will present the study and give the patient the information note. The physician will record the patient's nonopposition in the consultation report. The methodologist in social sciences must be informed of the patient's inclusion by sending an email containing the patient's first and last initials and the date of the V1 visit so that she can contact the investigating center to schedule her visit.

Visit V1

In the CFRCs of the control group, the physician will present the patient with information on diabetes management according to his or her usual practice. In the CFRCs in the intervention group, the physician will present the patient with information on diabetes management according to SDM (options, benefits, and risks) by using the information and decision support tool. The patient will be "activated" prior to the consultation, inviting him/her to ask questions using the "Ask 3 questions" tool. During the V1 visit for the control and intervention groups, the

investigator will fill in the patient's clinical data and SDM-Q-9 adapted to the physician immediately after the consultation. The patient fills in the questionnaires immediately after the consultation (the questionnaires are handed over by the methodologist or a member of the CFRC). The methodologist in social sciences will observe the physician-patient interaction during the consultation and complete the OPTION questionnaire; conduct an individual semistructured interview with the patient immediately after the consultation; ensure that the patient completes the SURE, CollaboRATE, SDM-Q-9, and Spielberger State-Trait Anxiety Inventory questionnaires (if the patient does not read French, the methodologist will read the questionnaires to the patient and fill them in with his/her agreement); and collect the patient's sociodemographic characteristics.

Decision-Making Visit (V2)

In the CFRC control group, insulin therapy decision-making will be performed according to the physician's usual practice. In the CFRCs of the intervention group, the decision-making visit will take place after a cooling-off period of 8 to 15 days following the V1 consultation. A discussion based on feedbacks from this period will take place between the physician and the patient, and either there is a common agreement on the decision taken (SDM) or the decision is taken by the patient or the decision is taken by the physician at the patient's demand. During this visit, the investigator will complete the SDM-Q-9 adapted to the physician immediately after the consultation. The patient fills in the questionnaires immediately after the consultation (the questionnaires are handed over by the methodologist in social sciences or a member of CFRC). The methodologist in social sciences will observe the physician-patient interaction during the consultation and complete the OPTION questionnaire, conduct an individual semistructured interview with the patient immediately after the consultation, and ensure that the patient completes SURE, CollaboRATE, SDM-Q-9, and the Spielberger State-Trait Anxiety Inventory. If the patient does not read French, the methodologist will read the questionnaires to the patient and fill them in with his/her agreement.

In the control and intervention groups, the methodologist in social sciences will attend the face-to-face consultation (possibly by videoconference if conditions require and allow) and will conduct the individual interview with the patient immediately after the consultation. If the patient is not available, the interview can take place up to V1+48 hours. The end of the research for patients in both groups is defined by the end of the individual interview at V2 or V1 for the control group if a decision is made following the consultation.

Health Care Professional Focus Groups

Two focus groups will be conducted in the intervention CFRCs (one at the start of the study and one at the end) and one in each of the 2 control centers by the methodologist in social sciences on the basis of a moderation guide containing the key items on which participants will be invited to discuss (barriers, facilitators of information and decision-making, dedicated time with and without SDM, information and decision support tool, etc). The discussion group will be made up of 4-8 health care professionals (physicians, nurses, physiotherapists, dietitians, psychologists, etc) depending on the center and will be as representative as possible of the CFRC's health care professional categories. In the intervention centers, the participating health care professionals will not necessarily have taken the e-learning training course. However, the group should be identical for both discussion groups unless a member is absent or leaves.

Data Collection and Analysis

Sample Size

As this is a pilot study, 40 patients will be included and interviewed over a 12-month period. The number of patients included corresponds to the active patient file of the 5 CFRCs over the 12-month inclusion period. Five physicians (1 in each center) will be involved in this study.

Analysis

All patients and health care professionals included in this study are in accordance with the inclusion and noninclusion criteria. The primary end point is the adoption or nonadoption of SDM from the patient's and health care professional's point of view. The secondary end points are patient knowledge; patient anxiety levels; patients' level of decisional conflict; patients' experience of information and decision-making procedures, and more specifically of SDM implementation; effect of SDM on the physician; and individual and organizational factors influencing SDM implementation.

Statistical Methods

Descriptive Analysis

A descriptive analysis of the characteristics of the patient population included (age, sex, history and severity of disease) and of the health care professionals on the CFRC teams (physicians, nurses, dietitians, psychologists, physiotherapists, etc, age, sex, profession, previous training in SDM) will be performed in the 2 study groups. Quantitative characteristics will be described by mean and standard deviation or by quartiles and minimum and maximum values depending on the shape of the distribution. Qualitative characteristics will be described by the numbers and percentages in each category. The comparability of the characteristics will be checked using the chi-square test for qualitative variables and the Wilcoxon test for quantitative variables. Data on the implementation of SDM in the intervention group will also be the subject of a descriptive analysis on the proportion of patients with at least one SDM consultation and the proportion of patients with 2 SDM consultations.

Analysis: Primary End Point

Adoption of SDM as perceived by the patient and measured using SDM-Q-9 will be analyzed in patients with no missing data on this criterion, although an approach to managing missing data may be considered. The frequency distribution of the 6 modalities of SDM-Q-9 will be described for each group in the patient unit. A total score will be obtained by summing the scores for each of the 9 questions. A transformation will be applied to obtain a total score between 0 and 100, with 0 indicating nonadoption of SDM as perceived by the patient and conversely 100 indicating adoption of SDM as perceived by

the patient. The total score will be described in each group by mean, standard deviation, median, quartiles, and range, and will be compared between the 2 groups with a nonparametric Wilcoxon test. For patients in the intervention group, the variation in the responses to each of the SDM-Q-9 questions between the 2 consultations will be tested using the McNemar test (test adapted to paired data). Total SDM-Q-9 scores between the 2 consultations will be compared using the Wilcoxon signed-rank test. The same analysis will be performed on the health care professional unit to compare the adoption of SDM as perceived by the health care professional. Discordances between patient and health care professional responses to each of the 9 questions on SDM-Q-9 will be described and tested using the McNemar test. The total SDM-Q-9 score obtained on the patient unit and the professional unit will be compared using the Wilcoxon signed-rank test.

Analysis: Secondary End Points

In accordance with the scoring rules of the OPTION grid, an OPTION score will be calculated for each patient-health care professional dyad if 100% of the 5 OPTION grid items have been completed. A total score between 0 and 20 will then be obtained by summing the answers to the 5 OPTION grid items between 0 and 4. The total score will be converted between 0 and 100, with high values indicating exemplary behavior by the dyad in adopting SDM. The OPTION score will be expressed as the mean and standard deviation for each group and will be compared using the Wilcoxon test.

In accordance with the scoring rules of the SURE questionnaire, a SURE score will be calculated for each patient if 100% of the 4 questionnaire items have been completed. A total score between 0 and 4 (a high value indicates a decisional conflict) will then be obtained by summing the binary responses of the 4 questionnaire items. The SURE score will be expressed as the mean and standard deviation for each group and will be compared using the Wilcoxon test. The percentage of patients whose SURE score is less than or equal to 3 (indicating a decisional conflict) will also be calculated in each group and compared using the chi-square test.

In accordance with the scoring rules of the CollaboRATE questionnaire, a CollaboRATE score will be calculated for each patient if 100% of the 3 questionnaire items have been completed. A total score between 0 and 9 (high values indicating a high level of SDM) will then be obtained by averaging the answers to the 3 questions between 0 and 9 on the questionnaire. The CollaboRATE score will be expressed as the mean and standard deviation for each group and will be compared using the Wilcoxon test.

A Spielberger State-Trait Anxiety Inventory score will be calculated for each patient if 100% of the 20 questionnaire items have been completed. A total score between 20 and 80 (high values indicating a high level of anxiety) will then be obtained by summing the scores associated with the 20 items. For questions 3, 4, 6, 7, 9, 12, 13, 14, 17, and 18, 1 point is awarded for not at all, 2 points for somewhat, 3 points for moderately, and 4 points for very much. For questions 1, 2, 5, 8, 10, 11, 15, 16, 19, and 20, the scoring will be reversed, that is, 4 points for not at all, 3 points for a little, 2 points for moderately, and 1 point for a lot. The Spielberger State-Trait Anxiety Inventory score will be expressed as the mean and standard deviation for each group and will be compared using the Wilcoxon test.

Semistructured individual interviews designed to assess the experience of information and decision-making procedures in the control and intervention groups and the effects of SDM on patients' and health care professionals' experience of care in the intervention groups only will be analyzed by means of a thematic content analysis conducted using NVivo 10 (QSR International) and 2 researchers participating in the study based on the interview guide developed and previously tested with patients at the CFRC in Lyon. The focus groups conducted in the control and intervention groups designed to analyze the individual and organizational factors influencing the implementation or nonimplementation of SDM will be transcribed on the basis of notes taken during the focus groups and will be analyzed on the basis of the interview guide developed.

Results

Forty patients will be included (8 patients in each center), that is, 60 consultation observations (2 consultations per patient in the intervention groups given the modalities of the SDM process) will be conducted in 2025. Eight focus groups will be conducted in the 5 centers (2 groups in each intervention CFRC and 1 group in each control CFRC) in 2025. This qualitative corpus plus responses to the patient and physician questionnaires will make it possible to know whether the practice of SDM in CFRCs is increased by an implementation strategy and to analyze the experience of patients and their relatives regarding decision-making modalities. Analysis of the outcomes and experience of the implementation of SDM are of importance to identify the facilitators and barriers to SDM from patients' and CFRCs' point of view.

Discussion

This is the first study protocol on cystic fibrosis treatment in France, which is designed to train health care professionals on SDM and implement and evaluate the outcomes of the SDM approach. Training materials and health care professionals trained in SDM could boost SDM implementation in cystic fibrosis therapy in French-speaking countries, where the so-called clinical champions in SDM are needed. Moreover, patients experiencing SDM could support and participate in the SDM acculturation process.

The aim of our study is also to propose an original study based on mixed methods combining quantitative and qualitative analyses by using validated evaluation tools (particularly in French) and to conduct the study with patients and health care professionals for whom the potential benefits are multiple: to support in decision-making concerning diabetes treatment; to improve communication between physicians, health care team, and patients; to improve the quality of experience of the decision-making steps; and to acculturate health care professionals to SDM and formalize their practice, thanks to SDM training.

The protocol and information and the decision support tool developed could serve as a basis for other situations in the field of cystic fibrosis, as in the case of lung transplantation, subject to the adaptations to be made. There are many opportunities for SDM in cystic fibrosis, but little is known about patients' experience of SDM [42]. The training materials and the teams already trained could prove to be the key to future success, with those trained becoming trainers for other centers. International comparisons could also be developed, notably within the framework of the La Collaboration Francophone sur la Prise de Décision Partagée FREeDOM (French collaboration on SDM), which brings together health care professionals, patients, researchers, and public decision makers, notably from Quebec, Switzerland, Belgium, and France, interested in adapting the approach developed to their countries/context.

Although this is the first French study to train health care professionals and implement and evaluate SDM in cystic fibrosis treatment, compared to the usual clinical practice, the number of CFRCs involved is limited, which will potentially limit the generalizability of the results obtained. This study will nonetheless be conducted at the national level. In addition, only a small number of patients with cystic fibrosis are concerned about the development of diabetes, which could impact the duration of our project in order to obtain the desired number of patients.

Acknowledgments

We would like to thank the patient partners and health care professionals of the 5 cystic fibrosis reference centers who participated in the development of this study and the Vaincre la Mucoviscidose Association for funding this study.

Abstract

Background: Sedentary lifestyles, poor nutritional choices, inadequate sleep, risky substance use, limited social connections, and high stress contribute to the growing prevalence of chronic diseases. Lifestyle medicine, emphasizing therapeutic lifestyle changes for prevention and treatment, has demonstrated effectiveness but remains underutilized in clinical settings. The Complete Lifestyle Medicine Intervention Program–Ontario (CLIP-ON) was developed to educate the rural population of Northern Ontario in lifestyle medicine to improve health outcomes and engagement.

Objective: This study evaluates the implementation and effectiveness of the CLIP-ON program for patients with chronic diseases in the Parry Sound area, focusing on lifestyle behaviors, health outcomes, enrollment, retention rates, and interdisciplinary team engagement.

Methods: This observational cohort study guided by the RE-AIM framework (Reach, Effectiveness, Adoption, Implementation, and Maintenance) includes pre- and postintervention assessments from participants and health care providers. A hybrid type II mixed methods design evaluates the intervention's effectiveness and implementation process in real-world settings through quantitative and qualitative data collection. CLIP-ON is tailored to the residents of the Parry Sound catchment area in Northern Ontario. Participants (≥18 years old) with chronic conditions such as prediabetes, type II diabetes, systemic hypertension, cardiovascular vascular disease, dyslipidemia, or high BMI (≥25) will be recruited through self-referral or provider referral. Approximately 10 participants per cohort will be enrolled in the CLIP-ON program, consisting of 22 weeks of weekly group sessions and monthly individual consultations with physicians, health coaches, kinesiologists, and registered dieticians either in person or through a web-based platform. CLIP-ON will cover the 6 pillars of lifestyle medicine through 14 group sessions followed by an 8-week supervised exercise program. Anthropometric and cardiometabolic variables will be measured before and after the program. Participants will be surveyed on lifestyle habits, wellness, perceived barriers, and program satisfaction at 3 and 6 months. Focus groups and dropout interviews with participants (n=10 per cohort) and providers (n=6 per cohort) will guide program

adaptations. Quantitative and qualitative data collected at baseline and follow-up will assess the program's implementation and identify barriers and opportunities for improvement.

Results: This study was approved by the Laurentian University Research Ethics Board (6021397) on July 6, 2023. The first cohort was enrolled in late 2023 and is still under evaluation. The second cohort began in mid-2024, and data collection is currently underway. A mixed methods analysis will be used at enrollment, program completion (22 weeks), and follow-up (6 months after program completion). Focus groups assessing the program's effectiveness and implementation will take place after the 22-week intervention. Data will be analyzed in early 2025.

Conclusions: This protocol provides insights into the implementation of this lifestyle medicine program and its impact on participants' health. The findings will guide future advancements and establish a scalable model for other communities.

Introduction

Background

Chronic diseases, also known as noncommunicable diseases (NCDs) such as cancer, cardiovascular disease, cerebrovascular disease, and diabetes, are among the leading causes of death in Canada, with their prevalence steadily rising [1]. Hypertension, the leading global risk factor for death and disability, remains uncontrolled in more than 50% of patients [2]. NCDs are responsible for over 74% of global deaths annually [2-4], significantly affecting vulnerable and low-income populations [5-7]. Despite clear benefits from improved lifestyle choices, including better nutrition, regular physical activity, and stress reduction, there remains limited research on the long-term sustainability of these changes and the role of physician intervention [5,7-9].

Sedentary lifestyles, poor nutritional choices, and increased stress play significant roles in chronic disease development [7,8,10], with type II diabetes affecting over 10% of the population worldwide [11]. Type II diabetes, primarily linked to cardiovascular disease, contributes to over 1 million deaths annually [7,12-14]. Chronic disease–related health care costs in Canada account for more than US $136 billion annually [15], emphasizing the need for lifestyle interventions to reduce this burden [1,14].

Lifestyle medicine is an interdisciplinary medical specialty that focuses on 6 key pillars such as dietary changes, regular physical activity, stress management, restorative sleep, positive social connection, and avoidance of risky substances such as alcohol and tobacco has been shown to improve outcomes in chronic conditions [16-18]. Moreover, with its patient-centered focus [6,19-21], lifestyle medicine addresses the root causes of disease, aligning with the P4 (Preventive, Predictive, Personalized, and Participatory) medicine approach [6,22,23]. Achieving optimal health through a maintained commitment to lifestyle medicine has been shown to reverse many stages of chronic disease, reduce hospitalization and hospital costs, improve chronic disease management, and promote better health outcomes [4,5,14,24-28].

Studies indicate that the adoption of evidence-based lifestyle medicine practices has gained traction, with numerous programs demonstrating effectiveness in improving health outcomes and promoting sustainable behavior change [9,29-31]. Other studies support the adoption of evidence-based lifestyle medicine practices across North America [9,20,32,33]. Such evidence highlights the potential for lifestyle medicine to be integrated into routine health care, paving the way for broader acceptance and implementation in various clinical environments.

However, despite these promising outcomes, effective implementation of lifestyle medicine in clinical settings remains challenging. A strong patient-provider collaborative relationship is essential for achieving adherence to treatment plans and informed health care decision-making [34]. The physician's role as a health coach is critical in this process, underscoring the importance of training clinicians in lifestyle medicine practices [5,12,16,35]. Yet, many physicians report a lack of confidence and skills in delivering lifestyle medicine effectively [20], especially in rural areas. During the COVID-19 pandemic, virtual and digital platforms, such as lifestyle management tools, were developed to support patients [10,36], which has proven to be crucial for equitable health care access [16,35]. These tools hold the potential to address barriers in underserved areas where health care resources are limited, particularly in rural settings.

In this context, it becomes essential to evaluate the real-world implementation of lifestyle medicine to identify both successes and challenges, ensuring that lifestyle medicine can be effectively integrated into routine health care. This is especially relevant in rural areas, where health care access is limited, and the burden of chronic disease is high. Parry Sound, a rural community in Northern Ontario with a population of 6879 and a catchment area of 42,824 (including 10% Indigenous residents) [26,29,36,37], experiences disproportionately high rates of diabetes (8%) and hypertension (20%) compared with the provincial average [27]. These factors make it an ideal location

for integrating lifestyle medicine into care. Incorporating traditional Indigenous teachings, which emphasize the interconnectedness of mind, body, spirit, and emotions, can bridge gaps between traditional Western medicine and Indigenous Healing Practices and improve population health outcomes [28,36,38].

Inspired by the New York Lifestyle Medicine program [36,38], in 2023 our medical and research team, in collaboration with the health care community in Parry Sound, developed an innovative and whole health program named the Complete Lifestyle medicine Intervention Program, Ontario (CLIP-ON). These comprehensive interdisciplinary aims are to educate participants on the 6 pillars of lifestyle medicine and inform them about their integration into daily life to mitigate chronic disease and enhance overall health. To facilitate the implementation of lifestyle medicine practices, various models and methodologies have been proposed [39]. Among these, the RE-AIM framework (Reach, Effectiveness, Adoption, Implementation, and Maintenance) serves as a valuable tool for evaluating the impact of lifestyle medicine interventions in diverse settings [40,41]. To the best of our knowledge, this is the first program in lifestyle medicine in a rural area in Ontario. Our overarching hypothesis is that the implementation of CLIP-ON will significantly improve lifestyle behavior, health outcomes, and participant engagement, with feedback from participants and health care providers informing real-time program improvements.

Primary Objective

To evaluate the implementation and effectiveness of the comprehensive web-based platform and in-person CLIP-ON program for patients with chronic disease in the Parry Sound area, focusing on its impact on lifestyle behaviors, health outcomes including cardiometabolic parameters, and participants' engagement.

Secondary Objectives

The secondary objectives of this study are (1) to assess the reach and adoption of the CLIP-ON program by evaluating participant enrollment, and retention rates and (2) to gather and analyze direct feedback from participants and health care providers to inform real-time program improvements and enhance the program's overall effectiveness.

Methods

Design

This protocol outlines an observational cohort study guided by the RE-AIM framework (Reach, Effectiveness, Adoption, Implementation, and Maintenance) and includes pre- and postintervention assessments from participants and health care providers (RE-AIM milestones Multimedia Appendix 1). A hybrid design type II mixed methods approach [42,43] will be used to simultaneously evaluate both the effectiveness of the CLIP-ON and its implementation process in a real-world setting. This will involve the collection and analysis of both quantitative and qualitative data.

The CLIP-ON program is an interdisciplinary lifestyle medicine intervention delivered both virtually and in person, specifically tailored for residents of the Parry Sound catchment area in Northern Ontario. Within this district are 3 First Nation Communities (Wasauksing, Moose Deer Point, and Shawanaga First Nations), each of which has requested access to CLIP-ON. The study design is summarized in Figure 1, and the participant's and health care providers' measurements are presented in Table 1. Following informed consent, each participant will have an initial appointment with a certified lifestyle medicine physician at West Parry Sound Health Centre before starting the CLIP-ON program. Participants will complete the Physical Activity Readiness Questionnaire (PAR-Q+) by the Canadian Society of Exercise Physiology [44] to identify risk factors during moderate physical activity. A Physical Activity Readiness Medical Examination (PARmed-X) [45] will also be completed for participants who had potential medical complications from exercise according to their response to the PAR-Q+. During this visit, they will undergo a medical review and physical examination. They will also receive a requisition for blood work to establish their baseline cardiometabolic data. Each participant will complete a baseline (intake Lifestyle and health) questionnaire on Google Forms with the assistance of a trained research staff member over the phone. This preprogram questionnaire will collect demographic and baseline information about their lifestyle according to the 6 pillars of lifestyle medicine. Cardiometabolic variables will be measured before and after the CLIP-ON intervention. Participants will be surveyed by phone at 3- and 6-months regarding lifestyle habits, wellness, perceived barriers, and program satisfaction. At the end of the program, web-based platform (through Zoom) focus groups with participants and health care providers will be conducted to discuss their experiences and provide feedback for program development. Focus groups and dropout interviews with patients (approximately 10 per cohort, anticipating a drop-out rate of 10% based on similar studies [29], and providers (approximately 6 per cohort) will provide iterative feedback, enabling program refinement. The 2 cohorts are planned, with potential for expansion based on the available funding. The study timeline is illustrated in Figure 2.

Figure 1. CLIP-ON protocol. The intake lifestyle and health progress questionnaire was inspired by the Lifestyle Assessment Short Form [46], the 36-Item Short Form Health Survey, and the Patient Health Questionnaire-9 [47,48]. The Physical Activity Readiness Questionnaire (PAR-Q+) [44] and PARmed-X [45] were used to measure physical activity readiness. The 6 pillars of health inspired by the American College of Lifestyle Medicine are nutrition, sleep, relationships, physical activity, risky substance use, and stress management [18]. Three- and 6-month health progress questionnaires were inspired by the questions used in the New York City Health [38,49,50], the Hospital lifestyle medicine program, and the Complete Health Improvement Program lifestyle medicine program at Vanderbilt University [51,52].

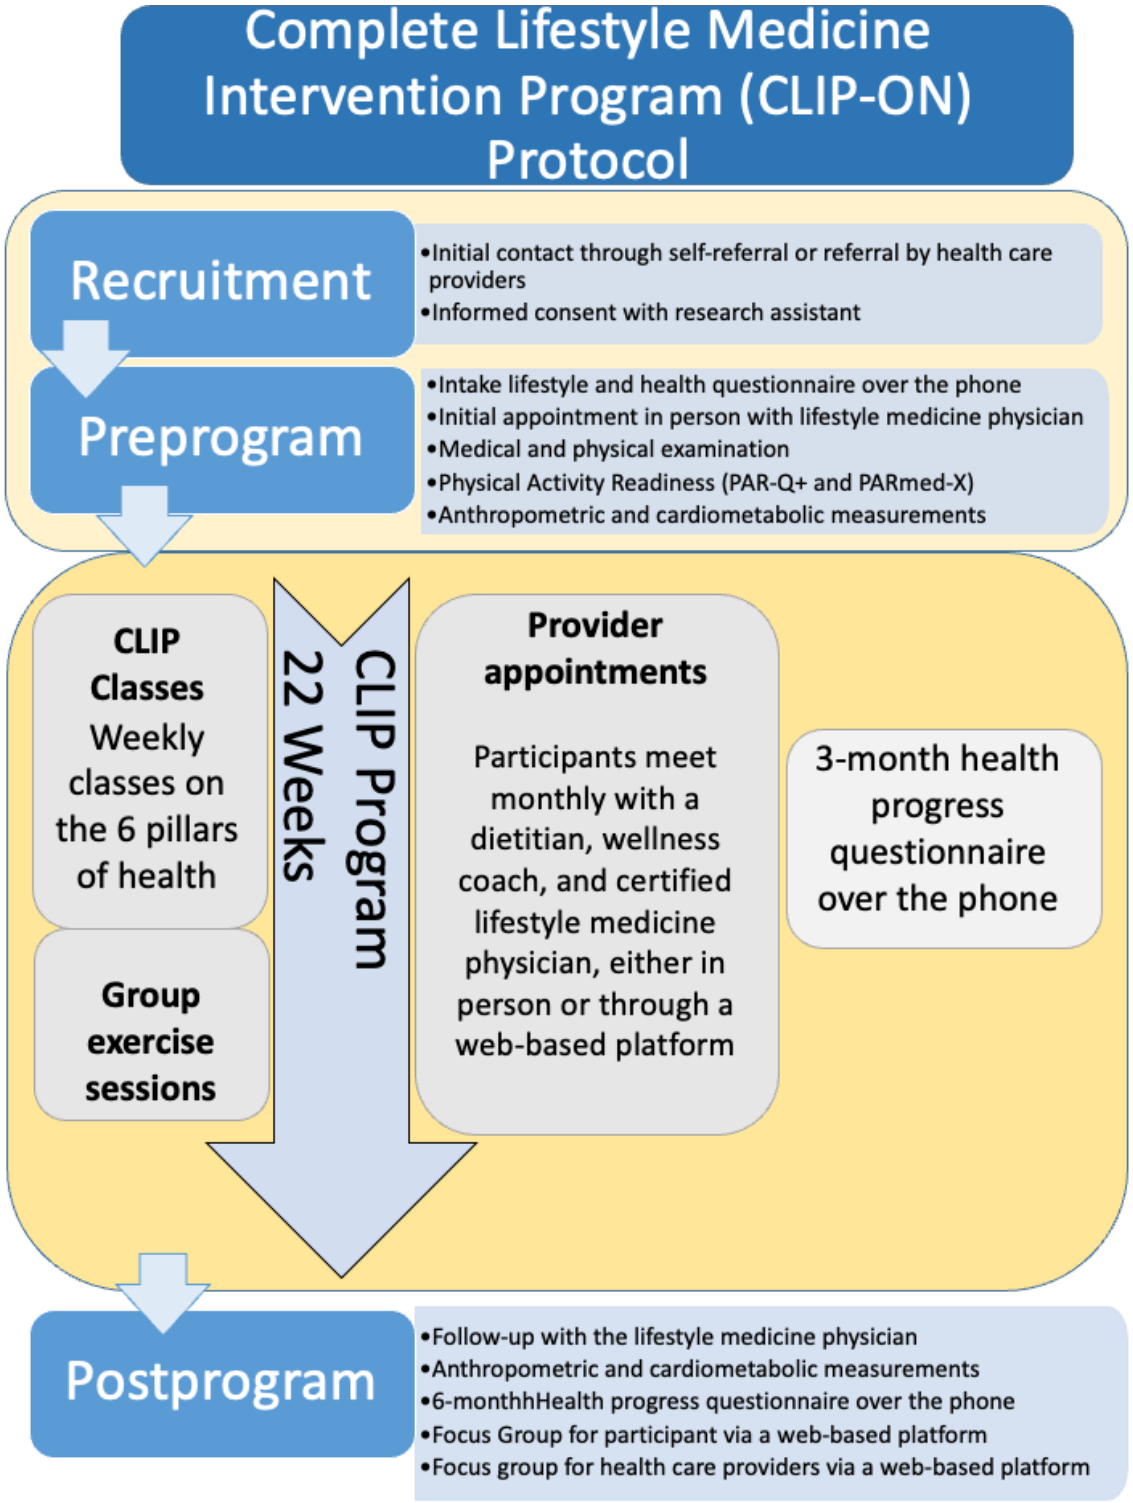

Table 1. Participants and health care providers measurements.

Measurement	Time	Variables	Details
Intake Lifestyle and Health Participants Questionnaire	Baseline, 6 months, and 12 months	Food consumption, motivation and confidence, neighborhood food environment, physical activity, media use and screen time, substance use, sleep, health, behavior, and well-being, and socio-demographics	Administered through phone or online, inspired by inspired by the Lifestyle Assessment Short Form [46], the short form survey instrument SF-36[a] and the PHQ-9[b] [47,48].
Health progress questionnaire[c]	3 months and 6 months	Similar to the intake questionnaire but includes additional questions on social support, satisfaction with the program	Conducted by phone with a research assistant
Anthropometric measurements	Pre- and postprogram	Health, weight, BMI, and waist circumference	Measurements taken by health care providers
Hemodynamic measurements	Pre- and postprogram	Blood pressure and heart rate	Measurements taken by health care providers
Cardiometabolic measurements	Pre- and postprogram	Hemoglobin, ions (calcium, magnesium, phosphate, sodium, potassium), Fasting blood glucose, Glycated Hemoglobin, cholesterol Lipid panels (total cholesterol, high-density lipoprotein cholesterol, low-density lipoprotein cholesterol, plasma, triglycerides) creatine glomerular filtration rate, Urine test: microalbumin, and albumin-creatine ratio	Blood and urine tests collected for analysis
Health care provider questionnaire	Preprogram	Provider social demographics, credentials, practice location	Completed before program involvement
Participants focus group	End of program	Experiences, benefits, challenges, program feedback, their thoughts on lifestyle medicine pillars addressed, and program continuation	Virtual focus group using a semistructured script led by an independent researcher or assistant
Health care provider focus	End of program	Feedback on recruitment strategies, their experiences, their thoughts on the content and materials provided, challenges encountered, future sustainability, suggestions for future program implementation cohort	Virtual focus group using a semistructured script led by an independent researcher or assistant

[a]SF-36: 36-item Short Form Survey.

[b]PHQ-9: Patient Health Questionnaire-9.

[c]These questionnaires include questions used in the Complete Health Improvement Program (CHIP) lifestyle medicine program at Linda Loma University and the New York City Health and Hospital lifestyle medicine program [38,49]. In addition, the Warwick, -Edinburgh Mental Well-Being scale guided the inclusion of questions pertaining to mental health [51,52]. Together, these existing surveys allow both quantitative and qualitative elements to be included in this study.

Figure 2. Timeline. It illustrates the key tasks throughout the study timeline. The first year focused on grant preparation, recruitment, preassessment, and intake questionnaires to prepare the first cohort. Year 2 emphasizes group sessions, individual appointments, end-of-program questionnaires, and postassessment for Cohort 1, while also initiating the same process for Cohort 2. Year 3 will primarily focus on data analysis and knowledge dissemination.

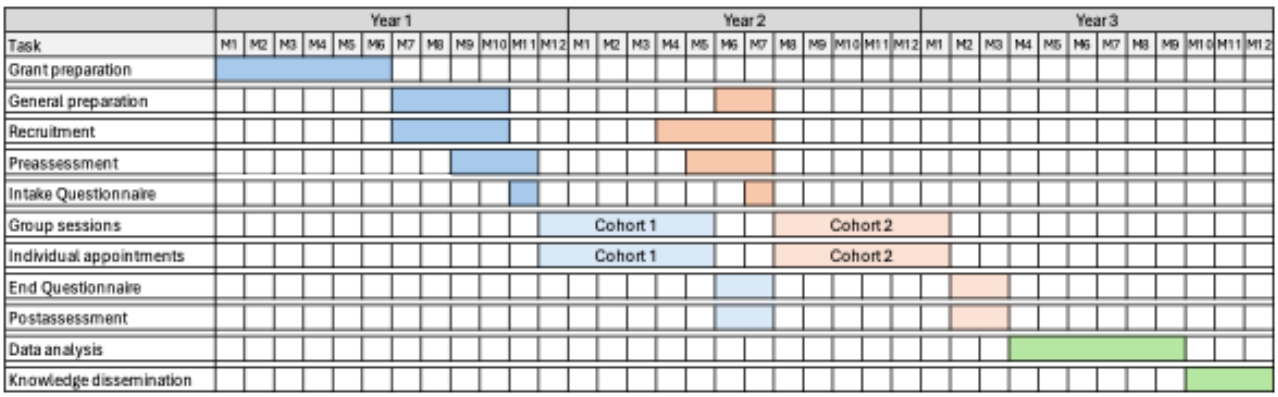

Figure 1 demonstrates participant flow throughout the CLIP-ON study, a hybrid lifestyle medicine program designed for rural Northern Ontario. The program addresses 6 pillars of health: healthy nutrition, regular physical activity, restorative sleep, stress management, avoiding risky substance use, and fostering positive relationships. Patients could meet health care providers in person or through a web-based platform. Group sessions and exercise classes during the 22-week program were available in 3 formats: in person, through a web-based platform, or as recorded sessions for later access. Intake lifestyle and health progress questionnaire inspired by the Lifestyle Assessment Short Form [46], the short form survey instrument SF-36 and the PHQ-9 [47,48]. Physical Activity Readiness Questionnaire: PAR-Q+ [44] and PARmed-X [45]. Three- and 6-Month Health Progress Questionnaire inspired by the questions used in the New York City Health [38,49,50] and Hospital Lifestyle Medicine program and the CHIP lifestyle medicine program at Vanderbilt University [51,52].

Participants

Inclusion Criteria

Adult participants (≥ 18 years) with chronic diseases such as prediabetes, type II diabetes mellitus, systemic hypertension, coronary heart disease, peripheral vascular disease, dyslipidemia, or health concerns related to excessive body weight (BMI≥25) will be recruited. Participants must reside in the Parry Sound, Ontario catchment area.

Exclusion Criteria

Participants with unstable medical conditions that prevent successful completion of program elements will be excluded. In addition, individuals who are unable to provide consent, do not meet the requirements of PARmed-X, and are unable to engage in a low-intensity, a professionally supervised exercise program will also be excluded.

Recruitment

Participants will be recruited through self-referral or referral by health care providers. Multiple avenues will be pursued to enhance recruitment efforts and reach a diverse population. Posters will be distributed throughout the Parry Sound community in high-traffic public locations such as grocery stores, coffee shops, libraries, and various departments within the Parry Sound Community Hospital. Pamphlets will be made available at health care provider clinics both within and outside of the hospital, including the Family Health Team and nurse-practitioner-led clinics. In addition, both posters and pamphlets will be distributed to local health care providers, who will be encouraged to share on social media (Facebook and Instagram [Meta]) in accordance with the ethical agreement to maximize outreach to the target population. These comprehensive recruitment strategies aim to ensure saturation of the rural environment and ensure equal opportunities for eligible participants to join the program.

Implementation Assessment

The CLIP-ON implementation assessment is guided by the RE-AIM framework which defines 5 dimensions: reach, effectiveness, adoption, implementation, and maintenance [40,41]. These dimensions will also help guide enhancements to the CLIP-ON program. Further details are provided in Multimedia Appendix 1.

Description of the CLIP-ON Program

Overview

The CLIP-ON program will consist of 22 weeks of weekly group sessions held at the local Parry Sound Bobby Orr Community Centre and monthly individual consultations, either in person at West Parry Sound Health Center or virtually, with an interdisciplinary team including physicians, a health coach, and registered dieticians. Participants will be encouraged to attend all 22 weekly classes and exercise sessions in person. However, a web-based platform option will be available for instances when they are unable to attend. Both the group class sessions and exercise sessions will be recorded for participants to access later. Each participant will receive a cookbook, exercise bands appropriate for their fitness level, and US $14.22 gift cards for local grocery stores as compensation for their time in completing program surveys and participating in focus groups.

Fundamentals of Lifestyle Medicine Group Class

CLIP-ON will cover the 6 pillars of lifestyle medicine through 12-14 group sessions on the Fundamentals of Lifestyle Medicine followed by an 8-week supervised exercise program developed and supervised by a kinesiologist. Table 2 outlines the topics covered in these group classes with a brief description of each. These classes will address the importance of the human microbiome and nutrition, fitness, positive relationship integration, stress and sleep management, and navigation of substance use toxicity and addiction. Concurrently, participants will discuss goal setting and planning with their lifestyle medicine physician, health coach, and dietician to incorporate knowledge and skills developed through the classes into their lives while motivating their success in the program.

Table 2. Topics and descriptions of each Fundamentals of Lifestyle Medicine group class.

Class topic	Class description	Providers
Introduction	An overview of what lifestyle medicine is and small group discussions for participants to meet each other.	Lifestyle medicine physician
Microbiome	Mostly focused on the gut microbiome, what it does, how every pillar can help build and maintain it, and what happens if we do not.	Lifestyle medicine physician
Nutrition	Two classes, one focused on explaining the recommendations of Canada's food guide, and another on discussing food preparation, practical cooking tips, and reading food labels.	Dietitian
Physical activity	Two Classes, one on the importance and benefits of physical activity and The Canadian Society of Exercise Physiologists' recommendations, and another class on how to move safely.	Kinesiologist
Sleep	Two classes, one on the benefits of sleep and what happens if we do not get enough sleep, another class on how to build our sleep hygiene, and an overview of insomnia and Cognitive Behavioral Therapy for insomnia.	Lifestyle medicine physician
Stress	Two classes, one on the impact of stress and the different ways it can manifest itself in our lives, and another class on stress management techniques.	Health coach
Social connections and positive psychology	One class on the impact of social isolation and the Positive Emotion, Engagement, relationships, Meaning, and Accomplishment (PERMA) [53,54] model of positive psychology for happiness and fulfillment.	Lifestyle medicine physician
Relationships with ourselves and others	One class on the concepts of Mindful Self-Compassion was developed by Kristin Neff and Christopher Germer, and Nonviolent Communication was developed by Marshall B. Rosenberg.	Lifestyle medicine and health coach
Risky substances and addictions	One class on the impact of addictions, the risk factors that can lead to addictive behaviors, and how to build our own resilience.	Lifestyle medicine physician
Conclusion	Discussion of takeaways and habit-building tips.	Lifestyle medicine physician

Exercise Group Class

An 8-week exercise program will be led by a registered kinesiologist and will follow the Fundamental Lifestyle Medicine group class session. The program will be structured yet adaptable to accommodate each participant's abilities and limitations. Before the exercise program, the kinesiologist will present the Education Sessions-Fitness Fundamentals, where they will explain why participants should exercise and how to be safe doing so. A booklet describing all activities will be shared with the participants that outline safe exercise guidelines, the rating of the Borg care of perceived exertion [44,55], when to stop exercising (symptoms and what to do), how to adapt the program, and exercises plan with picture of each exercise. The kinesiologist will then teach the entire exercise program in group sessions with the participants. Each session will last 1 hour and will follow this sequence warm-up, resistance training, cardio, flexibility, balance, core, and cool down. The exercise will use body weight resistance and a physiotherapy band appropriate for each person's capacity.

Enrollment

Participants will be screened according to the inclusion and exclusion criteria by the physician during their initial medical consultation. Eligible participants will be informed about the study's purpose, procedures, potential risks, and benefits during the informed consent process before enrolment. Participants will be made aware of their right to withdraw consent at any point during the study without any impact on their care.

Retention

The research staff and health care providers will strive to build strong rapport with participants encouraging them to attend the 22 weekly classes held in person at the local Parry Sound Bobby Orr Community Centre. If participants are unable to attend in person, a web-based platform option will be provided, along with access to recorded sessions. This approach ensured accessibility and adaptability to meet diverse patient needs. Attrition will be closely monitored, and for those who choose to leave the study, a structured exit interview with a research assistant will be conducted to gather feedback and identify potential areas for improving the program.

Ethical Considerations

This study received ethics approval from the Laurentian University Research Ethics Board (6021397) on July 6, 2023, and adheres to the guidelines stated in the Declaration of Helsinki. This study was registered at ClinicalTrials.gov (NCT06192251) in November 2023. Trained research staff informed participants of their right to withdraw themselves and the information collected on them up until the time of withdrawal, and informed consent was obtained. Patient data is available only to program health care providers and is segregated from research data. Participants are assigned a research code following the informed consent process, which links their research data through the study to allow appropriate analyses. Participant information is deidentified, and results will be published in this manner as well to ensure confidentiality.

Results

The first cohort of participants was enrolled in late 2023 and is still under evaluation. Data collection for the second cohort began in mid-2024 and is currently underway, with a projected end date in early 2025. A total of 16 participants have been recruited as of November 2024. Data analysis will be conducted in mid-2025, and we anticipate submitting the final manuscript by the end of 2025. A mixed method analysis [42,43] will be used to analyze the quantitative and qualitative data, collected individually at enrollment, program completion (22 weeks), and follow-up (6 months after program completion). Focus groups will be conducted after the 22-week intervention to assess the program's effectiveness and implementation.

Initial findings indicate that participants have gained knowledge about lifestyle changes, particularly in stress management and health behavior choices, and positively impacted their friends, family, and community by sharing their experiences. As more data is analyzed, it is anticipated that participants who commit to making changes will show improvement in their physical and mental well-being with the knowledge and practices learned from the classes and interdisciplinary health team.

In addition, initial participants included members of the local First Nation communities who raised concerns about accessibility for other First Nations such as challenges with significant travel and limited access to web-based platforms. In response to these concerns, there is confirmed interest in hosting a CLIP-ON cohort within these communities to ensure equitable access for all interested members.

Discussion

Expected Outcomes

We anticipate that these findings will support the long-term goal of establishing a lifestyle medicine program for rural Ontario communities that combines education, digital platforms, and interactions with an interdisciplinary health team. Its holistic, patient-centered approach to medicine strives to promote lifestyle changes that can prevent and treat chronic diseases, transform patient care in a manner that has been demonstrated to be successful in large urban centers and encourage its adoption and adaptation by health care providers across Canada. Our long-term goal is to demonstrate that CLIP-ON positively impacts community health and decreases health care use by reducing the impact of chronic illness.

Comparison to Previous Studies

CLIP-ON is the first lifestyle medicine program that will be conducted virtually and in-person in a rural Canadian community setting, while other Canadian lifestyle medicine interventions, such as Canadian Health Advanced Nutrition for Graded Exercise (CHANGE), have been implemented in large primary care settings in a physical format only [9,33]. This study will investigate the impact of incorporating all 6 pillars of lifestyle medicine as opposed to selected pillars [49-52,55-58]. It is also designed for patients with broad chronic diseases compared to other lifestyle medicine studies that focus on patients with specific chronic diseases [57,59-61]. Like the New York City lifestyle medicine program, CLIP-ON is built around all 6 pillars of health while providing individual support, goal setting, dietary recommendations, and monitoring support of an interdisciplinary health team [29,30,38]. However, Parry Sound's catchment area spans 9222 km^2 which is much larger than New York City's 790-km^2 urban setting [26,62]. The Parry Sound region includes 8 municipalities and townships and 4 First Nation communities housing over 42,000 residents who sometimes must travel long distances to access just primary care [26]. Therefore, understanding the unique challenges faced by rural Ontario communities will allow modifications to the program design that will be considerate of socioeconomic status, geographic and transportation barriers, preexisting patient-physician relationships, and cultural diversity.

The ability for participants to attend all programming virtually and in person was a core design to enhance program accessibility. This hybrid structure will also allow the onboarding of health care providers located throughout the province to engage in CLIP-ON more easily. Considering the vast catchment area of Parry Sound, limited transportation methods, and financial disparity within the region, it is understood that all participants may not have or have access to weekly transportation for classes. The research team will assist in identifying patient transport services to facilitate participant attendance at key program sessions wherever possible to enhance accessibility. A preexisting patient-physician relationship may result in discomfort for either participants or providers or introduce biased treatment towards some participants. Therefore, the research team will ensure that participants are matched with providers that they do not have an existing professional relationship with. Finally, special considerations will be incorporated for local Indigenous populations to be inclusive and respect their cultural requirements, including a land acknowledgment before every session and including providers with related experience and understanding of individual challenges and cultural differences.

These design elements distinctly position CLIP-ON as a whole health program designed to help all patients incorporate changes in various aspects of their lives in a setting where a lifestyle medicine program has yet to be introduced and piloted.

Strengths

CLIP-ON is the first lifestyle medicine program designed for rural communities in Ontario. This included extensive engagement with local health care providers and community members to understand their unique challenges and preferences. It incorporates specific design elements such as virtual programming, which increases program accessibility for patients facing geographic barriers so that they can attend classes, exercise sessions, and meetings with health care providers remotely. The hybrid delivery model provides flexibility, allowing patients to choose in-person or virtual participation, which is crucial for geographically isolated individuals. In addition, it enables the recruitment of remote health care providers, increasing the feasibility of building an interdisciplinary health team for the program. This flexibility offers CLIP-ON to be a sustainable, impactful, and scalable model of preventative health care.

The involvement of an interdisciplinary team of health care professionals, including physicians, dietitians, health coaches, and kinesiologists, provides a comprehensive care approach that addresses various facets of participants' health, enhancing the likelihood of sustainable health improvements. Furthermore, the program's use of the RE-AIM framework ensures that implementation is evaluated through a robust and credible scientific approach, facilitating future scalability and applicability to other regions.

Initial observations have noted that the group structure and interactions during lifestyle medicine classes and exercise sessions facilitate social connectedness within the first cohort. The program's focus on peer support and social interaction has led to increased participant accountability, as individuals share challenges and strategies within the group setting. Research shows that this peer support is often key to maintaining long-term behavior change [63]. Finally, the 2-cohort design of this study enables efficient incorporation of feedback from cohort one to enhance the program design for cohort two. The patient-centered approach, which integrates real-time feedback from participants and health care providers through focus groups and surveys, ensures continuous refinement of the program to meet participants' needs and further enhance satisfaction and engagement.

Limitations

This study has some limitations. Parry Sound's small core town population of 6879 combined with the geographic barriers associated with its vast catchment area and lack of public transit limited the initial recruitment to only 8 participants in the first cohort, as opposed to the anticipated 10-12 [25]. This small sample size may limit the statistical power of the study, making it difficult to establish significant findings that are generalizable to other rural communities. To mitigate this, we are actively exploring strategies such as broader outreach to health care providers within the catchment area and forming partnerships with community organizations to raise awareness of the program.

Initial feedback also suggests that some participants found the program duration of 6 months to be too short for achieving and maintaining meaningful lifestyle changes. Extending the program duration could allow participants more time to solidify lifestyle adjustments. In addition, longer follow-ups will support the long-term impact of lifestyle medicine on chronic disease management. To facilitate this, additional follow-up sessions and group support beyond the 6-month mark are being established to reinforce lifestyle habits. This could offer a more gradual transition toward self-management for participants.

The web-based platform, while increasing accessibility for most, may present technological barriers for older participants or those unfamiliar with using web-based platforms. This could potentially reduce engagement for certain segments of the population, especially if support for technology use is not adequately provided. To alleviate this, we have introduced a brief training session for participants on how to use the virtual platform, and technical support is now available throughout the program.

Future Directions and Dissemination Plan

We plan to conduct a follow-up assessment at 12 months and beyond to evaluate the sustainability of lifestyle changes and improvements in health outcomes among participants to provide valuable insights into the long-term impact of the CLIP-ON program. We will also explore the possibility of scaling the CLIP-ON program to other rural communities in Northern Ontario, considering adaptations based on the unique needs and cultural contexts of those populations. We will collaborate with local Indigenous communities to incorporate traditional health practices and teachings into the CLIP-ON program. This integration may enhance cultural relevance and improve health outcomes among Indigenous participants. We also plan to investigate the use of mobile health applications and web-based platforms to enhance participant engagement and accessibility such as tools for tracking progress, providing education resources, and facilitating communication with health care providers.

The results of this study will be shared locally through grand round presentations and with the hospital senior team and board members. There is a commitment from West Parry Sound Health Centre to support this study, and findings are regularly shared with senior leadership, the local education group executive, local primary care provider family health teams, and the Parry Sound Ontario Health Team. We will provide the results of the findings to each of these groups in an appropriate presentation at their request. In addition, we will share the results through publication and presentation within our Northern Ontario School of Medicine University and through presentation at the annual research conference.

Conclusion

This protocol paper will provide valuable insights into the implementation of a lifestyle medicine program, which will be evaluated for its impact on participants' health. The goal is to establish and disseminate an effective framework for secondary prevention, management, and in some cases reversal of common chronic diseases. By assessing the real-world implementation of this program, we aim to identify both successes and areas for improvement, ensuring the feasibility and sustainability of integrating lifestyle medicine into routine health care practices.

This comprehensive evaluation will not only guide future advancements in lifestyle medicine but also help establish a culturally inclusive and scalable model that can be adapted to benefit other communities, particularly those in resource-limited or rural settings.

Acknowledgments

The authors thank the health care providers, research administration team, patients, participants, and learners for their contributions and support to the CLIP-ON pilot implementation study. Very special thanks to the New York Lifestyle Medicine team, notably

Dr Michelle McMacken and Stephanie Albert who provided us with mentorship and direction regarding research tools and questionnaires. This program would also not be feasible without the incredible support from our entire local health care community. We would like to underline the support of Caitlin Champion, Connie Foster, Susan Garagan, Katie Hogue, Peter Istvan, Kathryn Knight, Karen Mills, John Neary, Natalie Pelto, Margaret Rundle, Kallie Stapleton, Heidi Stephenson, Ellen Walker, and Wil Smith. Special thanks to the West Parry Sound Health Centre Ambulatory Care and Emergency Department teams, Delores McKay, Melanie Sanford, and Magdalena Tarko from the Parry Sound Friendship Centre. Thanks to the Canadian Association for Lifestyle Medicine, formerly the Canadian Lifestyle Medicine Advocacy Group for their support and mentorship of Zahra Kassam, Sheila Lakhoo, Rikin Patel, Richa Agnihotri, and Tushar Mehta.

This study is funded through a Northern Ontario Academic Medicine Association Clinical Innovation Opportunity Grant. Providers are compensated at standard Ontario rates for their services (Health Coach, Dietician, Kinesiologist, Lifestyle Medicine Physician).

Funding for this study was supported by a Clinical Innovation Opportunity Grant from the Northern Ontario Academic Medicine Association (march 2023).

We confirm that no authors have potential competing interests, and all authors have equally contributed to each phase of the study, critically reviewed, and approved the manuscript.

Data Availability

The datasets generated during the study are available from the corresponding author upon reasonable request.

Authors' Contributions

MJ and CR are coprincipal investigators. All authors contributed substantially to the conception and design, data acquisition, data analysis and interpretation, drafting of the paper or critical revision for important intellectual content, and giving final approval of the submitted version. MJ, LA, and CR conceptualized the study. LA, MM, DF, NR, and JST provided administrative support. MJ, KB, MF, DF, SK, DL, CR, and EMC, participated in the development and teaching of the lifestyle medicine intervention. All authors contributed to the manuscript writing approval.

Conflicts of Interest

JST holds research grant funding from the Canadian Institute for Health Research, the Social Science and Humanities Research Council of Canada, and the Canadian Cancer Society. She was paid from the grant associated with this project to run the focus groups. All other authors declare no conflict of interest.

Abstract

Background: There is limited evidence of high-quality, accessible, culturally safe, and effective digital health interventions for Indigenous mothers and babies. Like any other intervention, the feasibility and efficacy of digital health interventions depend on how well they are co-designed with Indigenous communities and their adaptability to intracultural diversity.

Objective: This study aims to adapt an existing co-designed mobile health (mHealth) intervention app with health professionals and Aboriginal and/or Torres Strait Islander mothers living in South Australia.

Methods: Potential participants include Aboriginal and/or Torres Strait Islander pregnant women and mothers of children aged 0-5 years, non-Aboriginal and/or Torres Strait Islander women who are mothers of Aboriginal and/or Torres Strait Islander babies, and health professionals who predominantly care for Aboriginal and/or Torres Strait Islander mothers and babies. Participants will be recruited from multiple Aboriginal and/or Torres Strait Islander–specific health services under the local health networks around metropolitan South Australia. In this study, data collection will be carried out via culturally safe, and family-friendly yarning circles, facilitated by Aboriginal research staff to collect feedback on the existing mHealth app from approximately 20 women and 10 health professionals, with the aim to achieve data saturation. This will inform the changes required to the mHealth app. All focus groups and interviews will be audio recorded and transcribed verbatim. Data will be inductively analyzed using realist epistemology via NVivo software (Lumivero). Themes about the mHealth app's cultural acceptability, usability, and appropriateness will be used to inform the changes applied to the app.

Results: With the feedback received from participating women and health professionals, changes in the smartphone app will be made to ensure the intervention is supportive and meets the needs of Aboriginal and/or Torres Strait Islander mothers and families in South Australia. Participation of community members will promote ownership, community engagement, and implementation.

Conclusions: A co-designed, culturally sensitive, and effective digital health intervention is likely to support Indigenous mothers and their children facing health disparities due to the disruption of Indigenous culture by colaying a foundation for a potential clinical trial and wider implementation.

Introduction

The impact of colonization on Indigenous populations' health across the globe is well recognized [1]. The ongoing disadvantages of intergenerational trauma and structural violence have resulted in disparities in health outcomes between the Australian general population and Aboriginal and/or Torres Strait Islander communities [1]. Decolonization of interventions, health care organizations, health service provision, and policies are recommended as solutions.

Mothers and babies getting optimal care and support for a good start to life is a priority of the Australian National Aboriginal and/or Torres Strait Islander Health Plan 2013-2023 [2]. However, despite policies, strategies, and funding to mitigate the disparities in pregnancy and birthing outcomes, closing the gap is yet to be achieved [3]. The importance of traditional family and kinship ties and knowledge of birthing and parenting practices remain largely unrecognized in the mainstream health services accessed by Aboriginal and/or Torres Strait Islander communities [4,5]. This contributes to poorer health outcomes experienced by Aboriginal and/or Torres Strait Islander pregnant women, babies, and young children compared with Caucasian Australians [2,4,6]. Aboriginal and/or Torres Strait Islander women of childbearing age (15 years and older) are overrepresented in behavioral risk factors impacting health outcomes. In a recent Australian National Health Survey, a large majority of First Nations women failed to meet guidelines for physical activity, and vegetable or fruit intake [7]. Furthermore, 36% reported daily tobacco smoking, and 35% reported experiencing high or very high levels of psychological distress [7]. The cumulative effects of disadvantage and poorer health outcomes of women subsequently impact infant mortality for Aboriginal and/or Torres Strait Islander babies, which is 2.1 times the rate of non-Indigenous infants [8]. This highlights the urgency of more effective, ground-up, community-led resource and service development [9].

Mobile health (mHealth) apps are being used increasingly for health promotion because of their potential for greater reach [10,11]. Despite their growing popularity, very few evidence-based mHealth interventions for Aboriginal and/or Torres Strait Islander Australians exist [12]. A recent Aboriginal and/or Torres Strait Islanders survey of 398 women aged 16-49 years found that most respondents owned a smartphone, had internet access, and used social media daily [13]. This suggests that a smartphone app may be an effective health promotion tool for Aboriginal and/or Torres Strait Islander women or carers with children.

Evidence-based literature offers many perspectives on co-design. The term "co-design" is often used in research to describe a methodology that involves stakeholders in the "design of services, strategies, environments, policies or processes that impact them" [14]. Digital health solutions designed and developed in the context of mainstream health systems predominantly neglect socioeconomic determinants that are fundamental in understanding and addressing the distinct health challenges that Indigenous communities face [15]. Such an oversight might be rectified by integrating culturally safe co-design practices during the design and development phases [15]. Consequently, this project proposes that the culturally sensitive adaptation of a co-designed mHealth intervention has the potential to significantly benefit the health of many Aboriginal and/or Torres Strait Islander families within South Australia and nationally.

The mHealth program, Jarjums, co-designed with Aboriginal and/or Torres Strait Islander people was developed in New South Wales in collaboration with Aboriginal communities and found to be highly acceptable by women and health services [12]. The co-design of the app ensured culture was weaved throughout the project and the mHealth app [12]. The purpose of this mHealth app is to provide information and health behavior change strategies in the domains identified or selected by the co-design participants. The app explores women's and babies' health and well-being topics through 6 individual modules. These include (1) smoke-free families, (2) safe drinking, (3) feeling good, (4) women's business, (5) eating, and (6) exercising. The modules exploring children's health and well-being include (1) breathing well; (2) sleeping; (3) milestones; (4) feeding and eating; (5) vaccinations and medicines; and (6) ears, eyes, and teeth. Each module includes key messages around the benefit of changing behavior related to illness progression, tips addressing barriers to behavior change, cues for action, and links to further information.

As there are over 250 language or national groups with differing laws and customs across Australia, the current project will develop an adaptation of the intervention for South Australian–based Aboriginal and/or Torres Strait Islander women. The aim of this study is to consult with health professionals, mothers, and carers to culturally adapt a mHealth program called "Growin' Up Healthy Jarjums" for use by Aboriginal and/or Torres Strait Islander mothers and carers living in South Australia. This research will directly address gaps in the health evidence base and build on existing knowledge by ensuring that programs developed and effective in 1 location, are adapted and tested before they are implemented in the intended population in another location.

Methods

Study Design

This is a multisite project and will be conducted at 3 different Aboriginal health care services.

There are 3 levels of involvement of Aboriginal and/or Torres Strait Islander people in this project. These are (1) Aboriginal and/or Torres Strait Islander chief investigators, (2) project governance by a separate Aboriginal and/or Torres Strait Islander Governance Group, and (3) Aboriginal research assistants (ARA).

The Governance Group will oversee the conduct of the project and guide the interpretation of data, dissemination, and translation of study findings. All members have extensive experience working in Aboriginal and/or Torres Strait Islander health care. Specifically, the group comprises research experts, organizational and departmental leaders from various affiliations including universities, government health strategy and research departments, local health networks, maternal and child service providers, and community representatives. The ARAs are local community members and involvement in Aboriginal health services is a crucial component of the research to build trust, safety, and engagement. The ARA involvement also supports capacity building for Aboriginal and/or Torres Strait Islander research.

The framework for the cultural adaptation process will be based on the stages of cultural adaptation stepwise model of Barrera et al [16-19]. Barerra et al [16] describe 5 stages to culturally adapt evidence-based interventions for the purposes of reducing health disparities among culturally diverse populations and include considerations for intercultural diversity. These stages of adaptation include (1) information gathering, (2) preliminary adaptation design (including modifications), (3) preliminary adaptation tests, (4) adaptation refinement, and (5) cultural adaptation trial [16].

In this qualitative study, the existing co-designed mHealth app, Growin' Up Healthy Jarjums, will be adapted by using focus groups and interviews to collect data on participants' perceptions, experiences, and ideas about the app. We will conduct sessions using traditional yarning style methodology, to ensure culturally responsive practices are respected. Yarning is an established culturally appropriate process to conduct research with Aboriginal and/or Torres Strait Islander people to both establish rapport and collect information [20]. The sessions will be predominantly conducted by ARAs.

The eligibility criteria include Aboriginal and/or Torres Strait Islander women aged 16 years and older living in South Australia, who are currently pregnant, or mothers of children aged 0 to 5 years. Non-Indigenous women, of similar age are also eligible if they are pregnant with or are mothers of Aboriginal and/or Torres Strait Islander children aged 0 to 5 years. All documents prepared to convey the study information and consent are in English. However, there is a possibility that eligible, interested women may not be able to communicate in English. Such instances will be managed on a case-by-case basis with the support of language interpreters.

Focus groups will be conducted with an estimated 4 to 6 women in each group, up to 20 women in total. It is expected that data saturation will be achieved with 2 to 3 focus groups with approximately 4 to 6 women each. The actual number may vary depending on achieving data saturation.

Recruitment of participants will involve ARAs directly approaching women in the waiting area or room of the participating sites. Information sheets, leaflets, and consent forms will be available to use for recruitment support. Eligible women may directly approach the research team after reading the study information poster at any of the participating sites or the information leaflet provided to them by clinic staff of the participating sites. Furthermore, participating clinics will have project handouts to offer to eligible women.

In addition, participants will be asked if they would like to pass the study information on to a friend or family member who can then choose to connect with the research team to obtain further information and potentially participate. Individuals will be screened for eligibility when they contact the research team by phone. Women who consent to participation will be invited to join a focus group or interview with an estimated duration of 1.5 hours. At the start of the focus group or interview, participants will be asked to complete a face-to-face survey with demographic, cultural, and socioeconomic items. The survey has been adapted from a previously piloted study and deemed to be appropriate by Aboriginal and/or Torres Strait Islander mothers [21,22]. The ARAs will also spread the information to their circle of friends or family and co-workers and recruit via word of mouth.

Health professionals who predominantly care for young Aboriginal and/or Torres Strait Islander mothers or children will also be recruited for interviews. They will be recruited to the study using a separate information sheet and consent form by either the ARAs or the non-Aboriginal and/or Torres Strait Islander Research Fellow involved in the project. This process will involve explaining the participant information sheet and consent form to the health professional. All participation is voluntary, and health professionals will be informed that their decision to participate, or not, will not impact their role or position.

The purpose of including health professionals is to ensure that the messages provided in the app are aligned with the evidence-based messages used within their practice. To garner their views on the use of the app as a tool to connect with Aboriginal and/or Torres Strait Islander families (one of the aims of the app), the appropriateness of the app will also be explored. Health professionals will be interviewed for input into the content and features of the mHealth app until data saturation is achieved.

Once the adaptation process is complete and all the suggested feasible changes are made in the app. Further work regarding the feasibility of the app will be undertaken by asking representative women or carer population to use the app for 4 weeks.

The snowball methodology is predicted to facilitate the recruitment phase of the project. Participating health service managers who agree to support the project will be sent an invitation email to circulate to their staff with the staff study information sheet.

A focus group or interview guide will be used to guide the discussion, although focus groups or interviews will be

conducted using an iterative process, with the information gathered from initial focus groups used to guide the dialogue and resources used in sequential groups. Phone interviews may be conducted with participants if this is preferred. If required, an interpreter service will be used to provide support to potential participants who require language interpretation.

The focus group or interview discussion will primarily focus on how an mHealth intervention designed for this community would differ from the "Growin' Up Health Jarjums" program. Participants will be prompted to discuss images and artwork, language, videos, content, and delivery features of the original app.

All focus groups and interviews will be audio-recorded, with participant consent, and transcribed verbatim by a professional transcription service that will sign a confidential agreement before providing their service.

Participating women and health professionals can withdraw at any time, without giving a reason, throughout the study. Consent to participate can be retracted by contacting the research team; in-person, by phone, or via email. The contact information for the study team is provided on the study information sheets.

If the participant requests a specific response to be removed from the transcriptions, then the researchers will make reasonable attempts to achieve this. However, it may not be possible to remove every detail of a participant's contributions as it can be difficult to identify individual contributions within the focus group transcriptions.

If participants become distressed during the focus group or interviews when health content for the app is discussed such as child health, smoking or alcohol, and other drugs, a study-specific distress protocol will be adhered to. All events will be recorded and follow-up will be performed.

A generalized data-driven, inductive, thematic analysis will be completed with the transcribed, deidentified data [23]. Inductive analysis is a process in which data coding is undertaken without fitting it into any preexisting coding framework. An ARA and investigator will independently code themes using NVivo software (Lumivero) and complete analysis and write-up with the project team and project Investigators. The data will be interpreted sensitively with the input of ARAs. All personal, identifiable information will remain anonymous in reporting. Deidentified data analysis will be used in manuscripts for publication in peer-reviewed journals and for poster and oral presentations at national and international conferences or symposiums.

The feedback received from women and health professionals will be used to change the app by the technical team. The edited app will be screened by women for acceptability in a follow-up study.

Ethical Considerations

This project has been granted ethical approval by the Department of Health and Wellbeing Human Research Ethics Committee (2022/HRE00262) and Aboriginal Health Research Ethics Committee (#04-22-1018). A cross-institutional approval has also been obtained from Flinders University. Participation in this study is voluntary. Potential participants will be informed, both in writing on the consent form and verbally during the consent process that they can choose to not participate. Their decision not to participate will not jeopardize their relationship with their organization, health care providers, and research team and will not affect the delivery of care to them. Data will be anonymized during the transcription process and all identifiable, personal details of participants will be removed. Participating women will be reimbursed with a Aus $50 (US $33.64) shopping voucher for their time and provided with refreshments.

Results

The short-term outcomes of this research will include the start of the development of a culturally appropriate mHealth app to support Aboriginal and/or Torres Strait Islander maternal and child health. It is anticipated that the app will be a tool for women to connect with each other, connect with health professionals, and access evidence-based, culturally responsive health information in a way that is meaningful to them. The design, content, and features of the app will be a collaboration of ideas, stories, and evidence from women, the research team, and health services. Participants will have the opportunity to suggest additional areas of health or additional modules to include in the app. Potential benefits for participating women include opportunities to learn new information, and to engage with and comment on the use of new technologies. Participation of women will also promote ownership and community engagement of the project.

The anticipated long-term outcomes of the research include the contribution of the data to the knowledge on the preferences and potential use of a mHealth app for improving health outcomes of Aboriginal and/or Torres Strait Islander women and children. The resulting data will be used to source further funding opportunities for testing the feasibility, acceptance, and effectiveness of the app in a clinical trial. Ultimately, this app aims to promote health and reduce the rates of noncommunicable and communicable diseases among Aboriginal and/or Torres Strait Islander women and children. Findings may inform local and regional policies and provide advice on how to incorporate these new technologies as part of existing programs and practices.

As of July 2024, the project is ongoing in South Australia. The first phase of data collection will finish in September 2024 and the results will be shared with stakeholders in the form of reports, peer-reviewed publications, and conference presentations.

Discussion

The data might identify additional needs by participating women and health professionals. That will determine the scope of future research and implementation of mHealth technology related to Aboriginal and/or Torres Strait Islander women and children.

We anticipate that this new digital health intervention will help to reduce health disparities among Aboriginal and/or Torres Strait Islander mothers and their children, laying a foundation for a potential clinical trial and wider implementation.

A strength of this study includes its sensitivity to culturally responsive research methodology. This is woven throughout the study design from the governance model and the inclusion of ARAs to the way in which members of the community will be recruited and the flexibility of the consultation process.

Some anticipated limitations include challenges with recruitment due to the nature of engaging with a specific cultural group. The study does rely on the shared understanding of ARAs with the community and it is anticipated this will foster the development of trusting relationships with participants and support recruitment.

Finally, while the app is currently designed for the South Australian–based Aboriginal and/or Torres Strait Islander community, there is diversity within the community and therefore, this could limit engagement. Questions about how to improve the cultural responsiveness of the app will be asked while gathering feedback.

Concurrently, a recent review on barriers and facilitators of engagement of Indigenous peoples with mHealth interventions revealed themes that echo the need for effective and timely co-design practices in this field [24]. Co-design has been identified as one of the most important factors determining the uptake of web-based therapeutic interventions for Indigenous communities or populations [25]. The review findings support the inclusion of culturally sensitive methodology as well as Indigenous governance and community consultation.

Project outcomes will be provided to organizations and participants while ensuring participants' confidentiality. Ethical reports and funding body reports will be completed and provided to the relevant figures. We anticipate that there will be numerous opportunities to share and use the data gathered from this research, including dissemination to research institutes, health organizations, and community groups.

Furthermore, this research can inform policy makers and peak organizations of the needs of mothers and families with young children.

Acknowledgments

This research was funded by The Hospital Research Foundation in 2022 (project ID: 2021/76-83100-01). We would like to acknowledge the intellectual contribution of Cassandra Brown, the Aboriginal Research Assistant, to the design of the project.

Data Availability

The data that will come out from the study will belong to the Aboriginal and/or Torres Strait Islander Community. Due to the sensitivity required in sharing and spread of that data, it will only be available upon reasonable request made to the corresponding author after approval from the project governance. The corresponding author will review any requests received with guidance from the Aboriginal and/or Torres Strait Islander Governance Group of the project.

Authors' Contributions

SI developed and designed methodology, provided resources, supervision and oversight, validation, and contributed to writing, reviewing, and editing. AD contributed to project administration and data curation. OE contributed to data curation, writing, and project administration. AB and CR contributed through review and editing. KC and KH contributed through review and editing as well as governance and design. NB contributed through review, editing, and software/application advice. CTR contributed through review, editing, and resource acquisition. SP contributed through review, editing, and study conceptualization. BB contributed through research supervision, design of methodology, resource and funding acquisition, review and editing, and conceptualization.

Abstract

Background: Among cardiovascular diseases, adult patients with congenital heart disease represent a population that has been continuously increasing, which is mainly due to improvement of the pathophysiological framing, including the development of surgical and reanimation techniques. However, approximately 20% of these patients will require surgery in adulthood and 40% of these cases will necessitate reintervention for residual defects or sequelae of childhood surgery. In this field, cardiac rehabilitation (CR) in the postsurgical phase has an important impact on the patient by improving psychophysical and clinical recovery in reducing fatigue and dyspnea to ultimately increase survival. In this context, compliance with the rehabilitation program is a key element for the therapeutic benefits of the program. The increase of mobile health care devices and software has greatly extended self-care capabilities across the spectrum of health care activities. Moreover, the possibility of telemonitoring the progress of this self-care provides elements of empowerment and awareness of one's state of health. As a branch of telehealth, CR can be optimized and facilitated using remote telemedicine devices.

Objective: The principal goal of the Innovation in Postoperative Rehabilitation Training and Monitoring (IPOTERI) study is to design, realize, and test a composite and integrated system for postsurgical rehabilitation therapies at home specialized for cardiac surgery. The secondary aims are to implement the system in a "real-life" context of postcardiac surgical rehabilitation, and to create a data set and a data collection methodology to prototype data analytics algorithms and artificial intelligence techniques for customizing the rehabilitation pathway.

Methods: The IPOTERI method consists of a telemonitoring platform that guarantees continuity of postoperative care, an intelligent home station based on an Android app for the patient with a user-friendly interface to record vital signals (electrocardiogram, blood pressure, oxygen saturation, and body weight) and access the planning of rehabilitation activities, and a decision support system that communicates with hospital medical records to transmit alerts and specific support information for the formulation and updating of the treatment and care plan.

Results: The pilot test started in June 2023 (protocol number 20406/2021) including 50 patients who will be monitored for 12-14 weeks using the developed platform, as described in the Procedures subsection of the Methods section.

Conclusions: The IPOTERI approach, based on the processing of data recorded during the monitoring of telemedicine devices used at home during the postsurgical rehabilitation of a cardiac patient, together with clinical data from the perioperative and postoperative periods could have positive effects on adherence to the rehabilitation program and clinical improvement as well as result in overall improvement of quality of life.

Introduction

General Background

Cardiovascular diseases (CVDs) represent the leading cause of death worldwide, which are responsible for 17 million deaths annually according to the World Health Organization [1]. This figure is expected to increase, as it is estimated that 23 million people will die from CVDs worldwide in 2030, accounting for 31% of all deaths globally [2]. People with CVDs typically require steady assistance and management by both the patient and their caregivers, mainly due to comorbidity with other pathologies, including high blood pressure, diabetes, and hyperlipidemia.

Among CVDs, adult patients with congenital heart disease represent a population that has been continually increasing, mainly owing to the improvement of the pathophysiological framing, including the development of surgical and reanimation techniques that have contributed to enhanced survival of these patients into adulthood [3]. Recent studies indicate that approximately 20% of patients with congenital heart diseases will require surgery in adulthood and 40% of these cases will necessitate reintervention for residual defects or sequelae of childhood surgery [4]. In these patients, the benefits of cardiac rehabilitation (CR) techniques are particularly important and clinically impactful during the postoperative period.

Clinical Background of the CR Field

CR is an evidence-based program that is considered part of secondary prevention, which is focused on three main aspects: patient education, health behavior modification, and exercise training [5]. CR programs primarily target patients with ischemic heart disease, heart failure, or following cardiac surgery to reduce mortality and morbidity. A complete rehabilitation plan should include both a physical and psychological agenda, encompassing clinical evaluation, pharmacotherapy, psychological support, training, assessment and reduction of risk factors (both physical and psychological factors), and patient education for lifestyle modification. Thus, the gold standard of CR is an approach integrating health behaviors such as increased physical activity, improved dietary habits, and smoking cessation, along with promotion of medical adherence and psychosocial well-being strategies. There are multiple reported benefits of CR in patients following cardiac surgery. Several studies have documented that in addition to speeding up psychophysical recovery, CR improves clinical parameters, namely by reducing fatigue and dyspnea, ultimately resulting in increased survival with a drop in mortality at 10 years after surgery reaching up to 14% [6]. Interestingly, the benefit in terms of major event-free survival correlates with the number of rehabilitation training sessions to improve quality of life and reduce cardiovascular risk factors [7-9].

Although the clinical importance of CR is officially recognized, the proportion of patients admitted to a rehabilitation program remains small and there is overall low patient compliance [10]. Several factors may contribute to this low enrollment rate in CR programs, including physicians' and patients' approaches toward CR. In general, the percentage of patients who adhere to CR is variable, depending mainly on age, gender, and the presence of preexisting neurological complications [11]. Moreover, in addition to poor adherence, the capacity of services for CR in primary care is hindered due to limitations of human resources and adequate space in hospitals to support rehabilitative programs.

To overcome these problems, an alternative method to the traditional center-based CR (CBCR) model is home-based CR (HBCR), which is a new method that can be carried out in different settings, ranging from the home to a park, owing to the support of telemedicine.

Evidence from published studies comparing CBCR and HBCR has revealed that in some cases, the results are overlapping with improvements in 3- to 12-month clinical outcomes and no differences in hospitalization rates [12]. In particular, benefits have been documented regarding functional improvement, managing risk factors, and well-being perception. With respect to compliance, HBCR is associated with a lower dropout rate and higher degree of responsiveness and perseverance compared to CBCR [13]. For these reasons, an important aim will be to extend the applicability of HBCR to different patient subgroups, including older adults, women (who tend to have relatively poor compliance [14]), and high-risk patients. Based on current evidence, it is reasonable to believe that HBCR can be targeted to patients in a stable state with low to moderate risk. Furthermore, despite international guidelines recommending CR, there are no unique programs tailored according to pathology or country of origin. For example, in Italy, CR is part of the rehabilitation plan in the hospital; however, according to the Italian Survey on Cardiac Rehabilitation (ISYDE), the Italian cardiology rehabilitation network is only able to offer the intervention to approximately 60,000 patients per year against an estimated demand of more than 300,000 patients per year [15]. To reduce the imbalance between supply and demand, the ISYDE project was developed with the goal of obtaining a detailed snapshot of the number, distribution, facilities, staffing levels, organization, and program details of CR units in Italy.

Considering the increasing burden of CVD, from an economic perspective and taking into account the increasing pressures facing health systems, cost-effectiveness is an essential consideration for CR program development. Previous data on economic evaluations of HBCR have found positive effects compared to traditional care, although the heterogeneity in methodologies may limit the validity of these findings [16,17].

Mobile Health for CR

Advances in mobile networks and the proliferation of smartphones and tablet devices constitute a global service delivery platform for many industries, including health care, and could offer the potential to broadly diffuse more intensive self-monitoring, feedback, and self-management tools at reduced cost. The increase of mobile health care devices and software has greatly extended self-care capabilities across the spectrum of health care activities. Current smartphones allow users to easily access a wide range of health educational materials and services anywhere at any time. Health apps running on smartphones or other portable devices enable the remote monitoring of vital parameters to diagnose health problems, track responses to treatments of chronic illnesses, detect drifts from the control condition, and provide early warning signals of potentially dangerous changes in a patient's health status. In this context, mobile phone interventions have become increasingly popular in the global health and development sectors as a potentially inexpensive and effective way to communicate with and deliver services to people. In particular, telemedicine offers the possibility of the prolonged longitudinal monitoring of patients, which would help to highlight early and subclinical signs of diseases or complications that could manifest at a later date, and thus allow therapeutic intervention at a stage of higher reversibility. In this field, where CR is needed but insufficiently implemented, alternative rehabilitation models using new resources of communication technologies (eg, mobile- and web-based platforms, wearable sensor devices) is a new challenge to deliver supervision, education, and counseling. With these technologies, it will also be possible to consent and improve continuity of care in vulnerable populations.

HBCR, as a branch of telehealth, can be optimized and facilitated with the use of remote telemedicine devices [18]. However, some studies demonstrated that there are no substantial differences in rehabilitation programs practiced using telemedicine or according to conventional protocols in terms of functional improvement, control of risk factors, well-being, and rehospitalization and survival rates [19-21]. In contrast to CBCR, HBCR associated with telemedicine appears to be able to improve some of the shortcomings of traditional rehabilitation programs [22]. These traditional services are often associated with high costs, both to the health care system and to the patient who must make multiple trips to the rehabilitation center during the treatment process or needs to be admitted directly to intermediate care facilities dedicated to rehabilitation only.

The Box 2.0 Study Protocol is an ongoing trial with the objective of achieving the early diagnosis of complications after cardiac surgery (for atrial fibrillation, heart failure, and surgical wound infections) through the application of telemedicine and mobile devices (ie, smart technology) [23]. In particular, the Box 2.0 study is focused on the use of smartphone apps for the remote assessment of certain vital signs, including oxygen saturation, electrocardiographic tracing, arterial blood pressure, body temperature, body weight, and actigraphy. In general, the availability of remote monitoring of the patient makes it possible to customize CR programs according to the limits and functional capacity of each patient, thereby increasing adherence to the suggested rehabilitation program. In practice, telemedicine allows the realization of a patient-centered rehabilitation approach, which is an essential element of precision medicine [24]. This practice aims to encourage the independence of patients, including older adults, which would allow them to stay in their familiar environment while maintaining an acceptable quality of life.

Although HBCR based on a patient-centered perspective is capable of improving the participation rate, the effectiveness and achievement of the program depend on the patient's attitude toward technology. In recent years, technology use in health management has involved populations of all age groups; however, the age group of 65-74 years represents the principal consumers of health digital tools, with higher adoption than found among those aged 18-34 years. Specifically, in the cardiology field, cardiac telerehabilitation is a mobile health tool that uses telecommunication technologies such as smartphone apps, wearable devices, and video consultations to propose remote CR services to increase convenience for patients while reducing health care costs. In addition, HBCR may bypass several barriers at the patient level, including transport difficulties; at the health care professional level, such as low endorsement; and at the health care system level, mainly due to limited facilities available providing this method. Furthermore, administering rehabilitation pathways outside the hospital environment by using remote monitoring and communication devices with patients would enable the acquisition of data (eg, heart rate during exercise and daily physical activity) in the context of the patient's daily routine; thus, the data collected will be more realistic, enabling designing a more personalized treatment program.

Study Aim and Objectives

The Innovation in Postoperative Rehabilitation Training and Monitoring (IPOTERI) study aims to create a tailored CR intervention using a mobile platform to support treatment during the postsurgery period with the goal of achieving the improvement of clinical and functional parameters and quality of life. The overall objective of the project is the analysis, design, implementation, and testing of a composite and integrated system for postsurgical rehabilitation therapies, specializing in cardiac surgery.

The project envisages the development and industrialization of a monitoring system that applies telemedicine techniques, combines microservices with innovative devices (ie, wearable and minimally invasive devices), and enables the continuous monitoring of the patient's main vital parameters to provide real-time feedback during the execution of the rehabilitation exercises assigned to the patient in the individual phases of the rehabilitation therapy. This will be achieved through the implementation of software systems capable of not only supporting the rehabilitation pathway but also of enriching the program with innovative devices and eHealth services. This system can help to support additional and alternative pathways to traditional hospital pathways and will be further capable of integrating artificial intelligence (AI) techniques that support physicians in telemonitoring.

The hypothesis of the clinical study is that processing of data, both qualitative and quantitative, collected at home during the

postsurgery period using eHealth devices, together with clinical data related to the perioperative time window using AI algorithms will be an effective approach for personalizing and then optimizing a postsurgery CR path. We here describe the protocol for the design, realization, and clinical testing of a composite and integrated system for postsurgical rehabilitation therapies at home focused on cardiac surgery.

Methods

Ethical Considerations

The research and ethics described in this study have been reviewed and approved by the institutional review board of the Ethics Committee of the Vast Area Northwest of Tuscany for Clinical Trials (protocol 20406). All procedures performed in the pilot study will be in accordance with the ethical standards of the institutional and/or national research committee and with the 1964 Helsinki Declaration and its later amendments or comparable ethical standards. All participants will provide written informed consent after a thorough review of procedures and questions and will be informed of their opportunity to opt out of the study at any time. All study data will be deidentified. No participation fee will be given to the patients, and all patients will enroll in the study voluntarily.

Setting

The IPOTERI project is a public-private partnership comprising a multidisciplinary team, including research centers, health care facilities, technological enterprises, and cybersecurity experts.

General Aspects of the IPOTERI Rehabilitation Platform

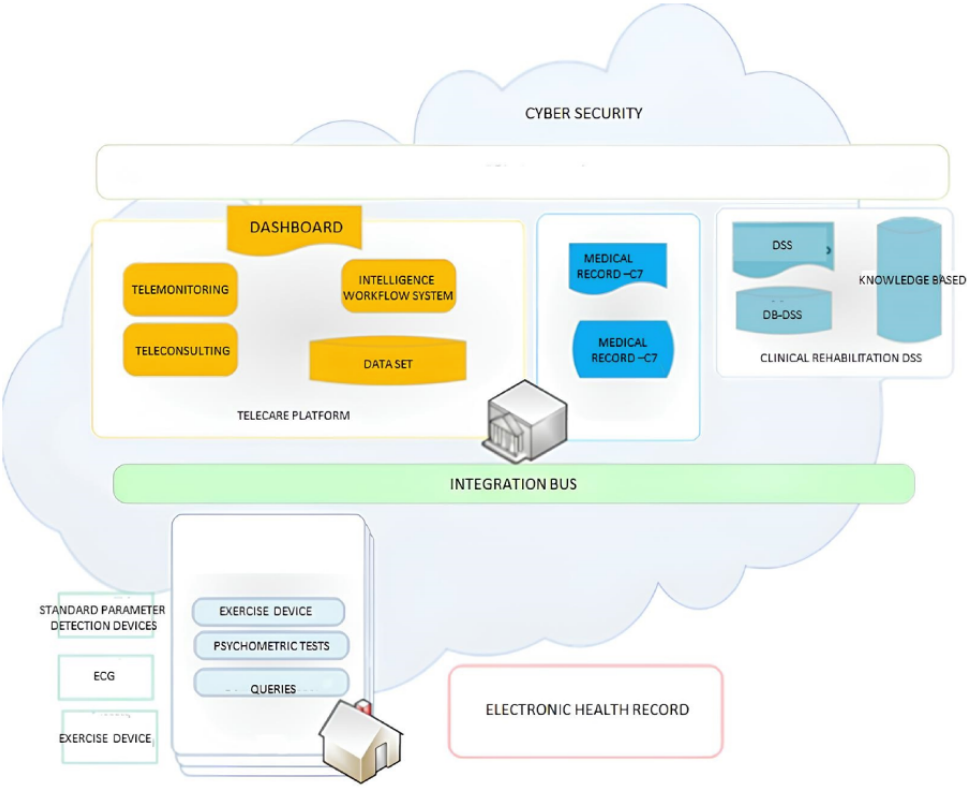
Platform Design Process and Overview

To define the best configuration of mobile support services for patients, we used the following methodology:

1. Formative research to determine the best way to implement HBCR, including a literature review, retrospective analysis of clinic data, and evaluation of eHealth devices potentially included in HBCR.
2. Development of the HBCR intervention: we implemented a software system that can support the rehabilitation pathway, but also enriched it with innovative devices and eHealth services that support the doctor in telemonitoring.
3. Pilot feasibility study: we will conduct a pilot study with patients who will receive the intervention to provide a context for testing the developed systems on a larger population sample.

The components of HBCR consist of a telemonitoring platform, an intelligent home station, and a decision support system (DSS) (Figure 1).

Figure 1. General architecture of the IPOTERI system. DSS: decision support system; C7: medical records; ECG: electrocardiogram.



Telemonitoring Platform

The IPOTERI platform guarantees continuity of postoperative care and includes the following main functions: (1) activation of the telemonitoring process with detection of vital parameters, also in continuous mode, according to a protocol set by the doctor; (2) monitoring of rehabilitation activity, with feedback on the quality of exercise; (3) management of alerts for home events; and (4) verification of the adequacy of the patient's vital

parameters and adherence to the proposed rehabilitation program through AI techniques.

The IPOTERI platform is divided into different levels: (1) the at-home level with the Intelligent Home Data Acquisition System; (2) the territorial level with the "Telecare Platform" system, a centralized system for collecting and analyzing data from patients' homes and hospital records; (3) the central level with the intelligent BUS system for connecting the components of the overall system; and (4) the hospital level with an integrated electronic medical record system that operates autonomously in the hospital and manages the clinical data of patients enrolled in the study.

Smart Home Station

The smart home station (SHS) is based on an Android app with a user-friendly interface for the self-recording of patients' vital signs. The interactive part is supported by a dashboard, as shown in Figure 2. From this dashboard, the patient can access the planning of rehabilitation activities and their illustrations by means of videos and also can request a video consultation or participate in activities planned by the doctor. The SHS is also able to integrate data and information from wearable and noninvasive devices to enable the continuous monitoring of vital parameters and support the performance of assigned physical rehabilitation activities. The devices consist of a wearable, noninvasive sensor capable of continuously recording vital parameters such as electrocardiogram (ECG), heart rate, blood pressure, and oxygen saturation, and a weight balance to detect weight variations. The SHS consists of medical devices integrated with two apps: eVoDroid that is integrated with the weight balance and Umana that is integrated with the Umana T1 sensor for ECG monitoring. The eVoDroid system is an app used to receive data via Bluetooth synchronization with integrated devices; the app detects the sensor and the acquired data are displayed in the appropriate fields. It is possible to repeat the measurement, confirm it, and cancel it. There is also a manual data screen, allowing the user to add the data directly. After specifying the type of measurement, the obtained values can be input in the editable fields provided. The Umana app allows data to be received via Bluetooth synchronization with the T1 heart monitor. Once the connection is established, continuous real-time monitoring of the ECG signal and the display of other parameters, including heart rate variability, oxygen saturation, and blood pressure, are possible. The saved data are sent to a server for further analysis of the detected signal.

At the territorial level, a dedicated "patient portal" has been defined in the Telecare Platform to carry out different activities (eg, view the agenda, carry out televisits, request a consultation) related to the rehabilitation plans along with associated video tutorials (Figure 3).

Figure 2. Smart home station. BPM: beats per minute; SpO2: peripheral capillary oxygen saturation.

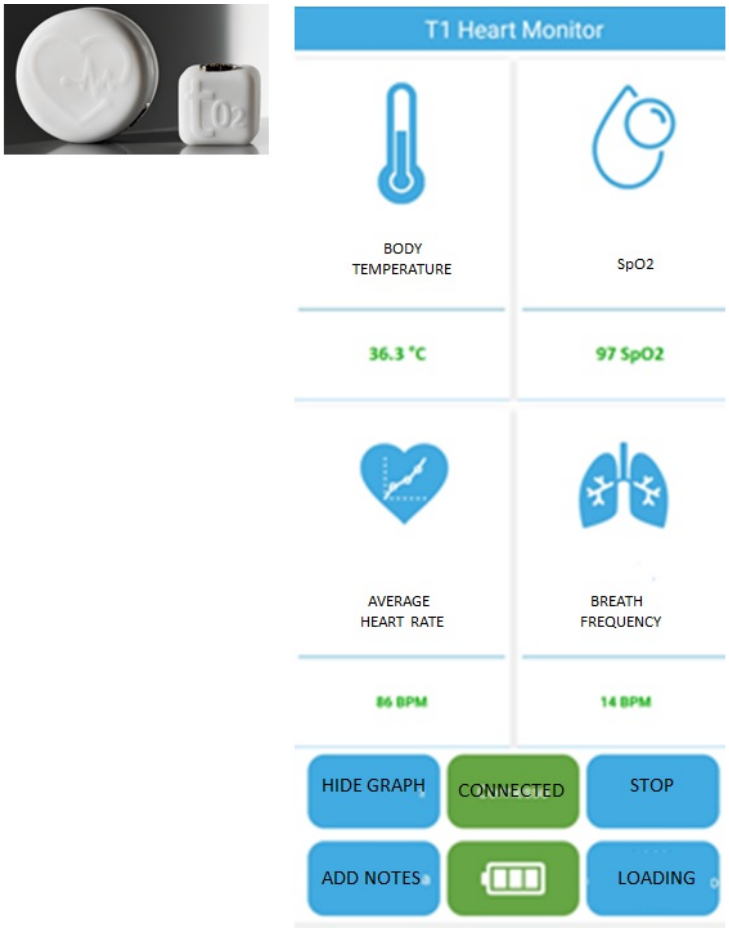


Figure 3. Telecare Platform for access to rehabilitation plans and related video tutorials.

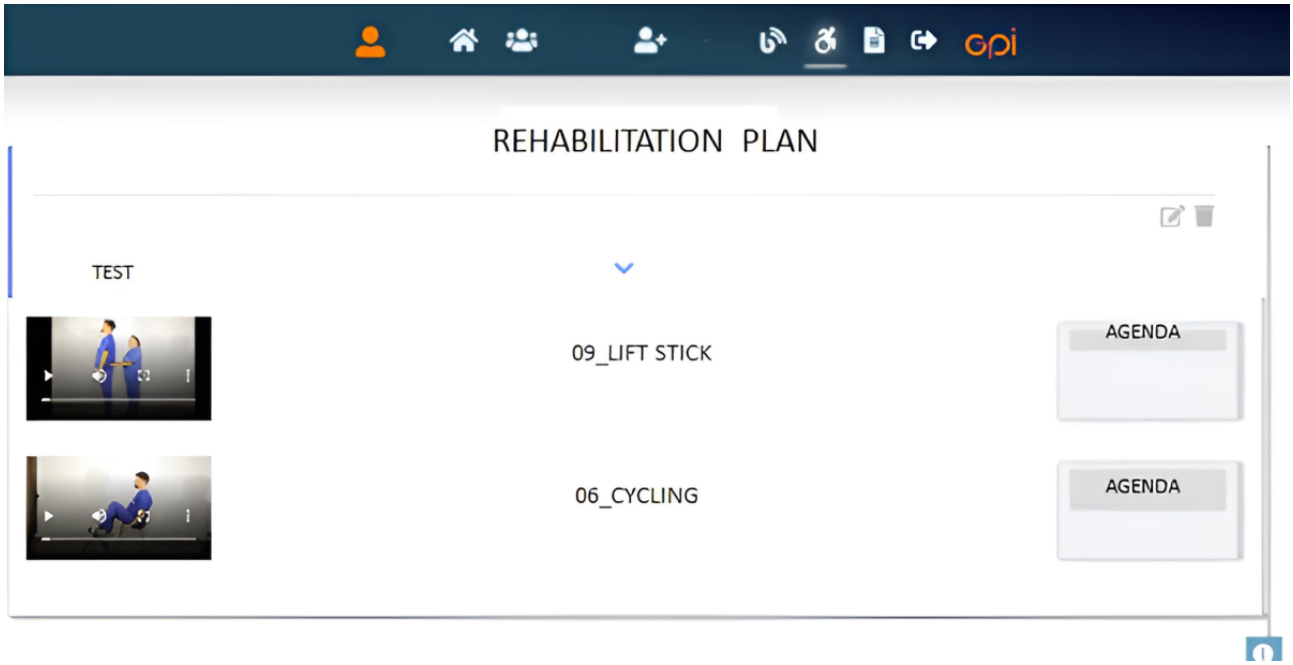
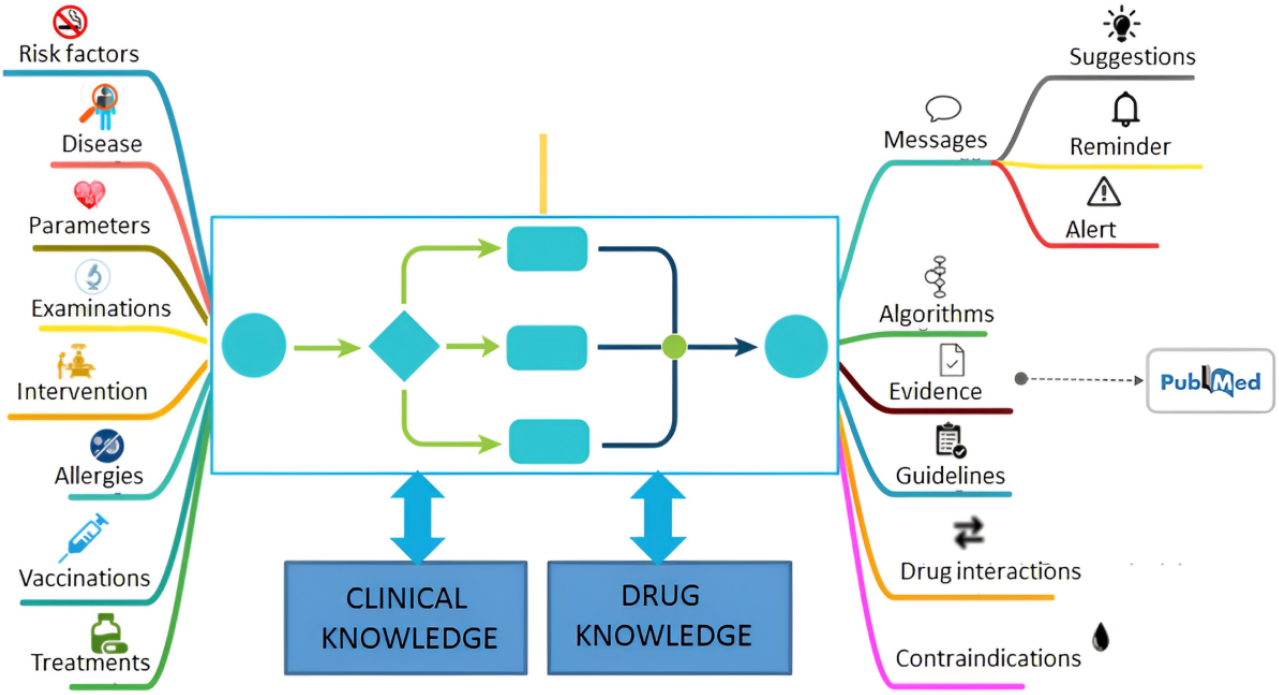


Clinical Rehabilitation DSS

The DSS facilitates the analysis of data collected during the telemonitoring process with hospital clinical data. The DSS communicates with hospital medical records (Figure 1) to transmit alerts and specific support information for the formulation and updating of the treatment and care plan (Figure 4).

Figure 4. Clinical rehabilitation decision support system.



Pilot Test

Study Design and Aims

In the pilot test, patients will be enrolled among those receiving coronary-artery bypass grafting without complications in the postoperative period. During this pilot study, we will receive reports of several technical issues that could affect the functionality of the system. Thus, the data obtained in the pilot study will serve as a guide in the development of a telemonitoring system, including a software and hardware platform based on telemedicine monitoring microservices, to be applied within the project to a wider population.

Pilot Population to Test the IPOTERI Platform

The study participants will be divided into two groups: (1) an HBCR group and (2) a control group with the same clinical profile. The HBCR group will include all patients who will

undergo cardiac surgery procedures and will be submitted to telemonitoring. The control group will be established to have the same clinical profile as the HBCR group but without telemonitoring to serve as a comparison group. The inclusion criteria are as follows: 18 years and older, no major complications after surgery, and good internet connectivity at home. The main exclusion criteria are stage 4 renal failure or undergoing dialysis treatment, overt chronic respiratory insufficiency, previous cerebral ischemic or hemorrhagic event, and cognitive impairment. Allocation to the HBCR group will be based on the patient's preference.

Procedure

After obtaining informed consent, preintervention clinical data will be collected, including anamnestic and instrumental data as well as predischarge data (Figure 4). At 7 to 21 days after discharge, patients will return to the hospital and will be submitted to a functional assessment by performing an aerobic exercise test, the 6-minute walking test (6MWT), according to a standard protocol. The patient will walk along a flat, hard, and measured corridor, with cones marking the turning points set by a physiotherapist [25]. The heart rate, distance traveled, arterial saturation, symptoms, and blood pressure will be monitored at the beginning and end of the exercise according to the normal clinical practice of the 6MWT. The step rate, expressed as the number of steps per minute, and the total number of steps will also be recorded. Heart rate and step rate will be recorded at the onset of symptoms and in the early stages of the exercise. The pace will be measured at the onset of symptoms and in the first 3 minutes of exercise according to the exercise table prescription.

Quality of life will be assessed based on the Psychological General Well-Being Index questionnaire [26]. During the entire monitoring period (12-14 weeks), a patient, doctor, or rehabilitator will be able to activate the teleconsultation services via a home kit. At the end of the study period, patients will undergo hematochemical examinations, echocardiogram, and functional assessment with the 6MWT. Patients who will be recruited and included in the personalized rehabilitation plan will be instructed on how to perform the functional test at home, which is aimed at assessing their rehabilitation progress and to help customize the rehabilitation program. The patient will be able to choose an exercise modality involving free walking outdoors or indoors, using an exercise bike, or a walker. If the patient performs the aerobic exercise by walking, they will be required to maintain a specific cadence or heart rate throughout the exercise. The rehabilitation program will be set based on these measurements at 60% of the walking cadence or maximum frequency reached for the first week, 70% for the second week, 80% for the third week, and 90% for the fourth week. The patient should exercise for at least 20 minutes in the first week and for at least 30 minutes per day in the following weeks. If the patient has difficulty maintaining the prescribed training goals, they will have the opportunity to interact with the doctor who can either maintain the current step increase in activity or go back one step. The rehabilitation exercises will be monitored and customized during the rehabilitation pathway through feedback with the rehabilitation therapist who will have the possibility to connect with the patient and review the execution of the exercises through the devices in the kit.

During this period, vital parameters such as ECG, respiratory rate, blood pressure, body temperature, and oxygen saturation will be recorded. All data from the rehabilitation phase will be collected and stored on the information and communications technology (ICT) platform and made available to the patient via a tablet gateway connected to the data collection center. The medical and rehabilitation staff may consult the acquired data to modify the rehabilitation program based on cardiac parameters, exercise perception, and general well-being.

At the end of the rehabilitation period, patients will undergo routine hematochemical examinations, echocardiogram, and functional assessment by the 6MWT, and they will complete the quality of life questionnaires again. In the 4th week, the patient will be tested at home by performing a walk at the maximum possible speed on a flat surface, either outdoors or indoors, for 6 minutes. During this exercise, the system will measure the continuous heart rate, respiratory rate, step rate, and oxygen saturation, and the data obtained will be used by the doctor and therapist to assess any changes in the exercises compared to the baseline examination. Based on this assessment, the doctor could decide to increase the intensity of the aerobic exercise to be performed by the patient, as described above. All data from the rehabilitation phase will be collected and stored on the ICT platform and made available to the patient via a tablet gateway connected to the data collection center. These acquired data will be available for consultation by medical and rehabilitation staff to modify the physical rehabilitation program on the basis of cardiac data, perception of effort, and general well-being.

At the end of the trial, a questionnaire will be filled out to assess the ease of acquisition of the proposed system, the ease of data transmission, and the level of comfort in managing rehabilitation with the help of the devices for the monitored patients. In addition, intervention satisfaction will be assessed with the following two items: "Overall, how satisfied are you with the IPOTERI tool?" and "How satisfied are you with the possibility of jointly participating in the IPOTERI therapy?" Fatigue severity will be assessed using the Borg rating of perceived exertion scale [27]. The scale is a very simple numerical list. Participants are asked to rate their exertion on the scale during the activity, taking into consideration feelings of physical stress and fatigue, disregarding any factor such as leg pain or breathlessness but focusing on the whole feeling of exertion.

AI Tools

The application of data-driven, machine learning (ML)–powered AI tools to the data collected will help to determine patterns, assess patient stratification, or compute meaningful indices for the clinicians to interpret. In the case of an insufficient population size, data *verticality* (ie, the amount of data *per patient*), or data heterogeneity, specific ML techniques will be used to enable the subsequent definition and testing of clinically relevant tasks once the data become sufficient. More precisely, an important step will be to provide appropriate *patient embedding*, which is paramount to unlock the ability to quickly and easily define and test prediction tasks over the patient

population at a later date. *Embedding* a patient's data involves converting all of the data available for a patient into a fixed-sized vector (ideally of smaller size), which can be used to train ML models (ie, classifiers and clusters) once a sufficient number of patients are available for formal analysis.

Embedding is often performed by *encoders*, which are neural networks that are trained to perform a relatively straightforward task (eg, perform the identity function in the case of *autoencoders*), featuring an architecture with a relatively small internal layer of nodes. These nodes are therefore forced by the training process to "encode" the information presented at the input stage in a fashion that is appropriate to perform the task at hand. Encoders are used in lossy compression such as for feature extraction and several other tasks. In this study, we can use encoders to obtain a compact and actionable patient representation among all heterogeneous data types available for each patient.

Results

The pilot test started in June 2023 (protocol number 20406/2021) including 50 patients who will be monitored for 12-14 weeks using the developed platform, as described in the Procedures subsection of the Methods section.

Discussion

Projected Significance

This pilot study is designed to assess the acceptability, potential efficacy, and potential working mechanisms of the IPOTERI platform, a web-based tool for a postsurgery CR intervention.

To our knowledge, IPOTERI represents the first pilot experiment of the Italian experience of an HBCR program associated with telemedicine monitoring in a patient group who underwent cardiac surgery. The aim of the IPOTERI project is to develop a home-based patient telemonitoring system with the final goals of reducing the number of hospitalizations and outpatient visits, improving the communication between patients and hospital staff, and improving the psychological and emotional dimensions of CR. In the pilot study, we will provide a comprehensive description of the different components of the IPOTERI platform and the first release of the platform from patient enrollment to the rehabilitative program. The availability of remote patient monitoring will make it possible to customize CR programs according to the individual patient's functional limitations and capabilities. In turn, this would have the advantage of increasing adherence to rehabilitation programs.

In practice, telemedicine enables the realization of a "patient-centered rehabilitation approach," which is an essential element of precision medicine [28]. Moreover, prolonged monitoring of multiple physiological parameters of the patient can facilitate establishment of a large data bank, both in qualitative terms (number of variables) and quantitative terms with the same variable monitored over time. The accumulation of big data will necessitate the application of ML algorithms to integrate and analyze the data with a complex and dynamic approach. In this field, AI represents a potential new avenue for the integrated analysis of clinical, instrumental biohumoral data acquired longitudinally that are currently in the DSS along with data collected at single time points.

The requirement for AI in this context is becoming increasingly relevant in the age of telemedicine, which will facilitate the collection of a considerable amount of data, especially in the case of cardiovascular medicine given the complex and multifactorial physiopathological mechanisms underlying CVDs [29,30]. Scientific evidence already exists on the potential applications of AI in cardiology, using both structured and unstructured data, including data obtained from cardiac imaging methods and from eHealth devices [31-34]. For example, a recent position paper of the European Preventive Cardiology Association emphasized the usefulness of AI for the development of algorithms to improve an individual's response to exercise so as to optimize CR in the prevention and treatment of CVDs [35].

Furthermore, the introduction of AI techniques has made it possible to develop predictive variables for outcomes of interest such as adherence to a rehabilitation program and quality of life, which would otherwise likely be neglected because these have not been considered conventional clinical parameters [36].

Limitations

Although IPOTERI is a noninvasive technique offering a highly novel and potentially beneficial rehabilitation program, some patients may not be open to adopting this different approach and may prefer other traditional treatments. Moreover, although IPOTERI might improve patients' perceived well-being as the patient feels monitored, the scalability of this approach to clinical parameters is still unclear. There is a potential limitation related to the approach that could affect the adherence to the rehabilitation protocol. The results, rather than being related to methodological correctness, may be related to the usability of the different devices by the patients, who are often disinclined with technology. One way to reduce this problem will be to have the protocol managed by highly qualified operators, training patients appropriately, and enrolling them voluntarily according to a certain predisposition to using such devices.

Conclusions

The CR tool presented here could be feasible, safe, and comparable to the traditional in-hospital rehabilitation approach, indicating that rehabilitation after cardiac surgery can be carried out at home if planned with an integrated and user-friendly telemedicine service. The IPOTERI approach based on the processing of data, both qualitative and quantitative, recorded during the use of telemedicine monitoring devices at home by a patient during rehabilitation following cardiac surgery, together with clinical data referring to the perioperative and postoperative periods could have potentially positive effects on adherence to the rehabilitation program and clinical improvement, as well as in terms of quality of life. This project aims to evaluate the impact of telemedicine platforms on patients during postoperative rehabilitation. The possibility of adopting the same program in different contexts warrants future studies on a larger population to explore the actual effectiveness of telemedicine-based CR programs. The IPOTERI platform will be tested in only patients with a stable status; thus, future

developments could consider the application of this platform in the management of patients with postoperative complications. Studies are also needed to assess the possibility of adopting the same program in different clinical settings, considering the possible implementation of hybrid CR models including components of both CBCR and HBCR.

Acknowledgments

The project described in this protocol is funded by the Programma Regionale Fondo Europeo di Sviluppo Regionale Toscana 2014-2020.

Abstract

Background: TheKeep.Ca was built to facilitate engagement with those experiencing cancer in Manitoba, Canada. Constructed between 2020 and 2024 with a group of patient advisors, the website includes information on engagement activities including research participation, the patient advisor role, and how those experiencing cancer can access these Manitoba activities. A link allows visitors to register to be contacted about activities that match their demographics, cancer history, and activity preferences. After TheKeep.Ca was constructed, this protocol was developed to establish TheKeep.Ca as a platform for scientific research focused on optimally engaging those experiencing cancer.

Objective: We asked the following questions: (1) What was the patient advisors' experience who participated in developing TheKeep.Ca? (2) What are the baseline characteristics of website traffic and registrants at TheKeep.Ca? (3) How does registering with TheKeep.Ca impact the cancer experience?

Methods: The planned launch date for the website and initiation of research activities is January 2025. For objective 1, the active patient advisors (N=6) participating in the website project will be invited to participate in project activities including with responses to a question prompt sheet, semistructured audio-recorded interviews, or both. Responses and interviews will be analyzed using reflexive thematic analysis to understand and inform practices for patient engagement on projects. At the website launch, TheKeep.Ca will become publicly accessible and indexable on internet search engines, but no additional promotional interventions will take place in the initial 6 months resulting in visitors primarily from web search traffic. For objective 2, Google Analytics and website registrant data collected during the first six months will be analyzed to obtain baseline characteristics of website visitors. For objective 3, an online survey will be emailed to registrants six months after the website launch characterizing their website experience, the activities they participated in, and collecting feedback on the website. For objectives 2 and 3, quantitative data will be analyzed using both descriptive and inferential statistics, and qualitative data from open-ended questions will be analyzed using thematic analysis guided by an inductive descriptive semantic approach.

Results: This study was approved by the University of Manitoba Health Research Ethics Board on December 12, 2024 (HS26614-H2024L263). Institutional approval from CancerCare Manitoba is pending as of December 23, 2024. Findings from objective 1 are expected to be finalized within the first six months after the website launch. Those from objectives 2 and 3 are expected by the 12-month mark. Reporting will include peer-reviewed journals, conferences, and a lay-language summary on TheKeep.Ca.

Conclusions: The research outlined in this protocol will facilitate understanding patient advisors' experience in developing TheKeep.Ca. It will also characterize the website' effectiveness and its impact on the cancer experience, providing a baseline and direction for future research and development.

Introduction

Background

The experience of living with cancer is not uniform, and not limited to patients currently receiving treatment. Comprehensive definitions of survivors of cancer include not only those receiving active treatment, those diagnosed and treated in the past but also the friends and family that support them [1]. Similarly, as a leading cause of morbidity and mortality for the global community, cancer does not selectively impact a specific population defined by race, lifestyle, or geographic location.

Because cancer can, and does, impact every human community, engaging with those impacted by cancer, in a way that seeks to understand how cancer services can be improved to provide optimal biomedical care in a way that is respectful, equitable, and supportive of the diverse lifestyles and identities of those living with cancer is essential for the promotion of ethical human care. Nonclinical trial research and work designed to obtain feedback from those with lived experience (eg, such as patient advisors) on service delivery initiatives are two ways that health care professionals can learn how cancer services can be developed to support better the diverse community of those impacted by cancer. However, identifying survivors of cancer to participate in such work can be challenging.

This project started with the goal of creating a website for connecting those experiencing cancer in Manitoba, Canada, with opportunities to improve the cancer journey for others. The website would allow interested survivors of cancer (1) the opportunity to join a database that would facilitate their voluntary participation by notifying them about emerging patient engagement opportunities in Manitoba such as nonclinical trials research or to function as patient advisors. Such a website would facilitate engagement with the Manitoba population with cancer without impacting other existing programs, including clinical service delivery, in the province. The website would be a platform used to study how to better recruit individuals for cancer research; (2) and a tool for rigorously exploring how online approaches can be used to overcome challenges to achieving representative engagement with Manitoba's diverse population with cancer that includes, but are not limited to, Indigenous peoples, recent immigrants, and those living in urban, rural, and remote communities.

Understanding Barriers to Recruitment for Nonclinical Trials Research

Language barriers, lack of infrastructure, costs related to advertising and supporting accessibility, and the functional capacity of participants living with illness are just some of the barriers that can impact the recruitment of representative samples for all types of research work [2,3]. In contrast to clinical trial research, which is generally integrated into the participants' health care, conducted by well-established teams with dedicated infrastructure to support participant recruitment, and comes with the incentive of possibly receiving an experimental intervention that may be superior to the standard of care [2], nonclinical trials researchers face unique challenges. Nonclinical research, such as qualitative and quantitative survey research, as well as longitudinal observational studies, often function with less infrastructure support, clear benefit to the participant, and require commitments on behalf of the participant outside of their responsibilities as recipients of clinical care [4].

Additionally, nonclinical trial studies are often "one-offs" undertaken by trainees, such as graduate and postgraduate researchers, as part of the completion of educational programs. Those responsible for the success of such projects (ie, the trainee) may have less access to gatekept patient populations and other supportive infrastructure, such as research nurses [2]. Unfortunately, these barriers likely result in fewer high-quality research projects, ultimately involving smaller, nonrepresentative samples, and delays in project completion—negatively impacting the quality and diversity of the scientific literature, accessibility to potential participants who may find benefit in participating in such research projects, and the professional trajectory of talented researchers.

Exploring Barriers to Patient Engagement

Outside of the research recruitment setting, for health care teams, including clinicians, researchers, and administrators, being able to connect with a diverse group of individuals with lived illness experience is becoming increasingly recognized as valuable for program development and improvement [5]. Engagement with individuals functioning as patient advisors to inform project planning, research design [6,7], and infrastructure development is increasingly recognized as an essential process for evolving patient-centered care [5,8,9]. However, as an area of research, understanding how to effectively identify, recruit, and engage with individuals is still evolving [5,10,11]. For instance, it has been suggested that patient advisors may be more likely to be individuals that are passionate about engaging with the health

care system than the average patient, resulting in the population of individuals that is engaged with patient advisory work being less likely to be representative of the general patient population [8].

Important work is being carried out to explore how to create better and more meaningful patient engagement opportunities. For instance, aspects of patient engagement such as the timing of activities concerning project lifecycle [6], mitigating power imbalances [11,12], and evaluating outcomes of patient engagement [9] have an evolving body of literature in the spirit of moving from passive to authentic patient engagement [5,9,10,12]. However, questions related to recruitment for engagement appear to be less robustly addressed. A recent systematic review including 142 studies explored patient engagement as a part of research [9]. While the review did identify several different ways that participants were identified, including internet postings, paper advertisements, and invitations from clinicians, studies involving a specific analysis of the impact of different approaches on recruitment effectiveness were not found [9]. As identification of individuals for patient advisory work is often not embedded in the clinical practices of frontline care providers, it is likely that many of the same challenges to recruitment that face nonclinical trial research exist for patient engagement. Work exploring which recruitment approaches for patient engagement are most effective, and how these approaches enable engagement with different populations is important.

Using Online Infrastructure to Optimize Engagement

Using physical spaces primarily intended for clinical service delivery presents challenges for meaningfully engaging with patients and their friends and family about topics not directly related to patient care. In these clinical areas, such as in ambulatory oncology clinics, patients and their accompanying friends and family members may be already overwhelmed with information regarding their disease and its management [13]. On the other hand, online web spaces can be more easily purpose-built around the needs and interests of those experiencing specific aspects of an illness journey and can be accessed after clinical visits have concluded, during times convenient to the individual [13]. Importantly, the population with cancer is well documented to rely heavily on online information as part of the cancer journey, with some studies demonstrating daily rates of internet use related to cancer exceeding 80% [14]. If carefully developed to meet the needs of those living with cancer, online spaces may be effective at supporting engagement between those living with cancer and health care professionals working to evolve the cancer journey.

Research Objectives

This protocol outlines how a website intended to support and provide meaningful patient engagement will be studied to advance the science of effective engagement with those living with cancer. As outlined below, TheKeep.Ca website was developed through collaboration with a team of dedicated patient advisors with the aim of creating a webspace to facilitate connecting researchers and health care teams with those who have lived cancer experience as well as providing meaningful resources for those living with cancer in Manitoba and beyond. In addition to helping TheKeep.Ca evolve to better serve the needs of the cancer community in Manitoba, the outcomes from exploring the research objectives outlined in this protocol are intended to provide useful guidance for those intending to embark on pragmatic longitudinal patient engagement projects, such as the development of patient-centric websites, and contribute meaningful findings to the scientific literature regarding how to best engage, online, with those experiencing cancer.

Research Questions

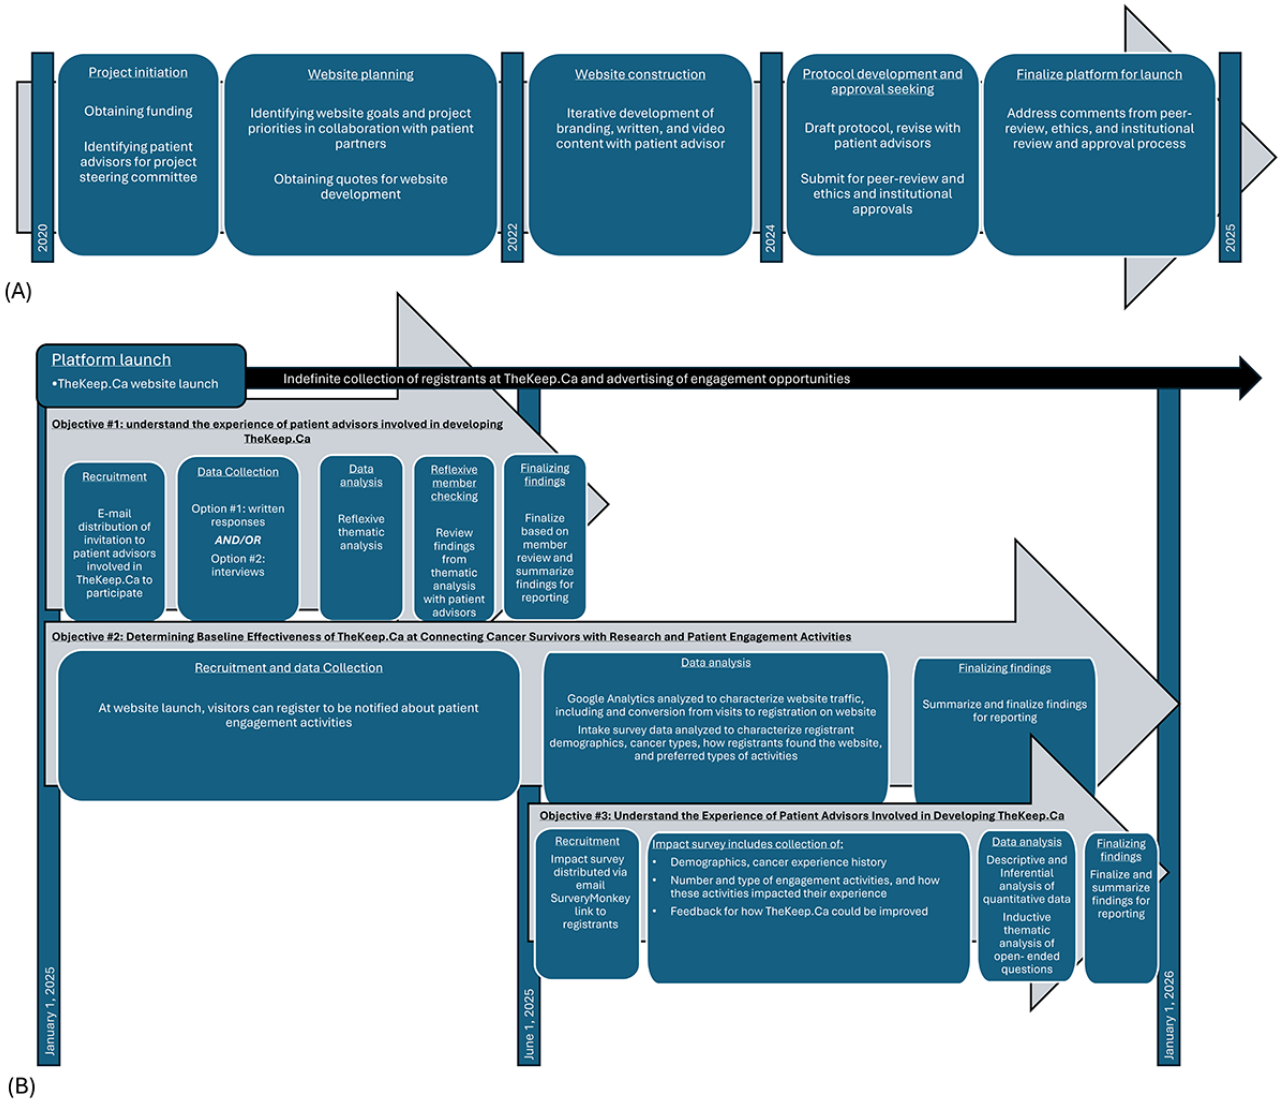
1. What was the experience of the patient advisors who participated in the development of TheKeep.Ca?
2. How effective is TheKeep.Ca at engaging with the population with cancer in Manitoba in the six months after going live?
    - What are the characteristics of website visitors?
    - What is the conversion rate from unique website visitors to website registrants?
    - What are the characteristics of registrants on the website database?
3. How do the patient engagement activities that TheKeep.Ca facilitate impact the cancer experience for website registrants?
    - How does participating in engagement activities promoted by TheKeep.Ca impact the cancer experience?

Methods

Building TheKeep.Ca

Before initiating research activities, TheKeep.Ca website was developed over 4 years through several steps (Figure 1A). After funding had been obtained for the project, patient advisors, including past and present patients with cancer at CancerCare Manitoba (CCMB), were invited to join a patient steering committee to guide the project that was facilitated by the lead author (MT). The patient advisors were recruited both through the CCMB patient advisor program and by psychosocial staff at CCMB.

Figure 1. Development of TheKeep.Ca and proposed research activities. (A) TheKeep.Ca was developed over 5 years with a group of patient partners beginning in 2020. Patient partners informed goals for the website, content development, research priorities, and methods. (B) In the six months following the website launch, the patient advisors' experience of being involved in TheKeep.Ca project will be explored using a qualitative approach. Six months following the launch, data from the registration surveys and Google Analytics will be used to characterize the website's effectiveness in engaging with the survivors of cancer population in Manitoba. A survey exploring the impact of registration on the TheKeep.Ca website will also be deployed at the 6-month mark with the results used to address the impact of the website on the cancer experience.



Through videoconferences, emails, and an online discussion board, the priorities for the website were identified by the steering committee. These included items to satisfy the requirements of the secured funding (ie, a website to inform website visitors about the role of being a patient advisor, a research participant in nonclinical trials research, and a method to populate a database of individuals interested in participating in these roles). Additionally, while the patient advisors identified several important components that could be added, developing a resource directory of supportive care for cancer resources to be hosted on the website curated by patients was selected as the initial patient advisor-championed project to be included on the website.

After the steering committee was formed and the key components were identified, the website was developed in coordination with a professional media design firm (Argyle Media Inc). Facilitated by the lead author (MT), the patient advisors on the steering committee participated in all aspects of developing the website branding, including providing both initial ideas and iterative feedback to the media firm for the logo and site design. Additionally, the patient advisors also participated in content creation for the website, including working alongside a freelance videographer and 2 science communication writers.

In total, 10 current or former patients were involved in the project, however, 4 left the project during its course for reasons including, but not limited to, competing priorities and changes in health status.

Studying TheKeep.Ca

Once the website was completed, this protocol was developed. Feedback was obtained from the patient advisor steering committee regarding what research objectives they considered important to include regarding the value of a patient engagement website. The protocol was developed by the lead author (MT) and last author (DEM), and then reviewed by the patient

advisors, with revisions to this study's tools and methods made in response to their feedback before submission for peer review.

A schematic outlining the timeline for the activities described in this protocol is presented in Figure 1, including the development of TheKeep.Ca (Figure 1A) and the research activities proposed in this protocol (Figure 1B).

Research Objective 1: What Was the Experience of Participating in Developing TheKeep.Ca?

The patient advisors who continue to participate in the development of TheKeep.ca (N=6) through membership in the patient engagement steering committee will be invited to share their experience of partnering in the development of TheKeep.Ca. This will be completed within the context of a research study as a voluntary activity. Those who are interested in participating will be invited to contact the last author (DEM) of this protocol, who will obtain informed consent (Multimedia Appendix 1 for the consent form). They will then receive a short intake questionnaire to collect demographic information and details about their cancer experience (Multimedia Appendix 2).

Those who express interest in providing a voluntary written sample following the informed consent process will be provided with a question prompt to provide open-ended written responses (Multimedia Appendix 3). For those who consent to participate in a voluntary semistructured interview, an audio-recorded semistructured interview (estimated duration 60 to 90 minutes) will be conducted following the collection of all written responses. The semistructured interviews will be guided by an interview guide (Multimedia Appendix 4). The question prompts (ie, Multimedia Appendices 1 and 2) were developed by authors MT and DEM, based on feedback MT had received from the patient advisors on the steering committee involved in the project, and reviewed and revised by the steering committee before finalizing this protocol. Transcripts of the audio recordings will be prepared using a professional transcription service (ie, Scribie), and both the written survey responses and interview transcripts will be deidentified before analysis.

Reflexive thematic analysis (RTA) [15] will be used to analyze the data collected. RTA is a nuanced iteration of the thematic analysis approach initially described by Braun and Clarke [16]. Specifically, RTA explicitly addresses several methodological questions that have been identified since the initial publication describing thematic analysis by Braun and Clarke [16]. Specifically, RTA is not considered a positivistic, descriptive, rigid methodology. Instead, it embraces constructivism, an inductive flexible approach to data analysis, consideration of latent meaning, and an emphasis on the interpretation of the data by the researcher [15,17]. Compared to other iterations of thematic analysis, RTA was chosen because the experience of the patient advisors involved in the development of TheKeep.Ca was thought to be complex, with many aspects likely to be unknown a priori to the researchers, requiring more than a descriptive summary of the data collected to provide a meaningful exploration and contribution to the literature.

The steps for data analysis will be in keeping with those described for RTA [15-17], progressing in a relatively linear manner through six phases including (1) familiarization with the data once data collection is completed, (2) generating initial codes using line by line coding, (3) generating themes, (4) reviewing potential themes, (5) defining and naming themes, and (6) producing the report. In keeping with a nonpositivistic stance, the volunteers from the steering committee will be invited to provide member reflections in a group setting as part of phase 6 once a preliminary version of the report is ready. The purpose of this activity will be to "explore gaps in understanding … and consider how to acknowledge and present these in the written report" [15], as opposed to validating findings. The final report will be revised to reflect the findings from this final group activity.

Rigor and Trustworthiness

The trustworthiness of the research findings will be facilitated by ensuring practices that enhance credibility, transferability, dependability, and confirmability [18,19]. Prolonged engagement with this study's participants and data, as well as a review of study findings with participants before finalizing study results, are techniques that will be used to address the credibility of the findings. By providing a rich description of the data, the contexts in which it was collected, and the resulting findings, as well as by considering both latent and semantic themes, the transferability of this study's findings to other contexts related to patient engagement will be supported. Dependability will be supported by recording written field notes in addition to the audio recording of semistructured interviews, the keeping of a reflexive journal to document the processes and decisions related to the generation of codes during data analysis, and the use of NVivo (Lumivero LLC, version 13, released 2020) software which provides an auditable record of the steps by which the data was coded. Conformability, or whether the research findings follow from the data collected, will be supported through the techniques described in support of credibility, transferability, and dependability [18]. Additionally, conformability will be further supported by recording additional aspects of the research process in the reflexivity journal, beyond the specific decisions and processes related to the development of the codes. For instance, it is anticipated the DEM will record information about the daily experience of completing the data collection and analysis, as well as reflections on their personal experience with the research [18,19], in support of connecting personal experience with conducting research with the data and generated findings.

Reporting of the findings will conform with COREQ (Consolidated Criteria for Reporting Qualitative Research) guidelines to facilitate rigorous reporting [20]. In keeping with this, in addition to thorough reporting of study methods and findings reflecting the checklist items, a reflexivity statement will be included in the final report which will include, but not be limited to, a characterization of DEM's professional identity, and personal biases, assumptions, and reasons and interests in the research topic.

Research Objective 2: What Is the Baseline Effectiveness of TheKeep.Ca at Connecting Survivors

of Cancer With Research and Patient Advisor Activities?

Data from website visitor metrics and registrant data collected over the first 6 months after the website goes live will be used to establish a baseline of the effectiveness of TheKeep.Ca at recruiting members of the Manitoba population with cancer for engagement activities. Google Analytics will be used to provide metrics related to user activity on the website. The methodology for using Google Analytics to understand website traffic is informed by that used by previous authors [21]. Specific metrics to be used will include, but not be limited to, total users, type of devices used, geographic locations of users, session length, websites' pages viewed, number of page views per page, bounce rate (ie, number of users leaving the site without viewing additional pages), site entrances, and page interactions.

Data from registrants on the TheKeep.Ca engagement database will be used to further characterize the effectiveness of the website, as well as the population that it effectively engages within the first six months after going live. Specifically, respondent demographics, information about their cancer experience, preferred types of activities, and how they found the website are tracked as part of the registration survey (Multimedia Appendix 5).

Data analysis will include the generation of descriptive statistics of the website metrics and registrant characteristics. Descriptive statistics will be generated from both the Google Analytics data as well as the registrant data. Inferential statistics, including chi-square and *t* test (2-tailed), will be used to describe differences in Google Analytics metrics between website visitors from Manitoba and outside of Manitoba, as well as by device. Additionally, inferential statistics will be used to describe differences in disease characteristics and engagement preferences by registrant demographics, including age, gender, and location. Open-ended question data will be summarized using a descriptive semantic inductive approach to thematic analysis [15,16], with the aim of providing a simple summary of open-ended question data.

Research Objective 3: How Does Registration on TheKeep.Ca Impact the Cancer Experience?

After the initial 6 months after TheKeep.Ca has gone live, an online SurveyMonkey survey (Multimedia Appendix 6 for the survey) will be distributed to the website registrants who consented to be contacted with a follow-up survey as part of the initial registration questionnaire. Demographic data and information about the registrant's cancer experience (ie, date of diagnosis, type of diagnosis, patient vs informal caregiver, and treatment intent) will be captured, as well as the number and type of engagement activities they have participated in that were advertised on TheKeep.Ca. Using a combination of Likert-style responses and open-ended questions the survey will evaluate the experience of being a registrant on TheKeep.Ca, the effectiveness of TheKeep.Ca in connecting individuals with engagement opportunities, the impact of engagement activities on the experience of registrants, and identify ways that TheKeep.Ca can provide a better experience to website registrants. Descriptive statistics will be generated to describe the respondent population and the overall experience of the group. Inferential statistics will be used to identify differences between populations, based on demographics and cancer experience, and the impact TheKeep.Ca had on respondents' cancer experience. Open-ended question data will be summarized using a descriptive semantic inductive approach to thematic analysis [15,16], with the aim of providing a simple summary of open-ended question data.

Development of the research protocol related to objectives 2 and 3 was informed by the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) checklist to facilitate rigorous reporting [22]. For qualitative data, NVivo will be used to assist with qualitative data management and analysis. Quantitative data analysis will be conducted using SPSS (IBM Corp, version 27, released 2020).

Ethical Considerations

This study was approved by the University of Manitoba Health Research Ethics Board on December 12, 2024 (HS26614-H2024L263). Institutional approval from CCMB is pending as of December 23, 2024. Participants, including both registrants on TheKeep.Ca website as well as the patient advisors involved in the development of this project, did not receive compensation of any kind. Enrollment on TheKeep.Ca website is strictly voluntary, with informed consent being implied as part of the registration process.

All data will be deidentified before analysis. Data related to objective 1 will be linked to a master list, which will be destroyed following the completion of research activities outlined in this protocol. Data related to objective 2 (ie, registrant responses) will be deidentified before analysis for research purposes; however, names and contact information will be required to be retained on this data to facilitate screening and informing registrants of relevant patient engagement activities. However, this data will not be shared with any other party and be available only to the research team (ie, MT and DEM). Data from objective 2 is being collected in an anonymized fashion, with an absence of information that would support the identification of individuals. Notably, while the email addresses provided by registrants on the website will be used to collect data for objective 3, the responses will not be linked to the email addresses or the initial responses provided by the individuals at the time of website registration.

Patient advisor involvement, including participation on the steering committee, being listed as an author on this paper, and participation in the research activities related to objective 1, was strictly voluntary, and would not impact their ability to participate in any aspect of the activities related to this project. The patient advisors listed as authors on this protocol provided expressed written consent to be listed as such and fulfilled the criteria to be listed as authors in peer-reviewed journal publications, including active involvement in all aspects of the project and protocol development. Documentation of this consent was provided to the editor for review as part of this peer-reviewed process.

All images, names, and videos of individual thrivers of cancer presented on TheKeep.Ca website are used with expressed consent. The website does include stock images obtained from

a third party (ie, Adobe Stock Images) which are used per the images' respective licensing agreements.

Results

TheKeep.ca will go "live" after this study receives institutional approval from CCMB, becoming searchable on major search engines (eg, Google) and accessible to the public. The results related to research objective 1 are expected to be submitted for peer-reviewed publication within 6 months after the website becomes accessible to the public with results related to research objectives 2 and 3 being submitted for peer review by the 12-month mark. In addition to being presented in peer-reviewed manuscripts, the results will also be shared at national and international conferences as well as presented on TheKeep.Ca website in written and video format using layperson language.

Discussion

Principal Findings

Addressing the three research objectives outlined in the protocol is important for informing future work in several ways. Regarding research objective 1, better understanding the experience of the patient advisors who were, and continue to be, involved in TheKeep.Ca project is important for evolving how TheKeep.Ca project is conducted in the future, as well as informing how other projects where authentic longitudinal patient engagement is desired. While high-quality reviews [5,9] and frameworks to guide patient engagement activity planning exist [23], such as those available through the Patient-Centered Outcomes Research Institute [24], the findings from this work will provide real-world examples of the experiences, challenges, and lessons learned from a complex project where authentic longitudinal engagement with thrivers of cancer was foundational. Specifically, identifying what parts of this project have been frustrating, stressful, or otherwise not rewarding, for the patient advisors as well as which aspects were viewed as providing a positive and meaningful experience is expected to make a meaningful addition to the literature [10].

Regarding objectives 2 and 3, obtaining baseline data regarding how effective the website is at engaging those living with cancer both inside and outside of Manitoba, as well as the characteristics of the registrants, is important for guiding future work to better engage with the diverse population of individuals living with cancer both inside and outside of Manitoba. It is anticipated that the baseline Google Analytics data will provide meaningful insights per who engages with TheKeep.Ca website. Similarly, the initial registrant experience survey (ie, objective 3) will provide important data about how to enhance the experience of those that register on TheKeep.Ca. This data will reflect the experience of engaging with TheKeep.Ca in the absence of planned social media campaigns and advertising at the cancer center. As the website develops, and campaigns to promote the website are developed, the baseline data will provide a real-world comparison to gauge the effectiveness of promotional interventions such as social media advertising campaigns, paid Google Adwords campaigns, and posters placed in cancer care facilities, or private businesses. This data will be helpful not only for helping TheKeep.Ca evolve into a tool for engaging meaningfully with Manitoba's population with cancer but also for other groups endeavoring to engage with either specific populations or a representative sample of those impacted by cancer [8].

Limitations

This protocol has two main limitations. First, to address research objective 1, not all patient advisors who participated in the development of TheKeep.Ca will be able to be invited for interviews. At the time of protocol submission, three of the initial patient advisors involved left the project, for several reasons—not all of which were disclosed. While, from both a scientific and quality improvement perspective, it would be ideal to explore the reasons for dropping out from the project to provide a better experience for those in the future, however, out of respect for the privacy of the individuals that withdrew, this is not possible. Ideally, experience data related to participation in the project would have been captured longitudinally, throughout the project. However, the decision to establish TheKeep.Ca as a research platform was made relatively late in the project history, as such the need to formally collect rigorous experience data was not considered previously.

Second, there is a risk that initial recruitment to the TheKeep.Ca registrant database will be limited, resulting in limited data to address objectives 2 and 3. TheKeep.Ca, as a research platform, represents a novel endeavor, making predicting the initial recruitment rate and the resulting sample size for the first six-month sample size impossible. Additionally, as the goal is to obtain baseline data for traffic and engagement with the site, before additional advertising interventions as outlined above, traffic may be very low. As a result, it is recognized that the generation of meaningful inferential statistics may not be possible. Regardless, the initial data from the first six-month period will serve as an important baseline, essential for understanding the impact of future campaigns to promote the website and recruitment to the website registry.

Conclusion

The webspace that became TheKeep.Ca was initially proposed as a simple tool to connect those who have experienced cancer firsthand with opportunities to engage with researchers and other teams working to improve the cancer journey in Manitoba, Canada. However, through endeavoring to seek authentic [9] collaboration with a group of patient advisors over several years, the simple proposal evolved into something with the potential to become much more than that. In keeping with the original proposal, TheKeep.Ca is a catalyst, enhancing the capacity for connection between those willing to share their hard-won firsthand knowledge with health care professionals. However, it is also a place where patient advisors can contribute directly to improving the cancer journey, as it provides online infrastructure for patient advisor-led initiatives—such as the curated resource directory. Lastly, through a rigorous research program, beginning with the work outlined in this protocol, TheKeep.Ca project aims to achieve these goals while, at the same time, advancing what is known about patient engagement for the benefit of those living with cancer in Manitoba and beyond.

Acknowledgments

This work was supported by a grant from the CancerCare Manitoba Foundation.

Data Availability

To protect the confidentiality of the research participants, deidentified data, including qualitative data related to objective 1, and survey response data from objectives 2 and 3 will not be made publicly available. However, it may be obtained upon reasonable request to the authors, and subsequent approval of the request after review by the University of Manitoba Health Research Ethics Board.

Abstract

Background: Measuring vital signs (VS) is important in potentially unwell children, as a change in VS may indicate a more serious infection than is clinically apparent or herald clinical deterioration. However, currently available methods are not suitable for regular measurement of VS in the home or community setting, and adherence can be poor. The COVID-19 pandemic highlighted a need for the contactless measurement of VS by nonclinical personnel, reinforced by the growing use of telemedicine. The Lifelight app is being developed as a medical device for the contactless measurement of VS using remote photoplethysmography via the camera on smart devices. The VISION-D (Measurement of Vital Signs by Lifelight Software in Comparison to the Standard of Care—Development) and -V (Validation) studies demonstrated the accuracy of the app compared with standard of care (SOC) measurement of blood pressure, pulse rate (PR), and respiratory rate (RR) in adults, supporting certification of Lifelight as a class I Conformité Européenne medical device.

Objective: To support the development of the Lifelight app for pediatric patients, the VISION-Junior study is collecting high-quality data that will be used to develop algorithms for the measurement of VS (PR, RR, and oxygen saturation) in pediatric patients. The accuracy of the app will be assessed against SOC measurements made simultaneously with app measurements.

Methods: The study is recruiting pediatric patients (younger than 18 years of age) attending the Sunderland Royal Hospital pediatric emergency department of the South Tyneside and Sunderland National Health Service Foundation Trust. High-resolution videos of the face (and torso in children younger than 5 years of age) and audio recordings (to explore the value of crying, wheezing, coughing, and other sounds in predicting illness) are made using the Lifelight Data Collect app. VS are measured simultaneously using SOC methods (finger clip sensor for PR and oxygen saturation; manual counting of RR). Feedback from patients, parents, carers, and nurses who use Lifelight is collected via questionnaires. Anticipated recruitment is 500 participants, with subtargets for age, sex, and skin tone distribution (Fitzpatrick 6-point scale). Early data will be used to refine the algorithms. A separate dataset will be retained to test the performance of the app against predefined targets.

Results: The study started on June 12, 2023, and reached its recruitment target (n=532) in April 2024 after extending the deadline. Algorithm refinement is in progress, after which the performance of Lifelight will be compared with the SOC measurement of VS. The analyses are expected to be completed by mid-August 2024.

Conclusions: Data collected in this study will be used to develop and assess the accuracy of the app for the measurement of VS in pediatric patients of all ages.

Introduction

Measurement of vital signs (VS) is an essential part of clinical evaluation, providing important information about a patient's health; importantly, a change in VS may herald a deterioration in clinical condition [1] and may precede the emergence of physical symptoms during the early stages of an infection [2]. High pulse rate (PR) and respiratory rate (RR) have been shown to predict hospital admission in children [3]. Infections such as influenza, scarlet fever, and chickenpox are common causes of morbidity and mortality in immunocompromised children [4,5]. Three-quarters of children who develop severe sepsis from infection have a comorbid condition such as asthma, diabetes, cystic fibrosis, or cancer. Sepsis carries a mortality rate of almost 50% in the most vulnerable children [6]. Treatment of infection in children can be expensive, especially if intensive care is required.

Given that monitoring of VS is important in clinically vulnerable children to aid early detection of infection [7], a robust method that parents can use at home to measure VS is likely to be beneficial and would support remote initial assessment [8]. The measurement of VS is time-consuming and requires trained staff and multiple pieces of equipment, some of which need regular calibration. Accurate measurement of blood pressure (BP) using a sphygmomanometer requires the use of the correct size cuff for the patient. The physical contact of equipment can be uncomfortable and distressing for patients, particularly those with learning disabilities. Stress can affect BP, PR, and RR, such that the measurements may not accurately reflect the patient's state of health [7]. Standard of care (SOC) medical equipment is not suitable for regular measurement of VS in the home or community setting. Adherence to frequent VS monitoring using traditional technologies is low because of the inconvenience and stigmatizing nature of specialist hardware equipment (eg, thermometers, BP cuffs, and finger-clip oximeters) [7]. The COVID-19 pandemic has also highlighted the need for methods suitable for the remote or contactless measurement of VS that can be operated by people without specific medical training. The growing use of telemedicine since the pandemic also points to the need for easy but accurate measurement of VS.

Photoplethysmography (PPG) is an optical measurement technique that records changes in the light reflected from the skin surface due to volumetric changes in the facial blood vessels; small variations in perfusion provide valuable information about the cardiovascular system [9]. PPG has been used to measure PR [10,11], oxygen saturation [12], BP [13,14], and RR [10,15] and to detect atrial fibrillation [16].

Lifelight is an app being developed for the contactless measurement of VS using remote PPG via the camera on smart devices such as phones and tablets. The app captures the average color of regions of interest on the face 30 times every second for 60 seconds and sends these as red, green, and blue color values to a central server for processing, yielding VS values. The VISION-D (Measurement of Vital Signs by Lifelight Software in Comparison to the Standard of Care—Development) study in 2018-2019 measured VS in 8585 patients and healthy volunteers simultaneously using the app and SOC methods. The data were used for machine learning to develop the algorithms used to calculate VS. The subsequent VISION-V (Validation) study demonstrated the accuracy of the app compared with SOC methods for measuring PR, RR, and diastolic BP [17], providing the basis for the current Class I Conformité Européenne (CE) mark [18]. The app also received ISO 13485:2016 certification in August 2023 [19], and the accuracy of the app for measuring PR and BP against ISO standards in adults with stage 1 hypertension has recently been reported [20]. The VISION-MD (multisite development) study evaluates the app versus SOC in patients with a wide range of clinically relevant VS values, including critically ill patients, and across the full range of skin tones [21]. In VISION-MD, high-resolution full-face videos of participants' faces have been recorded, which has proved instrumental in improving the accuracy of VS measurement compared with the VISION-D and -V studies.

The VISION-Junior study explores the measurement of VS using a Lifelight app developed for pediatric patients (aged 18 years or younger) attending the pediatric emergency department. As in VISION-MD in adults, high-resolution full-face videos will be recorded. In younger children (younger than 5 years of age), the video will also include the torso to increase the surface area from which the signal is recorded, and because the torso is likely to move less than the face. Audio data will also be recorded, as crying, wheezing, coughing, and other sounds can also predict illness in children [22,23].

The aim of the VISION-Junior study is to assess whether the app can be used to accurately measure VS in pediatric patients. This protocol describes the collection of data that will initially be used to develop the algorithms for the measurement of VS in children. Later data will be used to assess the accuracy of the

app across the range of VS values encountered in children of different ages. The objectives are as follows.

The primary objective is to collect data to support the development of the app for the accurate measurement of PR, RR, and oxygen saturation in pediatric patients and to assess the accuracy of measurements against SOC methods. Secondary objectives are: (1) to assess—using the collected PPG data—whether other (direct or indirect) measurements can be made using the app, including temperature, BP, PR variability, and audio analysis; (2) to evaluate the impact of subject-specific variables on the PPG VS measurements (eg, medication, cosmetics, facial or body hair, and skin tone); (3) to obtain data to understand patient and parent or guardian or carer habits and preferences for VS measurement using questionnaires (Multimedia Appendices 1 and 2); and (4) to assess the usability of Lifelight Junior for measuring VS in pediatric patients through questionnaires completed by participating health care professionals (Multimedia Appendix 3).

Most of the data collected in the study will be used to train the app algorithms to measure VS in pediatric patients. The remaining data will be kept separate and used to assess the accuracy of the algorithms at regular intervals during the data collection period. The study delivery process will be responsive to this learning curve to increase the likelihood that the predetermined accuracy target for each VS estimation is achieved by the study end.

Methods

The design and protocol for this study have been informed by the VISION-MD study [21] and earlier VISION studies [17].

Participants and Recruitment

Approximately 500 pediatric patients are being recruited at the Sunderland Royal Hospital pediatric emergency department of the South Tyneside and Sunderland National Health Service (NHS) Foundation Trust. All pediatric patients (younger than 18 years of age) attending the pediatric emergency department are potentially eligible for the study. The exclusion criteria are critical illness (as judged by the treating physician), including unconscious patients, patients who were noncompliant in terms of excessive movement during the VS measurements, and patients whose parents, guardians, or carers do not speak English (required to give informed consent). The study aims to recruit according to age, sex, Fitzpatrick skin tone, and medical history criteria, as subsequently described.

The research nurse approaches the parents, guardians, or carers of potential participants identified by the clinical team about taking part in the study. Potential participants aged 17 or 18 years or the parents, guardians, or carers of younger children are provided with an ethics-approved information sheet explaining the study aims, what is involved, and the requirements for participation. Younger children also watch ethics-approved age-appropriate videos (for ages 5-10 and 11-16 years) explaining the study on a tablet device (Multimedia Appendices 4 and 5).

The information sheet and videos were developed in collaboration with the Young People Advisory Group North England and the South Tyneside and Sunderland NHS Foundation Trust Young Persons Group. These groups also provided feedback on the design of the study, consent/assent forms, and other study documents at 2 in-person meetings.

Study Procedures

Demographic data (age, sex, ethnicity, skin tone [Fitzpatrick 6-point scale [24] ranging from type 1 for skin that always burns to type 6 for skin that never burns]) are recorded on an electronic case report form using the Castor electronic platform. Medical history questions are limited to the presence or absence of conditions that might affect skin perfusion and pigmentation, cardiovascular processes, and any prescription medicines for these conditions.

The study staff records a set of premeasurement observations and the presence or absence of sweat on the participant's face; any facial hair on the cheeks; tattoos, jewelry, birthmarks, scars, or other features on the face; the use of foundation or concealer; and the position of the participant (seated, prone, supine or lying on one side).

Patients may also be recruited into 1 of 3 subprotocols depending on premeasurement observations (Table 1).

The study staff ensures that participants have been at rest for at least 10 minutes before VS measurement starts (which can include the period of data collection described previously).

Table 1. Subprotocols.

	Subprotocol	Description
1	Blood pressure measurement	Blood pressure will be measured at the same time as other vital signs using standard of care equipment (sphygmomanometer) in participants who are able to cooperate and stay relatively still
2	Electrocardiogram	A 3-lead electrocardiogram will be recorded to assess heart rate variability in a representative subset of participants (based on age, skin tone, and illness; see Table 3)
3	Questionnaire	Guardians, parents, or carers and children will be asked to complete a questionnaire about their preferences for Lifelight-type technologies versus standard of care methods for measuring vital signs

In each study session, VS is measured as per the subprotocol using the SOC equipment, while simultaneously capturing a video of the participant's face using the Lifelight Data Collect app running on a tablet (standard iPad). This app is a research tool that captures and uploads video data to secure cloud storage for research purposes only and is distinct from the CE-marked Lifelight medical device developed from data collected from previous studies. The Data Collect app does not display any VS estimates and is not used for clinical interpretation or analysis.

In each study session, at least 2 VS (PR, oxygen saturation, RR) and temperature are measured twice over a 60-second period using SOC equipment and methods.

A standard clinical finger clip sensor for the measurement of oxygen saturation and PR is placed on a finger. Oxygen saturation and PR are measured at 0, 30, and 60 seconds of the recording period and averaged.

RR is determined by counting chest rises throughout the 60-second period. The nurse may place their hand on the participant's chest to improve the accuracy of counting while being mindful not to obscure the camera's line of sight.

At the same time, a video of the participant's face (and torso in children younger than 5 years of age) and audio is captured for up to 3 minutes using the Data Collect app running on a tablet positioned approximately 1 meter away and angled toward the participant's face. Background luminosity is measured automatically. Recording is started and stopped by the research nurse via the iPad.

A maximum of 3 attempts at recording measurements is made. Once measurements have been completed, the study staff fill in postmeasurement questions relating to how much the participant moved, their position, whether they were wearing glasses, any hairstyle or other item (eg, face covering) that obscured any part of their face during the recording, and whether the app reported "face not found" at any point during the recording.

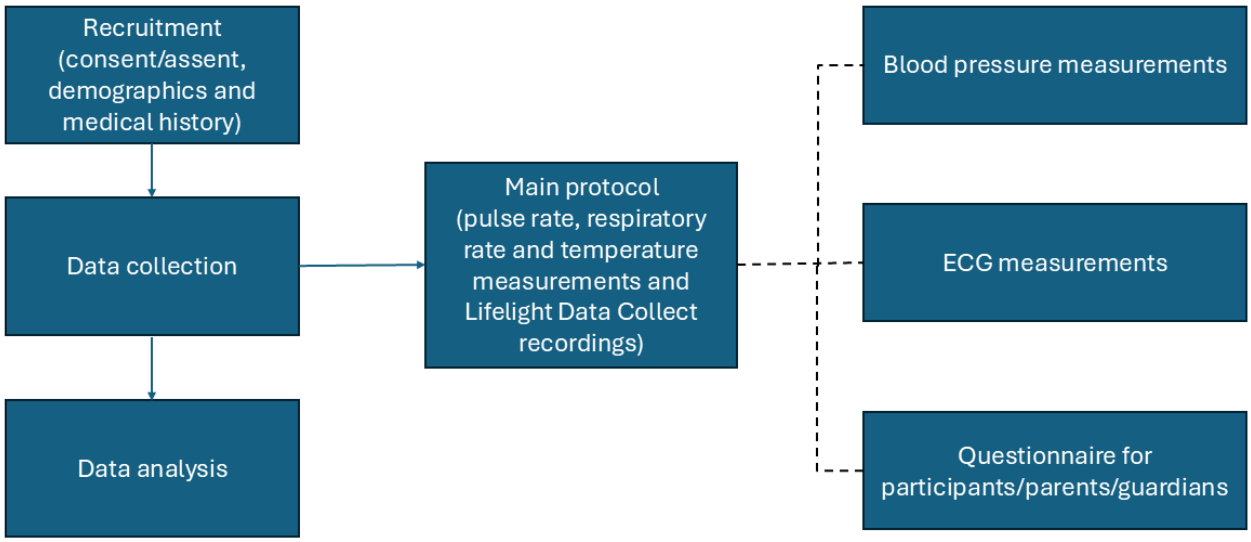
A questionnaire is also available to garner feedback on the technology from the clinical user's point of view (ie, the nurses who take the VS measurements). Questionnaire data are fully anonymized and recorded without any identifiable information.

Each study session, including approaching the participant, obtaining consent, and performing the study procedure takes about 30 minutes. Participants were not followed up after the VS measurements but continued to receive clinical care as appropriate for their condition.

Subprotocols

Participants are recruited into 3 subprotocols as appropriate (Table 1). Subprotocols 1 and 2 may be run concurrently with the main protocol if the research nurse considers it practical to also record BP and an electrocardiogram (Figure 1).

Figure 1. Study flow and data collection. BP: blood pressure; ECG: electrocardiogram.



Ethical Considerations

The study is being performed in accordance with the spirit and the letter of the Declaration of Helsinki, the Good Clinical Practice Guidelines, and the protocol and applicable local regulatory requirements and laws. The VISION-Junior protocol was approved by the Health Research Authority and Health and Care Research Wales (IRAS reference 321956) and the Newcastle North Tyneside Research Ethics Committee on March 30, 2023. Informed consent is obtained electronically using Castor eConsent, a secure NHS-compliant platform. Informed consent is provided by participants aged 16 years and older and by the parent, guardian, or carer of younger children. Children younger than 16 years of age are also given the opportunity to sign an assent form. As the study is noninterventional, participants will not receive financial compensation for participation but may be offered small incentives such as stickers or certificates. Participation in the study is entirely voluntary, and participants may withdraw from the study at any time. Specific, explicit written consent was obtained from all individuals featured in the videos provided in Multimedia appendices 4 and 5, permitting use for publication purposes.

Privacy and Data Collection

Each study participant is assigned a unique sequential patient identifier; no identifiable data are stored. All documents are stored securely and can only be accessed by study staff and authorized personnel. The code linking the patient identifier to their personal information is kept within the hospital study site and can only be accessed by the research team within that site.

For each reading, a high-quality video of the face (and torso in young children) and an audio file are saved to the internal storage of the iPad in encrypted form and transmitted directly

to the sponsor's NHS-compliant cloud server. Files were automatically deleted following upload to the server.

All data collected about participants during the study will be kept strictly confidential and handled according to the General Data Protection Regulations. Videos and audio recordings collected during the study constitute personal data as it may be possible to identify participants. Full-resolution, full-face, or torso video data are required to develop Lifelight Junior into a clinically useful device; the analysis cannot be performed using blurred videos. The data collected for research purposes only (not clinical care) are processed within the legitimate interests of Xim Ltd.

Data Handling

Analysis of the videos uses the encrypted files, which, in most cases, are processed automatically within a secure cloud infrastructure (ie, without any person viewing the videos); in rare cases, it may be necessary to analyze a video manually if the recording is not as expected. The analysis results in anonymized aggregate datasets. No decrypted files are stored at any point in the processing. The electronic case report forms are stored and managed using the Castor electronic cloud.

Performance Targets

While Lifelight is certified as a class I CE medical device [18], the performance of Lifelight Junior needs to be appropriate for routine clinical practice in pediatric patients. Table 2 lists the performance targets for Lifelight Junior for measuring VS in pediatric patients; training data collected during VISION-Junior will support progress toward these targets.

Table 2. Performance targets in VISION-Junior.

Vital sign	Performance target	Reference
Pulse rate	Root mean square error ≤5 beats per minute	[25]
Respiratory rate	Maximum error of 5 breaths per minute for 100% of measurements	Minimum standard met by all approved respiratory monitors
Oxygen saturation	Maximum error tolerance 4%	[26]

Sample Size

An estimated 500 pediatric patients (18 years old or younger) will be recruited into the study. This sample size is informed by the previous VISION-D, VISION-MD, and VISION-Acute studies [17,21]. However, the sample size cannot be formally calculated because it depends on the incremental improvement in the performance of the app achieved through machine learning using the training data generated early in the study. The split between training and testing data will be determined during the study according to the quality of the data collected. The study management team monitors the progress of data collection and accuracy and updates the study teams weekly. The study will continue until the accuracy of the app for measuring VS in pediatric patients is sufficient for various clinical use cases.

In addition, recruitment targets according to age, sex, Fitzpatrick skin tone, and medical history have been defined, as shown in Table 3, to ensure accuracy in a broad range of clinically relevant patients.

Table 3. Demographic and medical history recruitment targets.

	Targets
Age	≥12% aged 0-1, 1-2, 2-5, 5-11, 11-14, 14-18 years
Sex	≥40% male; ≥40% female
Skin tone	15% of participants will have Fitzpatrick skin tones 4, 5, or 6 (this is not a hard target as achieving this figure depends on the demographic diversity of the study region)
Medical history	≥40% in each of the following categories: • Febrile (≥38 °C) • Afebrile • Ill (as judged by the clinical staff); to ensure a spread of conditions, no more than 50% of recruited patients will have an acute respiratory illness (eg, bronchiolitis, asthma, virus-induced wheeze, pneumonia, and croup) • Well, including pediatric patients with a minor injury

Data Analysis

All statistical analyses will be performed using Python (Python Software Foundation). Training data will be used for machine learning to improve the performance of Lifelight Junior for measuring VS in pediatric patients. Appropriate machine learning models will be developed according to the data collected. This is likely to include signal processing and measurement algorithms for PR and RR, and multilayer neural network-based approaches for BP, similar to those used in the adult version of the app.

The separate set of test data will subsequently be used to determine the performance of the app for measuring VS in pediatric patients. Correspondence between VS measurements predicted by the app and the measurements taken manually using SOC methods will be compared using regression coefficients, mean error, and SD, and compared against the

performance targets set out in Table 2. An accuracy target will be considered met if the mean error and SD for the app measurements are at least equal to the target (Table 2). Heat maps or scatter plots will also be developed.

Linear regression will be used to assess the impact of skin tone on the accuracy of the app for measuring each VS, using the Fitzpatrick skin tones as the explanatory variable.

Quantitative data from the questionnaires will be summarized. Thematic analysis will be used to analyze free-text responses to identify perceptions of the app and variations in the way patients, their parents or carers, and health care professionals interact with it and any challenges they encounter.

All analyses will be completed per protocol since there is no intention to treat. There will be no imputation of missing or implausible data, and any missing, implausible, or problematic readings will be excluded from analysis.

Results

The study started on June 12, 2023, and as of December 20, 2023, had recruited 303 participants. The study was extended until the end of March 2024 to enable the target recruitment (500) to be met; 532 participants had been recruited as of April 5, 2024.

Data are currently being used for machine learning to refine the algorithms to improve clinical accuracy. We anticipate that final analyses to determine the performance of the app against the targets set out in Table 2 will be complete by mid-August 2024. The performance of the app will be determined across the range of VS values encountered in children in clinical practice by comparing the VS values recorded using PPG versus standard methods.

Discussion

Principal Findings

This paper reports the protocol for obtaining data to develop algorithms for the measurement of VS in children using the app, and to evaluate the performance of the app against SOC measurement of VS in pediatric patients of all ages.

Monitoring of VS in children is challenging because existing methods (eg, BP measurement via an arterial line or cuff; PR and RR via electrodes, adhesive pulse oximeters, and adhesive temperature probes and thermometers) are either invasive or contact-based and can cause discomfort, pain or distress, may disturb sleep, and may damage paper-thin skin, potentially increasing the risk of infection. Frequent VS measurement using different techniques is also resource-intensive. The app being developed will provide contactless noninvasive measurement of VS.

Data collected in this and other studies will be used to train algorithms to develop the app for the measurement of VS in pediatric patients. The app aims to provide a risk-measured way for nonexperts to measure VS quickly and nonintrusively, and therefore, detect any early signs of deteriorating health or infection. This will make it easier for clinically vulnerable or immunocompromised children to attend school and interact with their peer groups, meeting their mental, physical, social, and educational needs, whilst providing reassurance to parents, guardians, or carers. Early detection of infection before any significant clinical deterioration occurs means that treatment can start sooner, improving the likelihood of a full recovery [27] whilst also potentially avoiding hospital admission and intensive care, which are expensive for the child's family (lost income, expenses) and health care providers. Lifelight can also be an effective tool for at-home monitoring and triage, reducing the burden on carers, emergency services, and hospitals. It may also be useful in nonspecialist health care settings such as primary care and prehospital care where specialist pediatric equipment is not available. Several other devices for the measurement of VS are currently being developed but all require physical contact, whether through a finger, the wrist, or the chest, and only one (Biospectral) is able to measure BP.

Limitations

This research may have some limitations. BP is inherently more complex to measure than PR and RR, in terms of the data form and machine learning and because reference measurements are less accurate. As with any recording device, signal quality may be compromised if the participant moves excessively or if light levels are insufficient. However, we expect the use of high-resolution video recording to overcome such issues. In addition, measurements can be easily repeated if a recording is of poor quality.

Skin type is a potential source of error with PPG devices, as melanin absorbs green light, potentially increasing errors in measurements in dark-compared with light-skinned individuals [24]. However, we have already shown that skin type does not affect the accuracy of Lifelight [17]. Although the Fitzpatrick Skin Type Scale is the current gold standard [24], its use has been criticized because of racial bias, weak correlation with skin color, and broad within-group variations in skin tone. Spectrocolorimetry, which uses multiple variables to categorize skin tone objectively, has been proposed as an alternative [24], which may be incorporated into later studies to confirm our findings.

Conclusions

The results of this study will be disseminated via submissions to relevant journals and conferences. The study team will explore different avenues and formats for the dissemination of the study findings with the Young People Advisory Groups and other groups to ensure a wide public audience, for example, through coproduced public talks, studies in community communications, and social media.

Acknowledgments

Study activities conducted at the South Tyneside and Sunderland National Health Service Foundation Trust are funded by an Invention for Innovation (i4i) Connect award, awarded to Xim Limited by the National Institute for Health and Care Research (NIHR204468). The authors would like to thank Kirsty Parker of Xim Ltd for helping to set up the study, Prof Alison McConnell for advice on child physiology, Lieke van Putten for data analysis, and Helen Barham (The Text Doctor) for writing support (funded by Xim).

Data Availability

The datasets generated or analyzed during this study are not publicly available due to their commercially sensitive nature, as mandated by Xim Limited's grant funders and investors, but are available from the corresponding author upon reasonable request.

Authors' Contributions

The VISION-Junior protocol and patient-facing documents were developed by NM, LF, GS, MK, GM, JF, JH, and IM and informed by the Young Persons advisory group North East (YPAGne) and the South Tyneside and Sunderland National Health Service Foundation Trust Patient and Public Involvement group. Statistical methods were developed by MK.

Conflicts of Interest

MK and GM are employees of Mind over Matter Medtech, which provides contracted services to Xim Limited, including grant bid writing, clinical trial design and management, health economic analysis, and regulatory submission support. However, the company has never contributed directly to the technical design or development of Lifelight and has not received benefits from Xim Limited other than financial payment for contracted work. SW and JF are employed by Xim Limited, the manufacturer of the technology. IM and JH have received compensation from the manufacturer for advisory services and have no conflicts of interest. NM, LF, and GS were responsible for facilitating the study and have no conflicts of interest.

Abstract

Background: Comprehensive and formalized digital health care ecosystems in health sciences tertiary education in South Africa do not currently exist, but they have the potential to influence teaching and learning, research, and community engagement.

Objective: A total of 3 key objectives underpin the study, that is, determining the health care curriculum needs and required content for the development of a formalized digital health ecosystem, determining the level of readiness of staff and students to participate in a digital health care ecosystem, and determining whether community engagement and strategic partnerships can contribute to the sustainability of a digital health care ecosystem.

Methods: A multipronged approach will be used to address the objectives, with a mixed methods design being undertaken. The qualitative phases will be phenomenological in nature, and triangulation of information along with thematic analysis will be conducted on the collected data. Quantitative data will be collected prospectively and cross-sectionally and analyzed using descriptive analysis. Sampling will include subject experts for the Delphi technique, staff and students at the University, clinical training and education partners, and community leaders. This study has received ethical approval from the Sefako Makgatho Health Sciences University Research and Ethics Committee (SMUREC/H/260/2023:PG).

Results: Data collection for the first phase will begin in January 2024 and conclude in December 2024. Phase 2 and 3 of the study will be conducted concurrently, with data collection starting in January 2025 and concluding in December 2026.

Conclusions: The establishment of a digital health care ecosystem has the potential to benefit staff, students, and communities through stakeholder collaboration, educational opportunities, research projects, and improved service delivery.

KEYWORDS

health sciences; digital ecosystem; curriculum; community engagement; tertiary education institutions

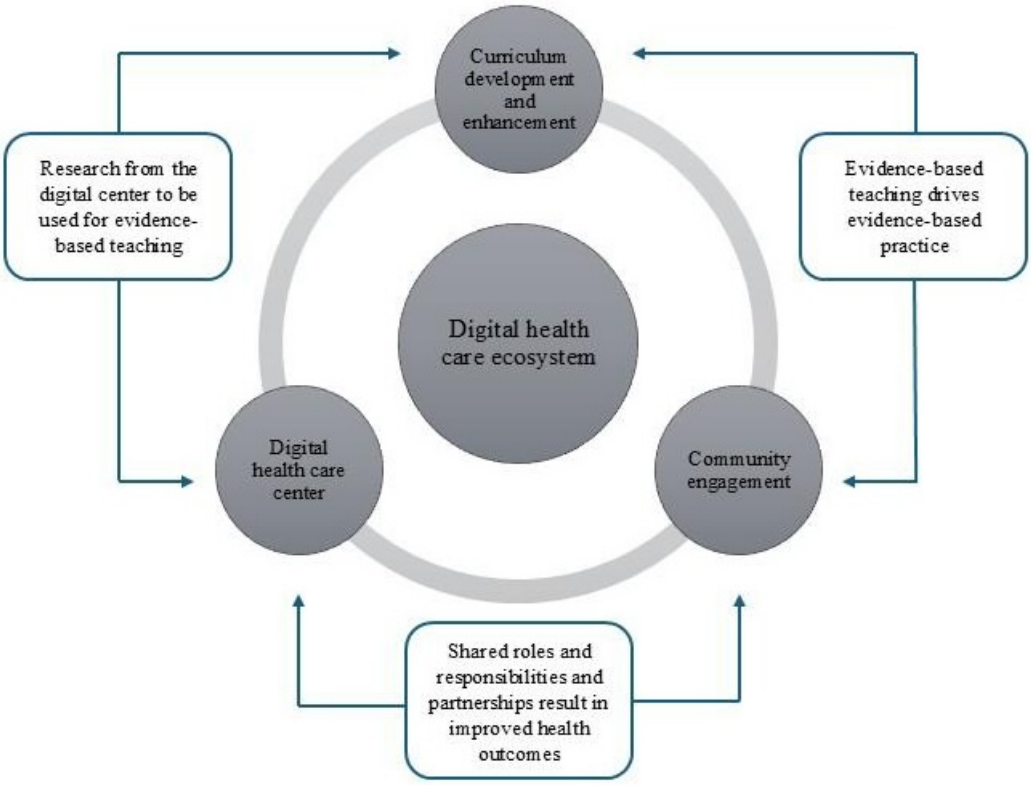
Introduction

Digital health care ecosystems are described as patient-centric models of health care delivery with the aim of encouraging collaborative, cross-organizational health care processes through technology-driven platforms [1]. The use of telecommunications and digital technologies to provide health care, monitor public health, and develop new and improved methods of delivering awareness programs is referred to as digital health care [2]. According to the World Health Organization (WHO) [2], "digital health" is a global term that encompasses concepts such as electronic health, telehealth, wearable devices, mobile health, and new developments in the field of artificial intelligence to support public health systems. The definition also includes the use of electronic patient and medical record keeping.

The benefits of digital health care are extensive, including serving populations in rural and remote areas with interventional and preventative care [3], the collation and pooling of medical data, and the organized and confidential management of patient records [2]. However, despite these benefits, there is evidence to suggest that health care professionals (HCPs) are inadequately trained to effectively use technology within the health care space [4-6]. This issue is especially true in the African context [7]. Despite Africa accounting for 23% of the global burden of disease, the continent has not optimized digital health care technologies to address challenges in health care service delivery [7]. South Africa has been passive in its efforts to ensure that HCPs are adequately trained. The COVID-19 pandemic highlighted the lack of preparedness in digital health care, which has been attributed to insufficient exposure to digital health care training during the tertiary education training of HCPs [8,9]. This is important because the lack of digital health care competencies and skills could pose significant challenges to the health care industry. Potential challenges that may arise from a lack of digital health care skills include reduced efficiency [10], ineffective use of digital health care tools [11], reduced patient satisfaction due to low HCP confidence [12], increased risk of errors [13], and lack of globally relevant skills [7].

Challenges faced by the health care system and universities during the pandemic were threefold [8,14,15]. First, staff and students were not well trained or competent in providing digital health care to patients. Second, some universities were not well invested in digital health care infrastructure. Third, the acceptance of communities to receive care via digital technologies was uncertain, considering the lack of consultation and stakeholder engagement [8,14,15]. It becomes apparent that countries, through their health care systems and tertiary training institutions, need to do the following three things: First, create, construct, and integrate curricula that align with the needs of a new era of HCPs. Second, provide the necessary infrastructure to allow student learning and clinical training opportunities within the digital health care space. Finally, to actively engage with communities to ensure their integration, involvement, and acceptance of digital health care services. The combination of these 3 elements creates what is referred to as a digital health care ecosystem [16]. Therefore, the objectives of the study were threefold: first, determining the health care curriculum needs and required content for the development of a formalized digital health ecosystem; second, determining the level of readiness of staff and students to participate in a digital health care ecosystem; and third, determining whether community engagement and strategic partnerships can contribute to the sustainability of a digital health care ecosystem. Figure 1 illustrates the envisaged digital health care ecosystem (Figure 1).

Figure 1. Digital health care ecosystem.



Methods

Study Design

A multiphase study, consisting of a mixed methods approach (ie, qualitative and quantitative designs) will be undertaken. The quantitative phases of the study will follow a prospective, cross-sectional design [17], while the qualitative phases will be phenomenological in nature, aiming to explore the experiences of participants [18]. The methodology for each of the 3 phases will be presented separately.

Phase 1: Developing and Obtaining Accreditation for a Digital Health Care Curriculum

During phase 1 of the study, the researchers aim to address 3 subobjectives to meet the main objective of this phase. The 3 subobjectives will be discussed separately, as their design and data collection procedures differ (Textbox 1).

Textbox 1. Curriculum development.

Subobjective 1

Determining digital health care content and gaps in the current curriculum using gap identification frameworks when reviewing and analyzing curricula within a Health Care Sciences School.

- **Study design:** A quantitative, retrospective document review will be undertaken.
- **Sample:** A total of 6 published curricula from the Departments of Physiotherapy, Occupational Therapy, Human Nutrition and Dietetics, Nursing Sciences, and Speech-Language Pathology and Audiology will be included for review. Curricula from other departments or those that have not been published will be excluded from the review.
- **Data collection:** Each curriculum will be reviewed by the research team using the READ approach. The competencies, skills, and attitudes questionnaire [19] will be used to capture the data. Descriptive statistics will be applied to analyze the data.

Subobjective 2

Investigating the knowledge, skills, attitudes, and graduate attributes to be included in a digital health curriculum for students in a Health Care Sciences School.

- **Study design:** A prospective Delphi technique [19] will be undertaken.
- **Sample:** Potential participants for the Delphi expert panel will be identified through author and reference lists that will be compiled from a literature review, as well as referrals from academic directors and members of the academic community. To ensure diversity and representativeness in the participant group, a purposive sampling method will be used. Expert panel members will be considered for inclusion if they have published at least 2 or more papers or book chapters on digital health care, and if they are health care professionals. Experts with competing interests (such as digital health care company owners) will be excluded from participation.
- **Data collection:** Experts in digital health care (both national and international) who meet the eligibility criteria will be invited to participate in the study. Email invitations will be sent to all identified experts to participate in the Delphi study. Once consent is obtained, the first round of the survey will be sent via a Google link. Participants will have the option to add additional topics not included in the first-round survey, which will be added in the second round. After the first round, participants will be provided with the average ratings for each topic from the previous round. The second and third rounds will involve rating, scoring, and reaching a consensus on the survey items. An 80% agreement will be considered as consensus.

Subobjective 3

Developing a digital health care curriculum for a Health Care Sciences School in terms of module outcomes, content, teaching strategies, assessment outcomes, and submitting for evaluation and accreditation.

- **Study design:** An action-based approach to curriculum development will be undertaken [20].
- **Sample:** Task-team members, consisting of the researchers participating in the study will be included.
- **Data collection:** Information collected from the document review and the Delphi technique will be combined to establish the syllabus. A curriculum matrix will be developed based on the syllabus and will be populated with learning outcomes, assessment criteria, and assessment methods. The curriculum will be developed in accordance with the guidelines of the Health Professions Council of South Africa and the Council of Higher Education (South Africa). Once the curriculum is approved, it will be implemented. After six months of implementation, it will be assessed and changes will be made as needed.

Phase 2: Developing a Teaching, Learning, Clinical, and Research Center Situated Within a Health Care Sciences School

The second phase of the study aims to address 2 subobjectives in order to achieve the main objective for the phase (Textbox 2).

Textbox 2. Establishing a digital health care center.

Subobjective 1

Conducting a readiness and needs analysis among staff and health care professionals regarding digital health care training needs.

- **Study design:** A quantitative, prospective survey design will be undertaken.
- **Sample:** All staff members associated with a Health Care Sciences School at a selected university will be included. Staff members will be selected for participation if they are part-time or full-time academic staff in the following departments: Physiotherapy, Occupational Therapy, Human Nutrition and Dietetics, Nursing Sciences, and Speech-Language Pathology and Audiology. To ensure a 50% distribution with a 5% margin of error and a 95% CI, 184 participants are required. All staff members in the School of Health Care Sciences will be targeted for inclusion to account for noncompletion of surveys and attrition during the study.
- **Data collection:** After obtaining permission from the Dean, an email with information and consent forms will be sent to all relevant staff members in the school. The questionnaire will be adapted from Bingham et al [21]. The link to the questionnaire will be emailed to all academic staff members. Once a questionnaire has been completed, access to the questionnaire will be terminated to prevent multiple submissions from the same participant. Descriptive analysis will be conducted on the collected data.

Subobjective 2

Developing a care services plan for the digital health care center and reviewing and consulting on existing technology and business plans to develop and validate the proof of concept for the establishment of a digital health care ecosystem.

- **Study design:** A qualitative explorative design will be undertaken.
- **Sample:** Snowball sampling will be conducted with at least 6 academic staff members from each department (refer to subobjective 1 for the list of departments), and data collection will cease once saturation is reached. Academic staff members with experience in clinical planning and involvement in health services programs will be included.
- **Data collection:** Staff members will be invited to participate in focus group interviews after obtaining permission from the Dean. A focus group interview schedule with open-ended questions will be used. The interviews will be voice-recorded and transcribed verbatim. Thematic analysis will be conducted using Tesch's eight-step model [22].

Phase 3: Evaluation of the Impact of Community Engagement in the Design, Establishment, Content, and Delivery of Digital Health Promotion Projects Offered Through the Digital Health Care Ecosystem

The third and final phase of the study is divided into 2 subobjectives (Textbox 3).

Textbox 3. Community engagement.

Subobjective 1

Evaluating the health needs of the local community.

- **Study design:** A cross-sectional, descriptive survey design will be undertaken.
- **Sample:** All relevant community stakeholders, including medical doctors, traditional healers, community leaders, and community health workers, will be considered for inclusion in the study. Purposive and network sampling will be used to identify as many relevant parties as possible for inclusion in the study. All community stakeholders, who have resided in the community surrounding the institution where the study will be conducted for at least 2 years, will be included. Community stakeholders with a conflict of interest (such as financial interests in the project) will be excluded from participation.
- **Data collection:** Known community stakeholders will be recruited for participation, and network sampling will be used to identify as many stakeholders as possible. Questionnaires will be circulated electronically to all participants. The questionnaires will be an adapted version of the Cooper University Health Care Health Assessment Survey [23]. Once a questionnaire is completed, access will be terminated to prevent multiple submissions. Descriptive analysis will be conducted on the collected data.

Subobjective 2

Exploring digital health care attitudes and service suggestions of shared roles and responsibilities of community members that can be implemented through digital health care in the specific community.

- **Study design:** A qualitative explorative design will be undertaken.
- **Sample:** All relevant community stakeholders (as given in subobjective 1) will be considered for participation. Purposive and network sampling will be used to identify as many relevant parties as possible for inclusion in the study. Data collection will cease once saturation is reached.
- **Data collection:** Community stakeholders will be invited to participate in focus group interviews, using a schedule with open-ended questions. The interviews will be recorded and transcribed verbatim. Thematic analysis will be conducted following Tesch's eight-step model [22].

Recruitment

The population from the institution and its surrounding areas will be recruited for the study. Staff and students from the health sciences institution will be recruited from the following departments: Departments of Physiotherapy, Occupational Therapy, Dietetics and Human Nutrition, Public Health, Nursing Sciences, and Speech and Language Pathology and Audiology. The student population will consist of undergraduate students who are enrolled at the Health Sciences institution. All part-time and full-time staff members employed at the institution, who do not have a financial interest in participating, will be included in the study. Community stakeholders recruited for the study will be restricted to a 30-kilometer radius from the institution. Recruitment will be conducted through email communication, flyer distribution within the institution and surrounding community, and word of mouth.

Statistical Analysis

Due to the vast nature of the study, statistical analysis will vary for each subobjective. Quantitative data will be analyzed using SPSS (version 27; IBM Corp) software, while qualitative data will be analyzed using NVivo (Lumivero). To ensure optimal analysis of the qualitative data, Tesch's eight-step method of data analysis will be conducted before uploading the data into NVivo. Data will be prepared by transcribing all interviews verbatim. Coding will be conducted on data segments that share similar themes. Thereafter, categories and coding schemes will be developed based on the identified themes from a sample of the text. The coding scheme will first be tested on a relatively small sample to ensure that the scheme is applicable before being applied to the entire dataset. A researcher, who will not be involved in the initial development of the coding scheme, will assess coding consistency, after which conclusions will be drawn from the coded data [22].

Data Exclusion

For all quantitative phases of the study, data will be excluded from analysis if the dataset is incomplete (ie, if questionnaires are not fully completed). Data from all phases of the study will also be excluded if participants withdraw voluntary informed consent.

Validity and Reliability

The questionnaires that will be used in this study are adapted from previously developed and tested questionnaires, with additional questions drawn from the literature [19,21,23]. The content validity of the questionnaires will be conducted to ensure that the questionnaires have a fair representation of the constructs to be measured. Construct validity will be ensured by providing evidence that the theoretical structure of the questionnaire is relevant. Face validity will ensure that the questionnaire is transparent and relevant, as it appears to elicit information from the participants. A pilot study will be conducted with the aim of ensuring that the data collection tools are reliable. Construct and face validity will be determined by asking 10 health care professionals from different institutions across the country to provide feedback to the researchers. Health care professionals will be identified through purposive sampling to ensure that they have the necessary expertise regarding digital health care. Reliability will be determined by assessing whether the questionnaires answer the stated research questions, whether the questions are clear and unambiguous, and whether the language and terminology used are easy to understand. Following the pilot study, the questionnaires will be revised if needed.

Trustworthiness

Credibility will be ensured by building rapport and trust with the participants. The participants will be engaged in interviews to gain insights and understand their views. The researchers will ensure that honesty is maintained by giving information regarding the study to the participants. Dependability will be ensured by making the voice recorder and transcripts available to an external auditor for verification. Conformability and credibility will be ensured by conducting interviews until saturation is reached. Transferability is the ability to transfer research findings from one context to another [24]. The researchers will provide a thorough description of the research methods and setting in the research publications or any form of dissemination so that the applicability of the data to another context can be evaluated.

Ethical Considerations

As human participants will be used during the course of the study, ethical approval for the conduction of the study was obtained from the Sefako Makgatho Health Sciences University Research and Ethics Committee (SMUREC/H/260/2023:PG). Participants in all phases of the study will be provided with information pertaining to the phase that they are participating in, before being asked to sign a voluntary informed consent. Participants hold the right to withdraw from the study without providing reasons, and without prejudice. All data collected will be anonymized to ensure participants' privacy, and data will be stored in an encrypted electronic folder accessible only to the researchers. During the dissemination of results, the researchers will ensure that no identifying information is published. Participants in the study, regardless of the phase, will not receive remuneration for their participation. The research will be conducted in line with the regulations set forth by the Declaration of Helsinki.

Results

Phase 1 of the study will be conducted from January to December 2024. The second and third phases will be conducted concurrently, from January 2025 to December 2026. A detailed schedule of the study is provided in Table 1 below.

Table 1. Projected time frames of the study.

Phase	Subobjective	Timeline
1	To determine digital health care content and gaps in the current curriculum by applying the gap identification framework when reviewing and analyzing curricula within a Health Care Sciences School.	January-June 2024 (completed)
1	To investigate which knowledge, skills, attitudes, and graduate attributes should be included in a digital health curriculum for students in a Health Care Sciences School.	April-October 2024 (completed)
1	To develop a digital health care curriculum for a Health Care Sciences School, in terms of module outcomes, content, teaching strategies and assessment outcomes, and submit it for evaluation and accreditation.	October-December 2024 (completed
2	To conduct a readiness and needs analysis among staff and health care professionals regarding digital health care training needs.	January-April 2025
2	To develop a care services plan for the digital health care center and to review and consult on existing technology and business plans to develop and validate proof of concept for the establishment of a digital health care center within a Health Sciences School.	May-December 2025
3	To evaluate the health needs of the local community.	January-June 2025
3	To explore digital health care attitudes and service suggestions, as well as shared roles and responsibilities of community members that can be implemented through digital health care in the specific community.	July-October 2026
4	Final write-up of all information collected in the study	October-December 2026

Discussion

Principal Findings

The establishment of digital health care ecosystems in tertiary institutions has the potential to have a significant positive influence on health care delivery in a country [2-6]. To successfully establish a digital health care ecosystem, it is essential to develop relevant curricula. Curricula represent an institution's vision and mission and are expected to be contextually relevant and globally responsive to the diverse needs of communities [25]. A digital health care curriculum will ensure the long-term viability of such ecosystems, and studies have shown that both academics and students agree that the integration of digital health ecosystems is long overdue [26,27]. The proposed changes to the curricula will inevitably alter clinical training opportunities for students to ensure the development of digital health care competence.

The introduction of clinical digital health care training into formal education allows students to participate in areas such as interprofessional education, offering care to rural and remote areas (including exposure to international contexts), as well as improving their digital literacy and awareness of trends within the Fourth Industrial Revolution [8,28,29]. Literature indicates that the theoretical and practical components are connected and their combination ensures that students acquire not only the knowledge but also the clinical skills, competencies, attitudes, and important graduate attributes to provide excellent patient care [30,31].

In the development of digital health care curricula and clinical training, partnerships with community stakeholders are important to ensure that the integration of technology will empower community members [32]. Communities must be involved in the conceptualization, technology innovation, development, implementation, and monitoring of the health care system to ensure health care democracy and sustainability [32,33]. Well-structured community engagement has the potential to minimize the gap between research and policy by ensuring support from key stakeholders [34]. In addition, community involvement is an essential aspect of good health governance [35].

Due to the geographical limitations of the study (ie, recruitment of participants from a 30 km radius of the institution where the study will be conducted), the results that are obtained from the study may not translate to other health care institutions. However, the principles followed in the design and establishment of the digital health care ecosystem may be universally applicable.

Conclusions

The establishment of a comprehensive digital health care ecosystem will be used for providing digital health care knowledge, conducting clinical training with students using a variety of digital health care approaches and technology, and conducting research into digital health care. The center aims to encourage stakeholder collaboration, provide educational opportunities, stimulate research, and provide service delivery using digital health care services. Important activities, such as interprofessional collaboration and community engagement, will be facilitated through the establishment of a digital health care ecosystem. The center would offer multidisciplinary and transdisciplinary health care services to multiple rural and remote contexts, including schools, old age homes, hospitals, and homes.

Data Availability

Datasets generated or analyzed during the study are available from the corresponding author on reasonable request.

Abstract

Background: Glaucoma, a disease leading to the degeneration of retinal ganglion cells, results in changes to the optic nerve head that are often diagnosed late when visual problems arise. With the prevalence of glaucoma surpassing 76 million adults worldwide and with glaucoma being the leading cause of irreversible blindness in the world, the early detection and management of glaucoma is imperative. Digital ophthalmoscopes, such as the D-EYE (D-EYE, Srl), have emerged as a technology that uses smartphone cameras with an attachment on the lens to visualize the retina and optic nerve head without the need for dilation. The purpose of this pilot study is to examine the acceptability and feasibility of a D-EYE digital ophthalmoscope to screen for ocular pathology involving the optic nerve, particularly glaucoma.

Objective: This study aimed to demonstrate the effect of a smartphone-based ophthalmoscope as a potential vision screening tool for optic nerve head pathology in participants enrolled in this study. The first specific aim was to determine the ability of the D-EYE smartphone ophthalmoscope to gather high-quality imaging to be used for grading the fundus into low- and high-risk categories for eye pathology. The second specific aim was to determine the difference in the quality of data capture between still retinal images and 30-second retinal video recordings produced by D-EYE smartphone ophthalmoscopes.

Methods: This observational pilot study enrolled 110 patients receiving routine eye care at the University of Florida Health from February 2019 to February 2022 to assess the use of the D-EYE device in capturing still images and 30-second videos of the bilateral retina and optic nerves of each participant. Study participants completed a survey to gather demographics and past medical history data with a particular focus on previous eye health history. Images were reviewed by 5 ophthalmology residents with interrater reliability analysis performed to assess findings.

Results: Ophthalmology resident review indicated greater visualizability and clarity of the bilateral retina and optic nerves with 30-second videos of retinal imaging compared with still-image ophthalmic capture. Furthermore, an increase in visualizability and clarity allowed for a more accurate measurement of the cup-to-disc ratio, a diagnostic marker for glaucoma. In addition, the likelihood of referral of the glaucomatous and healthy sample groups to ophthalmologists indicated a greater sensitivity of digital ophthalmoscopes in being able to detect retinal abnormalities requiring early intervention and management, supporting the technology's use as a screening tool.

Conclusions: This investigation suggests that the use of smartphone-based digital ophthalmoscopes can be more effectively applied as a screening tool by capturing 30-second videos compared with still images alone. This novel assessment of an emerging technology in the field of ophthalmology may better equip further research as smartphone camera technology advances.

Introduction

Vision Screening and Digital Ophthalmoscopes

Vision screening is a valuable component of health maintenance as loss of vision may lead to severe impairment in everyday tasks, such as driving, ambulating, reading, and social participation [1,2]. Glaucoma, the second leading cause of permanent blindness in the United States, is the acquired loss of retinal ganglion cells within the optic nerve, resulting in the progressive loss of peripheral vision [3,4]. The 2 most common types of glaucoma in the United States are primary open-angle glaucoma and primary angle-closure glaucoma, with most patients presenting asymptomatically until the optic nerve damage is severe enough [5]. It was estimated that by the year 2020, over 3 million adults would have glaucoma in the United States with nearly half not knowing that they have the disease [6].

Existing methods of screening for glaucoma involve comprehensive eye examinations performed by ophthalmologists. Often, patients who are at a higher risk for eye pathologies, such as glaucoma, do not participate in such screening efforts, and even when diagnosed, do not attend follow-up visits for complete eye examinations to monitor the progression of the disease. This is especially true for patients in low-income socioeconomic demographics. A study examining poor longitudinal glaucoma follow-up in India found that, adjusting for age and sex, independent predictors of poor follow-up included lack of formal education, lack of escort, and belief that follow-up is less important if one has no noticeable visual changes [7]. In addition, studies at a tertiary hospital eye department found various social and demographic factors contributing to poor adherence to follow-up, as patients who are African American or Latino, or who live far from their eye care provider are at a greater risk of nonadherence to follow-up appointments [8]. Studies performed in 3 major hospital departments found that patients presenting with advanced glaucoma are more likely to come from an underprivileged area and be of lower occupational class, to have no access to transportation, and to have a lower education level [9]. Factors such as income, education, ethnicity, and lack of transportation suggest an association between low socioeconomic status and prevalence of eye disease as well as lack of follow-up for eye health appointments.

With vision loss from glaucoma being irreversible and there existing a multitude of barriers to follow-up, early detection and management of the disease is imperative and solidifies a need for easily accessible, highly sensitive diagnostic technology. In a study assessing the comparison of smartphone ophthalmoscopy with slit-lamp biomicroscopy for grading vertical cup-to-disc (CtD) ratio (VCDR) on 110 patients, smartphone ophthalmoscopy showed substantial agreement with slit-lamp examination for the estimation of the VCDR [10]. This success in the estimation of VCDR can be used for glaucoma screening in low-resource environments. When compared with the use of a traditional direct ophthalmoscope, a 2018 Nature publication found that smartphone ophthalmoscopy produced more accurate clinical descriptions of findings in a fundal examination than direct ophthalmoscopy [11]. In addition, the study suggested that the use of a smartphone-based alternative to the direct ophthalmoscope may improve the accuracy and quality of fundal examinations by nonophthalmologists [11]. Implementation of smartphone ophthalmoscope technology may potentially be an effective way to screen patients for diseases of the eye within primary care clinics. Such an intervention would address the loss of follow-up to specialty ophthalmology clinics for complete ophthalmologic examinations in low socioeconomic status patients with eye disease. Early intervention may allow for the timely, evidence-based management of eye disease and prevent late-stage morbidities such as progressive loss of vision and permanent blindness.

Specific Aims

This study aimed to demonstrate the effect of a smartphone-based ophthalmoscope as a potential vision screening tool for optic nerve head pathology, particularly glaucoma, in participants enrolled in this study.

- Specific aim 1: to determine the ability of the D-EYE (D-EYE, Srl) smartphone ophthalmoscope to gather high-quality imaging to be used for grading the fundus into low- and high-risk categories for eye pathology
- Specific aim 2: to determine the difference in quality of data capture between still retinal images and 30-second retinal video recordings produced by D-EYE smartphone ophthalmoscopes.

Methods

Participants

This pilot study will use an observational research design to assess the ability of the D-EYE to capture high-quality imaging that can be interpreted by ophthalmologists. Furthermore, the study will investigate the difference in quality of imaging between still images and 30-second videos of the retina for clinical use based on ophthalmology resident feedback. Trained research assistants who are familiar with the protocol for recruitment and eligibility to participate in this study will recruit patients in coordination with medical staff at their respective clinical sites.

The sample population will consist of 110 adults between the ages of 18 and 99 years (N=110). University of Florida (UF) Health Eye Center is the designated site where this study will be conducted.

Criteria to participate in this study include being a patient currently seen at the UF Health Eye Clinic and being between the ages of 18 and 99 years. The study will exclude patients matching the criteria such as loss of vision, blind patients, patients who require urgent procedures or are otherwise deemed unstable by medical staff, and patients with photosensitivity that prevents prolonged exposure to bright lights.

Participant data will be blinded from resident graders for review, and their existing medical records will provide a reference to determine the accuracy of interpretation from the ophthalmologist's review and offer insight as to the quality of imaging and preferred modality based on the reported interpretability and accuracy of the 5 resident reviewers.

Recruitment

Participants will be recruited in the study under the title, "The Utility of a Smartphone-Based Retinal Imaging Device as a Screening Tool in an Outpatient Clinic Settings." After identifying eligible participants for this study, trained research assistants will approach and recruit them. If these eligible participants are interested, a trained study member will review and obtain consent directly from the participant. A standardized informed consent script will be adhered to ensure consistency in the consenting process. Participants will receive a copy of the informed consent document.

Procedure

Research assistants, working in coordination with medical staff, will identify and determine the eligibility of patients entering the UF Health Eye Center for medical care. Consent will be obtained directly from the participants.

Before collecting the retinal imaging data, participants will complete a survey that provides pertinent demographic data, past medical history, and ophthalmology-specific questions regarding whether or not they have a diagnosed eye condition. After completion by the study participants, the paper files will be stored in a secured holding unit in accordance with the UF Institutional Review Board's guidelines.

Next, participants will have their retinal imaging collected by trained research assistants using the D-EYE. The D-EYE is a US Food and Drug Administration (FDA)–approved smartphone ophthalmoscope that was used over the course of this study. It is capable of gathering high-quality images and videos of the retina. The eye exam will occur in a low-lit room. Bilateral eyes will be examined by the D-EYE for 25-35 seconds. This footage will then be temporarily stored in the D-EYE encrypted app, along with the patient's medical record number and the patient's known eye pathologies (if any). The smartphone camera attachment is compatible with the D-EYE app, a Health Insurance Portability and Accountability Act (HIPAA)–compliant smartphone app. From the D-EYE app, the images collected (both still images and 30-second videos) can be uploaded to a UF-affiliated, secured Dropbox (Dropbox Inc.) that has been approved for data storage. The D-EYE smartphone app requires either a 4-digit password login, fingerprint scan, or face ID to access. Video and image recordings will not be stored on the device capturing the images but will be housed on the HIPAA-compliant UF Dropbox account.

The UF Dropbox cloud-hosting service will only be accessible to study personnel and resident ophthalmologists who are required to view the retinal imaging. Access to the UF Dropbox requires logging into the UF Health VPN and accessing the site through a password combination containing uppercase letters, lowercase letters, numbers, and punctuation marks.

The footage taken by the D-EYE will be reported to UF Ophthalmology residents through Dropbox. Five residents will then grade each fundus image based on (1) the clarity of the footage on a scale of 1-10 (still image vs 30-second videos), (2) whether the residents would refer the participant to an ophthalmologist for eye care, (3) whether to categorize the sample into the "healthy" or "unhealthy or needs care" category, and (4) if there are any optic neuropathies (glaucoma) present, stratifying the findings as either low, moderate, or high risk. Their responses will be cross-referenced with the patient's known eye history and the responses will be categorized as either hits, type I misses (resident lists as unhealthy but history suggests the eye is healthy), or type II misses (resident lists healthy but history suggests the eye is unhealthy).

Outcomes Measures

Certain listed measures will be collected for all participants. All data will be stored through a secured, university-affiliated Dropbox account approved by the Institutional Review Board, a HIPAA-compliant and university-supported app used for data capture and storage.

Primary Outcomes

Image Quality

The clarity of both the still images and 30-second videos will be rated on a scale of 1-10. Accuracy in determining CtD measurement will be assessed between the still imaging and 30-second videos with a determination of any differences in quality and measurements of data between the still images and 30-second videos.

Categorization

Based on the imaging results, the ability of residents to categorize participants' retinal imaging into either broad "healthy" or "unhealthy or needs care" groups.

Likelihood for Referral

Based on the imaging results, the residents will assess whether or not they would refer participants to an ophthalmologist for further specialized eye care.

Stratification

If there are any detectable optic neuropathies present, they will be stratified into either low-, moderate-, or high-risk groups based on the extent of the disease.

Secondary Outcomes

Interpretability

Assessment of eye health will be grouped into either hits, type I misses (resident lists findings as unhealthy but history suggests the eye is healthy), or type II misses (resident lists findings as healthy but history suggests the eye is unhealthy).

Interrater Agreeability

Assessment of the level of agreement between independent resident ophthalmology graders regarding the image quality, categorization, likelihood for referral, and stratification of retinal images (still images and 30-second videos) captured from the D-EYE camera attachment.

Statistical Analysis

The information collected from the study consists of categorical data, distinguishing between accuracy and inaccuracy. The authors will be performing an interrater reliability test using the Cohen coefficient for each of the ophthalmology residents making a diagnosis. This will provide the authors with a level of agreement. All tests will be 2-sided and *P* values <.05 will be considered statistically significant.

To test the first aim, the authors will have 5 ophthalmology residents grade D-EYE images on a scale of 1-10 for clarity for the use of low-risk and high-risk stratification. Low-risk and high-risk stratification will be judged based on the likelihood that the resident will refer the patient to a specialist. Their grades will then be averaged, the SD will be calculated, and interrater reliability will be determined. Furthermore, the authors will test the extent to which clarity can be used for making a diagnosis. They will ask the residents to make a diagnosis and compare their judgments to existing patient history. These results will be stratified into hits, type 1, or type 2 misses. These will be used to calculate proportional variability (PV; PV+ and PV) values. Interrater reliability will also be calculated.

Ethical Considerations

This study, which includes human participant research, was approved by the Institutional Review Board of the Florida Department of Health (UFIRB201801242). The informed consent forms used in this study provide participants with a description of the study, its qualitative and quantitative measures, potential risks and discomforts, and explicitly ask the participants for a voluntary agreement to participate and allow their data to be collected. To maintain privacy and confidentiality protection, study data are de-identified as all participants are assigned a numerical code. This code follows the format of OC001. Anonymity of all study participants is ensured. No compensation of any sort is offered to the human participants. This is stated in the informed consent form. No identification of individual participants is present in any images of this paper or any supplemental material.

Results

A total of 110 participants underwent retinal screening assessments using the D-EYE attachment to iPhone 7 (Apple Inc). Both still images and 30-second videos of the participants' bilateral fundi were captured and were then compared in order to assess the clarity and quality of the imaging.

The D-EYE video footage showed the ability to achieve optic nerve head visualization with an overall proportion of 0.827 being visualized by graders. This was a notable improvement compared with still images, where graders were only able to visualize the optic nerve head with an overall proportion of 0.752. As such, video footage captured by the D-EYE suggests efficacy compared with previously established tools, and when combined with portability and cost, it may prove to be a useful clinical tool for physicians who want to assess optic nerve head health. One previous study that assessed the D-EYE showed that still imaging was possible in 74% of undilated cases [11]. This research corroborates this finding and also suggests that more consistent and better visualization could be achieved through the use of video rather than still imaging.

The intraclass correlation coefficient found when comparing grader CtD assessments was 0.576, thus suggesting statistically significant consistency in analysis across graders. Literature on interobserver agreement of VCDR has found moderate agreement between 6 glaucoma experts (median weighted of 0.67) while using stereoscopic conditions [11]. Compared with standard-of-care technology, D-EYE video footage suggests comparable efficacy in making CtD measurements.

Discussion

Based on the review of 110 participants' fundal imaging by ophthalmology residents, the pilot study indicated greater visualizability and clarity of 30-second videos of retinal imaging through the D-EYE as compared with still-image ophthalmic capture. Furthermore, the CtD measurement was more reliably measured in the 30-second video group. In addition, the likelihood of referral between the glaucomatous and healthy sample groups indicated a greater sensitivity of digital ophthalmoscopes in being able to detect retinal abnormalities, supporting the technology's use as a screening tool. Participants noticed no change in compliance or pain associated with either of the methods used in the study.

By comparing grader assessments of the overall health of the eye (measured as a likelihood of referral) with self-reported glaucoma status by participants, the authors aimed to ascertain whether D-EYE video footage could be used to provide valuable judgments on the need for additional ophthalmic care. The use of this technology, based on the results, shows that this tool has similar value as specialized ophthalmology examinations in assessment for glaucoma. With vision loss from glaucoma being irreversible and the prevalence of glaucoma rising worldwide, implementation of this easily accessible, highly sensitive diagnostic technology could provide a multitude of health benefits while addressing any barriers to health care.

One primary limitation in the study design is the subjectivity that is associated with grading fundus images by ophthalmologists. This study attempts to limit that by operating with the input of 5 ophthalmologists grading each image acquired in an effort to reach a fair conclusion for each fundus image.

Integration of D-EYE technology into clinical settings confers advantages such as portability and steadily decreasing costs. This study has found that still images taken by the D-EYE are not yet clear enough to provide consistent optic nerve head visibility. Video footage, however, shows not only the ability to provide optic nerve head visualization, but also to assess important health metrics that can be useful both within ophthalmology clinics and in primary care settings. Future research should be aimed at assessing D-EYE efficacy in a larger population.

Acknowledgments

Thanks to the work of Dr Siva Iyer, MS, and Dr Sonal Tuli, Equal Access Research's research assistants, and the UF Health System that this study was made possible. Generative artificial intelligence was not used in any portion of the paper writing.

Abstract

Background: The use of data standards is low across the health care system, and converting data to a common data model (CDM) is usually required to undertake international research. One such model is the Observational Medical Outcomes Partnership (OMOP) CDM. It has gained substantial traction across researchers and those who have developed data platforms. The Observational Health Care Data Sciences and Informatics (OHDSI) partnership manages OMOP and provides many open-source tools to assist in converting data to the OMOP CDM. The challenge, however, is in the skills, knowledge, know-how, and capacity within teams to convert their data to OMOP. The European Health Care Data Evidence Network provided funds to allow data owners to bring in external resources to do the required conversions. The Carrot software (University of Nottingham) is a new set of open-source tools designed to help address these challenges while not requiring data access by external resources.

Objective: The use of data protection rules is increasing, and privacy by design is a core principle under the European and UK legislations related to data protection. Our aims for the Carrot software were to have a standardized mechanism for managing the data curation process, capturing the rules used to convert the data, and creating a platform that can reuse rules across projects to drive standardization of process and improve the speed without compromising on quality. Most importantly, we aimed to deliver this design-by-privacy approach without requiring data access to those creating the rules.

Methods: The software was developed using Agile approaches by both software engineers and data engineers, who would ultimately use the system. Experts in OMOP were used to ensure the approaches were correct. An incremental release program was initiated to ensure we delivered continuous progress.

Results: Carrot has been delivered and used on a project called COVID-Curated and Open Analysis and Research Platform (CO-CONNECT) to assist in the process of allowing datasets to be discovered via a federated platform. It has been used to create over 45,000 rules, and over 5 million patient records have been converted. This has been achieved while maintaining our principle of not allowing access to the underlying data by the team creating the rules. It has also facilitated the reuse of existing rules, with most rules being reused rather than manually curated.

Conclusions: Carrot has demonstrated how it can be used alongside existing OHDSI tools with a focus on the mapping stage. The COVID-Curated and Open Analysis and Research Platform project successfully managed to reuse rules across datasets. The approach is valid and brings the benefits expected, with future work continuing to optimize the generation of rules.

Introduction

In health research, there are dozens of standards that can be used to represent data, and a recurring challenge surrounding the adoption of existing standards versus the creation of yet more. The retrospective adoption of standards is conceptually simple but is much harder to implement in datasets that are still actively collecting new data. Clearly, if everyone adopted a single standard from the start of all data capture, then such a problem would not exist; the reality of course is very different and data handling practices still vary considerably between research projects and health care organizations. The Observational Medical Outcomes Partnership (OMOP) Common Data Model (CDM) [1,2] is an international open community standard to standardize the schema and contents of the data by using a standardized vocabulary and medical terminology into clinical domains of OMOP CDM. As a concept, the ability to map between a research ontology, such as the International Classification of Disease (ICD) and Systematized Nomenclature of Medicine Clinical Terms (SNOMED-CT), with a single representation within the vocabulary is of immense value [3]. For an organization with data that are not in OMOP, there will always be an effect required to convert the data from the source standard to the OMOP CDM.

The Observational Health Care Data Sciences and Informatics (OHDSI) [4] program collates a suite of open-source tools [5,6] that can assist in the process of the extract, transform, and load (ETL) stages to convert data from the original format to OMOP. There are also tools that can assist in finding the most appropriate concept to use from the vocabulary using a similarity search [7]. Therefore, tools and options do exist that can assist in the conversion of data to the OMOP common standard. However, if the organization either does not have the knowledge or the capacity to undertake the conversion, the “final mile challenge” can be significant. White Rabbit [6] can profile the data and produce a metadata extract. Rabbit-in-a-Hat [5] can allow a data engineer to capture the required transformations in note form. What is missing, though, is an end-to-end process and the conversion of the outputs into actionable code. At present, an individual would most likely generate an SQL command or software script to convert the data based on the interpretations of the Rabbit-in-a-Hat output. This would require local expertise to create. Organizations may have a desire to adopt or curate data to a single standard, but the local capabilities do not always exist.

The European Health Care Data and Evidence Network (EHDEN) [8] is a Horizon IMI program established to help with this gap that funds approved organizations to work with data owners to convert their datasets to OMOP. This is a competitive process that will support datasets that can bring the most value to the wider OHDSI [4] consortium for data sharing. Not all datasets will qualify for support from EHDEN given its finite resources (it clearly cannot support every project seeking to transform to OMOP), and as so, it has eligibility criteria on the periodic calls it makes for support [9].

Most ETL processes work based on having access to the data at the time of designing the conversion, and indeed, the OHDSI tools run on the source data; allow notes to be curated for how data should be converted; and typically require manual development of scripts to convert data from source to OMOP. This approach relies on a team having access to the data, which may not for privacy reasons be desirable in relation to health care and sensitive research datasets. Some organizations may be cautious in allowing external organizations with OMOP knowledge access to core systems and data to undertake the ETL process. In many cases, this will involve setting up legal agreements such as data sharing or confidentiality agreements or generating pseudonymized versions of the data, which are often lengthy and complex tasks.

While, OMOP offers significant power and opportunity as a unifying standard, allowing differences in terminology to be mapped to a single standard, it does suffer from the challenge that curating data to OMOP can still be quite an art form with different curators taking different approaches. The vocabulary used within the OMOP CDM can be downloaded from the website Athena [10]. There is not a single vocabulary set to use, and therefore, the curators may have preferred vocabularies to represent the data. The vocabulary is also periodically updated resulting in a concept changing domains between releases, such as from being in the Observation domain to the Clinical Occurrence domain. The consequence is that someone curating the data today may make a different decision in the future because the vocabulary has changed. The vocabularies in Athena are in English, and therefore, a base assumption of Carrot is that English is the language in use.

The FAIR (Findable, Accessible, Interoperable, and Reusable) principles [11] are a globally accepted set of standards to promote best practices in datasets. CDMs can aid datasets to become interoperable, as they standardize all data to a single model. However, in the quest for interoperability, it is important that the provenance of the data is not lost when it is converted, as there is a risk of an illusion being created because data from multiple organizations are the same. Therefore, while converting

data to OMOP can assist in making data FAIR, as it simplifies many of those challenges, it cannot be at the expense of understanding how data have been converted to OMOP.

There are many existing mechanisms to map and covert data [12-14] to the OMOP CDM, and those processes are well established. This paper does not seek to suggest the work presented here is better than any existing processes and protocols. The processes described here were in response to a specific set of constraints, such as limited availability of technical staff members, a desire to create a FAIR resource as a consequence, and most importantly that access to data was not available in most circumstances.

In this paper, we introduce Carrot, a software tool that aims to address these difficulties—namely the governance requirements around bringing OMOP expertise to the datasets, variations between individual curators within the OMOP framework, and the gap between current OHDSI tooling—while also automating as much of the process as possible. Carrot enables curators to map data to OMOP without needing access to the underlying data. This allows a central team of OMOP experts to undertake data curation of many datasets to enhance quality control and standardization while fulfilling a desire to ensure this central team never has access to data that would be in the scope of General Data Protection Regulation (GDPR). Separating the specialized OMOP knowledge from the application of the ETL process allows reduced and shortened governance work, saving data owners time and money in converting their datasets.

Similarly, Carrot provides tooling to guide curators toward standardization of their used OMOP terms wherever possible and automates much of the ETL process. In solving these challenges, Carrot brings reproducibility and transparency to the OMOP data curation process to assist datasets in meeting the increasing FAIR requirements.

Methods

Development Principles

The Carrot tools were developed using the Scrum Agile methodology [15] to deliver minimum viable products of each component followed by iterative development to expand the functionality over time. The team consisted of data engineers, OMOP experts, research software engineers, clinical academics, and patient and public representatives. All tools were made available via an MIT license [16] and hosted in GitHub repositories [17,18].

Privacy-by-Design Principles

The data held by an organization, referred to as a data partner, are identifiable personal data and within the scope of the Data Protection Act 2018 [19]. As such, we wanted to ensure the team undertaking the data mapping never had access to the underlying data and only operated on metadata that were outside of the scope of data governance regulations. Throughout the process, the only people to have access to or process personal data were the data partners. Such an approach was low risk and ensured privacy-by-design and data minimization principles were strictly followed.

Two software packages were created to separate the data conversion from the creation of transformation rules. The first software package was to handle the creation of mapping rules based solely on the metadata. This tool is called Carrot-Mapper [17,20]. The second software package was designed to reside within the data partner's network and use the rules to convert the data. This tool was called Carrot-CDM [18]. This approach defines two separate processes: one process to create the rules for mapping and a separate process that takes those rules and applies them to the data.

Reuse and Reproducibility

FAIR principles seek to ensure the required metadata are captured across the 4 categories of FAIR. Our desire is to embed these same principles into the design of Carrot such that the mappings generated were also FAIR. A key requirement of the software is that mappings from one dataset can assist in the mapping of another, reducing wasted effort. For example, significant work was undertaken in the United Kingdom to standardize questionnaires in response to COVID-19 that were used across many national cohorts [21], that way many different research cohorts agreed to use the same questionnaire rather than each creating their own to gather data from their participants related to COVID-19. Therefore, we wanted to ensure that once the questionnaire had been mapped for one data partner, it can be instantly applied to other datasets. Over time the efficiency can be increased as the mapping rules from previous work can be used in new work.

Data curation to a new standard could be considered an art form, as each individual undertaking such an activity may do so in a different way. As an artist may have a signature brush stroke, it is also true that data engineers will have their preference for how to convert data to OMOP. Therefore, to promote reproducibility our key principle was to minimize individual decision-making and the development of a standardized pipeline that produces the same results after each execution. That process was supported by features designed to provide feedback to the user regarding any curation issues compared with previously mapped datasets (see Mapping Standardization Tools section below).

Process Architecture

Overview

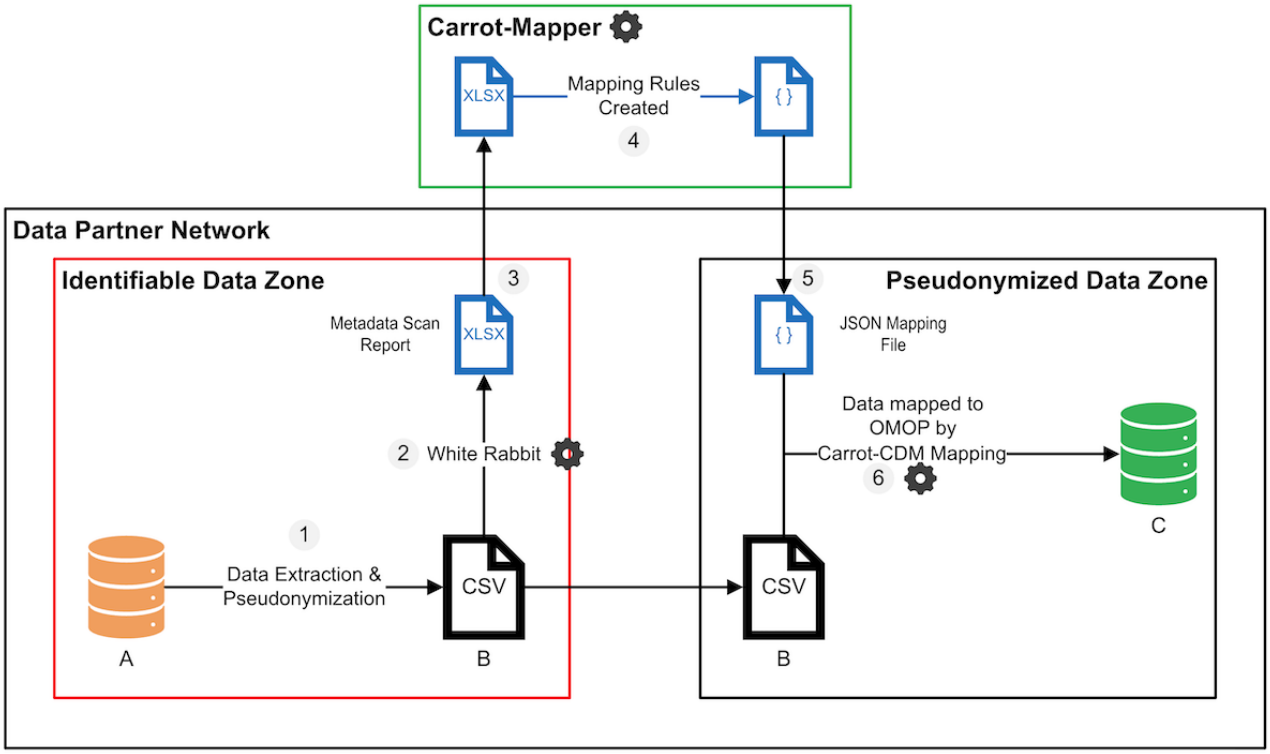
The mapping rule generation web application Carrot-Mapper is built using the Django Python web framework (Django Software Foundation), with the React JavaScript library for user interfaces, and PostgreSQL database. These are supported by serverless Azure Functions written in Python for asynchronous processing of the large amounts of data ingested with each new file upload. The Carrot-Mapper web application automatically deploys via GitHub Actions to Microsoft Azure infrastructure with each new release.

The minimal Carrot pipeline consists of 6 steps that are illustrated in Figure 1: (1) preprocess data to remove identifiable data and apply the standards in [22], (2) generate metadata report via White Rabbit [6], (3) transfer metadata file to Carrot infrastructure, (4) generate rules using Carrot-Mapper, (5) transfer rules to system housing data, and (6) use Carrot-CDM

to apply generated rules to transform pseudonymized data to OMOP standard.

Note that Carrot-Mapper and Carrot-CDM handle steps 4 and 6, respectively, of the above pipeline. The formats of the metadata report and mapping rules file are open, ensuring that data partners have the option to implement their own drop-in solutions instead of one or the other software tools to fit their own infrastructure if desired. The Carrot team runs a central deployment of Carrot-Mapper, which can be used by multiple projects. A private instance of Carrot-Mapper can also be run within the data partner's infrastructure, although this reduces the utility of the system as it cannot draw on existing mapping rules generated for previous datasets and nullifies some of the benefits of reduced governance requirements. We ask all data partners to check the metadata and the contents of the scan reports to validate that no identifiable or personal data leaves the data partner's network at any time.

Figure 1. Carrot pipeline overview. (A) The raw, identifiable dataset. (B) Deidentified data. (C) The OMOP standardized deidentified dataset. OMOP: Observational Medical Outcomes Partnership.



Minimizing Input From Data Partners (Step 1)

Each data partner remains responsible for the management of their data, including generating a pseudonymized and deidentified extract. There are some preprocessing steps that they must perform to use the tool, but we have minimized the workload on each data partner. In order to simplify the later steps of conversion to OMOP, we also ask the data partner to follow the steps at [22] under "Data Preparation," namely, presenting the data in a series of CSV files, with one CSV containing demographic data, all measurements in the metric system, dates and date times in the ISO-8601 format, digit grouping symbols removed, decimal numbers rounded to a maximum of 2 decimal places, CSV files encoded with UTF-8 and Unix and Linux line endings; and CSV file names limited to 30 characters.

The data partners do have a vital role in ensuring their data is represented correctly and all local insight is maintained during the process. What we have sought to minimize at this stage is the involvement of technical teams and to remove that burden.

Generating Metadata (Step 2)

The pseudonymized dataset held within the data partner's infrastructure (as generated by step 1 of the above 6-step process) is profiled by the open-source White Rabbit [6] data profiling tool, resulting in a metadata file known as a scan report. Alternatively, the scan report can be generated by hand or by other tools, so long as the resulting scan report file (an Excel file containing multiple sheets) has the correct structure.

The scan report details the tables and fields of the dataset, along with values present in each field. The Carrot data standards [22] instruct the data partner in the correct setup of the White Rabbit tool to ensure identifying data is not inadvertently present in the scan report. This includes setting the "Minimum Cell Count" to at least 5 to reduce the probability of possibly reidentifying conditions being included. The scan report should then be checked to remove any remaining data values that could be deemed confidential or sensitive.

A data dictionary may be optionally supplied. This can provide (1) vocabularies associated with certain fields and (2) descriptions of values when the field names and values are not self-explanatory. As an example, it would be possible to specify that a column contains SNOMED values. As the system is using

the contents of the Athena system for OMOP, 18 existing vocabularies (eg, SNOMED-CT [23], ICD v9 [24], and Healthcare Common Procedure Coding System [25]; Multimedia Appendix 1) can be specified. The structure of the data dictionary is defined on the Carrot standards page [22].

Importantly these scan reports can also be used by the data partner to register the datasets within publicly available metadata repositories, such as the Health Data Research Gateway [26]. In doing so, we continue our theme of reducing the burden and ensuring one process can result in many benefits.

Uploading Scan Report and Data Dictionary Files (Step 3)

Both the scan report and optional data dictionary files are then transferred to the OMOP experts. The OMOP experts upload the scan report file and optional data dictionary file to Carrot-Mapper via a web form. This creates a new scan report instance within the system, with the user able to specify accompanying settings such as the project and dataset to which the scan report belongs, and the visibility and access to the scan report for other users. See the Users and Projects section below.

Upon upload of the scan report file (which can take a few minutes to process large and complex datasets), the Carrot-Mapper tool records all tables, fields, and values within the scan report file. This enables users to visually navigate the structure of the dataset within the mapping tool for the purposes of manual mapping (below) via the browser.

Each scan report has a status field that can be used to track the progress of the scan report upload and the manual mapping process, using the statuses “Upload in Progress,” “Upload Complete,” “Upload Failed,” “Mapping 0%,” “Mapping 25%,” “Mapping 75%,” “Mapping Complete,” and “Blocked.” This status field is automatically updated and can also be set manually from the main scan reports list page, for example, to progress through the stages from “Mapping 0%” to “Mapping Complete.”

The centralized system allows previous mapping rules to be reused. For example, assume a field “Sex” is provided with the value “M,” and this has previously been manually mapped to the OMOP concept 8507 “Male” in one scan R=report. In the case where a later scan report is uploaded with another field “Gender” and the value “M,” the system automatically applies the previous mapping rule to this value in this field in the new scan report. In this way, the utility of the system increases over time, as mapping rules are saved, and the manual effort required to generate mapping rules is reduced. This is particularly the case where a new scan report is supplied that describes a dataset that has been previously partially mapped, or where multiple datasets adhere to a shared standard. Only mappings from scan reports marked with the status “Mapping Complete” are eligible to be considered for reuse. This mechanism allows trusted and verified rules to be replicated, while works in progress are not mined for rules to apply to new scan reports. This mapping reuse algorithm runs at the time when a scan report file is first uploaded. The limitation is that it can only reuse rules when the column name is an exact match and the value is also an exact match. It has no intelligent processes to either translate from languages (such as Spanish to English) or to auto-correct for potential spelling mistakes (“Gendar” to “Gender”).

Additionally during this initial upload process, there is the automated mapping from recognized vocabularies. In the case where an entry in the data dictionary indicates that a field is encoded in a recognized vocabulary, the system will automatically create mappings to the (possibly multiple) standard and valid OMOP concept codes associated with each source code. Some scan reports can contain thousands of unique values in such fields, and as such, this feature can save days of repetitive and error-prone work for OMOP experts.

Throughout this stage, it is always clear how a rule was generated, whether it was manual, a reuse of an existing rule, or using the OMOP in-built relationships (such as mapping ICD to SNOMED). The interfaces of Carrot indicate this as M for manual, R for reuse, and V for vocabulary-based rule generation.

Generating Rules (Step 4)

Carrot-Mapper has been created as a web-based tool to assist in the generation of rules. A core reason for establishing a central tool for creating rules is that they can then be reused across projects and datasets. However, the requirement that Carrot-Mapper support rule reuse, and thus mappings related to multiple datasets be stored in a single location, also necessitates user authentication and granular permissions to control access to uploaded data (see Users and Projects section below for more details).

Once a scan report file has been uploaded and processed, manual mapping can proceed. The OMOP expert can navigate the contents of the scan report, organized in a hierarchical manner. The system allows the user to select a field or value and mark it with the desired target OMOP concept codes, as well as remove any incorrect codes (including reviewing those generated through vocabulary lookup or mapping rule reuse in step 3 above). At any stage in the mapping process, the user can see a summary view of the mapping rules currently extant and review, discuss, and remove any mapping rules. Once a user is satisfied that they have mapped all of the required fields and values, they can set the scan report status as “Mapping Complete,” which also makes the mapping rules defined in that scan report available for reuse by other scan reports. Mapping rules can be exported in CSV format (for human readability and review) or in JSON format for ingestion into the Carrot-CDM ETL tool at the next stage of the pipeline.

Mapping Rule Generation

Rules are generated using internal logic to minimize the work required from a user who wishes to add a new rule. Each table must have one field identified by the user as a “Person ID” field and one field as “Date Event,” which can be defined via the web application. For every field and value, the user can input the target OMOP concept ID. The web application handles this by looking up the OMOP ID in the OMOP database to access the OMOP term. This term is then mapped to a valid term and the related domain. These data points (valid term, domain, person ID, and date event) are sufficient to define a mapping rule. This feature removes some of the technicalities of OMOP

from view, allowing the user to focus purely on the most accurate OMOP representation of the data.

Transfer Mapping Rules to Data Partner Network (Step 5)

The mapping rules JSON file, as exported in the previous step, is transferred into the data partner's network. These are the only data that enter the data partner's network.

Data Transformation (Step 6)

Within the data partner's infrastructure, the data partner sets up a machine with the Carrot-CDM tool installed. The Carrot-CDM package is an ETL tool to convert a dataset to OMOP using supplied rules. Built with Python, the package can be readily installed in the environment hosting the dataset. The task of Carrot-CDM is to convert the CSV files containing the dataset into an OMOP dataset, based upon the mapping rules generated by Carrot-Mapper.

Carrot-CDM operates by constructing a CDM object, containing a number of tables representing the tables or domains used in the OMOP schema. At present, these tables are a subset of all of those defined by OMOP, due to the priorities of the datasets and pipelines that have used Carrot until now. Once the CDM has been appropriately constructed, then conversion of the contents of the dataset can proceed. The OMOP mapping experts send the mapping rules in JSON format to the data partner, and the data partner loads the mapping rules file into the machine. The data partner also copies their pseudonymized dataset into the machine. Carrot-CDM is used to transform the dataset to the OMOP standard using the mapping rules provided. Carrot-CDM is platform independent and can be used via either command-line interface or graphical interface, depending on the user's preference.

Carrot-CDM handles both one-time data transformation and incremental transformation of an expanding dataset as new data is made available, using the same mapping rules as in the one-time case. Carrot-CDM can either monitor for the addition of new data and perform the transformation immediately or run on a schedule to run a transformation of new data added in each period, such as via a server-based scheduler. This means that longitudinal datasets, or those otherwise growing over time, can be efficiently mapped to OMOP. Carrot-CDM supports streaming, enabling essentially infinite datasets to be processed, as working memory is not a limiting factor.

Data Partner Validation

The data partners clearly hold the vital contextual information to provide assurance that the data mapping is appropriate and correct. Therefore, through steps 1, 2, and 6 (Figure 1) of the process, the data partner is consulted and many questions and clarifications are sought between both parties. The metadata extraction and initial upload can often highlight some discrepancies in data format and can highlight where the data dictionary does not exactly match all of the data picked up in the scan report. Therefore, the recommended process is for a highly collaborative and iterative process whereby the Carrot team has the insight in the process of curating data to OMOP, while the data partner has the insight and understanding of their data.

Users and Projects

Carrot-Mapper assigns user accounts to individuals and has an internal data model to organize dataset mappings and administrate access to them. These structures are projects, datasets, and scan reports. The basic unit is the scan report, formed from a single uploaded scan report file generated by the White Rabbit tool. Each scan report is a member of a single dataset. Multiple scan reports can be organized into a single dataset to represent successive iterations of a single dataset, such as with the addition of new tables, fields, or values. The usage pattern of datasets and scan reports is left to the user's choice.

At the highest level, projects represent the abstract notion of a view of a collection of datasets that are of interest to a particular group of users. A user must be a member of a project to access the datasets associated with that project. A many-to-many relationship means that datasets can be present in multiple projects, and it is sufficient that a user is a member of any related project to access a given dataset.

Assuming that a user has access to a given project, user access can then be further controlled on the level of datasets and individual scan reports. Permission to view datasets and scan reports is controlled first by setting their visibility as either "Public" or "Restricted," and then more granular viewing, editing, and administration operations can be controlled at the per-user level.

Mapping Standardization Tools

An additional internal tool within Carrot-Mapper highlights related OMOP concepts that are the target of mappings in the dataset corpus. This is provided as feedback to the mapping team to highlight misaligned target concepts (ie, those which are descendants or ancestors of other target concepts in the hierarchical OMOP structure) and encourage iterative convergence on a standardized OMOP vocabulary. Users are free to ignore this guidance if they choose, but the presentation of the potential inconsistencies places this information in the user's hands without extra effort.

Management

Carrot-Mapper presents users with a dashboard to show relevant statistics such as the total number of scan reports processed and mapping rules generated, grouped by data partner, and to track the progress of scan reports from the upload stage through to the completion of the mapping process.

User access to datasets and scan reports is configurable via dedicated administration pages for each, placing the user control into the hands of the dataset administrators to reduce reliance on the central Carrot-Mapper team.

Ethical Considerations

Research ethics approval was not required for this project as each data partner maintains their own governance and ethics for the original research studies. Anyone requiring access to the platform to perform research needs to apply for their own ethics

approval. The data partners who use the Carrot system and methods in this paper will need to have the required ethics in place for the collection, storage, and use of data in place.

Results

As of July 2024, the installation of Carrot-Mapper has been used to generate mappings for 39 scan reports to the OMOP standard. There are 129 dataset objects across 13 projects. A total of 60,269 mappings have been generated, through manual means (n=6159), automatic (n=45,316), and reuse between scan reports (n=8794). These numbers are only for those scan reports marked as "Mapping Complete," indicating that they have been accepted as correct by the users, and their associated mappings are now available for reuse by new datasets. More (n=92,071) mappings are currently in progress without having been marked as archived or as completed.

This use of Carrot tools has been adopted by a number of projects, including COVID-Curated and Open Analysis and Research Platform (CO-CONNECT; see below), Alleviate [27], Defining Mechanisms Shared Across Multi-organ Fibrotic Disease to Prevent the Development of Long Term Multimorbidity (DEMISTIFI),

Mother and Infant Research Electronic Data Analysis (MIREDA), the National Institute for Health and Care Research Nottingham Biomedical Research Center, and most recently the East Midlands Secure Data Environment. Carrot is therefore an integral part of ongoing efforts by several organizations to standardize health data to the OMOP standard. Since Carrot-Mapper can be deployed by any user, with a separate database, it is not possible for the authors to accurately gauge the use of Carrot-Mapper beyond the centrally installed system deployed by the Carrot team.

Most mappings (over 75%) were automatically generated from vocabularies, indicating the importance and time-saving nature of the automated mappings feature. Existing mappings that have been verified are automatically reused on newly uploaded scan reports where they match, reducing wasteful replicated effort. While the proportion of mapping that is from reuse is currently low (less than 15%), we anticipate (and have seen even thus far) that as the number of mapped values increases, and iterations of the same dataset are progressively remapped over time, the number of reused mappings will rise compared with the number of manually added mappings. Even at this early stage, nearly 60% of the mappings that are not automatically generated from known vocabularies are from reuse.

Discussion

Principal Findings

Accessing and combining multiple datasets can be handled in a variety of ways. Principally, the choice of whether to standardize vocabularies then drives the choices available in further steps in any processing pipeline. Leaving datasets in their original formats requires later processing steps to understand and handle the heterogeneity in the underlying data sources. While this can be handled on a case-by-case basis for small numbers of datasets, at scale, this requires the creation and maintenance of a large number of connectors and middleware given the plethora of possible data sources. This is the approach taken by systems with a limited number of data sources such as OpenSAFELY [28] but is not an approach that is sustainable for many smaller datasets and data partners.

Converting datasets to a standardized vocabulary reduces the heterogeneity of the datasets at an earlier step in the pipeline, simplifying later processing steps and reducing the dataset-specific knowledge required by users of the data. However, it places the onus on formulating a consistent and correct mapping to the standard vocabulary. It is also not possible to cover every use case with a single standardized vocabulary, so some pipelines may be best served by using the raw data, while other use cases may lend themselves to a specific standardized vocabulary that is inappropriate for other uses.

In choosing a common standard vocabulary, a number of competing factors must be considered, including the suitability of the vocabulary to represent the original datasets, ease of conversion, availability of required expertise and tooling, and adoption by others. A wealth of standard vocabulary candidates exist, including OpenEHR, OMOP, and PCORnet [29].

Converting a dataset to a common standard can sometimes be partially automated—in the case of OMOP, many research ontologies such as SNOMED can be mapped directly—but in almost all cases this conversion requires a human element to decide the most appropriate mapping. This brings with it privacy and data protection implications if the process of manual mapping relies upon providing access to the dataset. The EHDEN program funds the conversion of datasets to the OMOP standard by using approved organizations to perform the conversion. This relies on governance assurances to ensure that only trusted and approved individuals are granted access to the dataset under conversion. This can be a relatively quick method for converting high-priority datasets to the OMOP standard but will not enable the conversion of lower-priority datasets given the competitive nature of the process.

The Carrot tools take a different approach, by only extracting to a central system the metadata required from the dataset to formulate a mapping. In this way, experts in OMOP conversion with access to the central Carrot system can create a mapping from the original dataset to the OMOP standard without ever having access to either identifiable or pseudonymized and anonymized data. This removes some of the governance requirements. In addition, it allows the creation of a corpus of mapping rules that can be shared and reused between datasets, and compared and aligned over time. Finally, Carrot can automate much of the mappings required from recognized standard vocabularies, reducing costs and opportunities for error.

The generation of rules by automated processes does have the ability to create more harm than good, as a human has to check and correct any potential errors. The use of automation in Carrot is limited to two scenarios. The first is where a concept has already been formally mapped by the OHDSI vocabulary from a nonstandard to standard concept. The second is where a previously human-approved mapping can be reused because the column and values exactly match. The user is presented

with these and can see which rules were mapped from the vocabulary (marked with a V) and from reusing existing rules (marked with an R). We are currently gathering more evidence on the utility of these automated approaches and whether other automation is useful, such as the adoption of large language models.

The novel nature of the metadata access required by Carrot tools has created some additional governance issues, since many organizations did not have existing data access processes that were used to process lower risk metadata. In the use-case of CO-CONNECT, this required an extensive collaborative effort between our team and data partner organizations to satisfy them with the nature of the requests and to create new processes to enable them. This delayed some of the mapping work but is also an important output from the wider CO-CONNECT project.

Phenotype Generation

Bringing together the metadata from multiple datasets and their mappings to the OMOP standard enables leveraging the combined data to build phenotypes. For example, all fields and values across all datasets that are mapped to the OMOP concept code 317009 for asthma can be queried. In future work, we plan to provide a publicly available tool to present this information, allowing interested parties to interrogate the source values that map to a given OMOP concept code. This is valuable for understanding the varying ways in which this data is captured across datasets and allows external validation of the mappings generated by the central team.

Pipeline Integration

The Carrot tools have been built in such a way to be integrated into wider pipelines, as demonstrated in the CO-CONNECT project. The separation of the tasks into separate tools based on their requirements for human intervention provides a natural fit for integration into semiautomated pipelines. Work in this area continues, such as future extensions to support the postprocessing of OMOP data to encode relationships, work to further develop the JSON mapping rules file specification to fit common standards, and support of data-profiling tools in addition to White Rabbit.

Limitations

The Carrot tools remain under active development to extend and improve their functionality. In particular, work remains to monitor and handle the continual changes made to the OMOP vocabulary to provide reproducibility and transparency to the processes. The priorities of the initial use cases shaped the development process, in particular regarding support for OMOP tables. Further work is ongoing to widen the target OMOP tables the Carrot tools can support. The work presented has not run different methods in parallel; therefore, we make no claim over whether this approach is better, faster, or more efficient or uses less computing resources than others. Where data governance and protocols would allow such a comparison could be useful to evidence the benefits of the system. What we have sought to lay out is a protocol, supported by software, that was driven by the underlying constraints and challenges experienced.

The matching algorithm for reusing mappings across datasets is relatively simple, and ripe for further refinement as well as further user customizability. That is because even a small spelling mistake would prevent a match from being found. Additionally, Carrot cannot undertake any natural language processing, nor can it translate between languages.

Finally, further development remains to provide greater user ease, particularly around the self-administration of user accounts and streamlining the user journey to eliminate known areas that could be further automated.

While reducing some aspects of technical knowledge that are required by users (eg, removing the need for SQL knowledge typically required in most other workflows and automating the details of which OMOP concept codes relate to which target OMOP table), Carrot does still rely on an expert understanding of OMOP to be used to greatest effect. In this regard, it is to enhance rather than replace the capabilities of human curators and makes no claim to be able to process full datasets from end to end without human oversight and intervention. There is still a need for clinical specialties (eg, chronic pain) to agree on correct and consistent usage of terms to improve the interoperability of disparate datasets.

Conclusions

We have presented the Carrot tools, namely the Carrot-Mapper and Carrot-CDM software tools. These enable expert or novice curators to transform health datasets to the OMOP standard with access only to metadata, rather than the potentially sensitive data. This has the potential to radically reduce the governance work and cost required to perform this transformation, without sacrificing the expertise that can be brought by external curators.

Carrot-Mapper contains functionality to specifically reduce the repeated work required to map multiple datasets by reusing mappings between datasets. It further contains tools that can guide curators toward standardized mappings over time, reducing the dependence upon individual curators' different approaches to the preferred terminologies to represent data. All of this is achieved without ever exposing the sensitive data to the external team with OMOP knowledge.

Carrot-CDM is a robust and scalable ETL tool that can run within the data partner's infrastructure, completing the journey to an OMOP dataset without data movement beyond the data partner's boundaries, nor requiring external users to be granted access. In combination, the Carrot tools provide a means for OMOP experts to convert health care datasets to OMOP in a standardized manner, with reduced governance requirements compared with the existing tools available.

Acknowledgments

This work uses data provided by patients and collected by the National Health Service as part of their care and support. We acknowledge the support from COVID-Curated and Open Analysis and Research Platform (CO-CONNECT) funded by United

Kingdom Research and Innovation (Medical Research Council) and the Department of Health and Social Care (National Institute of Health and Care Research) (MR/V03488X/1) and supported by a consortium of 22 partner organizations whose infrastructure made this research possible.

The work builds on early pilot work supported by the University of Nottingham Impact Acceleration Account (EP/R511730/1) from the Engineering and Physical Sciences Research Council.

Subsequent work on Carrot was supported by Alleviate Hub (MR/W014335/1), the Advanced Pain Discovery Platform Data Hub, funded by the Medical Research Council, Eli Lilly, and Versus Arthritis, with support from Health Data Research UK.

It was also supported by the European project, Beyond COVID (BY-COVID).

Data Availability

There is no data to make available, but all the Carrot software is available on an open-source license.

Conflicts of Interest

AS, PRQ, and EJ were a part of the CO-CONNECT project. CC is director of the Alleviate pain data hub.

Abstract

Background: Poor symptom control and exacerbations of asthma diminish quality of life and pose a significant burden to patients and society. Implementing evidence-based management as recommended by the Global Initiative for Asthma (GINA), especially introducing inhaled corticosteroid–containing treatments, has the potential to vastly reduce exacerbations and the high burden of asthma in China. However, domestic implementation of the GINA recommendations has been unsatisfactory, especially in lower-level hospitals; thus, an enhancement to the awareness of and adherence to the GINA recommendations among Chinese physicians is needed to improve patient outcomes.

Objective: This study aims to bridge the gap between the GINA recommendations and the current clinical practice in China by demonstrating the benefits of an asthma quality improvement program (QIP).

Methods: A single-arm study will be conducted at around 30 hospitals across China to assess the impact of a specially designed asthma QIP. Approximately 1500 patients with asthma aged ≥14 years will be enrolled in participating hospitals and followed up for 48 weeks. The QIP—targeted at all pulmonologists and specialist nurses—will include an initial comprehensive training (including a pretraining questionnaire and posttraining quizzes) provided by a dedicated, qualified training team based on the GINA 2021 recommendations, followed by regular reinforcement learnings (integrated into the regular department lectures delivered by department directors), with multiple offline and online approaches (eg, an online patient management platform) provided as supportive tools. During this study, GINA implementation performance will be continuously monitored to inform necessary adjustments at the hospital level. The primary end point is change from baseline in the proportion of participants with an inhaled corticosteroid–based maintenance or reliever treatment at week 48. Secondary end points and exploratory end points include changes in clinical practice and patient outcomes such as treatment patterns, asthma control, and hospitalization rates due to exacerbations.

Results: This study has been completed, with 1500 patients enrolled and 1271 patients completing the study. The last visit of the last patient was on September 3, 2024, and the database lock was on September 28, 2024. Final analysis of data has started in October 2024.

Conclusions: The Change Asthma Clinical Practice through GINA Education and Implementation for All Patients With Asthma (CARE4ALL) study will hopefully help improve asthma management and patient outcomes in China by bridging the gap between evidence-based GINA recommendations and the current clinical practice.

Introduction

Asthma is a chronic inflammatory disease, characterized by repeated episodes of breathlessness, wheezing, chest tightness, and coughing, which affects more than 330 million people worldwide [1]. Within China, as reported by the China Pulmonary Health study, the prevalence of asthma is 4.2% among adults aged at least 20 years, representing 45.7 million patients, and it is anticipated to increase further due to changes in environment and lifestyle [2]. However, the current status of asthma management in China is far from satisfactory.

Asthma control is defined as the level to which the various manifestations of asthma have been reduced or eliminated by treatment [3]. As it is closely linked to patients' health status, the achievement of good asthma control has been set as the key element that drives patient management [3-6]. The rate of well-controlled asthma, as defined by the Global Initiative for Asthma (GINA), is only 28.5% in China's urban areas [7] and is expected to be even lower in remote areas [8]. Moreover, poor asthma control is associated with a much higher risk of exacerbations, which is a major cause of disease morbidity and medical resource use [9]. According to a multinational, cross-sectional survey, 17.8% of patients with asthma in China experienced at least one exacerbation within the past 12 months [10], much higher than 8.4% in the United Kingdom and 12.5% in the United States [11]. Previous studies revealed that the suboptimal asthma control and the high exacerbation burden in China might be largely attributed to underdiagnosis and undertreatment in asthma management [2,10,12]. Though the underlying reasons may be complicated, low awareness of and adherence to guideline recommendations among physicians, insufficient disease awareness, and poor treatment adherence (including incorrect technique of inhalers) among patients might all play a part [12,13].

The GINA strategy report (also known as GINA) has been updated annually since 2002 to provide physicians with up-to-date, evidence-based recommendations for asthma prevention and management [6]. Commencing asthma treatment with short-acting β_2-agonists (SABAs) alone has been a long-standing approach in the field [14], but concerns were raised as overuse of SABAs was shown to be associated with an increased risk of asthma-related death [15]. As more relevant evidence emerged, in 2019, GINA concluded that adults and adolescents with asthma should not be treated with SABAs alone for consideration of safety, regardless of asthma severity [14]. Since then, inhaled corticosteroid (ICS)–containing therapies have been recommended for all patients with asthma by both international and Chinese guidelines [6,8,14]. However, ICS-containing therapies are largely underused in China. For example, in a multinational cross-sectional survey conducted in 2020 on physicians (including general practitioners, family medicine physicians, or internal medicine physicians), the results from China showed that 31.9% of the respondents regarded inhaled SABAs only as the typical treatment of mild asthma, suggesting the suboptimal awareness of guideline recommendations among Chinese physicians [16]. Considering the critical role that physicians play in the delivery of asthma care, limited understanding and implementation of guideline recommendations would inevitably translate to compromised patient outcomes.

The unsatisfactory quality of medical care and the high disease burden call for national actions to increase physicians' awareness of and adherence to management recommendations to improve patient outcomes [17]. Studies from China have shown that interventions targeted by health care professionals at the hospital level can increase physicians' adherence to guideline recommendations and, in turn, improve patient asthma outcomes [18,19]. However, the existing studies either only conducted a short-term, one-off intervention program [18] or were limited to a single study center [19]. Such interventions can be better delivered in the form of a quality improvement program (QIP), which is a set of systematic and continuous activities designed to monitor, analyze, and improve the quality of health care processes [20]. QIPs for asthma care have been demonstrated to effectively change physician practices and improve clinical outcomes in other countries [21]. For example, the Enhancing Care for Patients With Asthma study, developed to augment the implementation of the Expert Panel Report 3 Guidelines in four American states [22], successfully improved the consistency of practices with the Expert Panel Report 3 Guidelines and subsequently decreased asthma-related emergency department visits and hospitalizations by 37.7% and 47.1%, respectively, based on a retrospective analysis [23]. QIPs have also been successfully conducted in China for other

diseases [24,25], but the feasibility and benefits of such QIPs for asthma care have not been assessed in China.

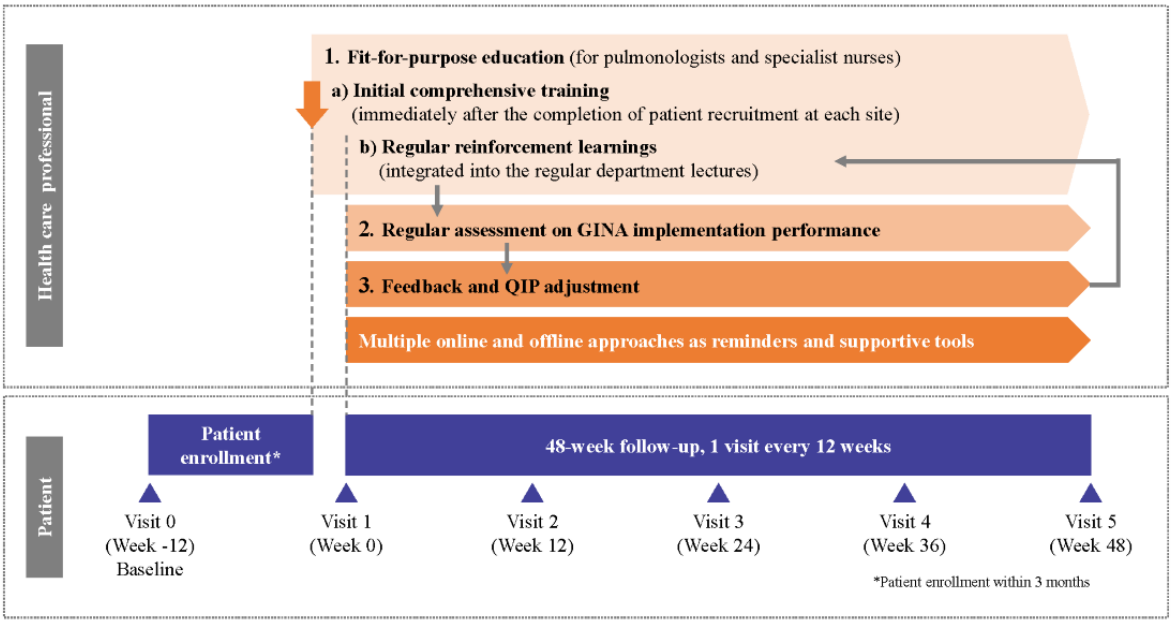
The Change Asthma Clinical Practice through GINA Education and Implementation for All Patients With Asthma (CARE4ALL) study will conduct the first-ever multifaceted QIP for China asthma care, targeting physicians with a specialization in pulmonary or respiratory care. The QIP aims to bridge the gap between the recommendations from the GINA 2021 (the latest update at the time of study design) and the clinical practice among participating health care professionals, and to improve patient outcomes through enhanced quality of care. By evaluating the clinical impact of such a QIP in a nationwide cohort, the ultimate objective of the CARE4ALL study is to pilot and establish a widely applicable QIP model for improving domestic asthma management in China.

Methods

Study Design

This is a multicenter, single-arm study (NCT05440097) with primary data collection to assess the impact of an asthma QIP in improving the adherence of health care professionals specializing in pulmonary or respiratory care to recommendations from the GINA 2021 and quality of care. This study's methodology and procedures are shown in Figure 1.

Figure 1. Study design. GINA: Global Initiative for Asthma; QIP: quality improvement program.



Study Sites and Participants

Site Selection

This study selected a total of around 30 tertiary and secondary hospitals that met all the following criteria: (1) classified as public general hospitals (excluding traditional Chinese medicine hospitals), (2) having an emergency unit and a respiratory department with wards and fundamental equipment (eg, spirometry), (3) having access to GINA-recommended treatment regimens, (4) visited by ≥500 patients with asthma in the past one year, and (5) willing to provide all pulmonologists with regular GINA education and comply with GINA 2021 recommendations. To represent the real-world asthma care situation in mainland China, hospitals were selected across as many provinces or municipalities as possible located below an altitude of 1500 meters, with a balance of hospital levels (preferably around 20 at the tertiary level and around 10 at the secondary level).

Patients

Outpatients with physician-confirmed asthma will be consecutively recruited at participating hospitals. Patients will be eligible for enrollment if they are ≥14 years old and provide written informed consent. Exclusion criteria include previous diagnosis of clinically relevant chronic respiratory disease other than asthma (eg, chronic obstructive pulmonary disease); any significant medical conditions that may put the patient at risk, influence this study's results, or hinder the participants from fully complying with this study's procedure; any medical conditions other than asthma that requires treatment with systemic or oral steroids; and participation in another clinical study with an investigational product administered in the last three months before visit 1 (Figure 1).

Study End Points

As the QIP aims to align physicians' clinical practice with GINA recommendations, study end points measured to what extent the physicians' practice complied with GINA-recommended best practice, which could be reflected in various aspects. First, patient medication patterns directly reflected whether physicians had prescribed asthma medications as recommended by GINA. Thus, the primary end point measured the change from baseline at week 48 in the proportion of patients receiving ICS-based maintenance or reliever medications (as the mainstay of the GINA-recommended asthma medication scheme), while several secondary end points were designed to characterize more fully the patients' asthma medication patterns (Textbox 1). Second, the physician's knowledge, skill, and action together reflected

their understanding of and ability to implement GINA strategies. Thus, the exploratory end points included measurements on the proportions of patients whose pulmonologists develop or review an asthma action plan (a GINA-recommended management tool) for them and check to ascertain their inhaler technique, as well as scores measuring the physicians' own asthma knowledge and inhaler technique (Textbox 1). Moreover, the physicians' patient management skills and the quality of their communication and education for the patients were expected to improve through the QIP, which in turn would positively influence the patients' disease knowledge levels and self-management behavior. As such, the exploratory end points included assessments of the patients' asthma knowledge, inhaler skills, and compliance, to serve as indirect indicators of the physicians' patient management proficiency (Textbox 1).

By aligning current clinical practice with GINA recommendations, the ultimate goal of the QIP is to enhance patient outcomes, as improved quality of care is expected to bring about better asthma management results. Therefore, several key secondary end points sought to evaluate changes from baseline in patients' asthma control (assessed by the five-item Asthma Control Questionnaire), and patients' health-related quality of life and incidence of severe asthma exacerbation were also evaluated as exploratory end points (Textbox 1). Together, these end points on patient outcomes will help demonstrate the clinical benefits that can be actualized through the QIP.

Textbox 1. Study end points and outcome measures. Asthma treatment at each study visit refers to the treatment received within the prior 12 weeks according to medical records. For instance, in the primary end point, "a participant with an ICS-based maintenance or reliever therapy at week 48" is defined as a participant who has used inhaled corticosteroid (ICS)–based maintenance or reliever therapy between week 36 and week 48 based on medical records and in-hospital or out-of-hospital prescriptions.

Primary

- Change from baseline in the proportion of participants with an ICS-based maintenance or reliever therapy at week 48.

Secondary

- Change from baseline in the proportion of participants with well-controlled asthma (five-item Asthma Control Questionnaire [ACQ-5] ≤0.75) at week 48.
- Distribution of ACQ-5 scores [proportion of participants with well-controlled (ACQ-5 ≤0.75), partially controlled (0.75<ACQ-5≤1.5), and not well-controlled (ACQ-5 >1.5) asthma] at weeks 12, 24, 36, and 48.
- Change from baseline in the proportion of participants on the treatment of ICS-formoterol as a reliever at weeks 12, 24, 36, and 48.
- Change from baseline in mean ACQ-5 scores at weeks 12, 24, 36, and 48.
- Change from baseline in the proportion of participants achieving an improvement in ACQ-5 of ≥0.5 units at weeks 12, 24, 36, and 48.
- Change from baseline in the proportion of participants with an ICS-based maintenance or reliever treatment at weeks 12, 24, and 36.
- Distribution of asthma treatment (eg, ICS-containing medications, ICS-long-acting β_2-agonist, ICS-formoterol, oral corticosteroids, leukotriene receptor antagonists, theophylline, and traditional Chinese medicine) at baseline and weeks 12, 24, 36, and 48.

Exploratory

- The proportion of participants whose pulmonologists developed or reviewed the written asthma action plan at weeks 0, 12, 24, 36, and 48.
- The proportion of participants whose pulmonologists watched the patient using their inhaler to check their technique at weeks 0, 12, 24, 36, and 48.
- Annual hospitalization rate due to asthma exacerbations per patient.
- Number of severe asthma exacerbations at baseline, weeks 12, 24, 36, and 48.
- Change from baseline in health-related quality of life evaluated by mean Standardized Asthma Quality of Life Questionnaire for 12 years and older scores at weeks 0, 12, 24, 36, and 48.
- Change from baseline in the proportion of participants with an ICS-based maintenance or reliever actual treatment at week 48.
- Change from baseline in mean Medication Adherence Report Scale for Asthma scores at weeks 12, 24, and 48.
- Change from baseline in the inhaler skill scores of pulmonologists at weeks 12, 24, and 48.
- Change from baseline in the inhaler skill score of patients at weeks 12, 24, and 48.
- Change from baseline in the scores of the asthma knowledge questionnaire for patients at weeks 12, 24, and 48.
- Change from baseline in the scores of the patient expectation of asthma treatment questionnaire at weeks 12, 24, and 48.
- Change from baseline in the scores of the asthma knowledge questionnaire for pulmonologists at weeks 12, 24, and 48.
- Level of asthma control at baseline by self-assessment and by the Global Initiative for Asthma assessment.
- Level of asthma control at baseline, weeks 0, 12, 24, 36, and 48.
- Patient characteristics and related symptoms after COVID-19 infection.

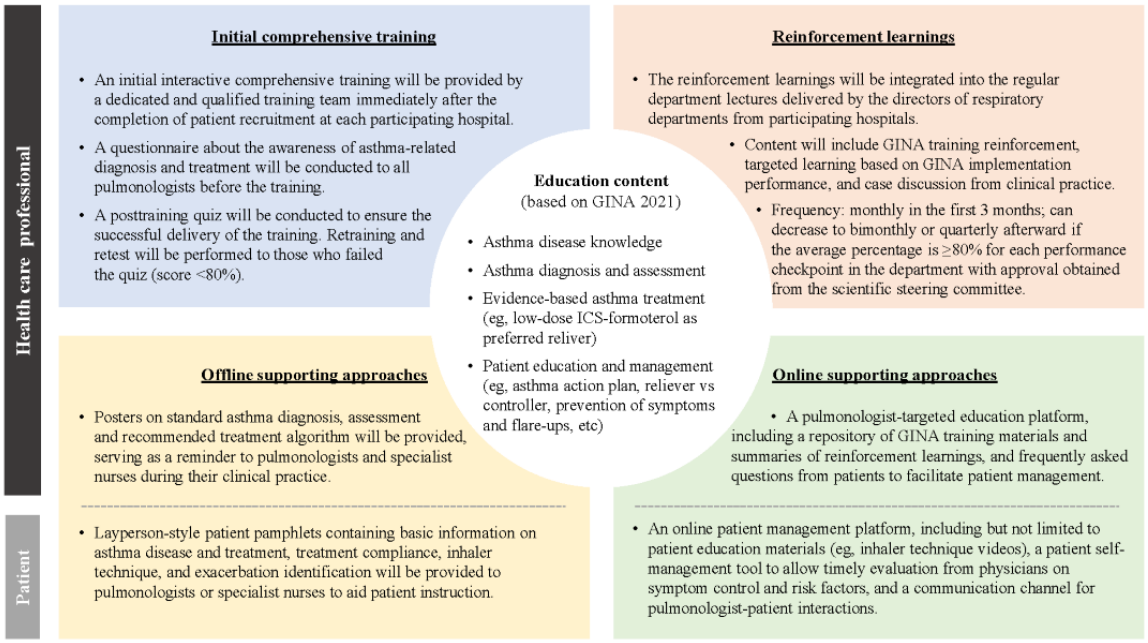
Interventions

The QIP delivered at the hospital level targeted all pulmonologists and specialist nurses at each participating hospital with the goal of encouraging asthma management per the GINA 2021 recommendations in their routine clinical practice. The program included initial comprehensive training, which was delivered by a dedicated qualified team (including asthma experts in the same province or region as the participating hospital) immediately after the completion of patient recruitment at each site. This timing of training commencement was designed to avoid biasing the baseline data of clinical characteristics by training-induced behavior changes. The education content was based on recommendations from the GINA 2021, including, but not limited to, asthma diagnosis and assessment, evidence-based asthma treatment and the scientific rationale, and patient education and management (eg, asthma action plan, the rationale for medication adherence, etc). A posttraining quiz was conducted to ensure the successful delivery of the training. Thereafter, pulmonologists and specialist nurses were required to attend regular reinforcement learnings to enhance their understanding of GINA-recommended asthma management and address practice gaps identified from the GINA implementation performance assessment. During this study's period, multiple online and offline approaches served as supportive tools to increase adherence to the GINA recommendations (Figure 2). In addition to pulmonologists- or nurses-targeted efforts, layperson-style patient pamphlets and an online patient management platform were developed to help enhance patients' adherence to asthma treatment (Figure 2). The platform housed patient education materials, incorporated a patient self-management tool, and provided a communication channel to facilitate physician-patient interactions.

A scientific steering committee consisting of external asthma experts, most of whom are committee members of the Asthma Group of the Chinese Thoracic Society, was established to control the overall quality of the QIP. The committee reviewed and approved the overall design of this study and ensured that the education plan and related materials were scientifically and clinically appropriate. The committee was also involved in the review and interpretation of this study's results.

Monthly assessments of GINA implementation performance were conducted to guide QIP adjustments (eg, targeted reinforcement learnings) at the hospital level. GINA implementation performance was assessed against 6 predefined key performance indicators (Textbox 2) for each participant's visit. The proportion of participants achieving each checkpoint was calculated at the hospital level, which can help identify gaps in GINA implementation and determine future targeted training needs. Assessment feedback was provided to the scientific steering committee and the directors of participating departments. If the GINA implementation performance was unsatisfactory at a participating department (defined as the average percentage at the department level lower than 80% for at least one performance checkpoint), the scientific steering committee discussed the root cause with the department director and provided instructions for an improved plan.

Figure 2. Multifaceted approaches designed to facilitate GINA implementation in the QIP. GINA: Global Initiative for Asthma; ICS: inhaled corticosteroid; QIP: quality improvement program.



Textbox 2. Key performance indicators for Global Initiative for Asthma implementation performance and data source.

Questionnaires collected from participating patients after each visit

- Whether or not the pulmonologist or the specialist nurse assessed the patient's symptom control over the past four weeks?
- Whether or not the pulmonologist or the specialist nurse watched the patient using their inhaler?
- Whether or not the pulmonologist discussed treatment adherence?
- Whether or not the pulmonologist developed or reviewed the written asthma action plan?
- Whether or not the pulmonologist reduced the dosage of asthma treatment? If yes, whether the patient had a pulmonary function test before dosage reduction?

Medical records

- Whether or not the pulmonologist has provided ICS-containing medication for maintenance or as a reliever?

Assessment and Data Collection

The electronic data capture system was used for data collection and query handling, and all data was recorded in the electronic case report form per prespecified instructions. All data were obtained from medical records generated during routine clinical practice except for the questionnaires to be completed by patients. During this study, usual care activities were performed as needed and no additional examinations were required.

At each study visit (including baseline and follow-up visits, Figure 1), medical records on asthma-related assessment and treatment during the past 12 weeks were collected, and two patient-reported outcome questionnaires—a five-item Asthma Control Questionnaire and Standardized Asthma Quality of Life Questionnaire—for patients aged 12 years and older was administered. The Medication Adherence Report Scale for Asthma, the asthma knowledge questionnaire for patients (study-defined, designed based on The Validity and Reliability of an Asthma Knowledge Questionnaire Used in the Evaluation of a Group Asthma Education Self-Management Program for Adults With Asthma), the patient inhaler skill assessment and the patient expectation of asthma treatment questionnaire (study-defined) will also be administered at baseline or follow-up visits (Multimedia Appendix 1). Additionally, patients' demographics, clinical characteristics within three months, and historical data (eg, asthma history, comorbidities, and comedication history) were collected at baseline, and hospitalization and outpatient visit records related to asthma were collected at follow-up visits (Multimedia Appendix 1). To better reflect real-world conditions, no free medications were provided in this study, and information on the sources from which patients purchase their medications was collected at baseline. Participants were encouraged to return to this study's hospital if they had asthma-related conditions or worsening symptoms. In case of emergency, they could choose to visit a hospital other than this study's hospital but were required to report it to study pulmonologists or study staff with supporting documents (eg, medical record of hospitalization summary). Data generated from other hospitals were collected as per protocol. A patient might withdraw from this study at any time at their own request; at the time of withdrawal from this study, an early study discontinuation visit was conducted for any data that needed to be collected.

Data Analysis

Sample Size Estimation

With a 30% dropout rate and a within-participants correlation of 0.25, approximately 1500 patients are required to provide an 80% power at a significant level of .05 to detect an increase from baseline of 5% at week 48 in the proportion of patients with an ICS-based maintenance or reliever therapy, which is assumed to be 40% at baseline [26].

Statistical Plans

The main analyses that assess the impact of QIP were performed using the full analysis set (FAS), which consisted of all enrolled participants with at least one nonmissing postintervention GINA treatment assessment. Baseline demographics and characteristics will be presented for all enrolled participants and FAS. Continuous variables will be summarized descriptively as appropriate. Categorical variables will be presented as frequency counts and percentages. When applicable, 95% CIs will be presented with estimates of proportions.

Analysis of the primary end point were conducted in the FAS with a mixed effect logistic regression model, considering the measurement time point (baseline or post baseline) as the fixed effect and hospital, pulmonologist, and patient as the random effects. In case of lack of convergency, the hospital and pulmonologist were removed from the model. A sensitivity analysis was conducted with a generalized estimating equations model including the same covariates as in the primary analysis. Secondary and exploratory end points were presented primarily with summary statistics. For the analysis of end points, by-visit end points were analyzed using observed data, and missing data were not imputed.

Subgroup analyses were performed as appropriate according to age (<18, 18–65, or >65 years), age of asthma onset (<20, <40, or ≥40 years), phenotype of asthma (allergic or nonallergic), hospital level (tertiary or secondary), occupation (asthma-related or not), baseline characteristic, questionnaire response status (with or without response), adherence, patient expectation of asthma treatment, asthma history, asthma severity class, type of the participating hospital department (pulmonary and critical care medicine or nonpulmonary and critical care medicine), geographic region (North or South), change from baseline in ICS-containing treatment (with-to-with, with-to-without,

without-to-with, or without-to-without ICS-containing treatment), and change from baseline in ICS-formoterol as reliever (with-to-with, with-to-without, without-to-with, or without-to-without ICS-formoterol as reliever). Any participants with a missing value for a predefined subgroup were excluded from the analysis of that subgroup.

Ethical Considerations

This study's protocol had been approved by the Ethics Committee of Beijing Chao-Yang Hospital, Capital Medical University (2022-KE-22).

Informed consent was obtained from a participant or their legally authorized representative before conducting any procedure specifically for this study on the participant.

Participants were assigned a unique identifier by the sponsor. Any participant records or datasets that were transferred to the sponsor contained the identifier only; participant names or any information that would make the participant identifiable were not transferred.

Participant payment outlines were discussed in the informed consent process. Participants were paid a CN ¥ 200 (approximately US $27.50 as of December 12, 2024) transportation fee per on-site visit for reasonable expenses incurred due to their participation in this study.

Results

This study has been completed, with 1500 patients enrolled and 1271 patients completing the study. The last visit of the last patient was on September 3, 2024, and the database lock was on September 28, 2024. Final analysis of data has started in October 2024.

Discussion

Rationale and Study Design

Poor symptom control and exacerbations of asthma impair work and activities, diminish quality of life, and pose a significant burden to patients and society [9,27]. Implementing evidence-based management as recommended by GINA has the potential to improve the quality of domestic asthma care and vastly reduce the disease burden of asthma in China [17]. In line with GINA recommendations, the latest versions of the Chinese guidelines and an expert consensus for asthma management also advocate for ICS-based maintenance and relieving treatment [8,28]. Meanwhile, ICS-containing medications such as budesonide and budesonide-formoterol have been included in China's National Essential Drug List and National Reimbursement Drug List, ensuring patients' access to these asthma medications (including those with special needs such as school-aged patients who may require more than one canister with a single prescription to maintain medication availability both at school and at home). However, at present, domestic asthma control is still unsatisfactory with patients' treatment patterns deviating from the GINA recommendations, suggesting that Chinese physicians' suboptimal awareness of and adherence to the recommendations [2,12,16] may be an important underlying factor that warrants further improvement. Experience from other countries has demonstrated that clinical benefits can be achieved through QIPs for asthma care [21-23]. As such, the CARE4ALL study will conduct China's first-ever nationwide multifaceted QIP targeting physicians with a specialization in pulmonary or respiratory care, which aims to transform the suboptimal asthma control status in China by bridging the gap between GINA recommendations and current clinical practice among Chinese physicians.

Expected Results

We expect that the physicians' awareness of and adherence to the GINA recommendations will be enhanced through the QIP, which would be manifested as more widespread clinical practices that are per evidence-based asthma management, including the implementation of standard, GINA-recommended treatment. We further anticipate that the improved quality of care provided by the physicians would translate to better asthma control and health-related quality of life among the patients. If this study demonstrates these benefits of the QIP in standardizing asthma management in China, this QIP could be considered as a standard model that the whole country can apply to reduce the burden of asthma in China.

Strengths

As the first nationwide QIP for asthma care with a prospective evaluation of clinical impacts in China, the CARE4ALL study has several strengths in its design which differentiate it from previous simple, small-scale educational interventions. First, multifaceted intervention will be provided for physicians to aid understanding and encourage close adherence to the GINA recommendations. The initial comprehensive training intends to familiarize physicians with GINA, which will be reinforced by regular learning sessions typically unseen in routine educational events. Additionally, both online and offline supporting materials are readily available to physicians for easy reference and patient education. Second, different from routine physician-oriented educational events and toolbox, this QIP will also provide physicians with support to facilitate patient management in clinical practice. As effective asthma care requires patients to be actively engaged in multiple self-management behaviors, improving patients' adherence with GINA-recommended practices (eg, ICS-containing medications, appropriate device technique, use of an asthma action plan, etc) is of great importance to the ultimate success of the GINA implementation. Notably, apart from layperson-style patient education materials aiming to raise patients' awareness of disease management and treatment strategies, an online patient management platform will be developed to facilitate timely evaluations of symptoms and effective physician-patient communications. These interventions are expected to improve patients' treatment adherence and consequently asthma control as demonstrated by previous studies [29,30].

Third, the GINA implementation at the hospital level will be monitored based on the 6 performance indicators and dynamically improved based on feedback from the scientific steering committee, which consists of national asthma experts. Therefore, all the participating hospitals can benefit from constructive instructions from the committee. Finally, while primary health care facilities in remote rural areas will be

excluded due to their inadequate administrative and data management capacity, this study will encompass both tertiary and secondary hospitals from as many provinces or municipalities as possible, aiming to provide unprecedented coverage to better represent the real-world situations in China [18,19]. In China's current medical system, most asthma patients are diagnosed and treated under specialist care rather than by general practitioners, thus this study, by specifically targeting pulmonologists, will exert a direct and substantial effect on shaping the clinical practice of asthma care in China's medical system. As such, experiences and lessons from the program will hopefully inform a valuable model for asthma care improvement in the whole of China as well as for similar programs for other chronic diseases.

This QIP is expected to exert a sustained impact on asthma care practices. First, unlike brief educational events [18], the intervention for our study will last for one year, providing a sustained framework for cultivating evidence-based clinical practice behaviors in physicians. Second, both online and offline supporting materials used during the QIP will continue to be accessible to physicians after the program finishes; coupled with continuous assessments of GINA implementation performance, these resources will aid in maintaining physicians' awareness and adherence to GINA-recommended asthma management. Lastly, by not providing free medications, this study will closely mirror any potential influence that medication accessibility or affordability may have on patients in real-world conditions, thereby enhancing the generalizability of the findings.

Limitations

This study has two key limitations. First, it lacks a concurrent control arm. Instead, it follows the before-and-after design and compares variables measured before and after the QIP, which is an approach often adopted in QIP-evaluating studies for the purposes of better reflecting real-world settings and maintaining simplicity. The effectiveness of this before-and-after design in reflecting the effects of QIP interventions has been widely demonstrated [23,31,32]. Second, multiple sources will be used for data collection, likely leading to missing and inconsistent data. Given that patients may be admitted to other hospitals due to exacerbations, data collection from multiple sources will be inevitable. Past and new hospitalizations out of the study hospital due to exacerbations will be recorded based on medical records rather than patients' personal accounts to reduce missing data and minimize recall bias.

Conclusions

In summary, the CARE4ALL study should help improve asthma management and patient outcomes in China by bridging the gap between evidence-based GINA recommendations and the current clinical practice. This multifaceted QIP is expected to provide valuable insights for further quality improvement in asthma care at the national level.

Abstract

Background: *:* With more than 60 million new cases around the world each year, traumatic brain injury (TBI) causes substantial mortality and morbidity. Managing TBI is a major human, social, and economic concern. In the last 20 years, there has been an increase in clinical trials in neurocritical care, leading mostly to negative results. The evaluation of neurological outcomes, predominantly as primary outcomes, using clinical scales (Glasgow Outcome Scale) has limitations that could explain these results. Moreover, patient-centered outcomes are seldom reported despite their recognized clinical relevance.

Objective: *:* The aim of this project is to establish a core outcome set (COS) for patients with moderate-to-severe TBI in randomized control trials in neurocritical care research.

Methods: This study will follow five distinct steps: (1) systematic review to identify outcomes that have been reported in trials; (2) semistructured interviews with patients and their families to identify their priorities after TBI and explore potential patient-centered outcomes; (3) health care stakeholder focus groups with clinicians, researchers, and policy makers to describe potential outcomes; (4) an eDelphi survey with stakeholder groups to make a list of previously identified core outcomes; and (5) a consensus workshop to establish a COS for moderate-to-severe TBI clinical trials.

Results: : The systematic review was published in August 2024. Regarding Step 2, 30 semistructured interviews of patients and relatives were performed from July 2021 to December 2023, and analyses were completed in October 2024. Step 3 is currently under development, and Step 4 is planned for the end of 2025. Step 5 is expected to occur during fall/winter 2026. **Conclusions**: Establishing a COS, to be consistently measured and reported in TBI trials in neurocritical care will ensure rigorous reporting, avoid bias, and improve the integrity, transparency, and usability of clinical research. The French context of the study is the main limitation, but we are seeking international collaboration on the project. The results of each step of the project will be disseminated through abstracts, publications, and patient associations.

Conclusions: Establishing a COS, to be consistently measured and reported in TBI trials in neurocritical care will ensure rigorous reporting, avoid bias, and improve the integrity, transparency, and usability of clinical research. The French context of the study is the main limitation, but we are seeking international collaboration on the project. The results of each step of the project will be disseminated through abstracts, publications, and patient associations.

core outcome set; outcomes research; patient-centered outcomes; traumatic brain injury; patient outcome; head trauma; patient-centered

Introduction

Despite advances in critical care medicine in the last decades, mortality in patients with traumatic brain injury (TBI) remains high at approximately 15% after trauma [1]. Survivors of TBI experience major consequences: mood disturbances [2], memory loss, neuropsychological impairment [3,4]. Caregivers also experience major burdens with strain, isolation, and disappointment [5,6].

Many work groups recommend that various outcome domains or outcome measurements [7,8] be collected to assess neurological recovery after TBI, mainly in the continuum of rehabilitation. Most often, this involves a combination of multiple measurement scales that collectively capture all dimensions affected by a TBI [9,10].

Nevertheless, in neurocritical care, the primary outcome in most randomized controlled trials (RCTs) is the Glasgow Outcome Scale [1,11]. Indeed, given the broad spectrum of sequelae after acute brain injury, Jennett and Bond [12] proposed the use of the Glasgow Outcome Scale in 1975 to assess neurological recovery after TBI. Since then, this 5-grade scale (death, vegetative state, severe recovery, moderate recovery, and good recovery) has been extensively reported in the neurocritical care literature to compare the efficacy of various treatments after trauma [13-15]. The Glasgow Outcome Scale was considered too simplistic, leading to the creation of an 8-grade extended version in 1981 [16]. The Extended Glasgow Outcome Scale is used extensively in neurocritical care literature to evaluate neurological recovery, often as a primary outcome in clinical trials [17].

Recently, major concerns have been raised regarding the relevance of these scales and their methodological limitations in neurocritical care clinical research. The Glasgow Outcome Scale has substantial interobserver variability, albeit possibly decreasing over time [18]. Nevertheless, this puts score reliability and accurate patient classification into question [19,20], which could lead to erroneous results despite rigorous analysis. Moreover, analysis of data from this scale is often inappropriate, since these data are generally considered continuous when they are ordinal [21]. In addition, assessment conditions can vary and affect patient evaluation. Evaluation can be performed via telephone [22] or face-to-face interviews, for only brain injury or all injuries (brain and peripheral body parts), or by trained or untrained assessors. These variables are frequently not described in other studies [3,11,18]. However, it is recommended that such assessments should be performed by a certified expert in the presence of the patient and caregiver [23]. Certain authors have recently questioned the consistency between these scales and patient quality of life [24,25]. This raises the question of a patient's understanding of their situation and handicap, which is never evaluated in randomized controlled trials, despite being recognized as an important factor [26]. The aforementioned methodological issues and limitations associated with these scales could explain the litany of negative results in neurocritical care research over the past 30 years [1,15,17,27,28].

Core outcome sets (COSs) can minimize reporting bias, promote consistency in clinical trials, enable direct comparisons of the effect of different interventions, and ensure that outcomes are relevant and important to patients, health care professionals, and caregivers [29]. Hence, the use of COSs for patients with TBI in neurocritical care could reduce the considerable inefficiencies in biomedical research. With more than 60 million new cases of TBI diagnosed globally each year [30,31], there is an urgent need to develop COSs in this area. Accordingly, this project aims to establish a COS for trials in patients with moderate-to-severe TBI included in interventional trials performed during the early phase of the pathology and other types of research including observational studies (eg, registries and other quality indicators for clinical care). This core outcomes set will improve the quality of trials, respond to patient needs, and help rectify decades of negative results.

Methods

Overview

The project will be developed in 5 steps according to the methodology of the Core Outcome Measures in Effectiveness Trials (COMET) initiative. The aim of the COMET initiative is to create a COS built by stakeholders, including patients [32,33]. First, we will perform a systematic review of the outcomes in TBI clinical research at the acute phase. Second, we will organize semistructured interviews with patients who survived moderate-to-severe acute TBI and their family caregivers. Third, we will organize semistructured interviews and focus groups of stakeholders involved in the health care pathway of patients with TBI. Fourth, we will perform an eDelphi survey. Finally, a consensus workshop will finalize the process.

Step 1: Systematic Review

Step 1 was completed in August 2024, and the original article was published [34]. We identified 29 domains related to the 557 different outcomes that will be used for interviews with health care professionals (Step 3) and the eDelphi survey (Step 4).

Step 2: Semistructured Interviews With Patients and Their Families

Explanation and Overview

We will organize semistructured interviews with patients in the late phase of TBI and their family caregivers. To the best of our knowledge, semistructured interviews involving both patients with TBI and their families have been poorly explored. Throughout the qualitative research, we will follow the Interpretative Phenomenological Analysis (IPA), a methodology described by Smith et al [35].

Participants and Recruitment

Patients with TBI aged 18 years and older and a family caregiver (the patient's choice) will be eligible to participate. A purposive sampling strategy will be used to organize a minimum of 15 semistructured interviews with the dyad (patient and their family caregiver). The aim is to perform individual semistructured interviews with patients alone and then perform another individual dedicated interview with relatives alone to avoid cross-contamination of interview responses between the 2 parties. However, given the potential challenges for patients (mood disorders, speech disorders, and difficulties in concentration), relatives may attend the patient's semistructured interview to assist them. The final interviews will depend on when data saturation is reached. We will define saturation as the point when new themes or variations of a given theme cannot be identified. Participants will be recruited from participating centers across France (Bordeaux, Nantes, Rennes, and Saint-Etienne, along with any other contacted centers). The patients and their caregivers will be asked by physical and rehabilitation specialists to participate in the study. Patients in the late phase of TBI will be recruited—defined as the moment when a patient has been discharged at least partially, meaning they no longer require full-time care in a health care facility. The consequences of TBI on their social and personal environments will be assessed.

The steering committee will carry out a sampling strategy to achieve maximum variation in demographics (age, sex, and socioeconomic status) and clinical characteristics (patients with good or poor recovery). We will follow the Consolidated Criteria for Reporting Qualitative Health Research (COREQ) guidelines [36].

Data Collection

Each semistructured interview, performed with an IPA approach according to participants' life experiences, will last a maximum of 90 minutes and take place remotely via videoconference. This is due to the uncertainties in the aftermath of the COVID-19 pandemic. In any case, these interviews will take place outside the hospital to encourage open discussion and limit the stories due to the feeling of disempowerment that could occur in a clinical setting. Each interview, performed by a nurse researcher (senior in qualitative research) and a PhD student, will cover the following for both patients and families: (1) an introduction (5 minutes), where the facilitator will explain the aims of the study and ask the participants to introduce themselves; and (2) the interview (60 minutes), where the participants and families will be asked to discuss their experiences of living with the consequences of TBI, including perceived benefits, harms, and complications related to the pathology and its treatments. The topic guide was tested with 3 dyads and adjusted accordingly (Multimedia Appendices 1-2).

Data Analysis

The interview transcripts will be imported into NVivo 12 software (v.1.8; QSR International) [37] to facilitate qualitative data analysis. We will follow the 7 IPA steps described by Smith et al [35]: (1) reading and rereading, (2) exploratory noting, (3) constructing experiential statements, (4) searching for connections in experiential statements, (5) naming the personal experiential themes and consolidating and organizing them, (6) moving to the next case, and (7) working with personal experiential themes to develop group experiential themes across cases. The IPA method reflects the experience, beliefs, values, attitudes, and reasons underlining participant choices, along with those of their relatives. The preliminary themes will be discussed with other investigators to ensure that the full range and depth of data are captured (investigator triangulation) and with patient associations for the full themes.

Step 3: Stakeholder Interviews

Explanation and Overview

Field investigations, in-depth and semistructured interviews, and focus groups will be performed to capture the expectations and practices regarding the management of TBI patients and to detail the range and depth of individual values, beliefs, and attitudes toward outcomes. These interviews or focus groups will not quantify the frequency of opinion. Reporting will adhere to the COREQ guidelines.

Participants and Recruitment

Interviews and focus group discussions will be conducted with the following stakeholder groups: (1) health care providers

(anesthesiologists, intensivists, neurosurgeons, rehabilitation specialists, nurses, and psychologists); (2) representatives from research, funding, policy, and other stakeholder organizations; and (3) patients and their relatives. A minimum of 60 stakeholders is expected at this point and will be identified from the investigator networks and by snowball effect. At this stage, the steering committee will reach out to stakeholders in other countries to participate in specifically dedicated interviews. Participants will be identified to obtain a maximum variation of representation in professional experience and responsibilities (health care providers and representatives from stakeholder organizations). Recruitment will continue until saturation has been achieved. Informed consent will be obtained from all participants and specific institution review board (IRB) approval will be sought.

Data Collection

From a grounded theory perspective [38], field investigations will be conducted in intensive care and rehabilitation units. Interviews and focus groups will incorporate the results from the systematic review and semistructured interviews with patients and their families, allowing other stakeholders to discuss these elements as well. Stakeholders will be asked to reflect and talk about (1) caring for patients with TBI, (2) the benefits and harms of TBI-related outcomes, (3) outcomes believed to be relevant and important to include in future clinical research, and (4) the results obtained from the semistructured interviews with the patients and their families. Face-to-face interviews will be conducted; however, if this is not feasible, web or telephone conferences will be arranged. Each interview will last between 60 and 120 minutes. The interviews will be recorded and transcribed verbatim.

A field researcher has been hired for a 24-month postdoctoral position to complete Step 3. She is a former intensive care nurse with a PhD in sociology from the University of Nantes and has extensive experience in field investigations and conducting interviews. She has no conflicts of interest related to the topic.

Data Analysis

Data analysis is expected to begin in 2025. Verbatim transcripts from interviews and focus groups will be transcribed word for word and anonymized. Following the grounded theory methodology [38], each transcript will undergo a constant comparison across individuals and stakeholder groups. Analytical themes will be developed inductively to identify the concepts relevant to the participants, from which a list of outcomes will emerge.

Step 4: Delphi Consensus Survey

Explanation and Overview

At this stage, international contacts will be established to conduct an international eDelphi survey [29,39,40]. This survey will gather opinions and organize the outcomes into a prioritized list. The Delphi method is an iterative consensus technique involving sequential surveys completed anonymously by a panel of participants with relevant knowledge and expertise, ensuring equal influence among all participants [41]. We will aim to retain a minimum response rate of 70% for all rounds.

Participants and Recruitment

There is no standard sample size required for Delphi processes. At this point of the protocol, there is no goal regarding the minimum number of stakeholders that will be involved in the Delphi process (ie, patients, family caregivers, nurses, allied health professionals, policy makers, and clinicians in critical care, rehabilitation, and neurosurgery). To ensure maximum variation in sampling, participants will be recruited by using a similar strategy, and approximately one-third of each stakeholder group will be recruited from the participating regions. The participants will be recruited through participating hospitals or institutions and patient organizations. Informed consent will be obtained from all participants.

Data Collection

Overview

The list of outcomes will be obtained from Steps 1, 2, and 3. The outcomes will be listed individually and grouped under each relevant domain according to the COMET initiative definitions [32,42]. The survey will be reviewed by the steering committee. The surveys will be completed over the internet by using a unique identifier, which will enable us to identify participants completing all 3 rounds of the eDelphi survey. At least 3 reminders will be sent to participants during the Delphi rounds.

Round 1

Participants will be asked to rate each outcome using the Grading of Recommendations, Assessment, Development, and Evaluation (GRADE) process [43]. The process recommends a 9-point Likert scale to rank importance. Rankings between 7 and 9 indicate outcomes of critical importance, those between 4 and 6 indicate outcomes that are important but not critical, and those between 1 and 3 indicate outcomes of limited importance. An option “unable to score” will also be available. All outcome domains will be randomized to minimize ordering bias. Participants can suggest additional outcomes and provide reasons for their rankings. The additional outcomes will be recorded (if not duplicated with a previous outcome), grouped in the relevant outcome domain by 2 members, and reviewed by the steering committee. We will review the distribution of scores for all outcomes for each stakeholder group (ie, patients/caregivers, clinicians, health professionals, etc). Any outcomes with a median or mean over 7 will be retained for round 2, along with additional outcomes retained by the steering committee.

Round 2

Participants will review the group scores and their own scores for each outcome. They will rerank the outcomes (including additional outcomes identified in round 1) using the 9-point scale and explain the reasons for any changes in their scoring. An outcome with a median or mean over 7, and with 70% or more participants in both stakeholder groups (ie, patient/family member and health professionals) rating the outcome to be of critical importance (7-9), will be included in round 3.

Round 3

Participants will be shown their own scores, along with the distribution of scores for each outcome across all stakeholder groups and within individual stakeholder groups. A summary of the results from Steps 2 and 3 will be provided. Participants will be asked to rerank all outcomes and indicate whether they should be included in the COS. To assess the relative importance of the outcomes, they will choose the most important and least important in each outcome domain.

At this point, the recruitment of stakeholders for Step 4 and the Delphi process will not be undertaken for at least 2 years. Data analysis of Step 4 (Delphi process) will be further elaborated and will not be more detailed at this stage.

Step 5: Consensus Workshop

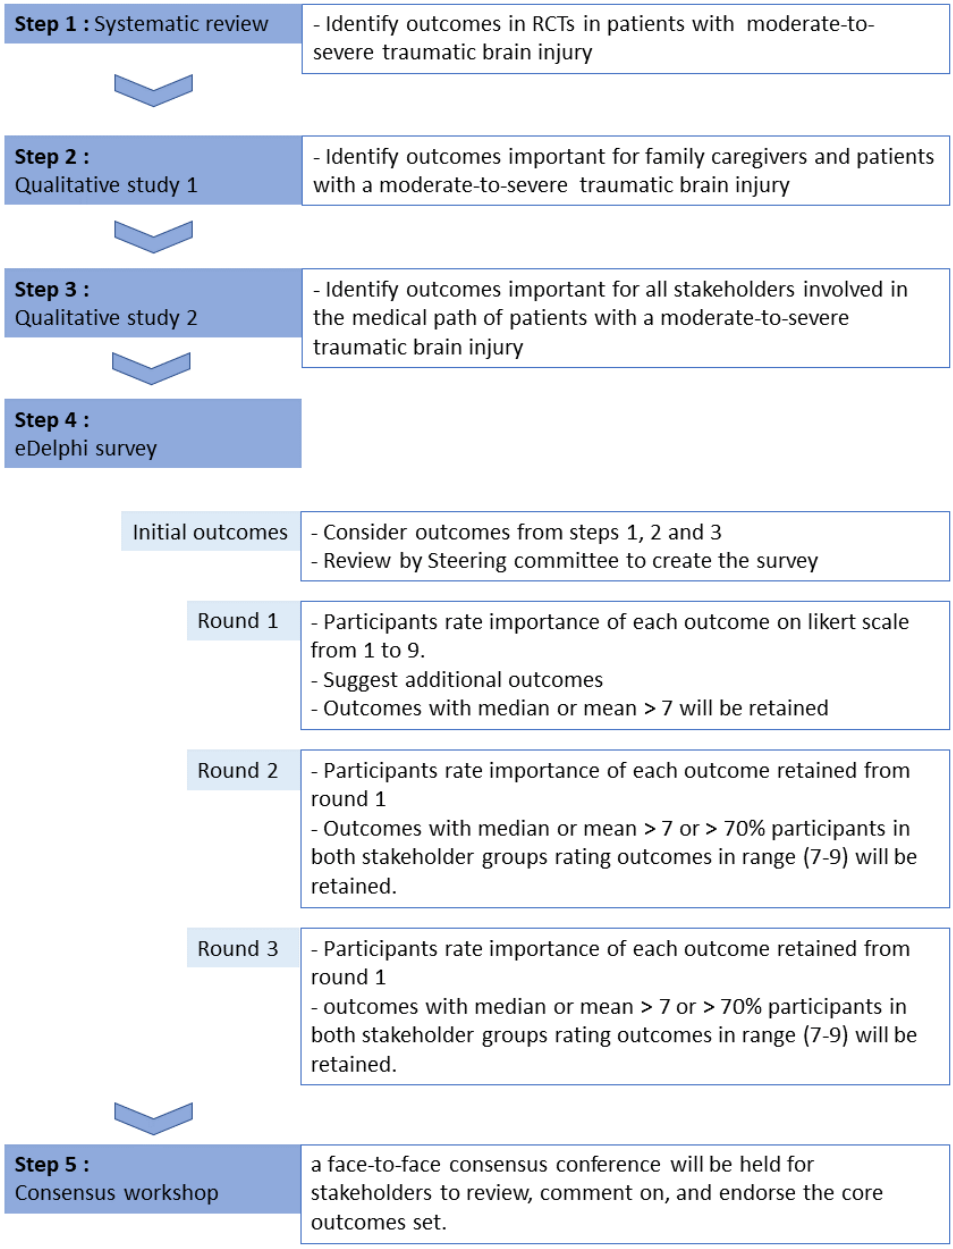
A face-to-face consensus conference will be held for stakeholders to review, comment on, and endorse the COS. This conference will be chaired by members of the steering committee. As of yet, the number and origins of participants at the workshop have not been established. This sample size is based on the Outcome Measures in Rheumatology (OMERACT) consensus workshop. Purposive sampling will be carried out to ensure maximum variation of demographic and clinical characteristics. Informed consent will be obtained from all participants. All discussions will be recorded and transcribed. The overall conference program is outlined in Textbox 1.

Given the timeline of the project, Step 5 will not be undertaken for another 3 years (around mid-2026). The articulation, organization of the workshop, and data analysis will be further elaborated but not detailed here. Figure 1 articulates the differences between the 5 steps.

Textbox 1. Conference program details.

1. Presentation of results: Detailed results from Steps 2, 3, and 4 will be distributed to the participants. The results will be presented during a plenary session of the consensus workshop, and the outcomes will also be shown according to the consensus classification.
2. Breakout group discussion: Participants will be divided into several groups. A trained facilitator will moderate a group discussion on the results from Steps 3 and 4, consensus classification of outcomes, similarities and differences in stakeholder groups, and the resolution of any disagreement, uncertainties, or issues identified.
3. Plenary discussion: Each breakout group will present a summary of their discussion. The conference chair will moderate the discussion.
4. Endorsement of core outcome set (COS): Participants will be asked to formally endorse the core outcomes set which will include the outcome classified as consensus.

Figure 1. Summary of the project regarding the development of a core outcome set in neurocritical care for patients with traumatic brain injury (TBI). RCT: randomized controlled trial.



Ethical Considerations

All steps will be performed according to the appropriate guidelines and regulatory processes.

Step 1

Ethical approval is not required for this step.

Step 2

Patients and relatives provided informed consent to participate in the semistructured interviews (CERAR IRB 00010254 - 2022–093). The analysis of the interview transcripts will be anonymized to respect privacy and anonymity. Finally, patients and relatives will receive €50 (US $52.12) each for compensation for their time to perform these interviews.

For the elaboration and recruitment of patients for Step 2 (semistructured interviews), the group is currently working with the association of patients and families (“Union Nationale des Associations des Familles de Traumatisés Crâniens”).

Step 3

Interviews and focus groups with health stakeholders will also comply with rules and regulations. Although no IRB is necessary in France regarding surveys [44], oral consent will be collected from participants. Verbatim analyses and data will be anonymized and deidentified.

Step 4

No health data are collected in Step 4. Moreover, IRB approval is not mandatory in France for this type of research. However, we will comply with all national authorities’ guidelines in case

of international collaboration. We will also comply with laws and regulations for the publication process.

Step 5

No health data are collected in Step 5. Moreover, IRB approval is not mandatory in France for this type of research, but we will comply with all national authorities' guidelines in case of international collaboration. We will also comply with laws and regulations for the publication process.

Results

Step 1 was completed, and the paper was published in August 2024 [34]. This systematic review was performed from January 2021 to October 2023.

Regarding Step 2, 30 semistructured interviews were carried out (15 patients and 15 caregivers) throughout France. The interviews were performed between July 2021 and December 2023. The results of the verbatim analysis (ie, group experiential themes through cases) were finalized in September 2024, and we expect to begin the publication process by the end of 2024. We aimed to understand the quality of life of both patients and family caregivers, focusing on what matters most to them in their daily lives. The elaboration of Step 3 began in May 2024. The aim of this part of the project is to understand different stakeholder points of view regarding the choice of end points in clinical research.

Although Steps 2 and 3 have not yet been achieved, we have already begun engaging with the scientific community, clinicians, health professionals, other health care stakeholders, and patient associations for the upcoming Delphi process, which is scheduled for the beginning of 2026. This proactive approach ensures that we will have the most comprehensive group of participants for the Delphi process. Step 5 will mark the finalization and dissemination of the COS. This step is preplanned to start in fall/winter 2026.

Discussion

Principal Findings

This project introduces a novel clinical research methodology for TBI through the development of a COS. This COS includes a rigorous multidimensional evaluation of the outcome of patients and encourages the integration of Patient-Reported Outcome Measures (PROMs) in this context. We believe this initiative will address decades of negative findings on this topic, emphasizing the urgent need to improve patient outcomes amid strained resources. The project involves various stakeholders, especially patients and family caregivers, in a rigorous methodological approach that has been successfully tested in other medical disciplines [32,45].

Many work groups have published common data elements [46,47] recommended for RCTs. However, these common data elements are unsuitable for RCTs targeting early interventions in neurocritical care. Notably, our systematic review [34] highlighted the low use of patient-reported outcomes in RCTs, despite increasing advocacy for their use by researchers [26,45].

The study's French context is its main limitation, but we are pursuing international collaboration to ensure its global relevance. Furthermore, given that health systems in high-income countries are often comparable, the findings should be globally applicable.

The results of each step will undergo scientific validation and publication. The dissemination plan includes communications in both national and international congresses involving key stakeholders in TBI research, such as anesthesiologists, intensivists, neurosurgeons, trauma leaders, neuropsychologists, and nurses. Targeted congresses include the French Society of Anesthesia and Intensive Care, European Society of Intensive Care Medicine, the European Society of Anesthesia and Intensive Care, and the International Brain Injury Association—among others. Publications will be submitted to peer-reviewed journals. Where resources allow, we intend to publish our findings in open access whenever possible. Finally, the final COS will be published in a major journal (eg, British Medical Journal, Lancet Neurology), given the initiative's importance and its potential to improve research quality.

We also intend to share our findings with patient associations and through social media. We will disseminate our findings through public engagement activities, based on existing initiatives in their respective countries/institutions, such as European Researchers' Night, alongside collaborations with private insurance companies (ie, AXA and MMA).

The COS will emerge from a consensus process designed to improve the quality and relevance of research evidence in neurocritical care RCTs involving patients with TBI. We expect that the COS will be used only in the RCTs but may also be valuable in other types of research, such as observational studies (eg, registries) and as quality indicators for clinical care.

Conclusion

This project aims to improve the integrity, transparency, usability, and impact of research related to patients with moderate-to-severe TBI. It will ensure that outcomes relevant to all stakeholders are consistently reported in trials, thereby minimizing outcome reporting bias. Ultimately, this will protect patients from potential harm, enable patients and clinicians to make informed treatment decisions, and allow researchers and policy makers to maximize the public value of research.

Acknowledgments

For this project, RC received grants of €345,000 (US $359,655) from Agence Nationale Pour la Recherche, the Région Pays de Loire "Programmes Investissements Avenir" (grant RC22_0349_1), Les Gueules Cassées, and the French Society of Anaesthesia and Critical Care (Société Française d'Anesthésie-Réanimation).

Data Availability

Publications will be made accessible as much as possible (eg, the Step 1 systematic review), depending on available funding. Full data may be available provided upon adequate request to the corresponding author.

Conflicts of Interest

None declared.

Abstract

Background: Due to advances in treatment, HIV is now a chronic condition with near-normal life expectancy. However, people with HIV continue to have a higher burden of mental and physical health conditions and are impacted by wider socioeconomic issues. Positive Voices is a nationally representative series of surveys of people with HIV in the United Kingdom. It monitors the physical, mental, and social health, well-being, and needs of this population so that they can be addressed.

Objective: This paper aimed to describe the methodology, recruitment strategies, and key demographic features of participants recruited for the second national round of Positive Voices (PV2022).

Methods: PV2022 was a national, cross-sectional questionnaire study that included people attending HIV care at 101 of the 178 clinics in the United Kingdom between April 2022 and March 2023. Data from the HIV and AIDS reporting system (HARS), a national surveillance database of people with HIV and attending care that is held at the UK Health Security Agency (UKHSA), was used as a sampling frame. The information collected in PV2022 included demographic and socioeconomic factors, HIV diagnoses and treatment, mental and physical health, health service use and satisfaction, social care and support, met and unmet needs, stigma and discrimination, quality of life, lifestyle factors, and additional challenges experienced due to the COVID-19 pandemic. Data linkage to HARS enabled the extraction of clinical information on antiretroviral therapy (ART), HIV viral load, and CD4 lymphocyte counts. Probabilistic sampling was used to provide a randomly selected, representative sample of people attending HIV care who could be invited to complete a paper or online questionnaire. At the start of 2023, due to under-recruitment mainly due to the impact of the monkeypox (Mpox) outbreak, a separate sequential recruitment strategy was initiated in 14 of the largest clinics to increase participant numbers.

Results: Of the 4622 participants who completed the questionnaire, 3692 were recruited through probabilistic recruitment and 930 through sequential recruitment. The overall response rate (measured as the number of people who completed a questionnaire of those who either accepted or declined) was 50%. Survey respondents represented approximately 1 in 20 people diagnosed with HIV in England, Wales, and Scotland. The median age of participants was 52 years, 3428 of participants were men, 2991 were White, and 1121 were Black.

Conclusions: PV2022 is currently the largest survey of people with HIV in the United Kingdom (as of September 2024). The PV2022 findings will be used to explore the health and well-being of the HIV population and examine associations with demographic, socioeconomic, lifestyle, and other HIV-related factors.

Introduction

In the last 2 and a half decades, advances in HIV treatment have greatly reduced the mortality rate among people with HIV [1]. As a result, HIV is now viewed as a chronic condition with near-normal life expectancy [2]. As the population of people with HIV is ageing (half are now aged 50 years and older) [3] and health service delivery models are undergoing continuous change [4], it is essential to understand the types and levels of health needs of people with HIV and to assess long-term outcomes and quality of life [5].

In 2022, there were 94,397 people diagnosed with HIV and accessing care in England [6]. It was estimated that 95% of people with HIV were diagnosed; 98% of those diagnosed were on treatment; and 98% of those on treatment were virally suppressed and therefore unable to transmit HIV [7,8]. Research has indicated that despite substantial improvements in prognosis for people with HIV on treatment and the high coverage of specialist HIV care, there remains a significant level of psychosocial need among people with HIV [9]. They experience higher levels of mental health symptoms [9], with the prevalence of depression and anxiety around twice as much as the general population [10-12]. High levels of perceived and internalized stigma associated with HIV status are experienced by people with HIV, impacting their mental health [13]. Socioeconomic issues, such as poverty, unemployment, unstable housing, lack of social support, and intimate partner violence have also been shown to impact people with HIV, affecting both physical and mental health [14-16]. Understanding these needs is particularly crucial following a period of significant changes in health and social care service provision, due to policies of austerity and the COVID-19 pandemic [17]. Positive Voices (PV) collects and analyses these types of data, providing valuable insights that are used to inform national HIV policy and prevention programs and to evaluate and commission HIV specialist services.

PV is a cross-sectional questionnaire study of people with HIV who receive HIV specialist care in England, Wales, and Scotland, carried out every 3-5 years. In 2014, an extensive pilot phase that included formative research with the HIV community and health care staff facilitated the development of the survey methodology, which was subsequently used for the national roll-out in 2017 (Positive Voices 2017 [PV2017]) [9,18]. Our paper aims to describe the methodology and study design of the second round of the study: Positive Voices 2022 (PV2022).

Methods

Study Design

PV2022 was a national, cross-sectional questionnaire survey of people with HIV attending HIV outpatient care in England, Wales, and Scotland. The questionnaire data were linked to clinical data on antiretroviral therapy (ART), HIV viral load, and CD4 lymphocyte count from the HIV and AIDS reporting system (HARS), a national surveillance database of people with HIV attending care, held at the UK Health Security Agency (UKHSA).

Setting

In December 2020, all HIV clinics that routinely report to HARS were emailed by the PV team and asked whether they wished to express an interest in becoming a PV2022 study site. A total of 101 clinics, over half (57%) of the 178 HIV clinics in the country, returned an expression of interest, 98% of whom were in England (99/101), 1 was in Scotland (1/101), and 1 in Wales (1/101). Sixty-two (61%) clinics had previously participated in the previous round of the study (PV2017). Initially, the recruitment of participants was planned to begin in 2021, but was delayed as patient attendance at clinics was disrupted due to the COVID-19 pandemic restrictions. In April 2022, the recruitment of participants began, as services had started returning to face-to-face consultations. However, following the pandemic, many clinics had adopted a hybrid approach of giving remote telephone or video consultations as well as seeing patients in clinic. Refer to Multimedia Appendix 1 for a list of participating clinics.

In this paper, “clinic staff” has been defined as clinicians (nurses or doctors) and researchers who worked in the participating HIV clinics.

Sample Size

HARS was used as a sampling frame to provide a representative, random sample of people with HIV within each participating clinic who could be approached to participate in the PV2022 survey. HARS is a surveillance database held at the UKHSA that consists of pseudonymized data on the demographic, clinical, and treatment characteristics of people with HIV that is reported each quarter year by all HIV service providers in England [19,20].

The population of patients attending the participating clinics was approximately 74,000. The sample was to include 1 in 5 patients attending each of these clinics. Data from the pilot study and PV2017 indicated a proportion of individuals would be nonrecruitable due to being deceased, no longer attending clinic, being lost-to-follow-up, having been imprisoned or having an incorrect hospital identification number. Therefore, considering this, a sample list of 17,121 patients was created with the assumption that approximately 14,400 would be recruitable. Based on the response rate in PV2017 and observed declines in response rates in other large population-based studies in recent years, the PV2022 response rate was expected to be between 30% and 50%, resulting in 4320 to 7200 participants being recruited. The precision of prevalence estimates of measures such as diagnosed depression, occurring at approximately 30% prevalence, would therefore be ±1.4% and ±1.1% (with 95% confidence) for the response rates of 30% and 50%, respectively. Within a key demographic subgroup comprising 10% of the population, the precision would be ±4.4% and ±3.3%, respectively.

Study Population and Selection

Clinic staff were asked to approach their patients who had been randomly sampled from HARS and included in a list provided by the PV team. Each selected patient was assigned a unique identifier that was displayed on their survey packs or could be used to access their online questionnaire.

The PV team had made efforts to oversample the transgender and gender-diverse HIV population by adding to each clinic's list all patients recorded on HARS who identified as trans or gender-diverse. This was carried out to ensure a sufficient number of participants from this population group were represented, as it had been reported that this cohort was experiencing larger health inequalities in comparison with the general population [8].

Inclusion Criteria

The inclusion criteria were people diagnosed with HIV, aged 18 years or older, residing in the United Kingdom, accessing care at a participating HIV clinic in England, Wales, or Scotland, and able to complete the questionnaire in English either online or on paper.

Exclusion Criteria

There were no set exclusion criteria, however the preselected patients were defined as nonrecruitable if they were unable to take part in the survey for any of the following reasons: moved abroad, transferred care to another clinic, lost contact with the clinic for more than 12 months, had died, had any mental or emotional issue affecting their ability to give implied consent, had a language barrier or literacy difficulties, or were imprisoned or deemed a vulnerable adult.

Study Management

PV2022 was a collaboration between the University College London (UCL) NICHE team, the UKHSA HIV national surveillance team, and a NICHE Patient and Public Involvement representative. "A Person-Centered Needs Informed Model of Care for People with HIV" (NICHE) is a National Institute for Health Research (NIHR) funded program of research to improve the health and well-being of people with HIV. The PV team oversaw all aspects of the research including the study design, the development of the questionnaire and study documents, the oversight of the ethics and governance processes, the monitoring of response rates and recruitment at the participating sites and considered strategies to support and boost recruitment.

Questionnaire Development

Half of the questions in PV2022 were identical to those in PV2017 and were considered core questions to the survey series. These included demographic and socioeconomic factors, HIV related factors, comorbidities, met and unmet health, social and welfare service needs, quality of life measured by EQ-5D-5L, height and weight, smoking and alcohol status by the Alcohol Use Disorders Identification Test-Consumption (AUDIT-C), recreational drug use and general practice (GP), and HIV clinic satisfaction, enabling assessment of trends over time in these factors. New items included in the PV2022 questionnaire included self-reported HIV viral load (whether undetectable or not at last test); questions exploring how well participants understood and trusted the concept of Undetectable equals Untransmittable (U=U), if U=U knowledge and trust impacted on how they felt about their HIV status, a modified version of the Duke-UNC (University of North Carolina) Functional Social Support Questionnaire [21], the 14-item Resilience Scale (RS14) [22], the General Practice Physical Activity Questionnaire (GPPAQ) [23], and questions on the impact of COVID-19 and the uptake of COVID-19 vaccines. In addition, the measure for anxiety and depression in 2017 [24] was replaced with standardized separate measures for depression and anxiety symptoms: the Patient Health Questionnaire-9 (PHQ-9) [25], and the General Anxiety Disorder Questionnaire-7 (GAD-7) [26]. Questions on stigma and discrimination were expanded to take account of internalized and other stigma and included an adapted validated stigma scale [27]. In addition, participants who completed the study online in PV2022 were able to opt-in to complete "Positive Outcomes," an HIV Patient Reported Outcome Measure (PO-PROM), a tool designed for use in clinical settings to assess the needs and concerns of people with HIV [28]. Table 1 details the topics included in PV2017 and PV2022 questionnaires. The PV2022 questionnaire was evaluated online by two groups of people with HIV (up to 10 per group) during November and December 2021. Members of these groups had previously participated in PV2017 and had provided their consent to be contacted again to take part in further research. They provided helpful feedback on the length of the questionnaire, the readability and phrasing of questions,

and the flow and overall order of questions. The questionnaire was modified accordingly.

Table 1. Questionnaire topics, questions, survey tools, and clinical data collected in Positive Voices 2017 and Positive Voices 2022.

Questionnaire topic	PV2017[a]	PV2022[b]
Demographics (age, gender, ethnicity, and sexual orientation)	✓	✓
Socioeconomics (education, employment, housing, financial status, and religion)	✓	✓
HIV diagnosis and treatment (year and country of diagnosis, year started on ART[c], adherence, and side effects)	✓	✓
Self-reported HIV viral load and when last test conducted	—[d]	✓
U=U[e] (understanding of and trust in U=U)	—	✓
Non-HIV diagnosed conditions and treatments (cardiovascular conditions, joint and bone, cancer, mental health, and other long-term conditions)	✓	✓
Mental health and well-being (mental health symptoms [General Health Questionnaire, GHQ-12])	✓	—
Mental health and well-being (depression symptoms [Patient Health Questionnaire, PHQ-9], anxiety symptoms [Generalized Anxiety Disorder questionnaire, GAD-7], modified DUKE-UNC Functional Social Support questionnaire [DUKE-FSSQ], and the Resilience Scale [RS14])	—	✓
Quality of life, life satisfaction and self-rated health (EQ-5D-5L,Office for National Statistics Life Satisfaction and self-rated health questions)	✓	✓
Disclosure and discrimination (disclosure, discrimination in health care settings)	✓	✓
Stigma (internalized stigma and anticipated stigma)	—	✓
Sex and relationships (partner status, sexual behavior, sexually transmitted infections diagnoses)	✓	✓
Women's sexual and reproductive health (pregnancy and contraception)	✓	—
Sexual satisfaction (physical and emotional sexual satisfaction)	—	✓
General health and lifestyle (height, weight, smoking, alcohol [Alcohol Use Disorders Identification Test-Consumption, AUDIT-C] and recreational drug use)	✓	✓
General health and lifestyle (exercise and physical activity [General Practice Physical Activity Questionnaire, GPPAQ])	—	✓
GP[f] and HIV service use and satisfaction (GP and HIV satisfaction, patient experience measures, and use of GP and HIV support services)	✓	✓
Health service use and satisfaction (expanded list of health and social care service use)	—	✓
Impact of COVID-19 pandemic (COVID-19 diagnosis, vaccination status, and access to technology for online appointments)	—	✓
Met and unmet needs (need for HIV related services, health services, social and welfare services)	✓	✓
HIV Positive Outcomes Patient Reported Outcome Measure (PO-PROM[g]) (online questionnaire only, opt-in option)	—	✓
Clinical information from HARS[h]		
Antiretroviral treatment regimen	✓	✓
Laboratory measures (viral load and CD4 lymphocyte count)	✓	✓

[a]PV2017: Positive Voices 2017.

[b]PV2022: Positive Voices 2022.

[c]ART: antiretroviral therapy.

[d]—: not applicable.

[e]U=U: Undetectable=Untransmittable.

[f]GP: general practitioner.

[h]HARS: HIV and AIDS reporting system.

Study Documents

Each participating clinic was provided with electronic copies of the study materials including the protocol, manual of operations, participant information leaflet, privacy notice, waiting room poster, and a password-protected study log that listed each clinic's sample list of randomly selected participants. Study documents such as the protocol were also available on

the study website [29]. Questionnaire packs, 1 for each participant within the clinic's sample, were dispatched by courier to the site. The pack consisted of a sealed envelope labelled with the participant's clinic number, hospital name, and unique identifier displayed on the outside, as well as the patient information leaflet, questionnaire, a freepost envelope, and a signposting sheet detailing community support organizations such as the Terrence Higgins Trust, a British charity that campaigns and provides services relating to HIV and sexual health.

Site Initiation Meetings

Each participating site attended 1 of the site initiation meetings that took place remotely on Microsoft Teams between February and March 2022. A maximum of ten clinic sites attended each meeting. Information on how to identify, contact, and recruit participants was explained, and a demonstration was given on the procedure for completing the study log (refer to Recruitment and Data Collection section). Sites were asked to nominate a PV2022 champion within their clinic who would act as the main contact with the PV team. All the site initiation meetings were completed by March 18, 2022, just before the recruitment of participants commenced in April 2022.

Recruitment and Data Collection

The first participant was recruited on April 11, 2022, and recruitment closed on March 31, 2023. At each site, clinic staff were asked to complete a study log on their recruitment outcomes and return it to the PV team each month. The information they recorded in their study log included the mode (whether in-person, email, text, or post) and date of each participant's initial contact, the survey distribution method (in-person, email, text, or post), the survey distribution date, the recruitment status (whether nonrecruitable, accepted, or declined), and the reason if the status was nonrecruitable.

The PV team provided a brief script for email and text message approaches as a guide for clinic staff. Online questionnaires were sent by a link by email or text message, or patients received their survey pack containing the paper questionnaire at their next clinic attendance. Clinic staff decided on the method of approach used in accordance with each participant's preferred and usual method of communication with their clinics.

Change to the Sequential Recruitment Strategy at Specific London Sites

Reviewing the study logs monthly, it was established that several sites were underrecruiting. Consequently, the recruitment period was extended from 6 to 12 months to allow clinics additional time to reach their recruitment targets. Further email correspondence with clinics revealed that many had resource pressures, fewer face-to-face clinic appointments after the start of the COVID-19 pandemic, and the 2022 Mpox outbreak had been an unanticipated challenge impacting upon recruitment, particularly in London. In response, the PV team designed a sequential recruitment strategy whereby a site could approach any eligible participant attending the clinic sequentially, that is, approach patients as they entered the clinic instead of contacting participants from their preselected sample list. In total, 14 HIV clinics across 7 NHS trusts in London that had recruited less than 10% of their minimum target after 8 months were offered a switch to the sequential recruitment strategy, which they commenced at the beginning of December 2022, having been sent new recruitment packs, survey labels, and a simpler study log that reflected the new strategy.

Participants recruited through the new sequential recruitment strategy were only able to complete the paper questionnaire. Staff were asked to encourage participants to complete their questionnaires in the clinic when they came for their consultation rather than taking them home, as questionnaires sometimes got lost, forgotten, or were not returned to the PV team at UKHSA.

Secure Storage and Transfer of Data

Paper questionnaires and study logs were securely stored within each clinic. The sites were responsible for collecting, storing, and returning the paper questionnaires completed in their clinic to the PV team at the UKHSA by using the Freepost envelopes provided in the participant packs or by courier.

Data Management

When paper questionnaires were received by the PV team, data were double data-entered (entered by 2 separate data input personnel) into Snap Survey software (Snap Survey Ltd) and each questionnaire was scanned. Online responses were extracted from Snap Survey as an electronic csv file. The data from both sources was then imported into Stata (version 15.0, StataCorp) and merged to create a master questionnaire data file. Data discrepancies between the 1st and 2nd date entries of the paper questionnaires were checked and resolved by referring to scanned copies of questionnaires.

Linkage

Data on ART use, the most recent CD4 lymphocyte count, and HIV viral load measurement were linked from HARS to the survey data using the participant's clinic ID number and unique identifier.

Data Security

Paper questionnaires were stored securely in locked cabinets at UKHSA where they will remain for a maximum of 10 years and then be securely destroyed. The online version of the questionnaire was hosted on a secure HTTPS connection and data were encrypted at the point of transmission and stored on a secure, dedicated, virtual server hosted at UKHSA.

All data were securely held at UKHSA, encrypted, and restricted to the PV team. Data collection, storage, and use were consistent with the procedures described in the NHS Information Governance Toolkit. A data-sharing agreement was developed to ensure the secure transfer of pseudonymized data between UKHSA and UCL for data analysis.

All researchers were trained to handle data according to Caldicott guidelines, the General Data Protection Regulation, and Section 60 of the Health and Social Care Act.

Ethical Considerations

The Positive Voices study was granted ethical approval by the London Harrow Research Ethics Committee (13/LO/0279) on March 28, 2013. All the updated documents for PV2022 were

submitted as a substantial amendment and subsequently approved on June 23, 2021. The patient information leaflet provided information on how the patients could participate, the potential risks and benefits of participation, and contact information for the PV team. Clinic staff were advised to tell each eligible participant that participation was voluntary and that their decision to participate would not affect their care. A privacy notice was available online with further information about data security [29]. Consent was implied on voluntary completion of the questionnaire. All participants received a digital gift voucher for 5 GBP (equivalent to US $6.50) as an acknowledgement for their time and consideration. This incentive was chosen based on findings from the formative work undertaken before the survey began, where participants expressed a requirement for an incentive. The PV team provided monthly feedback to sites showing the number of completed questionnaires received either by post or online from participants from their clinic. If a patient agreed to participate in the survey but no questionnaire had been returned, clinic staff were asked to send up to 3 reminders using the preferred method of contact initially used. Participants were not asked to provide identifiable information for the survey. However, at the end of the survey, participants were given the option of providing their personal contact details, either phone number or email address, if they were willing to be contacted for future research. If contact details were given, this personal information was unlinked from their survey data and stored securely on a separate password-protected database at UKHSA.

Results

Overview

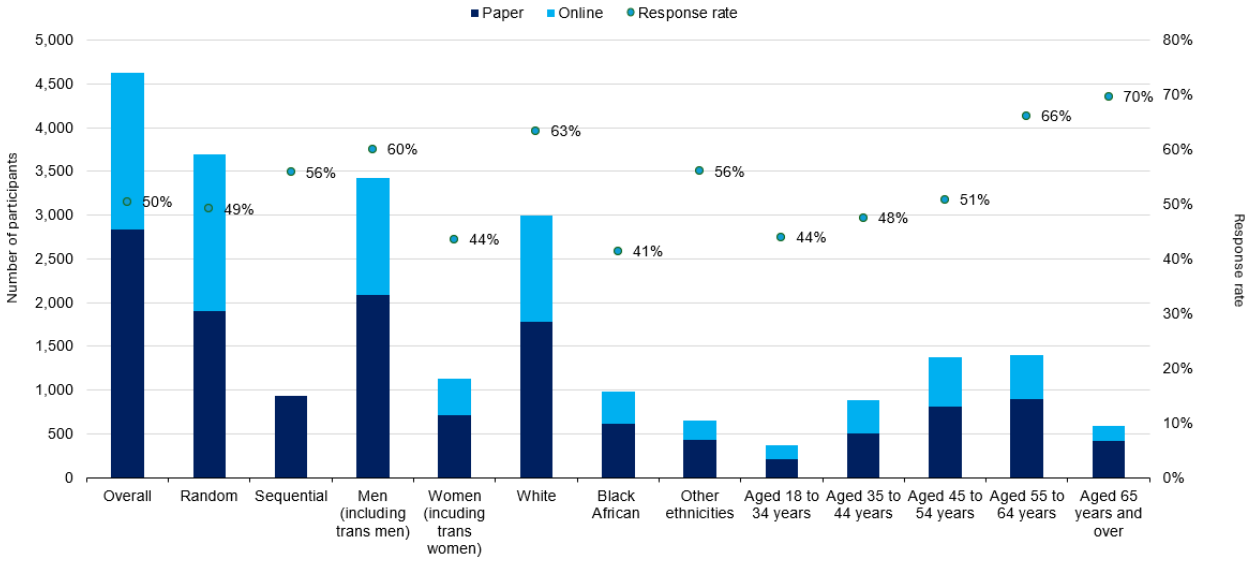
The PV2022 survey was completed by 4622 people diagnosed with HIV, representing approximately one in 20 people living with HIV and accessing care in England, Wales, and Scotland in 2022 [19]. Overall, 4540 participants provided sufficient demographic information to enable linkage to HARS to acquire additional clinical data, which included treatment information, viral load, and CD4 lymphocyte count. The most popular completion method was by paper questionnaires with 2829 (61%) compared with 1793 (39%) online questionnaires. A third (930/2829, 33%) of the paper questionnaires were completed by participants recruited sequentially. Of the 4622 participants, 1737 provided their phone numbers or email addresses as contact details regarding further research, and 897 completed the optional PO PROM questionnaire online.

Response Rate

To calculate the response rate, the number of completed questionnaires (n=4622) was divided by the number of people who accepted (n=8096) or declined to participate (n=1088), which gave an overall response rate of 50%. In addition, 4994 people had been contacted by email or text but had not responded, which may have reflected further declines although may also have been due to messages not being received, read, or being discounted as an unsolicited message. By including these nonresponses in the calculations, it would have given a response rate of 33%. The true response rate likely lies somewhere between 33% and 50%.

A total of 930 (20%) participants were recruited through the sequential recruitment strategy, a higher response rate (55%) compared with the original preselected participant recruitment strategy (49%, Figure 1). Of the 930 sequentially recruited participants, 906 were able to be matched to HARS: 222 (25%) of these had initially been preselected to take part in the survey. Response rates differed by demographic characteristics (taken from HARS) as shown in Figure 1. Men had a higher response rate (60%) (3428 completed out of 5715 accepted or declined) compared with women (1124/2580, 44%) and White people had a higher response rate (2991/4724, 63%) compared with Black African people (983/2380, 41%) or those of other ethnicities (648/1158, 56%). Response rates were also higher in older age groups, with the highest response rate (592/851, 70%) in the people aged 65 years or older (Figure 1). Multimedia Appendix 2 provides the corresponding numbers for all groups shown in Figure 1.

Figure 1. Positive Voices 2022 response rates by recruitment mode, gender, ethnicity, and age among participants of Positive Voices 2022 (N=4622).



Age, Gender, and Ethnic Distribution of PV2022 Participants

The median age of PV2022 participants (n=4620) was 52 (IQR 43-60) years, and about 3 quarters of participants had been diagnosed with HIV more than 10 years ago (Table 2). Nearly a quarter of participants were women (24%) and over a fifth (21%) of participants were Black African people (Table 2).

Gender identity of participants completing PV2022 broadly reflected the gender identity distribution of people accessing HIV care in the United Kingdom. However, there was some overrepresentation of men (6% higher), and underrepresentation of women (8% lower) compared with HARS data (Figure 2). A total of 67 PV2022 participants identified as transgender or gender diverse.

Compared with the national population of people accessing HIV care, Black African individuals were underrepresented in the PV2022 sample (10% lower), and White participants were overrepresented (13% higher; Figure 2).

Participants from the sequential recruitment route were younger compared to the preselected random recruitment strategy (median age 49 (IQR 39-57) years versus 53 (IQR 45-60) years, for sequential versus random recruitment respectively), overrepresented men (85% vs 72%) and White people (67% vs 64%) and underrepresented Black African people (14% vs 23%).

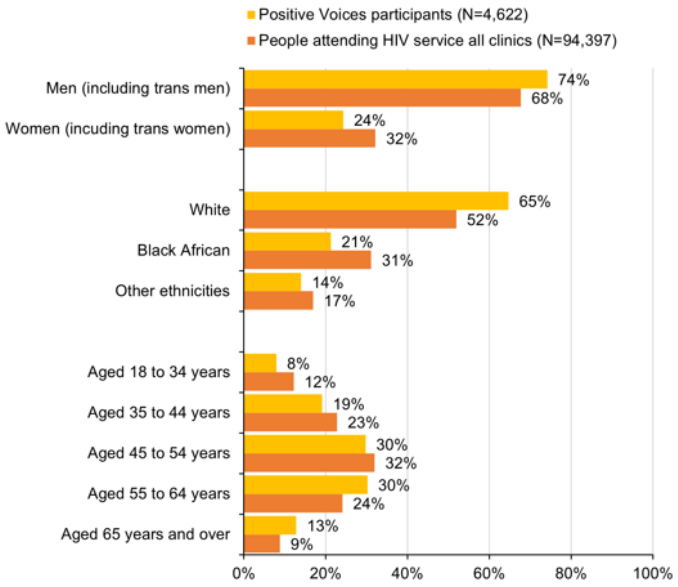
A higher proportion of participants who completed the online questionnaire were White compared to participants who completed the paper questionnaire (67% online vs 63% paper; Figure 1 and Multimedia Appendix 2.

Table 2. Demographics and year of HIV diagnosis among Positive Voices 2022 participants.

Characteristics	Participants (n=4622), n (%)
Age group (years)[a]	
18-34	369 (8)
35-44	885 (19.2)
45-54	1375 (29.8)
55-64	1397 (30.3)
65+	592 (12.8)
Gender	
Man (including trans men)	3428 (74.2)
Woman (including trans woman)	1124 (24.3)
Nonbinary	26 (0.6)
In another way	8 (0.2)
Prefer not to say and unknown	36 (0.8)
Ethnic group	
White	2991 (64.7)
Black African	983 (21.3)
Black other	138 (3)
Asian	189 (4.1)
Mixed	143 (3.1)
Other (including prefer not to say and unknown)	178 (3.9)
Year of diagnosis	
2019-2023	214 (4.6)
2014-2018	801 (17.3)
2009-2013	957 (20.7)
2004-2008	1063 (23)
2003 or earlier	1497 (32.4)
Unknown	90 (1.9)

[a]Age was missing for 2 participants.

Figure 2. Representativeness of Positive Voices 2022 participants compared with the national population of people with HIV who attended HIV services in 2022.



Survey Distribution Method

The survey approach method was available for 4375 of the 4622 responses received. Over half of these participants, 54% (2371/4375), were approached in person, 23% (1001/4375) were contacted by phone, 17% (727/4375) received a text message, 5% (214/4375) were contacted by email, and 1% (62/4375) received the questionnaire by post.

Discussion

Principal Findings

In this paper, we have described the methods, design and sample demographic characteristics of the Positive Voices 2022 study. PV2022 is the largest questionnaire study to date of people with HIV in England, Wales, and Scotland. The outputs from the study will provide a unique insight into the health and well-being of people with HIV, particularly regarding mental health, met and unmet needs, experiences of stigma, and the impact of COVID-19 pandemic [30]. The overall response rate for PV2022 was estimated to be between 33% and 50% compared with 52% for the previous iteration of the survey (PV2017) [9]. Several factors impacted on the response rate in PV2022. In particular, the first 6 months of the recruitment period (between April and September 2022) coincided with the Mpox *clade* IIb outbreak, primarily among gay and bisexual men in London and other large cities in England [31]. The impact of this outbreak on sexual health and HIV services resulted in a significant deployment of clinic staff and resources to manage the outbreak and to provide a vaccination program to contain the infection [31]. Feedback from some of the largest clinics that were open to recruitment for PV2022 over the duration of the Mpox outbreak suggested that recruitment had been challenging to prioritize during this period, particularly as the methodology required considerable clinic staff time commitment.

As a result of a challenging recruitment environment, the switch to sequential recruitment in December 2022 resulted in an improvement to study recruitment. This was mainly because the strategy of sequential recruitment did not require the administration time that had been required for the original strategy. Furthermore, as these participants were only able to complete the paper questionnaire and not the online version, clinic staff recommended questionnaires be completed within the clinic setting and discouraged participants from taking the questionnaires home, where they may have remained uncompleted or unreturned. Although this strategy was not always successful, the proportion that completed and submitted their questionnaire within the clinic was higher in comparison with the original recruitment strategy.

Other potential factors that may have impacted upon the response rate for PV2022 related to the COVID-19 pandemic. The widespread adoption of online health care appointments during the pandemic meant that fewer patients attended regular HIV appointments in person [32,33]. A recent systematic review identified interruption in attendance of in-person clinic consultations, reduced adherence to treatment, and a subsequent increase in mortality among people with HIV, as a consequence of the changes in service delivery due to the COVID-19 pandemic [34]. As the most effective mode of recruitment for PV2022 was in-person with clinic staff, the decreased frequency of participants attending clinic likely contributed to the lower response rate seen in PV2022 in comparison with PV2017. Less personal interaction between patients and clinic staff may also have impacted upon participants' enthusiasm for completing questionnaires when approached. When clinic staff were able to personally hand out the survey packs within the clinic, they were better able to explain the importance of the study and the impact the results would have on policy and service planning. Evidence suggests that initial approach and personal connection greatly impacts on survey completion rates in all populations [35,36] which has implications for future survey planning, particularly as some appointments remain online.

Recent evidence has suggested that survey fatigue and nonparticipation, had increased as a result of the proliferation of online surveys during and following the COVID-19 pandemic

[37]. Whilst the pandemic clearly impacted upon research in terms of recruitment and data collection, evidence suggests that the effects reached far wider. The pandemic exacerbated inequalities in health and access to health care, particularly amongst those living in economic hardship [38] and for Black African individuals and those of other minority ethnic groups [39], and the HIV population consists of a high proportion of these groups.

Strengths of PV2022 include the large sample size, the inclusion of a broadly representative sample of 1 in 20 people with HIV in England, Scotland and Wales (as evidenced by comparison with the national HARS database) and the linkage of participant self-reported questionnaire data to HIV clinical data from HARS. With increasing interest in patient experience and outcome measures, other clinical conditions could use a similar survey method to survey their patient group. PV2022 also has some limitations: as the study was only available to people with HIV in care, it did not represent those people with HIV who were not receiving care in 2022, whose mental and physical health, and experiences of health care, may be different and valuable for informing and improving HIV specialist services. Similarly, nonresponders to participate in the study may differ from responders with respect to health, lifestyle, and other factors. Further efforts to reach these groups and identify their needs are crucial. In addition, the sampling frame for the initial recruitment method was based on those attending care in 2020, and therefore our data are unable to represent those who have been newly diagnosed in the interim. Future work by the PV team will examine the recruitment challenges to PV2022 and will involve participant and public involvement groups and clinic staff. This will inform future rounds of the Positive Voices survey and optimize response rates.

PV2022 formed part of the formative work of the NIHR funded NICHE program of research led by UCL. NICHE aims to improve the mental and physical well-being of people with HIV by designing and evaluating a targeted psychosocial intervention as part of routine HIV care [29]. Findings from PV2022 informed the development of the intervention for the "Psycho-Social Intervention for People With HIV – Evidence From a Randomised Evaluation" (SPHERE) trial, which commenced in United Kingdom HIV clinics in August 2024. Results from Positive Voices 2022 have been published in a government report [30] that has directly informed the HIV action plan for England which aims to end stigma and inform interventions to improve patient-centered care and the provision of HIV clinical and support services. Further analysis of the data will be presented at HIV conferences, published in peer-reviewed journals and disseminated through the extensive NICHE PPI network.

Acknowledgments

The authors would like to thank all the PV2022 study participants who generously participated in this research. The authors would also like to thank the clinic staff in all the 101 participating sites for their hard work and dedication. PV2022 was conducted by the UK Health Security Agency and University College London and represents independent research funded by the National Institute for Health Research (Program Grants for Applied Research, A person-centered Needs Informed model of Care for people with HIV, to improve well-being, mental health and reduce socioeconomic disadvantages and stigma, (NICHE; NIHR202038). The views expressed in this publication are those of the authors and not necessarily those of the NHS, the National Institute for Health Research, or the Department of Health and Social Care. Funding was also received from the UK Health Security Agency and Gilead Sciences Ltd.

Data Availability

The data sets generated during this study are not publicly available due to ongoing analysis and dissemination plans by the NICHE and UKHSA teams. However, data may be available from the corresponding author on reasonable request.

Authors' Contributions

CK, AA, VM, AB, MK, VD, FL, CS, and AR contributed to conceptualization. CK, AA, VM, AB, MK, VD, FL, and AR managed methodology. CK, AA, VM, AB, CH, HK, AF, APM, AR, FL, JS, AS, and APM handled investigation. JS, CK, MK, FL, and AR wrote the original draft. Abstract

Background: An aging population in combination with more gentle and less stressful surgical procedures leads to an increased number of operations on older patients. This collectively raises novel challenges due to higher age heavily impacting treatment. A major problem, emerging in up to 50% of cases, is perioperative delirium. It is thus vital to understand whether and which existing geriatric assessments are capable of reliably identifying risk factors, how high the incidence of delirium is, and whether the resulting management of these risk factors might lead to a reduced incidence of delirium.

Objective: This study aimed to determine the frequency and severity of geriatric medical problems in elective patients of the Clinics of Oral and Maxillofacial Surgery, Vascular Surgery, and Orthopedics, General Surgery, and Trauma Surgery, revealing associations with the incidence of perioperative delirium regarding potential risk factors, and recording the long-term effects of geriatric problems and any perioperative delirium that might have developed later the patient's life.

Methods: We performed both pre- and postoperative assessments in patients of 4 different surgical departments who are older than 70 years. Patient-validated screening instruments will be used to identify risk factors. A geriatric assessment with the content of basal and instrumental activities of daily living (basal activities of daily living [Katz index], instrumental activities of daily living [Lawton and Brody score], cognition [6-item screener and clock drawing test], mobility [de Morton Mobility Index and Sit-to-Stand test], sleep [Pittsburgh Sleep Quality Index and Insomnia Severity Index/STOP-BANG], drug therapy [polypharmacy and quality of medication, Fit For The Aged classification, and anticholinergic burden score], and pain assessment and delirium risk (Delirium Risk Assessment Tool) will be performed. Any medical problems detected will be treated according to current standards, and no intervention is planned as part of the study. In addition, a telephone follow-up will be performed 3, 6, and 12 months after discharge.

Results: Recruitment started in August 2022, with 421 patients already recruited at the time of submission. Initial analyses of the data are to be published at the end of 2024 or the beginning of 2025.

Conclusions: In the current study, we investigate whether the risk factors addressed in the assessment are associated with an increase in the delirium rate. The aim is then to reduce this comprehensive assessment to the central aspects to be able to conduct targeted and efficient risk screening.

Introduction

Background

From the advances in surgical medicine with the development of less stressful surgical and anesthetic procedures, more and more older people are receiving surgical care who would not have been treated surgically a decade ago [1]. However, older age is associated with numerous additional problems, such as frailty [2], cognitive impairment [3,4], sleep disorders [5,6], and polypharmacy [7,8]. These age-associated problems are not routinely recorded but make older patients vulnerable. Perioperative delirium of vulnerable older patients is a major problem. Delirium is distressing for the individual, increases the burden of care, and has long-term negative consequences in terms of cognition, self-care ability, and prognosis [9].

Thus, incidences of perioperative delirium in older people are reported to be as high as 50% [10,11]. Factors influencing the incidence of delirium include duration and depth of anesthesia, the size of the surgical procedure, the duration of the preoperative fasting period, preoperative blood pressure, and frailty, brain disorders, hearing impairment, or history of sleep disturbances [12].

Perioperative delirium is a relatively common and serious complication after surgery [13-15]. The *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders* [Fifth Edition]) includes delirium into the broader category of neurocognitive disorders, which include acquired cognitive dysfunction [16,17]. Delirium is defined as an attention deficit disorder that develops over a short period of time, with additional cognitive impairment that cannot be explained by other preexisting neurocognitive impairments [18]. According to the *DSM-5*, the typical symptoms that characterize delirium are (1) “disturbance in attention,” (2) “disturbance develops over a short period of time,” (3) “additional disturbance in cognition,” (4) “disturbances in the first 2 criteria are not better explained by another preexisting disorder,” and (5) “disturbance is a direct physiological consequence of another medical condition, substance intoxication, or withdrawal” [19,20]. In general, the incidence of delirium in surgical procedures is 2%-3%, and in high-risk patients, it is even much higher at 50%-70% [11,21]. Nevertheless, precise causes as well as risk factors and incidences for the development of postoperative delirium are not yet known or deciphered [10].

In the literature, several potential risk factors for postoperative delirium are indicated. Among these are the duration and depth of anesthesia [22,23], the extent of the surgical procedure, the duration of the preoperative fasting period [10,24], the preoperative blood pressure, as well as frailty, brain disorders, hearing disorders, or sleep disorders in the history [2,25]. Delirium with its multifactorial genesis is a major challenge in risk stratification and diagnosis. Validated screening tools exist for many of the risk factors [26-32]. However, recording all risk factors is not effective in everyday clinical practice and is difficult to implement in terms of time. It is therefore necessary to compile a specialist assessment in order to identify patients at risk of delirium as effectively and reliably as possible.

Some of these risk factors are captured by validated screening instruments. Identifying risk factors allows better preoperative management [10]. Still, the regular recording of dementia, the need for assistance in daily life, or the accumulation of several diseases by geriatric screening to determine geriatric care needs is practically not established. Comorbid geriatric problems leading to functional limitations are therefore often overlooked, although they represent a major social and economic problem [33,34].

Aim of This Research

We aim to analyze which parameters of our comprehensive geriatric assessment are associated with the occurrence of delirium depending on the specialty, and what parameters are to be included in a time-effective, target-oriented, and implementable assessment.

Methods

Study Design and Setting

This prospective clinical observational study analyzes the frequency and risk factors for perioperative delirium in patients after surgical treatment in the Department of Orthopedics and Trauma Surgery, the Department of Vascular and Endovascular Surgery, General Surgery, and the Department of Oral and Maxillofacial Plastic Surgery of the University Hospital of Düsseldorf in the intensive care unit and normal ward. The University Hospital of Düsseldorf is the largest hospital in the state capital of North Rhine-Westphalia, Germany. It houses more than 50,000 in-patients per year [35].

Study Population

Inclusion criteria will be patients (aged 70 years and older) presenting for elective and emergency surgery at the Departments of Oral and Maxillofacial Surgery, Orthopedics and Trauma Surgery, General Surgery, and Vascular Surgery. In addition, we will also contact the included patients by telephone 3, 6, and 12 months after discharge to ask about their health status in a standardized way. No interventions are planned as part of this study, and any medical problems uncovered will be treated according to standard medical practice.

A case number calculation is hardly possible due to the sparse data. Therefore, one goal of this study is to collect robust data on the incidence of delirium and to be able to plan further studies on the basis of this solid data. Initially, we will offer participation in this study to all consecutive presenting patients who meet the inclusion criteria (Textbox 1). The initial recruitment period is planned to be 6 months. The goal is to enroll at least 100 patients per discipline, in total over 400

patients. If this number is not reached within this period, the recruitment period will have to be extended accordingly. Solid incidence figures are to be determined within the framework of this pilot study, so further studies can then be planned with possible case number calculation.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Patients presenting for elective surgery at the Clinic for Oral and Maxillofacial Plastic Surgery, Orthopedics and Trauma Surgery, General Surgery, and Vascular Surgery.
- Age 70 years.
- Consent of the patient or caregiver.

Exclusion criteria

- No consent to participate.
- Unstable clinical situation.
- Patients requiring palliative care.
- Very advanced dementia (Reisberg VI-VII).

Recruitment

Patient recruitment starts in August 2022. We have been in negotiations with other surgical disciplines for almost a year, aiming to include as many different surgical specialties as possible. We are therefore submitting this study protocol during ongoing recruitment. After inpatient admission in the respective disciplines, the eligible patients are informed about the clinical examination by the study doctor. The patients are given sufficient time to think about their participation and to discuss it with their caregivers. They can also clarify any questions with the study doctor. After the patient has given and signed his or her consent, he or she takes part in the study (Figure 1).

Figure 1. Study procedure overview. Timeline including recruitment, pre- and postoperative assessment, surgery, discharge assessment, and the assessment by phone after 3,6, and 12 months.

Measures and Parameters

In the context of this study, in addition to routine preoperative preparation in elective and emergency older patients, a geriatric assessment (Textbox 2) with the content of basal and instrumental ADL (basal ADL: Katz index [26]; instrumental ADL: Lawton and Brody score [27]; emotion: World Health Organization-5 scale [28]; cognition: 6-item screener and clock drawing test; mobility: de Morton Mobility Index and Sit-to-Stand test [29]; sleep: Pittsburgh Sleep Quality Index, Insomnia Severity Index, and STOP-BANG [30-32]; drug therapy: polypharmacy and quality of medication, Fit For The Aged classification, and anticholinergic burden score), pain assessment, and delirium risk (Delirium Risk Assessment Tool) is to be performed. The Fit For The Aged list evaluates drugs in terms of their benefit-risk profile when used in older patients. The aim is to reduce the number of potentially inadequate medications in patients aged over 65 years old [36]. In an emergency setting, the tests to record the acute status were carried out directly preoperatively. Tests such as sleep quality and well-being, which cover a longer period before the operation, were carried out postoperatively if not otherwise possible. Through this, the study gains a broad spectrum of possible risk factors while using validated and clinically approved assessment tools.

Textbox 2. Depiction of the pre- and postoperative parameters.

Preoperative parameters

- Age (years), gender, and BMI
- American Society of Anesthesiologists classification
- Comorbidities, risk factors, previous radio and chemotherapy
- Preoperative medication and calculation of anticholinergic load (anticholinergic burden score)
- Delirium Risk Assessment Tool
- Routine laboratory values

Geriatric assessment

- Katz index
- Instrumental activities of daily living score according to Lawton and Brody
- Mobility and strength
- de Morton Mobility Index
- Handgrip strength (Hydraulic hand dynamometer)
- Sit-to-stand test
- Emotion World Health Organization-5 scale
- Nutritional status
- Mini Nutritional Assessment Short-Form
- Skinfold thickness over the triceps muscle
- Brain performance
- 6-Item-Screener
- Clock-Drawing-Test
- Hearing ability
- Hearing Handicap Inventory for the Elderly-Short Form
- Sleep disorders or sleep quality
  - Pittsburgh Sleep Quality Index
  - Insomnia Severity Index
  - STOP-BANG–Risk score for obstructive sleep apneas
- Pain assessment

Postoperative parameters

- Nursing Delirium Screening Scale (routinely performed in the recovery room by anesthesia)
- Confusion Assessment Method
- Confusion Assessment Method-Intensive Care Unit
- Alertness, Abbreviated Mental Test 4, Attention, Acute Chance or Fluctuating Course
- postoperative pain assessment
- Mobility (de Morton Mobility Index, instrumental activities of daily living, and Katz index) before discharge

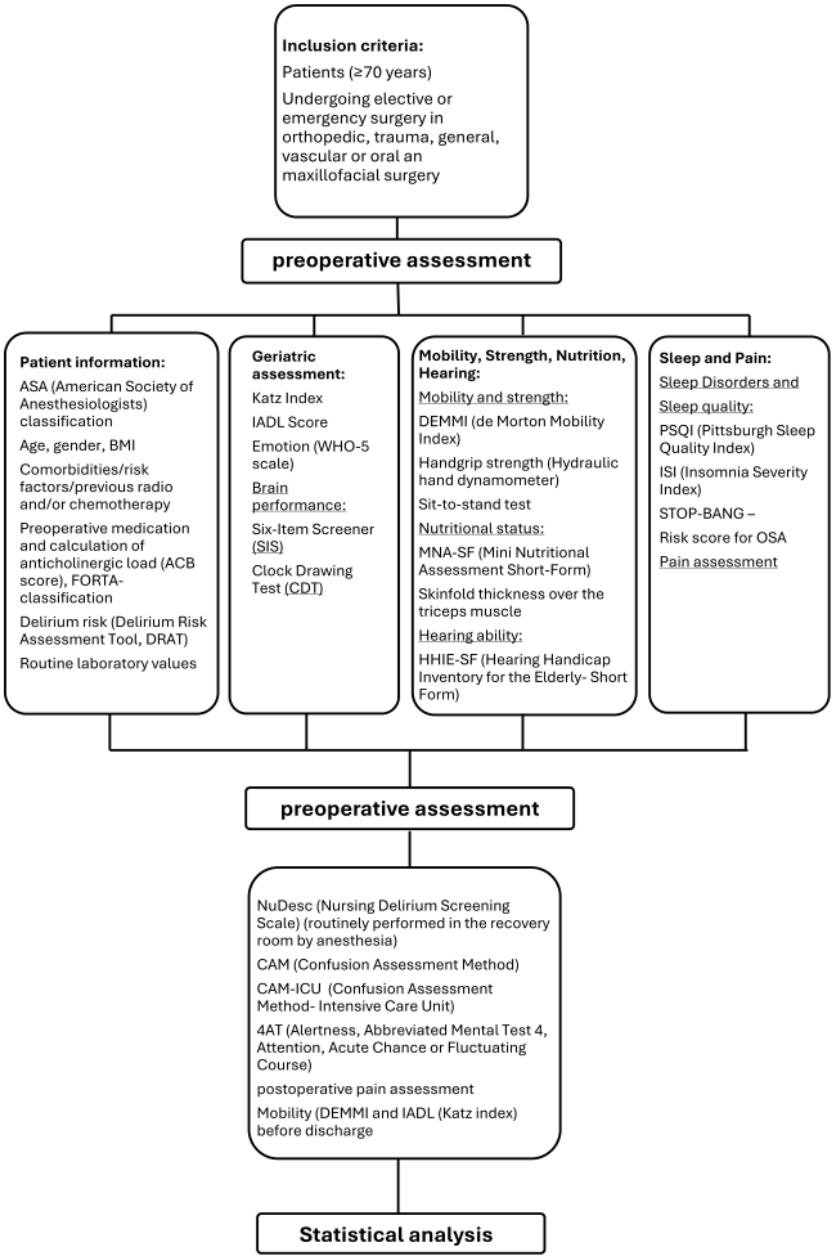
Follow-up

- Instrumental activities of daily living
- Katz index
- G8 screening test
- Pain assessment
- World Health Organization-5 scale

Testing is done every 8 hours in the Intensive Care Unit Confusion Assessment Method-Intensive Care Unit and twice daily in the normal ward (Confusion Assessment Method and Alertness, Abbreviated Mental Test 4) until postoperative day 7 or discharge [37]. Further testing is done as needed or after revision, operation, and so on.

Patients are assessed perioperatively during the daily ward rounds with a focus on their general condition and the presence of delirium. The instruments NuDesc, Confusion Assessment Method, which are routinely recorded in-house, and the Alertness, Abbreviated Mental Test 4, which was introduced in 2020, are used for this purpose [38]. The simultaneous use of these instruments also allows their comparison regarding their quality criteria and may lead to a reduction in monitoring effort in the medium term if one of these instruments proves to be superior (Figure 2).

Figure 2. Overview of preoperative evaluation, pre- and postoperative assessment, and analysis. 4AT: Alertness, Abbreviated Mental Test 4, Attention, Acute Chance or Fluctuating Course; ACB: anticholinergic burden; ADL: activities of daily living; ASA: American Society of Anesthesiologists; CAM: Confusion Assessment Method; CAM-ICU: Confusion Assessment Method-Intensive Care Unit; DEMMI: de Morton Mobility Index; DRAT: Delirium Risk Assessment Tool; FORTA: Fit For The Aged; HHIE-SF: Hearing Handicap Inventory for the Elderly-Short Form; IADL: instrumental activities of daily living; ISI: Insomnia Severity Index; MNA-SF: Mini Nutritional Assessment Short-Form; Nu-Desc: Nursing Delirium Screening Scale; OSA: obstructive sleep apnea; PSQI: Pittsburgh Sleep Quality Index; WHO: World Health Organization.



Follow-Up

We plan to contact patients by telephone 3, 6, and 12 months after discharge to inquire about their current health status. Here the patients are asked about changes in sleeping behavior, changes in medication, changes in mobility, and possible rehabilitation treatment. Furthermore, ADL and Katz, G8 Screening Test, a pain assessment, and the World Health

Organization–5 scale are recorded. Bellera et al [39] created the G8 geriatric screening test, which evaluates drug use, general health, age, mobility, nutritional state, and cognitive status.

Evaluation Outcomes

We aim to determine the frequency of perioperative delirium in patients after surgical treatment in the Clinic for Orthopedics and Trauma Surgery, in the Clinic for Vascular and Endovascular Surgery, and in the Clinic for Oral and Maxillofacial Facial Plastic Surgery at the University Hospital Düsseldorf in the intensive and normal care unit. We want to use the comprehensive assessment to create a risk profile for patients with delirium. The individual risk factors are to be evaluated with regard to their use in the context of a specialized geriatric assessment.

Statistical Analysis

The evaluation is performed as descriptive statistics with the listing of the frequencies of geriatric problems and perioperative delirium. To investigate the correlation between perioperative delirium and clinical and geriatric parameters, the correlation is determined. The parameters that correlate significantly with the incidence of delirium are examined in a further step in the context of logistic regression analysis for their concrete and independent influence on delirium incidence. Calculations are performed using the statistical program SPSS (version 28.0; IBM Corp) and Jamovi [40]. A *P* value of <.05 is considered significant. If the normal distribution of the dependent variables was confirmed by the Shapiro-Wilk test, homoscedasticity was confirmed by the Levene test and significant outliers were eliminated by boxplots, the mean differences were analyzed using the independent *t* test. The Mann-Whitney *U* test is used to analyze the mean differences of the dependent variables that were not regularly distributed. Chi-square tests are used to analyze bivariate correlations between relevant variables and the occurrence of delirium (delirium vs no delirium). The odds ratios of the relationships are calculated with 95% CIs. Two-sided statistical tests are used, and the α level of .05 is used to determine significance. Significance is defined as a *P* value of less than .05, very significant as a value of less than .01, and highly significant as a value of less than .001. To reduce the possibility of a type I error in repeated testing, Bonferroni correction is used [41]. The factors that cause delirium and that are classified as statistically significant at a significance level of *P*=.05 are determined using binomial logistic regression analysis.

Ethical Considerations

The study was approved by the Ethics Committee of the Medical Faculty of the Heinrich Heine University Düsseldorf (2022-1810). This study is registered in a publicly accessible database according to DvH2013, § 35 (DRKS-ID; DRKS00028614 [42]). Meeting the requirements for data protection and confidentiality, the data are pseudonymized. It is not possible to identify individual participants or users in figures and illustrations of the manuscript or supplementary materials. No compensation is provided to participants for research.

This study was approved by the ethics review board of the University Hospital of Düsseldorf (2022-1810_2) and all the participants provided written informed consent.

Results

The comprehensive preoperative geriatric assessment was developed to capture as many potential risk factors for delirium as possible. The findings aim to assist in the development of a specialist and condensed preoperative assessment. Recruitment started in August 2022, with 421 patients already recruited at the time of submission. Initial analyses of the data are to be published at the end of 2024 or the beginning of 2025. Recruitment will continue until August 2025. A final analysis will be issued in a subsequent publication.

Discussion

We intend to determine the frequency of delirium in the aforementioned specialist disciplines. Furthermore, a specialist risk profile is to be created using a comprehensive geriatric assessment in order to specifically identify patients at risk in the future.

Relevance of This Study

Delirium occurs particularly in older patients where (1) patients aged 65 years account for up to 40% of all surgical procedures, (2) 50% undergo emergency surgeries, and (3) 75% are affected by surgical mortality [43]. Also, prevalence is particularly increased in those patients who are older, neurocognitively impaired, or emergency-associated patients [44,45]. The reason why delirium is gaining increasing importance in the age group of older patients becomes clear against the background of 2 facts: first, because the total population is getting older, and second, because this group of patients is being operated more and more frequently [46].

Despite the clinical relevance of delirium, there is still no established screening that considers the risk factors of the older patient group in particular so far. This deficiency was the decisive criterion for the establishment of a screening system in the current study, which focuses on the special needs of these older patients. Building on this, the current screening system is therefore intended to create further prevention options in order to meet the needs of the older patient group.

Further on, the need for a new screening system arises from the fact that the presence of delirium is not only a patient-specific problem: postoperative delirium places an additional burden on hospital care in that the average hospital stay is prolonged by an average of 48-72 hours due to postoperative delirium. It is also associated with a 30-day mortality rate of 7%-10% [9,10,47]. The prolonged hospital stays that result, combined with the need for more intensive therapy, lead to increasing costs for the hospital and ultimately for the entire population [48]. A sound assessment that can act preventively on emerging problems and thus prevent the development of delirium, if necessary, would be of both individual and economic benefit.

Limitations

As described above, predisposing discipline-specific risk factors for the development of postoperative delirium have not yet been thoroughly investigated. The current screening system is intended to circumvent precisely this deficiency and to identify potential risk factors to prevent the development of such delirium in older patients.

Focus was placed on the extraction of clinically relevant examination procedures for the diagnosis of delirium and the elimination of irrelevant procedures, as there is often insufficient time in daily clinical practice to perform comprehensive examinations. General assessments that address the classification of postoperative delirium have already found their way into clinical practice [13,49,50]. However, these do not place a separate focus on the existing risk factors of the group of older patients, who should be given a separate status against the background of the problems described above. What has so far complicated the breakdown of such risk factors is the fact that it is insufficiently possible to distinguish between the normal aging process, the associated increasing physical degradation, and existing medical diseases that accelerate such a decay.

Method Criticism

The screening system presented here is intended to identify risk factors that can be used for regular screening of older patients. The findings of this study assist in preventing postoperative delirium in the future and reduce the frequency of perioperative problems and mortality in these patients [51,52].

The potential risk factors for the development of postoperative delirium already described above had an influence on the structuring of the screening system presented here. Therefore, the following examination parameters have also found their way into the present screening, which are (1) preoperative history, (2) geriatric assessment, (3) mobility and strength, (4) emotion, (5) nutritional status, (6) brain performance, (7) hearing ability, (8) sleep disorders and sleep quality, (9) pain symptomatology, and (10) postoperative evaluations. They are intended to help extract and further eliminate several different potentially delirium-inducing elements.

Further Questions

Recording systems have not yet been significantly established, that would be needed for determining dementia, the need for assistance in everyday life, or multimorbidity. These would also be important for determining geriatric care needs.

It has been shown that a geriatric assessment could make perioperative risks more understandable, also in the case of delirium [53]. Marcantonio et al [54] have already elaborated that such a geriatric assessment would reduce delirium by over 30% and severe delirium by over 50%. In this context, the question arises which parameters of such a geriatric screening system could be related to the reduction of delirium frequency.

Conclusions

We want to investigate whether the risk factors addressed in the assessment are associated with an increase in the delirium rate. The aim is then to reduce this comprehensive assessment to the central aspects to be able to conduct targeted and efficient risk screening.

Many of the known risk factors cannot be easily translated into risk prevention strategies comprehensively in everyday clinical practice. Since each discipline poses different challenges to patients, it is necessary to develop assessments that can be implemented in the individual disciplines.

Acknowledgments

We acknowledge all the people who participated in this study. All authors collected and analyzed the data and read and approved the final manuscript. HLM and HF designed the study. HLM, EA, PO, and HF wrote the paper. All authors read and approved the final manuscript. This work was financed with institute funds and the Paul Kuth Foundation (file number: 310, administrative district: Düsseldorf, registered office: Wuppertal, contact (c/o): Deutsche Bank AG Private Wealth Management Region Wuppertal, Friedrich-Ebert-Str.1-11, 42103 Wuppertal). The funder of the study has no role in study design, data collection, data analysis, data interpretation, or writing the manuscript.

Data Availability

The datasets used and analyzed during the current study are available from the corresponding author on reasonable request.

Abstract

Background: In South Africa, there is no centralized HIV surveillance system where key populations (KPs) data, including gay men and other men who have sex with men, female sex workers, transgender persons, people who use drugs, and incarcerated persons, are stored in South Africa despite being on higher risk of HIV acquisition and transmission than the general population. Data on KPs are being collected on a smaller scale by numerous stakeholders and managed in silos. There exists an opportunity to harness a variety of data, such as empirical, contextual, observational, and programmatic data, for evaluating the potential impact of HIV responses among KPs in South Africa.

Objective: This study aimed to leverage and harness big heterogeneous data on HIV among KPs and harmonize and analyze it to inform a targeted HIV response for greater impact in Sub-Saharan Africa.

Methods: The Boloka data repository initiative has 5 stages. There will be engagement of a wide range of stakeholders to facilitate the acquisition of data (stage 1). Through these engagements, different data types will be collated (stage 2). The data will be filtered and screened to enable high-quality analyses (stage 3). The collated data will be stored in the Boloka data repository (stage 4). The Boloka data repository will be made accessible to stakeholders and authorized users (stage 5).

Results: The protocol was funded by the South African Medical Research Council following external peer reviews (December 2022). The study received initial ethics approval (May 2022), renewal (June 2023), and amendment (July 2024) from the University

of Johannesburg (UJ) Research Ethics Committee. The research team has been recruited, onboarded, and received non–web-based internet ethics training (January 2023). A list of current and potential data partners has been compiled (January 2023 to date). Data sharing or user agreements have been signed with several data partners (August 2023 to date). Survey and routine data have been and are being secured (January 5, 2023). In (September 2024) we received Ghana Men Study data. The data transfer agreement between the Pan African Centre for Epidemics Research and the Perinatal HIV Research Unit was finalized (October 2024), and we are anticipating receiving data by (December 2024). In total, 7 abstracts are underway, with 1 abstract completed the analysis and expected to submit the full article to the peer-reviewed journal in early January 2024. As of March 2025, we expect to submit the remaining 6 full articles.

Conclusions: A truly "complete" data infrastructure that systematically and rigorously integrates diverse data for KPs will not only improve our understanding of local epidemics but will also improve HIV interventions and policies. Furthermore, it will inform future research directions and become an incredible institutional mechanism for epidemiological and public health training in South Africa and Sub-Saharan Africa.

KEYWORDS

HIV, key populations; Sub-Saharan Africa; big heterogeneous data; Boloka data repository

Introduction

In 2024, the world is at a critical juncture in the HIV response, counting down 6 years toward the global goal of ending AIDS as a public health threat by 2030 [1,2]. Despite the investment and focus on addressing HIV/AIDS, it remains a significant public health threat with persistent prevention and treatment challenges globally, regionally, in Sub-Saharan Africa, and in South Africa [1-3]. South Africa has the largest HIV epidemic in the world, with about 8 million people living with HIV, which represents approximately 1 in 5 of the estimated 38.4 million people living with HIV globally in 2022 [1,4]. While there has been a steady decline of 30.5% (n=198,311) in new infections in the last 5 years, the country still has an unacceptably high HIV incidence (South African National HIV, Prevalence, Incidence, Behaviour, and Communication Survey) [3-5]. South Africa has the largest HIV treatment program in the world to meet the treatment needs of the highest proportion of people living with HIV [1].

Key populations (KPs), including female sex workers and their clients, gay men and other men who have sex with men, transgender people, people who use and inject drugs, and incarcerated persons, face a disproportionate risk of HIV acquisition and onward transmission [6]. As a result of unmet prevention and treatment needs, 51% of new HIV infections are acquired by key populations and their sexual partners despite making up approximately 1.5% of the total adult population in Sub-Saharan Africa [1]. The estimated prevalence of HIV was 59.5% among female sex workers and 29.7% among men who have sex with men in South Africa in 2020 [3,4]. Given social network dynamics, the overall impact of the unmet needs of key populations on onward transmission may be even greater. Other modeling studies have a higher risk of onward transmission due to the unmet prevention and treatment needs among key populations using the transmission population attributable fraction over time ($tPAF_t$) [7]. This demonstrates the need for the specificity of the HIV response in characterizing and addressing heterogeneity in onward transmission for a more significant impact in the reduction of new infections. This disproportionate risk of HIV is driven by discrimination, stigma, and criminalization of behavior [8,9]. These same factors, alongside social network dynamics, make collecting data on HIV burden and specific HIV prevention and treatment needs challenging due to distrust of institutions and fear of poor treatment, arrest, or violence [10-12].

In South Africa, where there is robust HIV surveillance compared with other Sub-Saharan African countries, there is no specific mechanism or centralized system to gather and monitor key population data. The existing HIV surveillance systems include the district health information system (DHIS) and the integrated electronic registers, which both collect patient-level HIV data but have no identifiers for KPs, making it difficult to disaggregate data by these subpopulations [13]. The inability to disaggregate information among KPs can lead to misallocation of resources and services, perpetuating health inequities. This lack of adequate data can also lead to underestimation of the disproportionate risk of onward transmission and ultimately missed opportunities for targeted approaches that can lead to a significant reduction of new HIV cases [7,14,15]. Despite this lack of a centralized system, data on KPs are being collected on a smaller scale by numerous stakeholders, including program implementers, the government, academic partners, and others. There exists an opportunity to harness these different data sources for integration and in-depth analyses.

In generalized epidemic settings, there has been a tendency to focus the HIV response on the general population rather than KPs [16-18]. The scientific justification for the project presented here is that continued reliance on nonspecific population-based approaches to guide programs has limited the broader impact of the HIV response in a generalized epidemic setting like South Africa. At the same time, there is limited data to determine the extent to which a KP-tailored HIV response could reduce HIV incidence in South Africa [6,7,19-21]. A more specific HIV response will likely optimize the use of limited resources [7,20]. The proposed work can support program implementers, funders, and policy makers in making well-informed choices as to where, what, and whom to prioritize and how to deliver effective HIV

control programs to maximize health benefits at a population level. An effective control of the HIV epidemic in South Africa requires a focus on KPs [22].

To address the identified gaps in the field, we are in the process of designing and developing a big data platform called "The Boloka data repository" and harmonization of disparate data from multiple data sources. The Boloka data repository seeks to store a diverse range of data, including empirical, observational, and programmatic data, to improve understanding of HIV acquisition and transmission among KPs. In addition, the Boloka data repository seeks to evaluate the potential impact of HIV responses in South Africa in the context of a generalized epidemic setting. Boloka is a South African Sepedi, Sesotho, and Setswana word that means to "store or keep." In this case, we will store or keep big heterogeneous data. These data, including HIV-related and relevant data for KPs from the year 2000 onward in South Africa, can be used to inform policy and programming. By harnessing big heterogeneous data, more data-driven and ultimately more effective HIV response strategies can be generated.

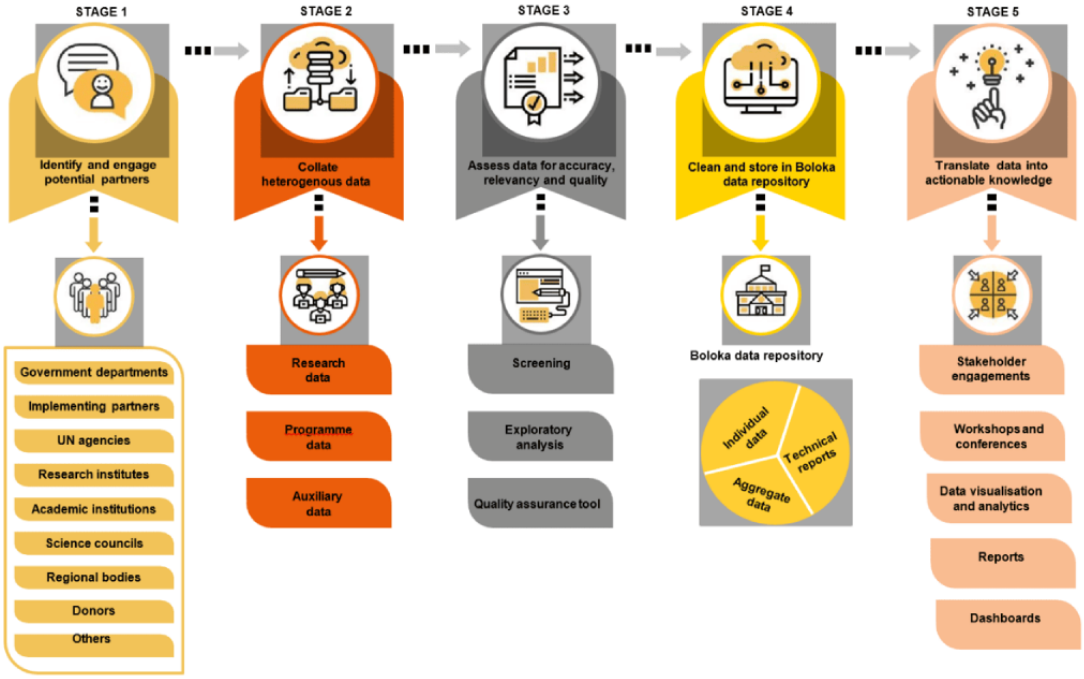
In this protocol paper, we describe the process for developing the Boloka data repository for South Africa. It is envisaged that once the Boloka data repository has been developed, it can be adapted to other countries throughout Sub-Saharan Africa. This study has 3 specific objectives: First, to build a Boloka data repository to handle data on KPs. Second, to collate available HIV-related data for KPs in South Africa from 2000 onwards. Third, to make the data user-friendly for use by stakeholders and authorized users.

Methods

Overview

To achieve the stated objectives, this study project will be developed in the following 5 key stages (Figure 1) [23].

Figure 1. The 5 stages of the Boloka data repository initiative [23], with permission from RNPM. UN: United Nations.



Stage 1: Engage Key Stakeholders to Develop Meaningful Data Partnerships

A range of stakeholders (potential data partners) will be engaged to explore data sharing partnerships and facilitate the collation as well as the organization of the diverse data sources (Table 1). A list of current and potential data sharing partners and the nature of data they are in possession of is being developed (Multimedia Appendix 1 shows the list of potential and current data partners as well nature of data).

A key stakeholder in this work is the South African National AIDS Council (SANAC), which will act as a partner in both the sharing of data and the facilitation of connections to additional potential data sharing partners. A transdisciplinary participatory approach will be adapted to develop meaningful partnerships ensuring collaboration between researchers and data partners, buy-in, project performance, co-ownership, and sustainability [24-26] guided by key principles of mutual trust, sharing, transparency, and responsibility [25,26]. Stakeholders will be given an opportunity to give input at all stages about various components of the Boloka data repository, including which data are collected, how they are stored, data confidentiality, data privacy, and data security, as well as how others may access them using the approved data management processes of the respective data partners. The Boloka research team will also engage with stakeholders regarding priority research questions that will be answered using the data (January 2024 to December 2026). This will ensure that the questions asked have use for those directly involved in the HIV response.

The data processing agreement (DPA) and data partnership or user and related agreements will be signed between the University of Johannesburg and the respective data partners

[27]. These documents will govern the rights and duties of the parties in line "Protection of Personal Information (POPI) Act number 4 of 2014," henceforth referred to as the POPI Act, and any other applicable data protection, security, storage, regulation, and legal requirements [28]. Through these agreements, it will be ensured that the collection, storage, use, disclosure, transfer, disposal, and other processing of any personal information is in line with the prescribed data protection law. The signed agreements will be stored at the University of Johannesburg records management unit.

The Boloka data repository initiative will be executed in the South African Medical Research Council/ UJ (SAMRC/UJ) Pan African Centre for Epidemics Research (PACER) Extramural Unit, which is part of over 40 research centers and institutes, and 20 prestigious national research and industry-funded chairs that the University of Johannesburg is hosting. The South African Medical Research Council/ UJ (SAMRC/UJ) Pan African Centre for Epidemics Research Extramural Unit is one of the flagship initiatives that is supported under the Global Excellence and Stature strategic initiative [29].

Table 1. List of current and potential Boloka Project data partners.

Partner category	Examples of data partners
Country coordinating mechanism	SANAC (South African National AIDS Council)
International and Regional UN Agencies	Centers for Disease Control and Prevention (CDC), UNICEF, United Nations Development Programme, UNAIDS, WHO, United Nations Population Fund.
Government Departments	National Departments of Health, Social Development, Correctional Services, Basic Education.
Nongovernmental organizations (NGOs), nonprofit organizations (NPOs), and other	Beyond Zero (BZ), Networking HIV & AIDS Community of Southern Africa (NACOSA), Sex Workers Education and Advocacy Taskforce (SWEAT), Aurum, TB/HIV Care, Right to Care, Sisonke, U.S. President's Emergency Plan for AIDS Relief (PEPFAR) funded organizations.
Science Councils	Human Sciences Research Council (HSRC), South African Medical Research Council, Council for Scientific and Industrial Research.
Research Institutes in Universities	Desmond Tutu HIV Foundation, Centre for the AIDS Programme of Research in South Africa, Perinatal Health Research Unit.
Local and international donors	Global Fund, President's Emergency Plan for AIDS Relief (PEPFAR), UNAIDS, European Union (EU), Department for International Development (DFID), Canadian International Development Agency (CIDA), Directorate-General for International Cooperation (DGIS), Bill and Melinda Gates Foundation (BMG).
National Universities	All South African Universities.
Regional economic communities	Southern Africa Development Community.

Stage 2: Acquire and Collate Heterogeneous Data

Overview

The Boloka data repository will leverage and collate available and diverse data from various sources across places, times, and populations (Multimedia Appendix 1 shows the list of potential or current data partners and data types). The inclusion and exclusion criteria (Textbox 1), as well as the Boloka data indicator tool (Multimedia Appendix 2), will guide the eligibility of the data source. The inclusion of HIV-related data from the period 2000 and onwards will enable the capturing of the developments that took place over time in the HIV field. The use of reliable and granular data collected over time is essential for improving population health, setting targets as well as developing strategies for targeted HIV response.

The team reviewed the Joint United Nations Programme on HIV/AIDS global monitoring tool and the National Department of Health (NDoH) national indicator dataset form used for global, regional, and national HIV reporting to identify primary and secondary indicators in line with global, regional, and national priorities. The team also reviewed existing validated questionnaires or instruments from various data partners to further refine priority indicators; from this, broader categories of HIV-related interest areas were formed (Figure 2). Accordingly, each potential data partner is required to indicate the primary and secondary indicators that they have collected data on the Boloka data indicator tool (Multimedia Appendix 2).

Where possible, data will be disaggregated at individual, facility, district, or sub-district levels to enable advanced analyses that are not possible with higher-order aggregated data. This will help us develop an in-depth understanding of various subsets of the populations within the larger datasets. Where data are aggregated, we will seek data disaggregated by sex, gender, age groups, socioeconomic status, geo-location, facility type, and temporal factors to understand a range of HIV indicators, including heterogeneity of HIV risk and burden, engagement in HIV services (treatment cascade, pre-exposure prophylaxis uptake and continuation), and population size estimates, among others. The process for requesting and accessing data varies based on the data type and institution. As such, the process of acquiring and collating the data for the different data types is discussed below.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria:

- Study topic: HIV, key populations, HIV prevention and treatment.
- Study area: South Africa.
- Language: English.
- Time frame: Collected in the year 2000 or later.
- Data type: Research and program data.
- Data regulation: Secondary dataset or study with primary consent, specifying that the original consent or ethics approval covers secondary analysis without additional consent from participants.

Exclusion criteria:

- Study topic: Non-HIV.
- Study area: Non–South Africa.
- Language: Non-English.
- Time frame: Collected before the year 2000.
- Data type: Social media data.
- Data regulation: In circumstances where primary consent is needed from the participants, such datasets or studies will be excluded as it may not be feasible to go back to the participants for reconsent.

Figure 2. Boloka HIV-related indicator list.

Research Data

For open access data, which is typically aggregated or deidentified individual data, we will adhere to procedures set by the respective institutions to obtain access in line with the POPI Act. This may require the submission of designated data access request forms before gaining direct access to the dataset. For data that are only available upon request, we will contact the data partner to understand their specific procedures for accessing data. This typically requires the completion of a data access request form and the sharing of relevant information, such as the project proposal, ethics approval, and timelines for analysis. For institutions such as the NDoH, district health information data is made available for public use upon request and completion of their data user agreement (DUA) forms. The data or indicators requested should be aligned with the approved National indicator dataset, which outlines the data elements and indicators collected by the NDoH. In such cases, the request and DUA forms will be completed to access data. For institutions in possession of data that are not typically available for public access (eg, implementing partners), we will seek to develop formal partnership agreements and additionally use the University of Johannesburg DPA to ensure adherence to the Protection of Personal Information Act in terms of data privacy and security before any data sharing. Once agreed upon, a formalized partnership agreement will be approved by the legal team of both parties. These agreements will be reviewed in accordance with the policies of the respective organizations.

Program Data

For institutions in possession of data that is not typically available for public access, we will seek to develop formal partnership agreements and additionally use the University of Johannesburg DPA to ensure adherence to the POPI Act in terms of data privacy and security before any data sharing. Once agreed upon, a formalized partnership agreement approved by the legal team of both parties will be signed. These agreements will be reviewed in accordance with the policies of the respective organizations.

Stage 3: Screen Data for Relevance and Quality

Overview

Once data are acquired and determined to be eligible according to the inclusion and exclusion criteria (Textbox 1), they will go through a process of screening and assessment for accuracy, relevance, quality, completeness, and consistency before inclusion in the Boloka data repository. Due to limited information and validated tools on how to specifically check for relevance and quality for some of the data types [30], we will adopt the Framework for Data Quality developed by the Federal Committee on Statistical Methodology (FCSM) [31] and the Information Quality Assessment Framework [32]. Below are further details on the data screening process by the different data types.

Research Data

For research data, a multistep quality assessment process will be carried out using the Global HIV Quality Assessment Tool (Multimedia Appendix 3) [33]. This tool will be used to review and verify the suitability and quality of research data sources in terms of study design and implementation, along with criteria for HIV indicators, specifically prevalence, incidence, engagement in the HIV care continuum, and population size estimates [33]. There will be close supervision and checks to minimize errors by using an honest data broker mechanism to manage and maintain datasets. In addition, 2 individuals (research assistants) will perform the initial quality assessment. Any discrepancies identified will be addressed by a third assessor (Project Manager and Principal Investigator [PI]). Exploratory analyses will be conducted to understand the nature of the data and identify outliers and missing data that will be cleaned for data quality and accuracy. This will be an iterative process to ensure that we leverage and assemble the best available data.

Program Data

It is important to highlight that program data present unique data quality challenges. Program data are typically aggregated to administrative units, and information on individuals is generally not available. Hence, it is not always feasible to link program exposure directly to an outcome [34]. In terms of screening the program data for inclusion into the Boloka data repository, the World Health Organization's "Data quality review: a toolkit for facility data quality assessment—Module 1: Framework and metrics" will be adapted for use [35]. This framework is made up of 4 dimensions. For this study, dimensions 1 and 2 will be used: completeness and timeliness of the data (dimension 1) and internal consistency of reported data (dimension 2). Dimension 1 focuses on the data elements and indicators collected. For example, the NDoH and implementing partners' data elements and indicators will be assessed and checked for completeness [35]. Dimension 2, that is, the internal consistency of the data, relates to the coherence of the evaluated data. In this regard, 4 metrics of internal consistency will be used [35]: (1) presence of outliers, (2) consistency over time, (3) consistency between indicators, and (4) consistency of reported data.

In this initial screening, articles, reports, and datasets will be excluded if their scope does not adhere to the inclusion criteria mentioned in Textbox 1. Data that focuses on the general population will be included in addition to data with a focus on KPs, as the general population provides important KP contextualization. Furthermore, data that have been empirically collected will be prioritized. Estimates and modeled data will be included but carefully reviewed to ensure they meet quality standards and are deduplicated within the datasets.

A report detailing the results of the quality assessment will be written. The report will include the recommendations for data quality improvement plans considering the context and existing constraints. A feedback loop will be used to engage with stakeholders on the potential data quality issues and anomalies, such as completeness of data, discrepancies, and inaccuracies. In addition, the data quality results will be available and stored alongside the data in the repository as part of the metadata.

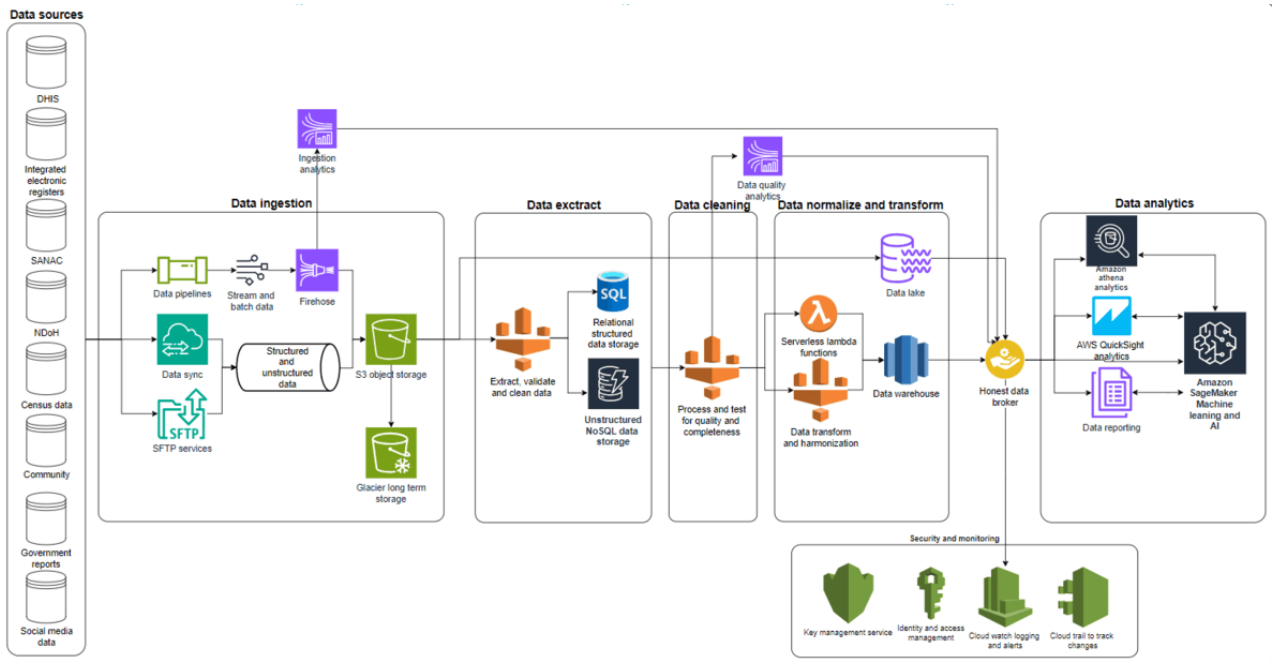
Stage 4: Clean and Store Data In A Data Repository

Overview

Data will be extracted from data sources and put into a staging area before being transformed and loaded into the data repository (Figure 3). We will use the Data Intensive Research Initiative of South Africa (DIRISA) platform, which will enable the provision of much-needed timely information at a level and scale that will improve understanding of HIV heterogeneities. Structured data will be preprocessed and normalized into a standardized format using the Boloka Data Harmonization Tool (Multimedia Appendix 4). The repository will be flexible and updatable for structured data by design [36]. Unstructured data will be stored in the NoSQL data store. Preprocessing will entail data cleaning, transformation, and integration to make the data complete for analysis. Data management will involve assembling multiple big, existing HIV data sources and datasets, capturing, preprocessing, cleaning, integrating, and building them into the Boloka data repository.

For disaggregated data, personal identifiable information will be encrypted and hashed to ensure anonymity and protect privacy. This role is also performed by the appointed honest data broker. Ideally, the Boloka data repository will not store any identifiable personal information, but a procedure in accordance with the POPI Act will be put in place for handling this issue if such information comes with the data. The honest data broker mechanism will be set up to screen the data for compliance in terms of the latter before it passes to the Boloka data repository. The resulting data repository will be responsive to the size and scope of the collected data. It will be dynamic and flexible to accommodate diverse data that has a high number of dimensions.

Figure 3. Envisaged Boloka data storage process flow. AI: Artificial Intelligence; AWS: Amazon Web Service; DHIS: District Health Information System; NDoH: Nation Department of Health; S3: Simple Storage Service; SANAC: South African AIDS Council; SFTP: Secure File Transfer Protocol; NoSQL: Not Only Structured Query Language.



Data Security and Access

The access to the data repository will be secured with login credentials (username and password) in conjunction with multifactor authentication (MFA) to ensure compliance with the POPI Act and avoid any confidentiality breaches as well as contravention of human rights. Access to the repository will be made to the PI and Project Manager through a formal and written request. Login credentials (password) will be updated on a 3-month basis to enhance layers of security and reduce the risk of unauthorized access.

Stage 5: Translate Data Into Actionable Knowledge

Knowledge created from available data will be applied to address real-world challenges. To ensure that findings are incorporated into program and policy decisions promptly, the study will establish a feedback loop with stakeholders and authorized users throughout the project lifespan. Knowledge sharing will be done through dissemination workshops, consultative meetings, reports, dashboards, data visualization, and other methods deemed appropriate. This will support open communication and 2-way feedback between researchers and stakeholders (Multimedia Appendix 5). This participatory process will contribute towards improved use of available data and narrowing the gap between science and practice. Various forms of analysis will be planned in partnership with stakeholders to answer research questions that are relevant to their respective organizations and national priorities. Ultimately, the translation of research will seek to strengthen health systems and, therefore, improve health outcomes throughout South Africa, specifically for KPs and other vulnerable populations. Our goal is to make the Boloka data repository an accessible tool that can be used by local, regional, and international stakeholders for more effective and efficient health care management, prevention, and programming.

The University of Johannesburg Strategic Communication Department designated official will promote and market the initiative using the University of Johannesburg's communication technologies, media, and platforms. They will promote public understanding of the study and research outputs throughout. This will include articles in the daily press, magazines, and other popular media, public lectures, and interviews or programs on television or print media.

Ethical Considerations

Ethics approval (May 2022), renewal (June 2023), and amendment (July 2024) have been secured from the University of Johannesburg, Faculty of Health Sciences, Research Ethics Committee for conducting secondary analysis of data (REC-1504-2022) (Multimedia Appendix 6). Data partners will only share deidentified secondary datasets, and no personal information of the participants will be retrieved as per the POPI Act and the University of Johannesburg DPA, which governs the sharing, storage, and use of personal information. For example, in cases of NDoH, the routine data is aggregated and not at an individual level. The South Africa National HIV Prevalence, Incidence, Behavior and Communication Surveys (SABSSM) data is open access and unique identifiers were used. Data handling, processing, and analysis will be guided by the University of Johannesburg DPA, POPI Act, and data partnership agreement or request form. There is no monetary compensation for the data partners for being part of the Boloka project.

Results

As of December 2022, the protocol was funded by the South African Medical Research Council following external peer reviews. Subsequently, the study received ethics approval from the University of Johannesburg, Faculty of Health Sciences,

Research Ethics Committee. The research assistants, students, and postdoctoral fellows who will partake in the creation of the data repository and subsequent analyses were recruited, onboarded, and received online training and resources in research ethics evaluation (TRREE), management and analysis of data in epidemiology (MADE), data types, and structures. The team will continue to tap into opportunities for professional development training, including sensitivity training for KPs and training on data privacy, specifically regarding the POPI Act and DIRISA functionalities for the duration of the study (January 2024-February 2027). The progress as of September 2024 is described below according to the 5 stages.

Stage 1: Identify and Engage Key Stakeholders to Develop Meaningful Data Partnerships

Overview

The stakeholder engagement is ongoing using the data partner tracking tool (Multimedia Appendix 7) listing potential and current stakeholders and their level of engagement with data (eg, district, provincial, and national) is in place.

Research Data

The research team secured open access data from 5 (2002, 2005, 2008, 2012, and 2017) South Africa National HIV Prevalence, Incidence, Behavior and Communication Surveys from the Human Sciences Research Council (HSRC) on January 5, 2023. Since the data is open access, no signing of DPA was required to access and secure the data. Engagement with stakeholders is expected to conclude in December 2026 in terms of finalizing data sharing agreements, and an example of the University of Johannesburg DPA has been shared for consideration by the potential data partners. An engagement with NDoH was done in 2022, and HIV-related routine data was secured (April 2024).

Program Data

The research team had a series of meetings with SANAC regarding the Boloka data repository. These meetings have established a strong partnership and system for the coordination of data-sharing partnerships. The partnership with SANAC is essential in ensuring that the Boloka data repository is used to guide national HIV strategy related to KPs. This strong relationship will ensure the complementarity of the Boloka data repository rather than duplication of SANAC's efforts to develop "The Situation Room," a central HIV data repository for program data in South Africa. The Situation Room, still in its infancy stages, seeks to enable data checks and balances, dynamic visualization, and sharing of the national, provincial, and district HIV data in the general population to monitor progress toward reaching set targets. The Boloka data repository will be a resource for KP data toward SANAC's efforts. SANAC introduced the research team to its implementation partners to acquire potential data partners, namely Beyond Zero [37], Networking HIV and AIDS Community of Southern Africa (NACOSA) [38], Sex Worker Education Advocacy Taskforce (SWEAT) [39], Sisonke [40], and AIDS Foundation South Africa (AFSA) [41] as well as Perinatal HIV Research Unit (PHRU) [42].

A series of engagements have been carried out with the respective organizations; the engagements are at different stages. Beyond Zero has been engaged since September 2022, and a final copy of the University of Johannesburg and Beyond Zero data-sharing agreement is under review by the Beyond Zero legal team before it is signed by both parties. A data partnership agreement with PHRU is expected to be finalized by the end of December 2024. For this partnership, the PHRU data-sharing agreement is being developed by their legal department. With AFSA, the agreement is in the early stages of communication. In addition to engagements with SANAC and its implementing partners, the research team has consulted with other community leaders who work or worked with community-based organizations, such as treatment action campaigns.

Stage 2: Acquire and Collate Heterogeneous Data

Overview

Significant progress has been made in securing program data, published research data, and technical reports. The security of the acquired data is prioritized during this interim period; thus, the data have been stored in a secure staging area and will later be moved to appropriate data storage software.

Research Data

Open access data from 5 cycles (2002, 2005, 2008, 2012, and 2017) of the population-based multistage cluster cross-sectional of up to 85,000 randomly selected households in South Africa has been secured from the HSRC (January 5, 2023). The South African HIV Behavioural, Sero-status and Media data is within the restricted access level. The data was accessed by completing a non–web-based internet data request form detailing the name of the project, a brief description of the intended use, and the expected date of project completion. The surveys provide data on HIV incidence, prevalence, antiretroviral therapy (ART), viral load suppression, drug resistance, risk behaviors, and HIV care, among others. The Key Population Implementation Science (KPIS) data on HIV testing and engagement in care was secured at Emory University (May 16, 2022) for the degree purpose of postgraduate students. Further, data on HIV testing proficiency was generated by a postgraduate student from the health care facilities in Eastern Cape Province (May 2023).

Data from the Demographic Health Surveys Program has been secured (August 2022). This required registration and submission of a data access request form along with the justification of the request. The demographic health survey collects indicators such as HIV prevalence, prevention and treatment, stigma, and discrimination, as well as sexual behavior. We also secured HIV-related data from the NDoH, and the data includes the following HIV indicators: HIV testing and HIV prevention; ART (ie, ART initiation, ART rate, viral load & CD4 T lymphocyte count testing, ART type, ART adherence); sexually transmitted infections; maternal and neonatal (antenatal HIV test, ART initiation, ART adherence, live birth, infant HIV test); management of inpatients and management of primary health care facility.

There are plans to use data from the 1173 NDoH High Transmission Area sites across South African provinces based in communities that function like clinics and provide services

to KPs. The NDoH's High Transmission Area program reaches key and vulnerable populations with HIV, tuberculosis, and sexually transmitted infections prevention and management services in key hotspots across the country.

Program Data

This protocol will also leverage a partnership with the largest HIV service provider for key populations in South Africa, TB HIV Care, a nonprofit organization, building on a decade-long period of dynamic and exciting work; preliminary discussions have already taken place with the Chief Executive Officer. TB HIV Care focuses on preventing, finding, and treating HIV and TB across 7 provinces and 22 districts in South Africa [43]. Its KP program provides services to sex workers and people who use drugs. Furthermore, data-sharing agreements are being drafted and checked for Beyond Zero, NACOSA, and AFSA, as detailed above.

Stage 3: Assess Data for Accuracy, Relevance, And Quality

Overview

The data received in stage 2 went through screening and assessment for accuracy, completeness, and consistency before its placement in the staging area. The data received was screened and filtered for relevance and inclusion by a member of the research team using the FCSM and the Information Quality Assessment Framework [32] where applicable.

Research Data

South African HIV Behavioural, Sero-status and Media data has undergone a quality check to assess the completeness of the data received. Using the Needs Assessment Form, the DHIS data received has been checked to assess the relevance of the data to the project aims. The assessment checked that the data included the relevant indicators and if the data was complete. This process has been done by 2 researchers on the team.

Stage 4: Clean and Store Data in The Boloka Data Repository

The data have been placed in the staging area before being stored in the data repository. South African Medical Research Council/UJ (SAMRC/UJ) Pan African Centre for Epidemics Research Extramural Unit secured cloud-based storage on the DIRISA platform on June 14, 2024. DIRISA is a "component of the National Integrated Cyberinfrastructure System that coordinates and promotes sound research data management practices and supports data-intensive research" [44]. The access will grant the University of Johannesburg permission to use the DIRISA platform, along with access to the support tools and resources. The resources have been shared to provide access to DIRISA training materials. Through this platform, KP data will be harmonized into a centralized storage area that is managed and protected. All data is to be cleaned and converted into a standardized format to create a structured, flexible, and updatable data repository. The designing of the Boloka data repository will be completed by December 2026. Multimedia Appendix 8 shows the summary of planned and executed milestones for this project.

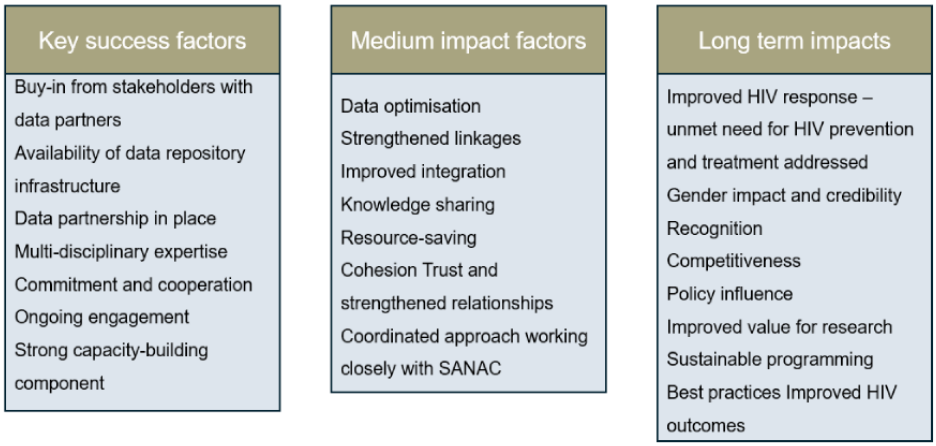
Stage 5: Translate Data Into Actionable Knowledge

Authorized users and stakeholders will have the capability to generate customized reports and export the data to applications such as Stata software (StataCorp) for further dissemination. Authorized users and stakeholders will submit a data request before receiving log-in credentials to access the data repository. Initial secondary data analyses using analytic methods attuned to the structure of available data, including cross-sectional and longitudinal analyses, are being conducted to improve our understanding of HIV among KPs for a targeted response. The proposed analyses will be a transdisciplinary collaborative effort to enable joint application of theories and methods to share conceptual frameworks, innovations, and best practices for solving public health problems. In this regard, the proposed analyses will be jointly finalized with program partners to identify priority research questions that will measure program progress, guide programmatic decision-making, and ultimately improve the response to HIV.

Data synthesis and initial analyses are being planned with a transdisciplinary team of infectious disease epidemiologists, public health scientists, statisticians, data scientists, data analysts, implementing partners, and data partners who will bring complementary expertise on global key populations insights, key population modeling, epidemiology, human rights, and the development of a sustainable data platform. We have already worked with some of the data partners to determine the research agenda that targets policy and practice outcomes, that is, determining common research questions, models, and methods to improve South Africa's HIV response. The doctoral students who will use the Boloka data repository for their dissertations have begun writing their research proposals and seeking ethical approval.

Some factors are critical for the success of this project in achieving the envisaged medium- and long-term impacts, as shown in Figure 4.

Figure 4. Key success factors for Boloka data repository and envisaged impacts. SANAC: South African National AIDS Council.



Discussion

Principal Findings

It is anticipated that there will be data challenges that are common across projects of this nature due to the POPI Act. The University of Johannesburg has already established a mechanism to address these. Potential POPI Act–related challenges have been highlighted in the University of Johannesburg DPA, which is standard for all data-driven projects.

The Boloka data repository will be a lasting resource for the country to guide regional policies and strategies to address HIV, particularly among KPs. Therefore, in addition to traditional research dissemination led by the research team and the proposed feedback loop (Multimedia Appendix 4), the data repository will be widely accessible to all data partners and stakeholders. This co-ownership with stakeholders will enable alternative possibilities for analyses and translation of data to real-world settings. The knowledge, historical context, and applied understanding that stakeholders possess provide opportunities for transformative change. The protocol will provide the opportunity to document lessons learned into a knowledge base, which may be applied to other countries in Sub-Saharan Africa.

The Boloka data repository will contribute to improved storage, retrieval, and access to KP data; linkages of surveillance data collection systems and other data collection efforts; integrated data reporting for monitoring national trends and patterns; recommendations for research, policy, and planning; as well as changes in current and future research. The Boloka data repository will provide a richer empirical basis for policy and program debates in a relatively neglected area of health research in the country. The data, along with its analyses and research outcomes, can form the basis of regularly reported statistics by stakeholders. The Boloka data repository will be maintained up to date to serve as a real-time sustainable resource to guide HIV planning, resource allocation, policy formulation, and programming.

Strengths and Limitations

The Boloka project seeks to build a complex data repository to house and analyze big heterogeneous data from KPs to guide the HIV response in South Africa and, ultimately, SSA. This initiative is crucial in developing policy recommendations for innovative methods towards ending the HIV epidemic in 2030. The Boloka initiative is a novel approach that has the potential to enhance knowledge translation. It will also provide opportunities for capacity-building among academic trainees and stakeholders. Furthermore, the Boloka repository will contribute to the optimization of the HIV data systems necessary for epidemic control. Various data types will be used through integrated analysis to uncover latent outcomes. However, the use of secondary data has limitations as no changes can be made toward improving internal validity. The data requested are from cross-sectional surveys that lack the ability to establish causality. Mitigation of data security, integrity, and confidentiality issues has been described in the relevant sections.

Conclusions

We posit that a truly “complete” data infrastructure that systematically and rigorously integrates empirical, contextual, observational, and programmatic data for KPs will not only improve our understanding of local epidemics but will also improve HIV interventions and policies. Furthermore, it will inform future research directions and become an incredible institutional mechanism for epidemiological and public health training. Achieving epidemic control in South Africa necessitates moving beyond HIV data silos, harnessing underused heterogeneous data, and conducting unconventional analyses. Creating a comprehensive and accessible data infrastructure inclusive of heterogeneous data will improve our understanding of HIV among KPs and accelerate the production of high-quality evidence. Empowered with this evidence, scientists, program leaders, community stakeholders, and policy makers will be able to tailor and optimize HIV service delivery to the most vulnerable populations, thus making the South African National Strategic Plan goal possible. The amassed evidence will provide opportunities for comprehensive and innovative analyses that seek to address priority research questions to improve our understanding of HIV among KPs, assist in setting program targets, guide programmatic decision-making, and ultimately improve the response to HIV in South Africa and other Sub-Saharan African countries. Efforts will be made to incorporate the findings from this study into the South African HIV response strategy.

Acknowledgments

The work reported herein was made possible through funding by the South African Medical Research Council (SAMRC; Project Code #57035; SAMRC File ref no: HDID8528/KR/202) through its Division of Research Capacity Development under the Mid-Career Scientist Programme through funding received from the South African National Treasury. The content hereof is the sole responsibility of the authors and does not necessarily represent the official views of the SAMRC." This research is also funded, in part, by the US National Institute of Allergy and Infectious Diseases (award R01AI170249). The content hereof is the sole responsibility of the authors and does not necessarily represent the official views of the funders.

Authors' Contributions

RNPM and SB conceptualized the protocol and initial draft of the manuscript and provided overall leadership for executing the review to completion. RNPM, EP, AR, KW, KR, KAV, AB, CS, BS, MS, MJ, LLO, KJ, HIS, XL, BO, NH, PD, FW, YAS, LM, MR, and SB contributed to the introduction, methodology, and progress updates of the study. RNPM, EP, KAV, AB, CS, BS, MS, MJ, LLO, KJ, and HS were responsible for engaging with key stakeholders and initiating the data-sharing process. RPNM and EP were responsible for engaging with the legal team and finalizing data-sharing agreements. LM and MR were responsible for the facilitation and linkage to key stakeholders. NH and PD provided insights into the Boloka Data Storage Process Flow. HS and KJ drafted the Boloka Indicator list; KAV and AB drafted the Boloka Harmonization Tool—and the rest of the team reviewed the tools for further input. RNPM was responsible for the management and coordination of review activities. All authors discussed the results and contributed to the final manuscript.

Abstract

Background: The 2019 Canada's Food Guide provides universal recommendations to individuals aged ≥2 years. However, the extent to which these recommendations are appropriate for older adults is unknown. Although ideal, conducting a large randomized controlled trial is unrealistic in the short term. An alternative is the target trial emulation framework for causal inference, a novel approach to improve the analysis of observational data.

Objective: This study aims to describe the protocol for a target trial emulation in older adults, with an emphasis on key aspects of a hypothetical sustained diet and physical activity intervention.

Methods: To emulate the target trial, nonexperimental data from the Quebec Longitudinal Study on Nutrition and Successful Aging (NuAge; N=1753 adults aged ≥67 years) will be used. NuAge includes 4 yearly measurements of dietary intakes, covariates, and outcomes. The per-protocol causal contrast will be the primary causal contrast of interest to account for nonadherence. The sustained intervention strategy will be modeled using the parametric g-formula. In the hypothetical trial, participants will be instructed to meet sex-specific minimal intakes for vegetables and fruits, whole grains, animal- and plant-based protein foods, milk and plant-based beverages, and unsaturated fats. The eligibility criteria, follow-up, intervention, outcomes, and causal contrast in the emulation will closely align with those of the target trial, with only minor modifications. We will attempt to emulate the randomization of treatment by adjusting for baseline covariates and prebaseline dietary habits.

Results: Data collection for NuAge was completed in June 2008. For this study, the main analysis was started in May 2024. Submission of the manuscript is expected by February 2025.

Conclusions: Emulating a target trial will provide the first evidence of the adequacy of the 2019 Canada's Food Guide recommendations for older adults in relation to health outcomes.

Introduction

Background

The latest edition of Canada's Food Guide (CFG) was published in 2019 [1]. Compared with the previous edition, key changes include the removal of the prespecified number of servings to consume each day, a shift toward qualitative (eg, "eat plenty of...") instead of quantitative recommendations, and the provision of universal recommendations instead of age- and sex-specific recommendations. In addition, CFG recommendations primarily aim to reduce chronic disease risk. The evidence supporting CFG recommendations focuses on reducing the risk of cardiovascular disease, cancer, and type 2 diabetes risk [2]. However, evidence from a nationally representative survey of adults aged ≥65 years from Canada suggested that greater adherence to recommendations was insufficient to meet calcium, vitamin D, and folate requirements [3]. In Canada, one-third of community-dwelling older adults are at high nutrition risk [4,5], highlighting the importance of maintaining adequate nutritional status in this stratum of the population. Similarly, in the absence of specific recommendations on the amount of protein foods to eat, older adults may be eating less protein than required to maintain muscle mass [6-8]. CFG also provides brief physical activity recommendations but without explicit acknowledgment of the importance of these recommendations for older adults [1]. Indeed, performing a minimal amount of physical activity is paramount to maintaining muscle mass [6,7]. Thus, the universal recommendations in CFG may not be appropriate for older adults because they face unique challenges in consuming a healthy diet [9] and may require specific nutritional strategies [10].

Ideally, a randomized controlled trial (RCT) should be conducted to investigate the adequacy of CFG recommendations in older adults. However, such an RCT is unlikely to be conducted in the short term. An alternative is the target trial emulation framework for causal effect estimation using observational data [11-14]. Informally, the target trial emulation framework aims to emphasize and resolve design challenges in observational data analysis by explicitly emulating a hypothetical trial to estimate a causal effect [11]. In nutritional epidemiology, common issues with design and analyses can yield results that are largely inconsistent with those of randomized trials [15]. For example, the lack of consideration of the compositional nature of diet can dramatically influence effect estimates, that is, increasing the intake of one food must be compensated by decreasing the intake of another food in substitution modeling [15-17]. Furthermore, diet is a lifelong sustained exposure. In an observational study, the effect of diet assessed at a given time may actually reflect the cumulative exposure to previous dietary habits. In turn, ignoring previous dietary habits may result in a misalignment of "time zero" [18], as dietary habits are not randomly assigned at the beginning of the observational study. In other words, ignoring previous dietary habits makes it impossible to distinguish the effect of prospective or hypothetical dietary modification from the effect of retrospective dietary habits. The target trial framework is a helpful tool to highlight and address common issues in nutritional epidemiology. Ultimately, a successful emulation of the target trial based on observational data could yield effect estimates that more closely align with those of a hypothetical future RCT. Example applications of the target trial framework include the emulation of interventions on diet [19-22], physical activity [23], or both [24].

Objectives

To the best of our knowledge, a target trial framework has not been used to assess the effect of adhering to CFG recommendations. Accordingly, this study aims, first, to describe the protocol for the emulation of a target trial using observational data from the Quebec Longitudinal Study on Nutrition and Successful Aging (NuAge [25]), which includes a cohort of 1753 adults aged 67 to 84 years at baseline, and, second, to address key aspects of the target trial emulation in the context of a sustained lifestyle intervention strategy involving diet and physical activity. Key aspects are the description of the sustained lifestyle intervention strategy, the attempt to emulate randomization, as well as assumptions and limitations specific to diet intervention. Notably, more general introductory texts to the target trial framework are available elsewhere [11,12,14].

Methods

Research Question and Hypothesis

Explicitly acknowledging the causal nature of a research question is a prerequisite to causal effect estimation using observational data [26-28]. This study aims to examine the adequacy of the universal dietary recommendations provided by CFG for older adults. Expressed as a counterfactual statement, we aim to answer the following question: What would be the difference in a given health outcome at the end of the follow-up if all eligible participants had increased their adherence to CFG recommendations on healthy food choices, compared to if they had maintained their habitual diet?

Specifically, among adults aged 67 to 84 years followed for 3 years, and compared with maintenance of habits, we aim to (1) estimate the causal effect of adhering to CFG dietary recommendations on markers of muscle health (eg, physical function and muscle strength), general health (eg, waist circumference, blood pressure, and glucose), and cognitive health (ie, Modified Mini-Mental State Examination) and (2) estimate the causal effect of adhering to a *reformulation* of CFG dietary recommendations, including more protein foods and a minimal physical activity recommendation, to amplify the positive health effects.

Accordingly, we hypothesize the following:

- *Hypothesis 1: adhering to recommendations positively influences general and cognitive health but does not influence muscle health.*
- *Hypothesis 2: increasing the consumption of protein-rich foods positively influences muscle health, and meeting minimal physical activity recommendations (≥30 min per day) further amplifies positive health effects.*

Study Design and Sample

Data from the NuAge prospective cohort will be used to emulate the target trial [25]. The NuAge cohort comprised 1753 generally healthy community-dwelling adults aged 67 to 84 years at baseline and followed for 3 years. The baseline and each annual follow-up evaluation included a comprehensive assessment of sociodemographic data, diet, physical activity, functional status, as well as physical and mental health status [25].

The NuAge sample is relevant to our research question. The target population of CFG recommendations comprises all individuals aged ≥2 years, which is compatible with the NuAge target sample of generally healthy older adults from the greater Montreal, Sherbrooke, and Laval areas of the province of Quebec, Canada.

Target Trial

The target trial framework has been suggested as a potential solution to improve the analysis of nutritional epidemiology studies aiming at causal inference [13]. Informally, the target trial framework helps to align the observational data analysis with that of a hypothetical trial. This framework is appropriate for the research question in this study, as we aim to estimate the effect of adhering to a hypothetical diet and physical activity intervention using observational data. The first step of a target trial emulation is the description of the target trial, that is, the protocol for the hypothetical RCT we wish to conduct [11,14]. The second step is the emulation, that is, describing how the target trial is emulated and conducting the study described in this protocol.

Table 1 presents the target trial and its emulation using observational data from NuAge. Key differences between the target trial and its emulation are that participants will be required to provide complete dietary assessment and covariate data at baseline (ie, eligibility component) and that we will attempt to emulate the randomized assignment by adjusting for dietary intakes before baseline as well as baseline covariates (ie, assignment component). Each part of the target trial and its emulation are described in the subsequent sections.

Table 1. Emulation of a dietary intervention target trial using observational data from the Quebec Longitudinal Study on Nutrition and Successful Aging (NuAge [25]).

Trial component	Target trial specification	Target trial emulation
Eligibility criteria	• NuAge inclusion criteria: individuals aged 67-84 years; living in Montreal, Laval, or Sherbrooke; not cognitively impaired; and free of disabilities in activities of daily living • Exclusion criteria: class II heart failure, chronic obstructive pulmonary disease requiring home oxygen therapy or oral steroids, inflammatory digestive diseases, and cancer treatment in the past 5 years	• The inclusion and exclusion criteria are the same as those specified in the target trial. • Furthermore, participants will be required to have complete baseline dietary assessment (at least one 24-hour recall with ≥500 kcal and FFQ[a]) and provide baseline covariate data.
Interventions[b]	• Each individual would be assigned to 1 of the 4 following strategies: • Control group (habitual diet, ie, typical North American diet) • Adherence to Canada's Food Guide recommendations on healthy food choices • Adherence to Canada's Food Guide recommendations on healthy food choices and including a high-protein reformulation • Adherence to Canada's Food Guide recommendations on healthy food choices, including a high-protein reformulation and a minimal physical activity component • Each strategy is followed until the end of follow-up. Participants assigned to a lifestyle strategy are expected to maintain their dietary intake or amount of physical activity at or above the prespecified threshold by the corresponding intervention strategy.	• The intervention component will be the same as that specified in the target trial. • Furthermore, we will assume that each dietary assessment period (ie, within 2 months beginning at each time point) accurately reflects the average diet in the interval between follow-ups.
Assignment	• Participants are randomly assigned to a dietary strategy but are not blinded to their assignment.	• We will attempt to emulate randomized assignment by adjusting for dietary intakes before baseline and baseline covariates.
Outcomes	• The outcomes are physical function and muscle strength, general health indicators, and cognitive health.	• The outcomes will be physical function and muscle strength, general health indicators, and cognitive health.
Time zero and follow-up	• The study starts at baseline and ends at incomplete follow-up or 3 years after baseline, whichever occurs first.	• The study will start at baseline and end at incomplete follow-up or 3 years after baseline, whichever occurs first. • An incomplete follow-up is defined as missing data for questionnaires (nonresponse or loss to follow-up) or missing outcome data at the end of follow-up.
Causal contrast[c]	• Intention-to-treat effect • Per-protocol effect	• Observational analog of both contrasts: • Secondary: intention-to-treat effect • Primary: per-protocol effect
Statistical analysis	• Intention-to-treat analysis: apply inverse probability weighting with adjustment for prebaseline and baseline factors associated with incomplete follow-up to account for study dropouts • Per-protocol analysis: apply the parametric g-formula algorithm to compare postintervention outcomes between groups receiving each treatment strategy, adjusting for pre- and postbaseline factors associated with adherence to intervention strategies and incomplete follow-up.	• Analysis will be the same as that specified in the target trial for both contrasts. • However, the observational analog will require additional adjustments for confounding at baseline and before baseline due to previous dietary pattern.

[a]FFQ: food-frequency questionnaire.

[b]Refer to the *Hypothetical Interventions* section for detailed intervention.

[c]The observational analog of the intention-to-treat contrast corresponds to the baseline values of the intervention, which are assigned and initiated at the same time.

Eligibility Criteria

The inclusion criteria for the target trial are the same as those for NuAge [25]. In the emulation, participants will be required to have at least one 24-hour dietary recall completed at baseline with ≥500 calories, as well as complete covariate data at baseline, as identified in the *Assignment* section.

Hypothetical Interventions

Overview

The hypothetical intervention strategies evaluated will be as follows:

1. No change in dietary habits or physical activity (similar to a control intervention)
2. Adherence to CFG recommendations
3. Adherence to CFG recommendations, including reformulation (ie, higher intake of protein foods)
4. Adherence to CFG recommendations, including reformulation (ie, higher intake of protein foods) and performing at least 30 minutes of aerobic physical activity

Physical activity recommendations are not traditionally at the forefront of CFG recommendations. However, CFG does mention that "at least 150 minutes of moderate-to vigorous-intensity aerobic physical activity per week ... is recommended to achieve health benefits" [1]. Thus, recognizing the key role of exercise in maintaining health and muscle for older adults, the fourth hypothetical intervention includes a formal physical activity recommendation. In the target trial, the physical activity corresponds to performing aerobic exercise of light to vigorous intensity for at least 30 minutes per day [6].

The Challenge of a Well-Defined Nutritional Intervention

Emulating a well-defined dietary intervention for CFG recommendations is challenging. First, recommendations in the latest edition of CFG are qualitative and flexible (eg, "eat plenty of vegetables and fruits" [1,29]). Thus, various suitable yet distinct dietary patterns can align with the recommendations. Second, CFG recommendations target both food intakes (eg, vegetables and fruits) and nutrients (eg, saturated fats). The nutrient-based recommendations can be met by modifying the consumption of various foods. For example, to achieve the hypothetical intervention of "decreasing consumption of calories from saturated fats," one could decrease saturated fats from dairy, nuts, and low nutritive value foods altogether. Arguably, the relationship between these food categories and a given health outcome may vary greatly.

To estimate a causal effect using observational data, the hypothetical interventions must be clearly defined to the point where "no meaningful variation" in the intervention remains [30,31]. In other words, the hypothetical diet interventions should be elaborated until no additional dietary characteristics are deemed impactful regarding the outcome of interest. Another consideration is that the modeling of hypothetical interventions should ideally be conducted with dietary intakes expressed using the same units. For example, mixing food intakes expressed in servings and grams in a statistical model may cause poor estimation of causal effects [17]. Finally, the statistical approach used to account for total energy or total food intake also affects the causal effect of interest and should be consistent with the research question [17,31-33].

Diet Simulations

For this study, adherence to CFG recommendations was defined based on simulated diets generated by Health Canada [34] and summarized in Multimedia Appendix 1 [34]. The simulated diets were designed to meet CFG recommendations on healthy food choices and nutrient requirements (Dietary Reference Intake).

These diets achieve near-perfect Healthy Eating Food Index (HEFI)-2019 scores (>78/80) through relatively high intake of recommended foods (ie, vegetables and fruits, whole grain foods, protein foods, and unsweetened milk and plant-based beverages with protein) and null intakes of foods not recommended (ie, non–whole grain foods; other low nutritive value foods; juice, sugary drinks and alcohol; and fatty foods rich in saturated fats). The HEFI-2019 score indicates the extent to which dietary intakes are consistent with CFG recommendations on healthy food choices [29,35].

Notably, the HEFI-2019 could have been used as a main exposure to measure adherence to CFG. However, the use of a composite score metric would not completely satisfy the criterion of a well-defined intervention to estimate a causal effect. First, high HEFI-2019 scores and high adherence to CFG recommendations can be achieved through many different strategies or dietary patterns. In the context of observational data, the specific strategies through which individuals achieve a high HEFI-2019 score would be based on dietary habits and patterns self-selected by the participants. This approach is similar to asking hypothetical trial participants to modify their intakes without clearly specifying how, which would obscure the estimated causal effect. Second, the HEFI-2019 score includes recommendations on foods and nutrients. As described earlier, mixing servings and grams in statistical models may cause poor estimation of causal effects [17].

We stress that the diets simulated by Health Canada were not actually consumed by older adults. Therefore, the simulated values for vegetables and fruits, whole grain foods, and plant-based protein foods *exceed* the 99th percentile of the distribution of usual intakes of these food categories, as estimated in adults aged ≥65 years from the Canadian Community Health Survey 2015–Nutrition [3]. In Table 2, the target intakes for vegetables and fruits, whole grains, and plant-based protein foods in the adherence to the 2019 CFG recommendations intervention were revised to correspond, at most, to the 90th percentile of the distribution of usual intakes among Canadians aged ≥65 years in 2015 [3].

Table 2. Emulation[a] of hypothetical diet and exercise interventions by sex in the Quebec Longitudinal Study on Nutrition and Successful Aging (NuAge) cohort [25].

Sex	Recommended foods (RA[b]/d)						Dietary supplement[c]	Foods and beverages not recommended (RA/d)[d]			Physical activity (min/d)[e]
	Vegetables and fruits	Whole grains	Plant-based protein foods	Animal-based protein foods	Milk and plant-based beverages with protein	Unsaturated oils and fats		Other foods	Sugary drinks and alcohol	Non–whole grains	
Control (no change)[f]											
Male individuals	—[g]	—	—	—	—	—	—	—	—	—	—
Female individuals	—	—	—	—	—	—	—	—	—	—	—
Adhering to the 2019 Canada's Food Guide recommendations on healthy food choices[h]											
Male individuals	6	1.5	1.0	2.0	1.0	1	No change	Minimum	Minimum	Minimum	No change
Female individuals	5	1.5	0.8	1.5	1.0	1	No change	Minimum	Minimum	Minimum	No change
Adhering to the 2019 Canada's Food Guide recommendations on healthy food choices, including extra protein[i]											
Male individuals	6	1.5	1.5	3.5	1.5	1	No change	Minimum	Minimum	Minimum	No change
Female individuals	5	1.5	1.3	3.0	1.5	1	No change	Minimum	Minimum	Minimum	No change
Adhering to the 2019 Canada's Food Guide recommendations on healthy food choices, including extra protein and physical activity											
Male individuals	6	1.5	1.5	3.5	1.5	1	No change	Minimum	Minimum	Minimum	30 or more
Female individuals	5	1.5	1.3	3.0	1.5	1	No change	Minimum	Minimum	Minimum	30 or more

[a]The emulation of all hypothetical interventions will be implemented using a substitution approach in statistical models. In all models, 1 variable for total food intake and 1 variable for total beverage intake will be included, and foods not recommended will be left out from the models (ie, non–whole grain foods; other low nutritive value foods; juice, sugary drinks and alcohol; and fatty foods rich in saturated fats).

[b]RA: reference amount.

[c]Dietary supplements were not intervened on but were, nonetheless, excluded from foods and beverages not recommended to avoid being considered in the substitution. In other words, participants would not be instructed to modify their dietary supplements in the hypothetical trial.

[d]Minimum indicates that consumption would be set at the smallest amount, permitting a concomitant increase in recommended foods to meet Canada's Food Guide targets. Portions for foods not recommended may vary on an individual basis.

[e]Physical activity corresponds to aerobic exercise of moderate or higher intensity [6].

[f]Values will be the averages observed at baseline in the NuAge cohort. In other words, values will be the observed intakes for the food categories or amount of physical activity when no change is applied.

[g]Not applicable.

[h]Values are derived from Health Canada's simulated composite diets of adults aged ≥71 years. Participants would be expected to meet these targets for each food category. The specific food choices within these categories would be at the participants' discretion. Values for vegetables and fruits, whole grain foods, and plant-based protein foods were truncated to correspond, at most, to the 90th percentile of the distribution of usual intakes among Canadians aged 65 years in 2015.

[i]Extra protein foods were added as follows: +0.5 RA of plant-based protein foods (eg, 25 g of nuts), +1.5 RA of animal-based protein foods (eg, 150 g of cooked unprocessed red meat, fish, or poultry or 3 small eggs), +0.5 RA of milk or plant-based beverage with protein (eg, 125 mL of milk or plant-based beverages with sufficient protein).

Because the 2019 CFG does not have a portion size system, reference amounts (RAs) were used as a proxy for servings. RAs are regulated quantities of foods that reflect the portion size typically consumed at 1 sitting in Canada. RAs were used by Health Canada to simulate a diet consistent with the 2019 CFG recommendations and dietary reference intake (Multimedia Appendix 1 [34]); therefore, RAs are adequate for this study.

Implementation

In the target trial, the sustained intervention strategy could be implemented as follows:

- Step 1: the participants' usual dietary intake and physical activity would be assessed by research dietitians at each study visit.
- Step 2: if reported food intakes and duration of physical activity were equal to or above the prespecified thresholds (Table 2), no change would be suggested to the participants' diet or physical activity. If food intakes or duration of physical activity were below the prespecified thresholds, participants would be instructed to increase food consumption to exactly the prespecified portions or increase physical activity duration to 30 minutes per day (when applicable).
- Step 3: if changes are required, participants would be instructed to decrease consumption of foods not recommended by the same amount as the increase in step 2. For example, if a 2-serving increase in vegetables and fruits is required to meet the prespecified intervention thresholds, participants would be instructed to substitute 2 servings of vegetables and fruits for non–whole grain foods; other low nutritive value foods; juice, sugary drinks and alcohol; and fatty foods rich in saturated fats.

In the emulation, for all hypothetical interventions, substitution will be implemented by including total intakes as a covariate and excluding foods not recommended from the models. More precisely, a variable reflecting total food intake (in RA/d) and a variable reflecting total beverage intake (in RA/d) will be included in all models. Hence, total food and beverage intakes will be constant across hypothetical diet interventions. In this approach to account for total energy, all model coefficients reflect the action of increasing intakes of recommended foods and a concomitant decrease in *any* of the foods not recommended [32]. On one hand, this approach can be potentially confusing [17,33], as the default interpretation of model coefficients assumes increasing the intake of each *food included in the model* while simultaneously decreasing the intake of foods *excluded from the model* [32]. On the other hand, the standard model is generally consistent with the implementation of dietary intervention in feeding trials [16,36,37]. The standard model also reduces the number of variables to be considered as intervention variables. Otherwise, 4 additional dietary components would have to be modeled for foods not recommended (ie, non–whole grain foods; other low nutritive value foods; juice, sugary drinks and alcohol; and fatty foods rich in saturated fats). Finally, the explicit description of the intervention strategies in the target trial protocol clarifies the estimand of interest, as done in an earlier study [19,31].

Notably, nutrient-based recommendations in CFG (ie, saturated fats, free sugars, and sodium intake) are not explicitly modeled to avoid the problems associated with mixed-unit models [17]. In the target trial, we assume that nutrient-based targets would be met by reducing consumption of foods not recommended (ie, non–whole grain foods; other low nutritive value foods; juice, sugary drinks, and alcohol; and fatty foods rich in saturated fats). In that regard, food-level substitution analyses in Canadians support this assumption for saturated fats [38,39].

The extra protein intervention consists of increasing the intake of both animal-based and plant-based protein foods by 1.5 and 0.5 RA per day, respectively, as well as milk and plant-based beverages with sufficient protein by 0.5 RA per day. Regarding the amount of food, this corresponds to adding 150 g of cooked unprocessed red meat, fish, or poultry or 3 small eggs; 25 g of nuts and seeds; and 125 mL of milk or plant-based beverages with sufficient protein while proportionally decreasing the intake of foods not recommended. In a previous RCT [40], older women aged 60 to 90 years were able to consume an additional 160 g of cooked lean red meat without substitution, thereby supporting the feasibility of the protein intervention in this hypothetical study.

Assignment

We will attempt to emulate random allocation or randomization by adjusting for dietary intakes in the year before the intervention, as well as adjusting for covariates at the start of the study. Covariates were identified using the causal diagrams depicted in Figure 1, based on background knowledge of the relationship between the hypothetical lifestyle intervention and outcomes.

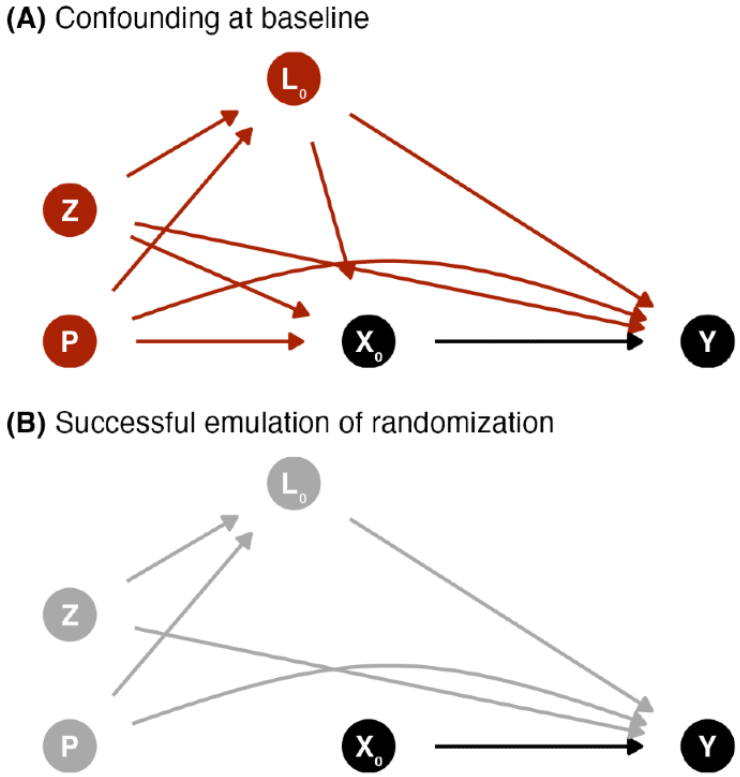
Dietary components that are the foundation for healthy eating in CFG include intakes of vegetables and fruits, whole grains, protein foods (plant- and animal-based protein foods, milk, and plant-based beverages with protein), and unsaturated oils and fats [1].

Covariates, including age at baseline, biological sex, region, education, living alone, smoking and drinking (alcohol) habits, major chronic diseases (ie, hypertension, diabetes, cancer, and heart disease), the number of medications, supplement use (eg, vitamins and minerals), and height and weight, are as follows:

1. *Z*, baseline covariates: age, sex, region, education, history of smoking, height, and former cancer history
2. *P*, previous exposure (ie, exposure of time-varying intervention before baseline): dietary habits before baseline
3. *L*, (time-varying) covariates: weight, number of medications, supplement use, living alone, major chronic diseases (eg, hypertension, diabetes, cancer, and heart disease), and smoking and alcohol habits
4. *X*, (time-varying) treatment: diet and physical activity habits
5. *Y*, end of follow-up outcome: muscle health, general health, and cognitive health

Contrary to dietary habits, data on physical activity habits before baseline were not collected in NuAge. In this case, the potential effect of previous physical activity habits will not be accounted for in the models that aim to emulate the sustained physical activity intervention strategy. For the models emulating the sustained diet intervention strategy only, physical activity habits during the study will be used as a covariate, hence mitigating the confounding of previous physical activity, at least to some extent.

Figure 1. Causal directed acyclic graph (DAG) depicting (A) confounding and (B) successful emulation of randomization using g-methods at baseline between the intervention strategy (X) and outcome (Y). Baseline covariates (both time-invariant [Z] and time-varying [L]) and previous diet and physical activity habits (P) must be considered to emulate randomization. Time-varying treatment and covariates are not shown in this DAG to focus on randomization emulation. Subscripts indicate the time points, where 0 represents baseline.



A successful emulation of randomization requires that there is no unmeasured confounding. However, this is never guaranteed with observational data. Thus, we emphasize our assumptions that (1) the causal graph accurately depicts the relationship under study and (2) the covariates included are a sufficient set of covariates to address confounding.

Outcomes

The primary outcomes will be the mean end of follow-up values for muscle strength (ie, handgrip using vigorimeter, elbow flexor, and knee extensor) and physical function (ie, normal and fast walking and "timed up-and-go"). Outcome values were measured according to a standardized protocol in NuAge [25].

For secondary outcomes, mean end of follow-up values for a set of relevant variables will be considered by domains:

- *General health:* waist circumference, blood pressure (systolic and diastolic), blood glucose, and estimated glomerular filtration rate
- *Cognition:* the modified Mini-Mental State Examination score

Time Zero and Follow-Up

In the target trial of a sustained lifestyle intervention, participants would be met at baseline and then regularly to ensure that diet and physical activity habits are consistent with the intervention assigned by the random allocation. The hypothetical diet and physical activity intervention would be assigned and initiated at baseline. In the emulation, annual follow-ups with comprehensive diet, physical activity, and covariate data collection are available to emulate the hypothetical intervention. Hence, participants would be followed from the study baseline (time point 0; ie, the time at which the intervention strategy would also be assigned and would begin), at each year (ie, time points 1 and 2), and until the end of the study (time point 3). We also assume that the diet and physical activity habits measured at each follow-up time adequately reflect the habits during the entire year.

The end of follow-up outcome measurements will be used to estimate the effect of the sustained lifestyle intervention strategy. Measures of dietary intake and physical activity throughout the study (ie, time point 0 to time point 3) will be used to emulate the sustained lifestyle intervention. Dietary intakes in the year preceding the intervention will be estimated using the frequency questionnaire completed at baseline (ie, time point 0). Missing covariate data at a given follow-up will be carried forward once, after which participants will be considered as having incomplete follow-up.

Causal Contrast

The estimand of interest in this study, the target causal effect of a sustained lifestyle intervention strategy, is

$$E(Y^{1,1,1,1}|C = 0) - E(Y^{0,0,0,0}|C = 0) \quad \textbf{(1)}$$

that is, the expected value of a given health outcome Y at the end of follow-up if all participants had increased their adherence to CFG recommendations on healthy food choices and physical activity, when applicable, at all 4 time points ($X_k=1$, *always intervene*) versus if all participants had maintained their habitual diet and physical activity ($X_k=0$, *never intervene*). The estimand

(equation 1) also indicates that all participants completed the intervention (C=0), that is, in the absence of incomplete follow-up.

The causal contrasts of interest are the observational analogs of intention-to-treat and per-protocol analyses [11]. Given the observational design, participants are not expected to have followed a treatment strategy unknown to them at the time of data collection. Therefore, the primary analysis will be the per-protocol contrast of a sustained lifestyle intervention strategy. In the per-protocol analysis, nonadherence to the hypothetical interventions can be accounted for. In the target trial, participants with a condition after baseline that would have prevented or limited participation in a hypothetical lifestyle intervention would be allowed to discontinue the intervention (eg, lengthy hospitalization, prolonged bed rest, and incident cancer). In the emulation, if such conditions occur in a sufficiently large number of participants, these participants will be "excused" from following the hypothetical intervention [23]. In other words, participants who would have been unable to pursue the study due to major events will not be considered as having incomplete follow-up if they attended the annual assessment. Allowing participants to discontinue adhering to the hypothetical intervention strategy mitigates confounding by the disease burden [23].

The intention-to-treat analysis will be a secondary analysis of a hypothetical point intervention, for example, dietary counseling at baseline only. Notably, it will not be possible to conduct an intention-to-treat analysis identical to that of a controlled study where the interest is to estimate the effect of being *assigned* to an intervention [11]. However, it is possible to conduct an observational analog of the intention-to-treat analysis. In the observational analog, the intention-to-treat analysis aims to estimate the impact of a hypothetical intervention in which adherence is measured at baseline only.

Statistical Analysis

Modeling of Hypothetical interventions

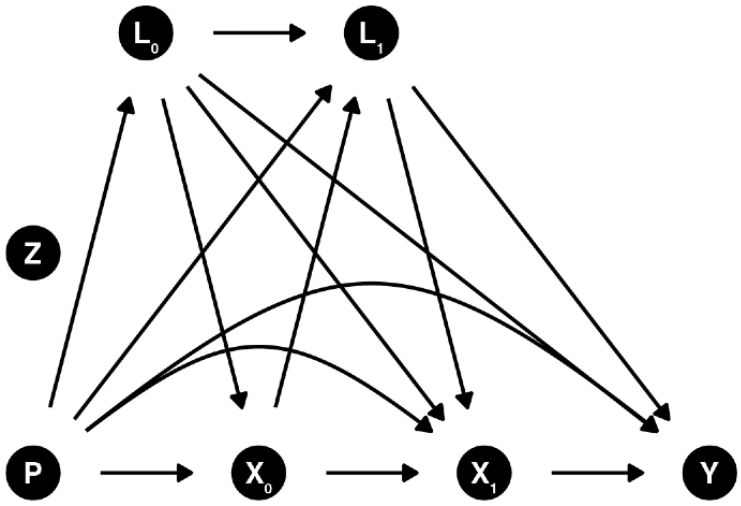
Stratification and multivariable regression (ie, covariate adjustment) are conventional statistical approaches to address confounding in nutritional epidemiology. However, the conventional approaches are not adequate to estimate cumulative treatment effects (eg, diet over time) in the presence of time-varying confounding (eg, weight status over time) and treatment (eg, previous diet) [41,42]. In this study, nonadherence to the hypothetical interventions and incomplete follow-up will be considered using general g-methods for the per-protocol analysis [11,42]. Among g-methods, the parametric g-formula provides the most flexibility for analyses involving hypothetical dietary interventions, as used in previous studies [19,22,43]. Briefly, in the context of an observational study, the parametric g-formula and its implementation into an R package (R Foundation for Statistical Computing) [44] use parametric models to predict the joint history of previous diet and physical activity habits (ie, the hypothetical sustained intervention strategy) and confounding variables. For example, linear regression models are used to predict continuous covariates (eg, body weight), while logistic regressions are used to predict binary or categorical variables (eg, indicator variable for dietary supplement use). The per-protocol causal contrast of the hypothetical intervention presented in Table 2 is then emulated based on Monte Carlo simulated data generated using the g-formula algorithm [44]. The parametric g-formula correctly accounts for time-varying confounding in the presence of feedback between the intervention and the confounding variables, as confounding is addressed using standardization [41,42]. Furthermore, standardization allows for estimating an average causal effect (ie, marginal effect) consistent with the estimand of interest (equation 1) rather than a conditional effect. In summary, "threshold interventions" that depend on the reported dietary intakes or amount of physical activity [43,45] and the parametric g-formula [44,46] will be used to emulate the intervention of *consuming at least x servings of food* and *doing at least x minutes of light to vigorous physical activity.*

Figure 2 presents the causal directed acyclic graph (DAG) of the hypothesized relationship between a sustained lifestyle intervention strategy (X_0, X_1) and an end of follow-up outcome Y for 1 follow-up after baseline (year 1). The model is limited to year 1 for clarity, but the hypothesized causal structure extends to additional follow-ups. The exposure of interest X_k is the joint and cumulative effect of a sustained diet and physical activity intervention strategy measured at baseline and follow-ups.

In the context of this target trial emulation (Figure 2), P includes dietary habits before the baseline assessment. P can have an effect on baseline dietary habits (eg, previous healthy habits increase the likelihood of baseline healthy habits) and dietary habits throughout the target trial emulation (eg, previous healthy habits increase the likelihood of adhering to healthy habits). Furthermore, P influences baseline and time-varying confounding. Finally, given the long-term effect of chronic exposure, P potentially affects Y directly.

The intention-to-treat analysis is similar to the per-protocol analysis. However, only baseline diet and physical activity habits and covariates are considered, as well as prebaseline diet and physical activity. In both the per-protocol and intention-to-treat analyses, loss to follow-up (eg, nonresponse or missing follow-up and health outcomes not measured) will be accounted for using g-methods such as inverse probability weighting.

Figure 2. Directed acyclic graph depicting the hypothesized relationship among previous dietary exposure, time-varying interventions (diet and physical activity), and covariates. Arrows from the Z node are not shown for clarity but would point toward all baseline and time-varying nodes, as well as the outcome. Only 1 follow-up is shown for visualization purposes, but the hypothesized causal structure extends to additional follow-ups. Subscripts indicate the time points, where 0 represents baseline and 1 represents time point 1.



Dietary Assessment

In NuAge, diet during the year before baseline was assessed using 1 semiquantitative food-frequency questionnaire [47]. Dietary intakes at baseline (ie, time point 0) and each annual follow-up (ie, time points 1, 2, and 3) were assessed using 3 repeated face-to-face interviewer-administered 24-hour dietary recalls.

Dietary intakes measured using 24-hour dietary recall are more accurate (ie, have less systematic error or bias) than food-frequency questionnaire [48-50] but are particularly affected by random measurement error (ie, within-individual random error) [50]. When several variables measured with errors are considered simultaneously in a regression model, the regression coefficients may be biased in any direction [51]. To account for random measurement error, the National Cancer Institute Markov Chain Monte Carlo (NCI MCMC) multivariate method could be applied [52]. However, the combination of the parametric g-formula and multivariate measurement error correction using the NCI MCMC method is not feasible. The NCI MCMC method estimates time-invariant measurement error–corrected intakes, while the g-formula algorithm is designed for time-varying exposures.

Recognizing the importance of accounting for measurement error, the correction for measurement error will be reserved for the secondary intention-to-treat analysis. For the intention-to-treat contrast, the time-varying values of exposure and the time-varying values of confounding are not considered. Thus, the NCI MCMC method will be used to obtain measurement error–corrected estimates of the relationship between dietary intakes measured at baseline and outcome at the end of follow-up. Notably, the three 24-hour dietary recalls collected at each time point contribute to reducing random errors, at least to some extent, even in the absence of measurement error correction.

Sensitivity Analysis to Assess the Impact of Measurement Error

For the secondary intention-to-treat analysis, results based on the measurement error–corrected and –uncorrected dietary intakes will be compared. The difference between the estimated relationships will allow to extrapolate the impact of not accounting for random errors in the primary *per-protocol* analysis.

Physical Activity Assessment

Physical activity throughout the study will be assessed using the Physical Activity Scale for the Elderly questionnaire [53,54]. Rather than the total Physical Activity Scale for the Elderly score, specific questions estimating the total time of physical activities will be used to be consistent with the intervention strategy.

Covariates and Subgroups

To the extent permitted by the number of observations for each outcome, continuous covariates will be modeled using restricted cubic splines with 3 to 5 knots (at percentiles 10-50-90, 5-35-65-95, or 5-27.5-50-77.5-95) [55]. Categorical covariates will be modeled to ensure a sufficient sample size at each level.

The effect of dietary changes will be estimated for the entire sample. The sample will also be stratified by biological sex to reflect both potential biological differences and, to some extent, gender differences (although not reported).

Variance Estimation

The variance will be estimated using a minimum of 200 bootstrap sample replicates to consider uncertainty at each step of the estimation [56].

Software and Code

The main statistical analyses will be conducted using R software (version 4.3.1 or greater) and the *gfoRmula* package [44,57]. The manuscript results will be generated using Quarto markdown (Posit PBC). Codes for main analyses and generation

of manuscript results will be shared in a publicly available code repository.

Ethical Considerations

The original NuAge protocol was approved by the research ethics boards of the *Institut universitaire de gériatrie de Montréal* and the *Institut universitaire de gériatrie de Sherbrooke* (Quebec, Canada). The NuAge Database and Biobank [58] has received approval by the *Centre intégré universitaire de santé et de services sociaux de l'Estrie—Centre hospitalier universitaire de Sherbrooke* Research Ethics Board. Secondary analyses of data from the NuAge Database and Biobank for the study described in this protocol are approved by the McGill University Research Ethics Board Office (#22-11-041).

All participants of NuAge provided informed consent. From the initial cohort of 1793 participants, 1753 (97.77%) agreed to the integration of their data and biological samples into the NuAge Database and Biobank for future studies.

Secondary analyses based on the NuAge Database and Biobank use deidentified data, which do not allow participants to be identified by the investigators.

NuAge participants voluntarily consented to participate and were not provided with monetary compensation.

Results

Data collection for NuAge was completed in June 2008. For this study, the main analysis based on the final curated data started in May 2024. The manuscript will be written according to the Strengthening the Reporting of Observational Studies in Epidemiology statement. We anticipate the submission of the manuscript to a peer-reviewed academic journal by February 2025.

Discussion

Principal Findings

In this study protocol, we have described a target trial to assess the effect of adhering to CFG recommendations on healthy food choices. The emulation will be performed using data from the NuAge Database and Biobank [58]. Benefiting from the flexibility of observational data, we also aim to compare adherence to multiple reformulations of CFG recommendations, including the effect of increasing the intake of protein-rich foods and the amount of aerobic physical activity on selected health outcomes. Furthermore, we have outlined the rationale for using simulated diets to emulate adherence to CFG recommendations, the process of selecting covariates to attempt to emulate randomization with causal diagrams, and the challenges of addressing random measurement error.

We emphasize that the purpose of emulating a target trial using observational data is to improve the quality of observational analysis [11,14]. In other words, the target trial framework aims to support the coherence between the causal research question and the observational data analysis [26]. However, estimating causal effects with nonexperimental observational data depends on strong assumptions. The key assumptions are that there are no unmeasured confounders, no measurement errors, and no model misspecifications (eg, functional form of covariates and model outcome distribution) [19]. We first recognize that the absence of residual or unmeasured confounding cannot be guaranteed. The extent to which this assumption is sufficiently satisfied depends on the appraisal of covariates considered. In that regard, we have used graphical tools, DAG, to explicitly describe our analytical assumptions and to identify confounding variables [59-61]. Second, the absence of measurement error assumption will not be satisfied considering the use of dietary intake data measured with 24-hour dietary recalls. On one hand, 24-hour dietary recalls have the least systematic error or bias compared with other common instruments, such as food-frequency questionnaires [48,49]. On the other hand, 24-hour dietary recalls are largely affected by within-individual random errors [50], which can cause bias in any direction in multivariable models [51], as in this study. This issue is mitigated, at least to some extent, by using average data from 3 repeated 24-hour dietary recalls at each follow-up. Sensitivity analyses comparing estimates based on measurement error–corrected and –uncorrected baseline dietary intakes will be used to assess the impact of random measurement errors. Third, the absence of model misspecification will be assessed by examining differences between the observed value of time-varying covariates and the predicted value of time-varying covariates as modeled with the g-formula.

Limitations

The strengths of this study and protocol include the explicit emulation of a hypothetical trial, the thorough description of the emulation of the sustained dietary intervention, and the use of background knowledge and DAG to derive a sufficient set of confounders. Limitations must be addressed. First, the NuAge sample size is relatively limited (N=1753), although comprehensive nutrition and covariate data were collected. Second, the target food intakes based on diet simulations from Health Canada *exceeded* the 99th percentile of the usual intake distribution of Canadians aged ≥65 years from Canada in 2015 [3]. A revision of the dietary intervention targets may be needed if observed dietary intakes in NuAge deviate significantly from targets (Table 2), as was done in a previous nutrition target trial emulation [22]. Third, the presence of random measurement error associated with 24-hour dietary recalls may bias estimates. Finally, the target trial emulation cannot replace an actual RCT. Evidence from an RCT will be required to confirm the value of either CFG recommendations or the enhanced CFG recommendations.

Conclusions

In conclusion, the target trial framework is useful for estimating the causal effect of adhering to CFG recommendations using nonexperimental data when an RCT is impractical [11,19]. Coupled with key assumptions, including the absence of unmeasured confounding, the absence of measurement error, and no model misspecification, we believe that the emulation will provide timely evidence regarding the effect of adhering to CFG recommendations in older adults and inform on the added value of a reformulation.

Acknowledgments

This work was supported by a Canadian Institutes of Health Research Fellowship award (MFE-181852) granted to DB.

Data Availability

The datasets analyzed during this study are available in the GitHub repository [62].

Authors' Contributions

The study was conceptualized by all authors. DB and SC were involved in the methodology. DB was involved in data curation, formal analysis, visualization, and writing of the original draft, and SC supervised the study. All authors reviewed and edited the paper.

Conflicts of Interest

DB was a casual employee of Health Canada (2019 to 2020) and held a doctoral training award from the Fonds de recherche du Québec - Santé (2019 to 2021). DB has no conflicts of interest. SC receives research funding from the Canadian Institutes of Health Research, Fonds de recherche du Québec, Canadian Foundation for Dietetics Research, Canadian Foundation for Innovation, and Canadian Cancer Society. None of these agencies has funded or been involved in this study. NP is the NuAge database administrator; NP and SC serve as NuAge steering committee members. NuAge was supported by a research grant from the Canadian Institutes of Health Research (MOP-62842). The NuAge Database and Biobank is supported by the Fonds de recherche du Québec (2020-VICO-279753); the Quebec Network for Research on Aging, a thematic network funded by the Fonds de recherche du Québec - Santé; and the Merck-Frosst Chair funded by La Fondation de l'Université de Sherbrooke.

Abstract

Background: Autism Spectrum Disorder (ASD) is a complex neurodevelopmental condition emerging in early childhood, characterized by core features such as sociocommunicative deficits and repetitive, rigid behaviors, interests, and activities. In addition to these, disruptive behaviors (DB), including aggression, self-injury, and severe tantrums, are frequently observed in pediatric patients with ASD. The atypical antipsychotics risperidone and aripiprazole, currently the only Food and Drug Administration–approved treatments for severe DB in patients with ASD, often encounter therapeutic failure or intolerance. Given this, exploring pharmacological alternatives for more effective management of DB associated with ASD is essential. Clozapine, noted for its unique antiaggressive effects in schizophrenia and in various treatment-resistant neuropsychiatric disorders, independent from its antipsychotic efficacy, remains underexplored in youths with ASD facing severe and persistent DB.

Objective: This study aimed to evaluate the efficacy, tolerability, and safety of clozapine for treatment-resistant DB in youths with ASD.

Methods: This is a prospective, single-center, noncontrolled, open-label trial. After a cross-titration phase, 31 patients with ASD aged 10-17 years and with treatment-resistant DB received a flexible dosage regimen of clozapine (up to 600 mg/day) for 12 weeks. Standardized instruments were applied before, during, and after the treatment, and rigorous clinical monitoring was performed weekly. The primary outcome was assessed using the Irritability Subscale of the Aberrant Behavior Checklist. Other

efficacy measures include the Clinical Global Impression Severity and Improvement, the Swanson, Nolan, and Pelham questionnaire-IV, the Childhood Autism Rating Scale, and the Vineland Adaptive Behavior Scale. Safety and tolerability measures comprised adverse events, vital signs, electrocardiography, laboratory tests, physical measurements, and extrapyramidal symptoms with the Simpsons-Angus Scale. Statistical analysis will include chi-square tests with Monte Carlo simulation for categorical variables, paired *t* tests or Wilcoxon tests for continuous variables, and multivariate linear mixed models to evaluate the primary outcome, adjusting for confounders.

Results: Recruitment commenced in February 2023. Data collection was concluded by April 2024, with analysis ongoing. This article presents the protocol of the initially planned study to provide a detailed methodological description. The results of this trial will be published in a future paper.

Conclusions: The urgent need for effective pharmacological therapies in mitigating treatment-resistant DB in pediatric patients with ASD underscores the importance of this research. Our study represents the first open-label trial to explore the anti-aggressive effects of clozapine in this specific demographic, marking a pioneering step in clinical investigation. Adopting a pragmatic approach, this trial protocol aims to mirror real-world clinical settings, thereby enhancing the applicability and relevance of our findings. The preliminary nature of future results from this research has the potential to pave the way for more robust studies and emphasize the need for continued innovation in ASD treatment.

KEYWORDS

neurodevelopmental disorders; clozapine; psychopharmacology; antipsychotic medication; autism spectrum disorder; youth

Introduction

The autism spectrum disorder (ASD) comprises a continuum of neurodevelopmental disorders that manifest in early childhood [1], characterized by impaired communication and social interaction, restricted and repetitive behavioral patterns, and occasionally impaired cognition or verbal language [2]. In the United States, the prevalence of ASD in 8-year-old children is 27.6/1000 (1 in 36 children) and 3.8-fold higher in boys than girls [3]. The diagnosis of ASD is an integrative process that includes the collection of current and developmental histories, direct observation, and clinical evaluation. Various standardized instruments may also support and substantiate the diagnosis [1]. Patients with ASD frequently present comorbid psychiatric conditions including, but not limited to, obsessive-compulsive disorder, intellectual disability, oppositional defiant disorder, mood and anxiety disorders, sleep disturbances, eating disorders, and attention-deficit/hyperactivity disorder [4].

The management of ASD involves a multidisciplinary approach, using behavioral and educational strategies to improve the patient's quality of life and promote independence. First-line behavioral treatments comprise applied behavior analysis, cognitive behavioral therapy, and social skills training [5]. While pharmacological treatments do not directly address the core symptoms of ASD, they are used to manage psychiatric comorbidities and severe disruptive behaviors (DB) associated with autism (ie, irritability, hetero-aggression, self-injury, tantrums, and severe oppositional defiant symptoms) [6]. DB are common and can be observed in up to 1/4 of children with ASD [7]. Thus, pharmacotherapy can be pivotal in protecting the physical well-being of both autistic individuals and their caregivers, mitigating social exclusion, and enhancing overall quality of life [8]. The atypical antipsychotics risperidone and aripiprazole are the only drugs approved by the United States Food and Drug Administration for the treatment of irritability associated with ASD, and they are commonly used to treat DB in this population [9]. However, many patients do not respond adequately: approximately 30% of patients fail to respond to risperidone and 50% to aripiprazole [10].

It is essential to highlight that there are other psychosocial therapeutic resources (eg, behavioral therapies) and pharmacological treatments (eg, antidepressants and mood stabilizers) for managing DB. However, some patients, with a pronounced treatment resistance to these approaches, require the use of antipsychotics for the management of more severe symptoms. For those who do not respond adequately to the antipsychotics commonly used in clinical practice, clozapine emerges as a "last-resort" therapeutic alternative, as these patients still demand alternatives.

Clozapine, the first atypical antipsychotic developed, is the treatment of choice for treatment-resistant early-onset schizophrenia (EOS) and is noted for its anti-aggressive effects across several mental disorders [11]. Observational studies have also demonstrated its benefits in reducing treatment-resistant DB in ASD [12]. For instance, Beherec et al [13] analyzed medical records of 6 patients with ASD with refractory DB receiving clozapine, noting a reduction in the number of days with aggressive episodes and concomitant antipsychotic dosing. In addition, Rothärmel et al [14] reported maintained long-term benefits and favorable tolerability in their initial 6-patient cohorts. They corroborated these findings with a replication study involving an additional sample of 13 patients who exhibited a significant reduction in DB (65.2%, *P*=.003), leading to improved quality of life.

Clozapine therapy requires caution and rigorous monitoring during treatment due to its potential health risks, which include severe neutropenia [15], myocarditis [16], and seizures [17]. However, for some children and adolescents with ASD, the

balance of risks and benefits is favorable, particularly when intense and treatment-resistant aggression leads to significant impairments [18]. Although preliminary and exploratory studies showed positive results, no prospective interventional studies with objective measures investigated the efficacy and tolerability of clozapine for treatment-resistant DB in pediatric patients with ASD, highlighting the need to explore it as a potential treatment for this subset of patients.

In this sense, this study aims to evaluate the efficacy, tolerability, and safety of clozapine in treating patients with ASD aged 10 to 17 years with DB resistance or intolerance to conventional antipsychotics. In addition, the study evaluates changes in adaptive functioning among patients and the impact of clozapine on caregivers' quality of life. Drawing on prior evidence regarding clozapine's specific anti-aggressive effects, this study explores its potential as a viable treatment for intractable cases. Accordingly, the hypothesis is that clozapine will prove efficacious and tolerable, with a safety profile acceptable for this clinical population. This article outlines the study protocol, which was initially drafted before the study's completion. Recruitment began in February 2023, and data collection concluded in April 2024. This protocol is now published to provide a comprehensive methodological description. Trial results will be reported in a future publication.

Methods

Study Design

This open-label, noncontrolled trial administers clozapine to all participants. The rationale for this study design, instead of a randomized controlled investigation, was based on the logistical and ethical challenges inherent in conducting a study within a pediatric ASD subpopulation characterized by refractoriness and severe DB. The study's framework facilitates direct observation of adverse events and potentially severe risks related to clozapine use in vulnerable patients. Independent evaluators carry out baseline and follow-up assessments.

Participants

The estimated sample consists of 30 patients aged 10 to 17 years who have been diagnosed with ASD and exhibit treatment-resistant DB.

Eligibility

Inclusion Criteria

This study includes patients of both sexes aged between 10 and 17 years with a confirmed diagnosis of ASD according to the *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders* [Fifth Edition]) [19] criteria. Also, they must present DB (eg, psychomotor agitation, angry outbursts, oppositional defiant behavior, property destruction, self-injury behavior, or hetero-aggression) that are not caused by a coexisting medical or psychiatric condition, which could act as a trigger for the onset of these symptoms. Individuals must exhibit severe symptoms, impairing different function domains, reflected by a score of 5 or higher (markedly ill) on the Clinical Global Impression-Severity (CGI-S) scale, specifically anchored to DB. Treatment resistance, as defined by the research team, refers to the continued presence of severe DB despite adequate treatment (therapeutic failure) or intolerance to at least 2 antipsychotic agents, with at least 1 being atypical.

Exclusion Criteria

Patients who present the following conditions are excluded: unstable clinical illness or condition preventing the use of clozapine (eg, refractory epilepsy and heart or hematological diseases); insufficient psychosocial resources to follow the study protocol strictly (eg, correct drug administration and weekly attendance to the research center for clinical evaluations and blood testing); previous failure to clozapine treatment due to inadequate response after sufficient duration and dosing (a minimum of 400 mg/day for 6 weeks) or due to intolerable adverse events, such as leukopenia or cardiotoxicity; or pregnant, breastfeeding, or fertile patients not using an adequate contraceptive method.

Recruitment

Our protocol uses a convenience sampling strategy. The study is disclosed in services for university hospitals, integral health of childhood and adolescence, and specialized assistance services for patients with neurodevelopmental disorders through informative material prepared by our research team, inviting patients, who meet the criteria for our study, to participate. Furthermore, we contact child and adolescent psychiatry outpatient clinics, special education institutes and ASD support groups in the metropolitan region of Porto Alegre in the state of Rio Grande do Sul (Brazil), disseminating our research and asking them to refer patients who could benefit from the intervention. It is also disclosed using traditional media (television, newspaper, and radio) and the Hospital de Clínicas de Porto Alegre (HCPA) social media website and institutional email. Legal guardians who intend to participate in the study contact the research team by phone or email.

Screening

Caregivers interested in participating are invited to a screening assessment with a child and adolescent psychiatrist experienced in ASD to determine the patient's eligibility for the study. During the evaluation, the psychiatrists verify the ASD diagnosis according to *DSM-5* criteria [19] and with the support of the Childhood Autism Rating Scale, Brazilian version (CARS-BR) [20]. Clinical features on the presence of severe DB and psychopharmacological treatment history are assessed. The research team informs caregivers about the study's objectives, procedures, potential benefits, and risks associated with clozapine therapy, including side effects, and the mandatory requirement for weekly blood tests. Selected patients undergo a baseline evaluation, which includes data collection, laboratory tests, an electrocardiogram, and a physical examination. The psychiatrist confirms cardiometabolic and hematological stability as part of this initial assessment.

Measures of Evaluation

Trained evaluators apply the following questionnaires and instruments before, during, and after the intervention:

Baseline Sociodemographic and Clinical Data

Data on age, sex, ethnicity, education level, socioeconomic status, clinical, and therapeutical history (eg, comorbidities, previous interventions, gestational and neonatal history, neurodevelopmental milestones, ASD diagnosis and support level, characteristics of DB, family psychiatric history, and response to previous and ongoing pharmacological treatments) are collected at the beginning of the study.

The CARS-BR

This scale comprises 14 items that help diagnose ASD in children and differentiate it from other developmental disorders [20]. It is fast to apply, suitable for all ages, and has objective and quantifiable scores through direct observation. The CARS-BR is used before and during the intervention to evaluate the central symptoms of ASD.

Schedule for Affective Disorders and Schizophrenia for School-Age Children–Present and Lifetime Version, DSM-5 Update

This semistructured interview evaluates the presence and severity of psychiatric disorders in children and adolescents in the present and throughout life [21]. In this study, it is used to assess psychiatric comorbidities.

CGI-S and Clinical Global Impression-Improvement

The Clinical Global Impression Severity (CGI-S) scale evaluates the global severity of the patient at baseline through an increasing score (1 to 7) considering the last 7 days [22]. The patient must score ≥ 5 (markedly ill) to meet the inclusion criteria. Also, the Clinical Global Impression–Improvement (CGI-I) compares the level of improvement or impairment of the patient every week after starting the pharmacological treatment through a score ranging from 1 (very much improved since the initiation of treatment) to 7 (very much worse since the initiation of treatment).

Aberrant Behavior Checklist, Irritability Subscale

Irritability is 1 of the 5 Aberrant Behavior Checklist (ABC) subscales with 15 items; it is easy to use and reliable [23]. This subscale is widely used in clinical trials to evaluate the efficacy of pharmacological treatments for irritability and DB in ASD, assessing several DB and changes over time. The ABC, Irritability (ABC-I) score change following clozapine treatment is the primary outcome of this open-label trial.

The Swanson, Nolan, and Pelham Questionnaire, Version IV

This questionnaire has 26 items to evaluate inattention, hyperactivity, impulsivity, and oppositional defiant behavior and is a complementary instrument to diagnose attention-deficit/hyperactivity disorder [24]. Our protocol uses this tool for additional assessment of DB.

Vineland Adaptive Behavior Scales, Third Edition

The Vineland Adaptive Behavior Scale, Third Edition (VABS-3) is a semistructured interview to evaluate adaptive behaviors divided into domains, such as communication (receptive, expressive, and written), daily living skills (personal, domestic, and community), socialization (interpersonal relationships, play and leisure, and coping skills), motor skills (gross, fine, and advanced motor coordination), and maladaptive behavior (internalizing, externalizing, and critical items) [25]. In our protocol, this tool evaluates how clozapine treatment impacts patients' adaptive behaviors.

Side Effects Questionnaire Based on the Ugvalg for Kliniske Undergelser Side Effect Rating Scale for Psychotropic Drugs

The Ugvalg for Kliniske Undergelser Side Effect Rating Scale for Psychotropic Drugs (UKU) scale is divided into 4 sections, with 48 items evaluating the physical, psychological, neurological, and autonomic side effects of psychotropic drugs [26]. Each item is scored from 0 to 3, reflecting the intensity of the side effects. The scale has been specifically adapted for this study to monitor clozapine's side effects comprehensively.

Simpsons-Angus Scale for Extrapyramidal Side Effects

This widely used scale consists of 10 items that evaluate the presence and severity of extrapyramidal side effects [27]. Each item is rated on a scale from 0 to 4, and the total score is obtained by summing the items and dividing them by 10, with scores up to 0.3 considered within the normal range. The Simpsons-Angus Scale for Extrapyramidal Side Effects (SAS) is a standard tool for evaluating drug-induced movement disorders.

Europe Health Interview Surveys Quality of Life, Abbreviated Instrument

The Europe Health Interview Surveys Quality of Life, Abbreviated Instrument (EUROHIS-QOL 8-item) assesses the quality of life across 4 domains, with 2 items per domain: physical, psychological, environmental, and social [28]. This study uses it to evaluate the caregivers' quality of life, thus monitoring the potential effects of clozapine treatment on this aspect.

Intervention

Throughout the study, a team of child and adolescent psychiatrists skilled in managing clozapine undertakes weekly evaluations of patients at the research facility. Out of 2 different evaluators assesses each patient. The first evaluator conducts the baseline assessment, and the second evaluator conducts all subsequent evaluations while following the same patient throughout the study protocol. This includes monitoring the therapeutic response of clozapine and managing any associated adverse effects. In addition, evaluators receive training to apply the evaluation measures accurately. Patients with significant medical comorbidities undergo specialist physician evaluation to confirm clinical suitability for the study. Eligible patients are prescribed clozapine therapy through a flexible titration regimen. Dose adjustments are made gradually over weeks to achieve a personalized dose. Implementing CGI scales during the titration phase facilitates the determination of an individualized fixed dose for each patient. Once the dosing has been stabilized, the clozapine intervention spans 12 weeks, during which the dose should remain constant. However, if necessary, minor changes may be made to ensure optimal patient outcomes. Blood tests

follows the schedule outlined in Table 1. In addition, physical evaluations, including measurements of blood pressure, heart rate, abdominal and pelvic circumferences, weight, and BMI, are carried out weekly.

Table 1. Study timeline and measures of evaluation. From the beginning of the intervention to a stable clozapine dose, the titration duration varies to determine the most appropriate therapeutic dose for each individual patient.

The initial dose of clozapine is 12.5 mg or 25 mg, divided into once or twice-daily doses. The starting dose of clozapine will be determined using an initial dose reference of approximately 0.3 mg/kg, rounded to the nearest multiple of 6.25 mg, with a maximum initial dose not exceeding 25 mg daily. Dose titration is tailored to the patient's response and tolerability, up to 600 mg daily. Clinical management of clozapine considers individual conditions and comorbidities. The therapeutic range for most patients is expected to be between 200 and 400 mg/day. After the clozapine dosage reaches 100 to 200 mg per day, gradual discontinuation of other antipsychotics commences using plateau cross-titration. While the study does not mandate clozapine monotherapy, it aims the reduction of other psychotropics, particularly antipsychotics.

Clinical Monitoring and Adverse Event Management

Patients and caregivers receive educational materials on clozapine treatment and psychoeducational guidance from psychiatrists. Also, they can contact the researchers via phone in case of emergency symptoms (eg, fever, flu-like symptoms, sore throat, dyspnea, chest pain, and seizures). Caregivers are instructed to search for emergency services in case of severe symptomatology. Moreover, the team of psychiatrists is available to other physicians as required.

The study follows guidelines for clozapine treatment in EOS [29]. During all visits, psychiatrists proactively manage side effects to alleviate patients' discomfort and optimize treatment adherence. If needed, side effects are treated symptomatically. Also, a consultant pediatrician and other specialists may be consulted whenever required. Advice on diet control and exercise is emphasized, and metformin may be used to mitigate weight gain and metabolic abnormalities from the beginning of treatment [30]. Prophylactic measures must be discussed with all caregivers to prevent constipation, and early prescription of stool softeners (ie, polyethylene glycol) might be used to avoid obstruction and ileus [31].

An electrocardiogram is performed before and after the clozapine treatment to assess the pharmacological impact on cardiac electric activity. Also, blood testing is performed before and during the treatment to monitor the risk of blood dyscrasias. To start clozapine therapy, patients must display the following hematological criteria: neutrophil >1500/µL and leukocyte >3000/µL [32]. Lithium carbonate may be prescribed to increase the neutrophil count in case of benign neutropenia [33], and the clozapine treatment must be suspended if neutrophil reduces under 1000/µL. Metabolic parameters (eg, fasting glucose, triglycerides, and cholesterol).

Data Collection and Management

Initial data is collected upon obtaining caregiver consent and confirming patient eligibility. Subsequently, qualified patients commence with clozapine therapy, marking the beginning of the treatment study and systematic clinical data acquisition. Measures of evaluation are applied as delineated in Table 1. Per the methodology of our study, we make provisions for remote consultations through video call using Google Meet, but only in exceptional circumstances in which patients cannot attend the research center personally. It is important to note that all participants must strictly adhere to the protocol of weekly blood sample collections, regardless of the consultation modality.

All evaluations are registered in HCPA's electronic medical record system, and data is collected and managed using the Research Electronic Data Capture (REDCap) hosted at the HCPA. REDCap [34,35] is a secure web-based software to support data capture for research studies. It provides an intuitive interface for validated data capture, audit trails for tracking manipulations and data export, automated export procedures for continuous data downloads in common statistical packages, and procedures for data integration and interoperability with external sources.

Outcome Measures

The study will assess the efficacy of clozapine in reducing DB, as measured by ABC-I scores. Secondary measures include the CGI-S and Clinical Global Impression Improvement scales, ASD symptoms (CARS-BR), adaptive behaviors (Vineland Adaptive Behavior Scale - third edition), hyperactivity, impulsivity, and oppositional defiant behaviors (the Swanson, Nolan, and Pelham questionnaire), and quality of life of caregivers (EUROHIS-QOL 8-item). The safety and tolerability of the treatment are evaluated using an adverse effects inventory, the SAS, physical evaluation parameters, and blood testing (Table 1).

Statistical Analysis

Overview

Qualitative variables will be presented as absolute and relative frequencies, and quantitative as mean and SD or median and IQR, as appropriate. The distribution of quantitative variables will be assessed using the histogram and quantile-quantile graph. Categorical variables will be compared using the chi-square test of independence with Monte Carlo simulation (when any cell in the contingency table presents an expected frequency < 5), and continuous variables before and after treatment will be compared using the paired *t* test or Wilcoxon signed rank test. The multivariate linear mixed model will assess the primary outcome to reduce possible confounding variables. The magnitude and direction of the association for quantitative secondary outcomes will be evaluated using the robust Poisson regression for binary variables and the generalized linear model for gamma-distributed variables. Multiple comparisons will be performed using the Bonferroni post hoc when needed. The significance level of 5% will be adopted for all analyses, which will be assessed using the PASW [Norman H. Nie] Statistics software (version 18.0 or higher) [36] and R [R Core Team] (version 4.3 or higher) [37].

Sample Size Calculation

The sample size was calculated to detect a reduction in the ABC-I score using the PSS Health tool (version 0.3.1) based on a relevant mean difference of 10 points [38]. Given a power of 99%, a significance level of 1%, and a SD of the expected difference of 9.7 [39], the calculation yielded a required sample size of 27 patients. Anticipating a 10% attrition due to losses and refusals, the sample size was adjusted to include 30 patients. Considering the vulnerable population and the demanding protocol, an over-enrollment strategy can be used to mitigate the impact of potential attrition further and ensure robustness.

Ethical Considerations

This study fully complies with the Regulatory Standards and Guidelines for Research with Human Beings (Resolution 466/12) and upholds the ethical principles of the Declaration of Helsinki. Informed consent is obtained from legal guardians, who may choose to withdraw the patient from the study at any time without consequences. Whenever possible, patient assent is sought. In cases where it is not feasible, the legal guardian decides on the patient's behalf. The study has received approval from the Research Ethics Committee of Hospital de Clínicas de Porto Alegre (CAAE 54677821.0.0000.5327), and its

protocol is registered in the Brazilian Registry of Clinical Trials (RBR-54j3726). The research team continuously supports the patients and their caregivers throughout the study, especially regarding the emergence of alert signs associated with clozapine use. The Brazilian pharmaceutical company Cristália supplied the clozapine (Pinazan) for the participants. However, the company does not influence the study design, intervention, data analysis, or publication of the results. This ensures that the research team can make independent decisions.

Results

Recruitment for the study commenced on February 10, 2023. A total of 33 patients were initially enrolled in the study. However, before the commencement of the intervention, 2 patients were withdrawn from the study due to their guardians' decision not to participate further, and 3 patients discontinued treatment due to adverse events. Data collection was completed by April 2024. No primary or secondary outcomes are being reported in this manuscript, as it focuses solely on describing the study design and methods. The results of the study are expected to be published by June 2025.

Discussion

It is anticipated that clozapine will demonstrate efficacy in reducing DB resistant to conventional treatments in youths with ASD. In addition, we expect to observe an acceptable safety profile by using rigorous monitoring in a pragmatic outpatient setting. In our view, this is the first quasi-experimental study to investigate the use of clozapine for this specific purpose and population. We foresee that our findings will align with several observational studies that have also highlighted clozapine as a valuable tool in similar cases.

Clozapine is recognized as a potential therapeutic alternative for addressing refractory aggressive behaviors in various neuropsychiatric disorders [12]. This study will explore the possibility that clozapine use may also extend to alleviating severe DB in children and adolescents with ASD. Regarding clozapine use to reduce aggression in young patients, a prospective open-label study showed a significant reduction of aggressive behavior in children and adolescents with treatment-resistant EOS during clozapine treatment for 12 to 24 weeks, reducing the need for emergency drugs and isolation [40]. In addition, observational studies suggested the efficacy of clozapine in patients with ASD and severe DB not responsive to conventional treatments [11,13,14]. However, only a small-scale, prospective intervention study explored the potential of clozapine in 3 children with ASD. In this study, Zuddas et al [41] evaluated 2 boys (8 years old) and 1 girl (12 years old) with DB resistant to haloperidol before and after the clozapine treatment. All children improved over 3 months, with a reduction in the Children's Psychiatric Rating Scale scores from 99 to 60, 99 to 80, and 81 to 53. Although the boys demonstrated gradual improvement until 8-month follow-up (from 60 to 50 and 80 to 53), the girl had a complete relapse of symptoms after 5 months, with similar scores to baseline [41].

Considering that other studies examining the role of clozapine in ASD with treatment-resistant DB have maintained an observational design, prospective clinical studies with objective metrics and larger samples are needed to evaluate its efficacy. Thus, the present study aims to investigate the efficacy of clozapine in mitigating treatment-resistant DB in pediatric patients with ASD. The treatment of DB in ASD may improve adaptive behavior, which could favor the development of socialization, communication, cognition, daily activities, and the quality of life of patients and caregivers [8,42]. Also, behavioral improvement and clinical stabilization could allow patients to engage in other therapeutic modalities or actively participate in community activities or programs.

This study's assessment of clozapine safety and tolerability in the pediatric ASD population is essential, particularly as these factors have been understudied in this group, unlike in patients with EOS [43]. A recent naturalistic study on clozapine in youth with neurodevelopmental disorders (ASD and/or ID) and treatment-resistant aggression showed significant improvements in clinical severity, functioning, and aberrant behaviors. Of the 26 patients, 61.5% were responders. Common side effects included increased appetite, sialorrhea, and repetitive behaviors, with 2 cases of seizures. This study supports clozapine's potential in managing aggression in this population [44]. In contrast to the recently published study, our approach adopts a more interventional design. We also emphasize early detection and management of clozapine-induced side effects and serious adverse events. This includes intensive clinical monitoring through weekly evaluations by child and adolescent psychiatry specialists, pediatric support, regular laboratory tests, and close collaboration between doctors and caregivers. Furthermore, our study will evaluate the acceptability of clozapine outpatient treatment in this population, with a particular focus on adherence, considering the drug's complex side effect profile, the frequency of required medical visits and blood tests, and the level of caregiver involvement. This approach aims to assess a practical framework for real-world clinical practice.

Regarding the limitations, the study features a small sample size and an uncontrolled open-label design, which introduces the possibility of biases, such as expectancy bias from both families and investigators. Nevertheless, this study constitutes an important initial step in clinical investigation, laying the groundwork for future controlled clinical trials with larger sample sizes. Furthermore, follow-up studies are necessary to evaluate the long-term efficacy and safety of clozapine.

Our dissemination plan involves publishing the results of this open-label trial in a high-impact international scientific journal, with the aim of providing evidence for the potential efficacy and safety of clozapine in managing DB in youths with ASD. Following this open-label clinical trial, our research team will conduct a longitudinal follow-up study with the same cohort to assess the sustained efficacy and safety of clozapine. In addition, a qualitative study is proposed to examine the caregivers' experiences with clozapine therapy. Therefore, this trial is envisaged as a foundational step informing subsequent research endeavors.

Acknowledgments

The authors thank the Brazilian pharmaceutical company Cristália for the generous donation of clozapine (Pinazan). We emphasize that this contribution will not influence any aspect of the study. This study was financed in part by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior – Brasil – Finance Code 001 and the Research Incentive Fund /HCPA). In addition, Luis Augusto Rohde receives a productivity-based grant from CNPq.

Data Availability

The dataset collected and examined in this study will be accessible through the lead author upon adequate request.

Authors' Contributions

ALST and MRBC collaborated on the conceptualization of the initial protocol, with GS, FM, LOC, EBB, LD, and ABF contributing to writing the original draft of the manuscript. RBB was responsible for formal analysis. The final writing with review and editing of the text was performed by ALST and OSB, with FM and GS handling the visualization of the manuscript. ASGM and LAR were responsible for supervision on all steps of the study design and manuscript editing.

Conflicts of Interest

LAR has received grant or research support and served as a consultant to the bureau of the speakers from Abbott, Adium, Apsen, Abdi-Ibrahim, Aché, Bial, Medice, Novartis/Sandoz, Upjohn/Viatris, and Shire/Takeda in the last 3 years. The ADHD and Juvenile Bipolar Disorder Outpatient Programs chaired by LAR have received unrestricted educational and research support from the following pharmaceutical companies in the last 3 years: Novartis/Sandoz and Shire/Takeda. LAR has received authorship royalties from the Oxford Press and ArtMed. Other authors declare no conflicts of interest.

Abstract

Background: Adherence and persistence to positive airway pressure (PAP) therapy are key factors for positive health outcomes. Home support providers participate in the home implementation and follow-up of PAP therapy for patients with obstructive sleep apnea (OSA). In Europe, home support provider service levels are country (or area) specific, resulting in differences in content and frequency of patient interactions. However, no robust evaluation of the impact of these differences on clinical and patient outcomes has been performed.

Objective: The AWAIR study aims to evaluate and compare the impact of different home support provider service levels on PAP adherence and persistence in 4 European countries.

Methods: This real-world, ambispective, cohort study—conducted in France, Belgium, Spain, and Portugal—will recruit adults with OSA who started PAP therapy between 2019 and 2023 and were followed by an Air Liquide Healthcare home support provider. Given the large number of eligible participants (around 150,000), the study will use a decentralized and digital approach. A patient video will present the study objectives and the participation process. A secure electronic solution will be used to manage patient information and consent, as well as to administer a web-based questionnaire. Retrospective data, collected during routine patient follow-up by home support providers, include the level of service and device data, notably PAP use. Prospective data collected using an electronic patient-reported outcome tool include health status, OSA-related factors, patient-reported outcomes including quality of life and symptoms, OSA and PAP literacy, patient-reported experience, and satisfaction with PAP therapy

and service. Hierarchical models, adjusted for preidentified confounding factors, will be used to assess the net effect of home support provider services on PAP adherence and persistence while minimizing real-world study biases and considering the influence of country-level contextual factors. We hypothesize that higher levels of home support provider services will be positively associated with adherence and persistence to PAP therapy.

Results: As of December 2024, the study has received approval in France, Portugal, and 2 regions of Spain. The study began enrollment in France in October 2024. Results are expected in the second quarter of 2025.

Conclusions: The AWAIR study has a unique design, leveraging an unprecedented number of eligible participants, decentralized technologies, and a real-world comparative methodology across multiple countries. This approach will highlight intercountry differences in terms of patient characteristics, PAP adherence, and persistence, as well as patient-reported outcomes, patient-reported experiences, and satisfaction with the home service provider. By assessing the added value of home support provider services, the results will support best practices for patient management and for decision-making by payers and authorities.

Introduction

Obstructive sleep apnea (OSA) is the most prevalent form of sleep-disordered breathing, affecting nearly 1 billion adults aged 30-69 years worldwide [1]. OSA is characterized by repetitive collapse of the upper airway during sleep, resulting in complete (apnea) or partial (hypopnea) airway obstruction [2]. OSA can cause daytime symptoms that impair quality of life and has been linked with a variety of cardiometabolic diseases, neurocognitive impairment, depression, road traffic accidents, and all-cause mortality [3-12]. Identification and management of OSA are therefore important to reduce those risks.

Positive airway pressure (PAP) therapy remains the gold standard treatment for severe OSA because high-quality evidence and long-term assessment are lacking for noncontinuous PAP therapies [13,14]. PAP therapy has been shown to reduce road traffic accidents, blood pressure, cardiovascular risk, and health care use [15-19]. However, the effectiveness and cost-effectiveness of PAP therapy are linked to sufficient daily device use, with regular and continued long-term usage [16,19-24], which appears challenging in all geographies [25,26].

In most European countries, home support provider companies supply the PAP device and support its use by the patient. However, the type and level of services provided differ markedly between countries. Services can range from mainly logistical support (ie, device delivery in Belgium, Germany, and the Netherlands) to a personalized support plan for patients integrating motivational interviews to enhance adherence (as in some regions of Spain and Portugal) [27-29]. Also, the number of regulated home visits varies from none to several per year (like in France and Portugal). The use of PAP telemonitoring also varies widely, being routine for almost all patients in France throughout the PAP treatment period [30] but not used (or only used in the first months of therapy or in specific situations) in other countries. Criteria for the reimbursement of PAP therapy also differ markedly between European countries and are likely to influence adherence and persistence. For example, while the fees paid to the home support providers in France increase as the number of hours of PAP use increases [30,31], in Belgium and Germany, nonadherence can result in the cessation of patient reimbursement.

The large number of patients treated with PAP therapy and the heterogeneity of home support provider service levels across Europe provide a unique opportunity to evaluate the optimal management approach. This requires an assessment of the added value of the service and of its impact on PAP adherence and persistence; quality of life; patient-reported outcomes (PROs), including quality of life and symptoms, patient-reported experience (PREs), and satisfaction.

Air Liquide Healthcare (ALH) is composed of several home support provider companies operating in more than 40 countries worldwide and 10 European countries. Support to patients with sleep apnea requiring PAP treatment is provided in all these countries. ALH designed the AWAIR (Assessment of the Benefit of the Home Support Provider Service Level Associated With Positive Airway Pressure Treatment in Patients With OSA on Treatment Adherence and Persistence: an International Real-World) study to assess and compare PAP adherence and persistence across 4 different European countries and according to the level of service. The study will consider the main confounding factors for adherence and persistence to PAP therapy and will provide unique information about differences in patient profiles across countries, PROs, OSA and PAP literacy, and experience and satisfaction with PAP therapy and service (PREs).

Methods

Study Design

This international, ambispective, real-world, cohort study is being conducted in 4 European countries (France, Belgium, Spain, and Portugal). It includes a retrospective analysis with the reuse of home support provider data routinely collected for PAP-related services and a prospective evaluation with the

collection of patient data using a web-based patient questionnaire.

Study Objectives

The main objective of the study is to compare PAP adherence and the PAP therapy persistence rate between countries and between different levels of home support provider service.

The study's other objectives are to (1) identify service components that influence PAP adherence and persistence; (2) identify factors associated with PAP adherence and persistence; (3) describe in each country sociodemographic and OSA-related clinical characteristics, home support provider PAP-related service, OSA and PAP literacy of participants (perceived and actionable competence), patient experience and satisfaction with PAP therapy and home support provider support, patient-reported OSA symptoms, and quality of life (determined using the EQ-5D-5L questionnaire [32]); and (4) describe patterns of PAP use.

Participants

Process for Selecting Patients

Eligible participants are adults (aged 18 years and older) who started PAP therapy between January 1, 2019, and December 31, 2023; for whom PAP services were delivered by an ALH affiliate in France, Belgium, Spain, or Portugal; and had a valid email address or smartphone number.

Potential participants were identified by applying these inclusion criteria to the data sourced from each home support provider database. In France and Portugal, all patients who met the above inclusion criteria were informed about the study. In Spain and Belgium, which have regional- or hospital-level regulatory processes, potential participants are only included from representative investigational sites. After providing the information about the study, patients who either consented to participate (Portugal, Spain, and Belgium) or did not "opt-out" (France) are enrolled in the study. These processes are described in more detail in the Ethical Considerations section.

The digital and decentralized nature of the study using e-consent and an electronic patient-reported outcome (ePRO) tool means that patients are not directly recruited by investigators. Instead, a secure electronic solution, Dr Data Consent, is used to provide direct and individual information about the study, obtain consent, and provide access to the web-based questionnaire. This solution is compliant with European and French legislation and regulations on the protection of personal data, as well as ethical guidance about patient's rights management. Its technology is powered by blockchain thus guaranteeing full traceability on e-consents.

Process for Contacting and Recruiting Patients

The list of eligible patients that was extracted from each home support provider database contains patient contact details (ie, email address or smartphone number). This list is uploaded into Dr Data Consent and an algorithm checks the validity of the contact details. Eligible patients with valid contact information receive an email or SMS invitation to connect to this platform for the consent process. The invitation does not include sensitive data.

An explanatory video is provided, within the Dr Data Consent account of each patient, to ensure that potential participants fully understand the study's aims, procedures, and their rights.

Those who provide consent are granted access to the ePRO tool and invited to complete the questionnaire, which should take them an estimated 10 minutes.

Ethical Considerations

The study protocol was developed in collaboration with a scientific committee composed of experts in OSA and methodologists from the 4 countries involved. The regulatory process and patient consent for a study with the reuse of data and a questionnaire were different for the 4 countries.

In France, the study followed the methodology MR-004 of the French Data Protection Authority (Commission Nationale Informatique et Liberté) concerning research that reuses data that have already been collected [33] and was approved by the local ethics committee of Angers University Hospital in November 2023 (2023-159). In Portugal, the study was considered observational and required approval by a central ethics committee; the approval was obtained from the ethics committee of Lisboa in May 2024 (24/24). In Spain, the study was considered observational and required approval by the ethics committee at each participating hospital; approval was obtained from the CEIm Hospital Universitario Ramón y Cajal of Madrid in July 2024 (095/24) and from the CEIm Hospital Universitario Doctor Peset of Valencia in December 2024 (127/24) and is pending for other regions. In Belgium, the study was considered interventional and required approval by a central ethics committee (Commissie voor Medische Ethiek Ziekenhuisnetwerk Antwerpen Institutional Review Board, Ziekenhuis aan de Stroom Middelheim) and by the local ethics committee at each participating hospital. Ethics approvals from the belgian central ethics committee are still pending.

In France, potential participants have the option to decline the reuse of their personal data through an "opt-out" process. Conversely, in Belgium, Portugal, and Spain, an "opt-in" process has been established, requiring explicit consent from participants to join the study.

No compensation is provided to participants.

Outcome Measures

Study outcomes, time points, and data sources are summarized in Table 1. An ePRO tool will be used to administer the patient questionnaire. The ePRO tool was designed to assess various aspects of a patient's status, condition, and experience at 2 time points: the time of ePRO completion and the beginning of PAP therapy. This included sociodemographic characteristics (age, relationship status, employment, education level, and social support), health status (BMI, smoking status, alcohol intake, comorbidities, sleep duration, and use medications to aid sleep), OSA-related factors (when PAP therapy was started, apnea-hypopnea index before starting PAP, and OSA symptoms), PAP therapy experience and satisfaction (tolerability of PAP, attitude to PAP, device noise, and level of motivation

to use PAP), patient experience and satisfaction with home support providers, quality of life (including current health status), and OSA-PAP literacy. The full ePRO questionnaire is provided in Multimedia Appendix 1.

Home support provider service will be assessed using 4 components: frequency of interactions between the home support provider and a patient; content of support (logistical, educational, supportive, or behavioral); personalization of support according to patient profile or needs; and telemonitoring (telemetry, data visualization, and alerts triggering home support provider interventions).

Table 1. Study outcomes.

Category and outcome	Time points	Source
Sociodemographic and OSA[a]-related clinical characteristics		
• Demographics (age and sex) • BMI	At the start of PAP[b] therapy	ALH[c] ERP[d]
• Occupational status and highest education level • Sleep characteristics: bed sharing, sleep duration, and sleep medication • Smoking status and alcohol consumption • BMI	At the time of ePRO[e] completion	ePRO tool
• Comorbidities: diabetes, stroke, myocardial infarction, coronary stenting or heart surgery, heart failure, cardiac arrhythmia, hypertension, GORD[f], COPD[g], asthma, chronic rhinitis, cancer, anxiety or depression, and insomnia	Before starting PAP therapy	ePRO tool
• Apnea-hypopnea index at the time of diagnosis	Before starting PAP therapy	ALH ERP and ePRO tool
PROs[h]		
• Symptoms: snoring, excessive daytime sleepiness, daytime fatigue, lack of energy, waking up feeling tired, poor sleep, falling asleep at the wheel, nocturia, abrupt awakening with choking and gasping, morning headache, irregular breathing during sleep, decreased libido, depression, anxiety, irritability, and memory or concentration difficulties	Before and after starting PAP therapy	ePRO tool
• Quality of life using the EQ-5D-5L [32]	At the time of ePRO completion	ePRO tool
OSA and PAP literacy		
• Perceived and actual competence related to disease literacy and PAP use assessed using 13 variables with binary responses	At the time of ePRO completion	ePRO tool
Experience and satisfaction with PAP therapy		

• Measured using a visual analogue scale for
  • Difficulty tolerating PAP (discomfort related to pressure, and mask)
  • Likelihood of continued use
  • Perceived health benefits
  • Global satisfaction
  • Noise acceptance/impact
  • Motivation to use
	At the time of ePRO completion	ePRO tool

Experience and satisfaction with home support provider		

• Measured using a 5-point Likert scale for
  • Home support provider availability for logistical support
  • Home support provider availability for educational support
  • Satisfaction with home support provider
  • Perceived value of home support provider
	At the time of ePRO completion	ePRO tool

Characteristics of PAP therapy		
• Type of PAP device and mask	At the start of PAP therapy	ALH ERP
• Elevated apnea-hypopnea index • Elevated unintentional leaks	1, 4, 6, and 12 months after starting PAP therapy and annually thereafter	Device data
Home support provider PAP-related service		
• Number and type of interactions (home visit, phone call, and digital interaction) • Number of mask changes • Implementation of telemonitoring	1, 4, 6, and 12 months after starting PAP therapy and annually thereafter	ALH ERP

Category and outcome	Time points	Source
PAP adherence		
• Mean number of hours per day of PAP use • Mean PAP use categorized as: 0-2 hours/day, 2-4 hours/day, 4-6 hours/day, and ≥6 hours/day • Proportion of adherent patients defined as (1) mean PAP use ≥4 hours/day, (2) mean PAP use ≥4 hours/day on ≥70% of days, and (3) mean PAP use ≥4 hours/day on ≥80% of days	1, 4, 6, and 12 months after starting PAP therapy and annually thereafter	Device data
PAP persistence		
• Percentage of days with or without PAP use defined as the ratio between the number of days with PAP usage (starting from 1 minute of use) over the number of days in the follow-up period • Patients without PAP discontinuation (still in therapy), with temporary discontinuation, or with permanent discontinuation • Patients still in therapy and with mean PAP use ≥4 h/day	4, 6, and 12 months after starting PAP therapy and annually thereafter	Device data and ALH ERP

[a]OSA: obstructive sleep apnea.

[b]PAP: positive airway pressure.

[c]ALH: Air Liquide Healthcare.

[d]ERP: Enterprise Resource Planning.

[e]ePRO: electronic patient-reported outcome.

[f]GORD: gastro-esophageal reflux disease.

[g]COPD: chronic obstructive pulmonary disease.

[h]PRO: patient-reported outcome.

Data Sources, Flow, and Management

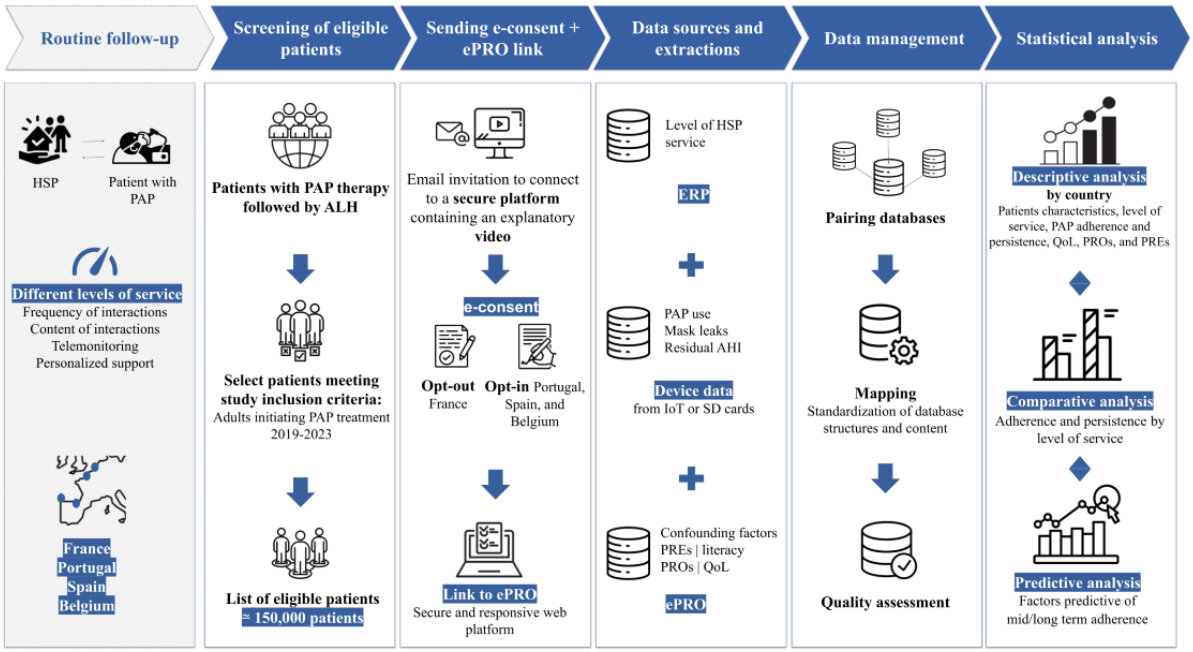
Potential participants will be identified by applying the inclusion criteria to the data sourced from the ALH Enterprise Resource Planning (ERP) systems. Initially, potential participants will receive an email or SMS invitation to connect to a secure platform for the consent process. Those who provide consent will be granted access to the ePRO tool and will be invited to complete the questionnaire, which takes about 10 minutes.

The study database will be created from 3 data sources: the ALH ERP systems that contain data routinely collected for PAP-related services; the database containing information about PAP device use (collected remotely through the Internet of Things or by download from device memory cards during home provider support visits); and the ePRO tool. Database structure and content will be standardized across countries.

Because the ALH ERP and PAP device use databases are primarily designed for administrative, logistical, and patient follow-up purposes, rather than research, all data will undergo thorough review for completeness, accuracy, and reliability before statistical analysis. These reviews will be conducted in accordance with a detailed data management plan, involving multiple experts with complementary areas of expertise. All decisions made during the review process will be fully documented.

All identifiable personal information will be protected and stored in the study database in pseudonymized form so that it cannot be viewed by the study sponsor or any external vendors that are processing the study data. A summary of data sources and data flow is provided in Figure 1.

Figure 1. Diagram of data sources and data flow. AHI: apnea-hypopnea index; ALH: Air Liquide Healthcare; ePRO: electronic patient-reported outcome; ERP: Enterprise Resource Planning; HSP: home support provider; IoT: Internet of Things; PRE: patient-reported experience; QoL: quality of life.



Statistical Methods

Sample Size

This study aims to include all adults starting PAP therapy managed by an ALH home support provider in the participating countries who met the selection criteria during the study time period. This approach minimizes selection bias and sampling errors, ensuring precise and reliable results. Inclusions will be possible at the national level (France) or only at some investigational sites in countries requiring regional or hospital-level regulatory processes. All potential participants will be informed whenever ethics committee approval is obtained from the respective regions or hospitals. It is expected that around 30% of the 150,000 eligible participants will not be enrolled due to the absence of (or incorrect) email, or refusal to participate. Therefore, the number of included patients is expected to be around 100,000. With a sample of this size, the probability of showing a statistically significant difference in adherence between different levels of service if one exists is >99%, even if there were important imbalances between groups.

Statistical Analysis

Statistical analyses will be performed according to a predefined statistical analysis plan (Table 2).

Table 2. Statistical analysis plan details.

Objectives	Main outcomes	Key explanatory variables	Statistical methods
Compare PAP[a] adherence and the PAP therapy persistence rate between different levels of home support provider service	• PAP adherence: (1) mean number of hours/day of PAP use and (2) adherent patients defined as those with mean PAP use ≥4 hours/day • PAP persistence: (1) percentage of days with PAP use, (2) patients still in therapy, and (3) patients still in therapy and adherent	• Fixed effect: Level of service (standard of care, personalized care plan, or high service level) • Random effect: Country	Multilevel model adjusted for selected confounding factors
Identify service components that influence PAP adherence and persistence	• PAP adherence: (1) mean number of hours/day of PAP use and (2) adherent patients defined as those with mean PAP use ≥4 hours/day • PAP persistence: (1) percentage of days with PAP use, (2) patients still in therapy, and (3) patients still in therapy and adherent	• Fixed effect: Frequency of interactions, content of support, personalization of support, and telemonitoring • Random effect: Country	Multilevel model adjusted for selected confounding factors
Identify factors associated with PAP adherence and persistence	• PAP adherence: (1) mean number of hours/day of PAP use and (2) adherent patients defined as those with mean PAP use ≥4 hours/day • PAP persistence: (1) percentage of days with PAP use, (2) patients still in therapy, and (3) patients still in therapy and adherent	• Fixed effect: Frequency of interactions, content of support, personalization of support, telemonitoring, sociodemographic characteristics, OSA[b]-related clinical characteristics, and characteristics of PAP therapy • Random effect: Country	Multilevel model
Descriptive Analysis	• Sociodemographic characteristics • OSA-related clinical characteristics • OSA and PAP literacy • Experience with PAP therapy • Experience with home support provider support • Quality of life • Home support provider PAP-related service	N/A[c]	Usual descriptive statistics: Analysis by country
Describe patterns of PAP use	• Mean PAP use categories over time	N/A	Data visualization such as Sankey diagrams

[a]PAP: positive airway pressure.

[b]OSA: obstructive sleep apnea.

[c]N/A: not applicable.

Patient Datasets

Retrospective data will be available for all included patients (included population). Prospective data from the ePRO tool will be available for the subset of patients who complete the questionnaire (ePRO population).

Multilevel Models

Individuals living in the same country share a common health care system, lifestyle, and climate, and tend to be more similar than individuals from other countries. Therefore, individuals are considered nested within a country. This correlation of observations violates the assumption of independence for standard regression analysis leading to biased standard errors of parameter estimates. Therefore, we will fit multilevel linear or logistic mixed models using the country variable as a random effect to test the association between adherence or persistence and levels of service while accounting for this nested data structure.

Confounding Factors

Potential confounding factors were identified a priori based on a literature review and clinician expertise, and include age, sex, BMI, sleep duration, symptoms before starting PAP therapy, occupational status, highest education level, bed partner, comorbidities, smoking status, alcohol consumption, apnea-hypopnea index at the time of diagnosis, and prescriber specialty. Factors consistently described as being associated with PAP therapy adherence or persistence will be automatically included in statistical models comparing the effect of service on adherence or persistence. Other potential confounding factors will be selected based on their association with adherence or persistence in a univariate analysis. Full details of the confounding variables considered and the supporting sources are provided in Multimedia Appendix 2. Quantitative bias analysis will be performed to evaluate the impact of unmeasured confounders using a metric named the e-value [34]. The e-value can be defined as the strength of association that an unmeasured confounding factor would need to have in order to explain away the observed association.

Data Visualization

Data visualization (eg, with the use of Sankey diagrams) will be used to represent the pattern of changes in mean PAP use categories over time.

Sensitivity Analyses

Sensitivity analyses will be performed after removal of data collected during the COVID-19 lockdown periods, and before and after June 2021 (the time of the Philips Respironics world product recall [35,36].

Ancillary Study

While the association between PAP adherence and costs has been demonstrated in the United States [21,23,37-42], data from Europe remain limited [43,44]. To further determine the benefits of home support providers, an ancillary study, named APAIR (Association Between Positive Airway Pressure Adherence, Morbi-Mortality and Costs Among Patients With Obstructive Sleep Apnea in France: Real World Study Using Claims and Telemonitoring Data), will be conducted in the subset of AWAIR study participants from France. APAIR will investigate the association between PAP adherence and persistence, and key outcomes (mortality, morbidity, and health-related costs). AWAIR study participants from France will be identified in the French Healthcare Claims Database (Système National des Données de Santé), which provides longitudinal patient-level data for approximately 99% of the French population [45]. Data on hospitalizations and sick leave related to the complications of OSA will be retrieved for these individuals. The aim of APAIR is to obtain data relating to new and more relevant thresholds for PAP adherence and the personalization of PAP therapy support (eg, for those with higher health risks or higher health care resource use).

Results

As of December 2024, the AWAIR study has received approval in France, Portugal, and 2 regions of Spain. Patient enrollment started in France in October 2024, with around 90,000 patients informed about the study. Results of the AWAIR study are expected in the second quarter of 2025.

Discussion

Study Rationale

The high and increasing number of patients with OSA treated with PAP therapy drives concerns among health systems regarding the associated health care resource consumption and costs. This has led some countries to implement significant changes in the patient pathway, notably toward more home-centered models [30,46]. Regardless of the care setting, PAP adherence and persistence are essential because they are associated with health benefits [19], whereas poor adherence and PAP therapy terminations have been associated with increased disability, health care resource consumption, and direct or indirect costs [47-49].

Despite a large body of evidence regarding the factors associated with PAP adherence [50] and persistence [25,51], and the reimbursement of PAP-related services in many European Union countries, there is currently a lack of evidence regarding the impact of home support provider services on these outcomes. In addition, although defined by country or local regulations, the level of home support provider service is poorly described. Differences exist in service frequency, content, and communication channels between home support providers and patients, the use of PAP telemonitoring, and the qualifications of home support provider personnel. Some of these components have been shown to impact PAP adherence [29,30,52,53].

Our working hypothesis is that a higher level of home support provider service would be associated with better PAP adherence and persistence. This study will also investigate between-country differences in terms of patient characteristics, OSA-related characteristics, and services, and identify which components of service are most effective at improving adherence and persistence.

We anticipate that this research will provide valuable evidence to inform decision-making by authorities and payers regarding the regular reassessment of services and associated tariffs. It could also support guidelines relating to the follow-up of individuals receiving PAP therapy.

Design Rationale

The comparative, real-world design with between-country comparisons was the most feasible approach for this study. A randomized controlled trial was not viable because home support provider services are implemented for all patients prescribed PAP. The need to include a control group without services in a randomized trial would have markedly reduced ethical approval and acceptance of the study and would have introduced important bias related to behavioral factors for those accepting home support provider management. Furthermore, the controlled conditions of clinical trials do not adequately capture the complexity of factors influencing adherence in real life. Furthermore, there was a need for evaluation of the real-world impact of home support providers on a representative, unselected population. Real-world studies provide information about outcomes with less rigid treatment patterns compared with a controlled trial [54] and bridge the gap between clinical research and everyday practice. We followed the Haute Autorité de Santé methodological recommendation for real-world studies, proposing a design consistent with identified questions, using preexisting high-quality data, integrating PROs and PRE, and ensuring transparency [55].

Strengths

One of the major strengths of this study is its large sample size, which enhances the representativeness of the population and the generalizability of the findings. The retrospective design allows for long-term evaluation of PAP adherence and persistence and ensures that there is no influence on participants' behavior because data were collected prior to their inclusion in the study. In addition, the AWAIR study will describe between-country differences in home provider services and patient characteristics for the first time, and report on patient satisfaction and experience with PAP therapy.

In contrast with conventional clinical trials, the real-world setting ensures that the results will reflect the usual course of care [56]. This is particularly important for evaluating adherence because it minimizes the risk of bias that could arise from study participation. Furthermore, real-world evidence is particularly relevant for meeting health authority post-approval effectiveness requirements [57]. Well-conducted comparative effectiveness research can provide valid results similar to randomized trials for this measure of known confounding factors [56], and can use methods (such as stratification, matching, or regression analyses) to account for or adjust for such factors and yield valid results [58]. In the real-world comparative AWAIR study, adjustment for potential confounders identified through literature review and clinical expertise, combined with the use of hierarchical models accounting for contextual differences related to the international nature of the study, will help the data to provide an accurate assessment of the net effect of home provider services on PAP adherence and persistence while minimizing the potential biases inherent in real-world studies. Additionally, the use of an ePRO tool facilitates the collection of data on confounding factors that would not otherwise be available in the retrospective database analysis, along with PROs, PREs, and health literacy across a large and diverse patient population from various geographic regions [59].

Limitations

Selection bias cannot be entirely ruled out because participants were required to have a valid email address or smartphone number to be eligible for the study. This may lead to underrepresentation of certain subgroups of PAP users, such as older adults. Patients who answer the questionnaire might also differ from those who do not answer it. In addition, this study will only include individuals who use PAP supplied by a home support provider affiliated with ALH and it is possible that the level or content of additional services may differ slightly from other home support providers in the same country. To assess the potential impact of such biases, we will compare the characteristics of our study population with published data on OSA, focusing on age, sex, and disease severity.

Data from the ePRO tool may be subject to recall bias and inaccuracy because participants will complete the web-based questionnaire at variable periods of time since the start of PAP therapy (up to 5 years later for those who started PAP in 2019) and medical data will directly be provided by the patient. Confounding bias other than the key confounding factors considered is another limitation, particularly with respect to medical follow-up (data that will not be collected in this study).

Finally, the period over which this study was conducted included times before and during the COVID-19 pandemic (including lockdowns), and the worldwide recall of a PAP device made by Philips Respironics [36]. Sensitivity analyses will be performed to determine whether these factors had any influence on the overall study findings.

Challenges

The study faced several challenges, including the regulatory classification of an ambispective study and the heterogeneous regulatory processes between countries. In France, the reuse of data for clinical research is facilitated by a simplified procedure that does not exist in other countries. Although the decentralized approach used in this study (ie, e-consent + ePRO tool) has advantages, especially in terms of managing a large number of participants, proposing the study to potential participants remotely can decrease the rate of enrollment. This is why a video-based approach was chosen because using videos to explain the research aims and procedures to potential participants of a clinical trial was preferred by patients over paper-based systems and improved their understanding [60].

Another challenge is the quantity of data to be processed due to the large number of participants and the daily PAP data collected over up to 5 years, requiring robust data management and quality control systems. Moreover, data were collected for routine home support provider services, in different countries with different services and enterprise resource planning systems, with different data collection processes, which adds another layer of complexity to the study. Therefore, those involved in the study need to have a good understanding of the data collection processes, data structures, formats, contents, and constraints of each system to allow standardization of data to constitute a research-ready database.

Opportunities

Clinical trials are critical in the assessment of health products and services. However, managing and executing randomized controlled trials pose significant challenges in terms of inclusion, data collection, follow-up, comparator group, and costs [61]. Specifically in patients with OSA treated with PAP, it was shown that recruitment strategies in randomized trials could result in a lack of representativeness of the participants, because only up to 20% of typical patients with OSA meet the eligibility criteria, limiting the generalizability of the results [62]. The expanding availability of real-world data combined with advancements in operational tools and methodologies presents a significant opportunity to develop alternative study designs that leverage existing data. Furthermore, the European Health Data Space will create a common framework in Europe for the reuse of health data for research [63]. The design of the AWAIR study integrates multiple real-world data sources (including operational databases, device data, and an ePRO tool), the use of comparative real-world methods, and the implementation of e-consent. This innovative approach not only makes the study more robust but also sets a precedent for future research in similar fields, particularly regarding the number of participants who will consent and complete the ePRO tool. The design allows the study to be continuously enriched with data from new countries to measure the effect of other service levels and also to extend patient follow-up to assess longer-term persistence or include other patients in the countries of interest to assess the impact of changes in service levels.

Conclusions

The AWAIR study has a unique design, leveraging an unprecedented number of eligible participants, decentralized technologies, and a real-world comparative methodology across multiple countries. This approach will highlight intercountry differences in terms of patient characteristics, PAP adherence and persistence, PROs, PREs, and satisfaction with home

support provider services. By assessing the added value of home support provider services, the results will support best practices for patient management and decision-making by health authorities and payers.

Acknowledgments

Medical writing assistance for the preparation of the first draft manuscript was provided by Nicola Ryan, an independent medical writer. This study was funded by Air Liquide Santé International, Paris, France.

Authors' Contributions

SA, MS, HT, CF, FB, and SB contributed to the study conception and design. HT and SO were involved in the regulatory process. JT, FG, PP, ICP, and LB provided the scientific validation of the outcomes and the content of the patient questionnaire. SA, HT, SB, HS, and BB designed the ePRO. MS, FB, SA, and CF provided the statistical methodology of the study. SA and MS outlined the first draft of the manuscript. All authors reviewed the manuscript and provided critical revisions of the manuscript. All authors approved the final version of the manuscript.

Conflicts of Interest

HS and BB have no conflicts of interest to declare. ICP, PP, LB, and FG have received consulting fees from Air Liquide Group. SA, JT, MS, HT, SB, and MHG are employees of Air Liquide Group. FB and CF are employees of Horiana, the contract research organization (CRO) of the study. SA, MS, and HT are shareholders at Air Liquide.

Abstract

Background: Tension-type headache (TTH) is the most common type of headache and the second most common health-related complaint among children and adults. Traditional Chinese medicine (TCM) offers unique therapeutic benefits in treating TTH. However, the lack of standardized evidence—such as inconsistencies in outcome selection and reporting in clinical studies, a lack of consensus on outcomes and measures, high risks of selective reporting bias, and missing data—has limited the development of robust evidence supporting the efficacy of TCM in treating TTH. Therefore, establishing a core outcome set (COS) is crucial for standardizing TCM clinical studies for TTH, thereby enhancing the quality and comparability of research findings.

Objective: This study aims to develop a COS for future clinical studies on the treatment of TTH with TCM.

Methods: The COS will be developed through the following 3 stages. First, systematic reviews and semistructured interviews will be conducted to identify potential essential outcomes, which will be evaluated by the steering committee to finalize a preliminary list of outcomes. Data will be processed using thematic analysis to ensure comprehensive coverage of relevant outcomes. Second, a 2-round Delphi survey will be conducted, inviting stakeholders, including health care experts and patients with tension-type headaches, to determine the importance of each outcome. Statistical analysis will be used to assess the level of consensus and prioritize outcomes based on predefined criteria. Third, a face-to-face consensus meeting will be held to finalize the COS and recommend measurement times for each outcome. Key outcomes will be interpreted based on their clinical relevance and feasibility of measurement, ensuring the COS is comprehensive and applicable in clinical settings.

Results: The protocol has been registered in PROSPERO, with the review commencing on October 1, 2024, and anticipated results by November 15, 2024. The systematic reviews will be finalized, followed by the Delphi survey and consensus conference in late 2024 and early 2025. The COS findings will be reported per COS-STAR (Core Outcome Set–STAndards for Reporting) guidelines, published in an international journal, presented at conferences, and disseminated to participants for clinical application.

Conclusions: This study is necessary as developing a COS for future TCM clinical studies in the treatment of TTH can maximize the value of data from individual trials and provide high-quality research evidence.

Introduction

Background

Tension-type headache (TTH) is a neurological disorder characterized by mild to moderate headaches [1]. It is the most common type of headache and second most common health-related complaint among children and adults [2,3], and negatively affects their ability to participate in various activities in school, sports, social, and home settings, especially when the headache becomes chronic and frequent [4]. Many studies have shown that TTH significantly impacts mood, sleep, and liveliness; anxiety or depression is more common in patients with headaches than in those without headaches [5-7].

Traditional Chinese medicine (TCM), which includes Chinese herbal medicine, acupuncture, and massage, plays an increasingly important role in the treatment of TTH [8-13]. In particular, acupuncture is frequently used to treat TTH [14] and has been approved as a supplementary therapy option for TTH by the European Federation of Neurological Societies [15]. Several randomized controlled trials (RCTs) of TCM for TTH have been conducted in China. Although an individual RCT is valuable, pooling data from numerous RCTs can give more substantial evidence to support therapeutic decision-making [16]. The normalization and homogeneity of research outcomes are crucial when pooling data from multiple studies. However, we found the following problems in the selection and reporting of outcomes in RCTs and systematic reviews on the effects of TCM on TTH.

Many studies only reported the effectiveness rate of composite indicators [17], and certain clinical studies failed to include critical or relevant outcomes, such as headache frequency, severity, duration, impact on quality of life, and analgesic use. As a result, these studies were not suitable for secondary analysis [18], which precludes the incorporation of many results into systematic reviews or meta-analyses. This limitation undermines the ability to provide higher-level evidence for clinical practice, thereby diminishing the research's value and contributing to unnecessary waste. In addition, selective reporting of results may exist in current clinical studies, as researchers are more likely to select statistically significant results, leading to overestimation of outcomes and exaggeration of efficacy [10,13,19]. Outcome measures were poorly defined, with total effectiveness rates inconsistently defined using a variety of concepts [17]. The outcome measures for different studies were heterogeneous, and systematic reviews have shown significant heterogeneity among studies, which is not conducive to intervention comparisons and meta-analysis [10,11,13]. Furthermore, outcomes were developed without considering the opinions of patients and other stakeholders. The International Headache Society Committee proposed an evaluation of outcomes in clinical trials [20]. However, there is still a lack of consensus on the collection and reporting of RCTs of TCM for the treatment of TTH, which limits the comparison and aggregation of data from individual trials and reduces their research value.

Therefore, to address the above problems, it is necessary to develop a core outcome set (COS) for TCM clinical studies (COS-TCM) for TTH. Developing, disseminating, and implementing a COS can address and overcome inconsistencies in outcome selection, measurement, and reporting [21]. Currently, there is no specific COS-TCM for TTH. After searching the Core Outcome Measures in Effectiveness Trials (COMET) database, we identified 1 COS associated with TTH. The International Headache Society Committee proposed an evaluation of TTH outcomes in clinical trials in 1995 (1st edition) [22] and 2010 (2nd edition) [15]. However, the standardized outcome set in COS may be biased toward Western patient populations and lack access to Chinese clinical experts and Chinese patients. There are no COSs available that include outcomes relevant to TCM syndromes. Therefore, developing a COS-TCM for TTH will enhance the quality of evidence from clinical studies of TCM for TTH, promote the translation of clinical research into clinical practice, and provide recommendations for health care decision-making [23,24].

This study was registered in the COMET Initiative (1473) and will be conducted according to the Core Outcome Set-STAndards for Development [25] and Construction of Core Outcome Set of TCM Clinical Trials guidelines [26]. This study protocol referred to the Core Outcome Set-Standardized Protocol Items [27], which are shown in Multimedia Appendix 1.

Scope and Aim

Aim

This study aims to develop a COS for future clinical studies on TCM for the treatment of TTH, in order to improve the use of evidence synthesis by standardizing outcome reporting and guaranteeing that all studies contribute valuable data.

Scope

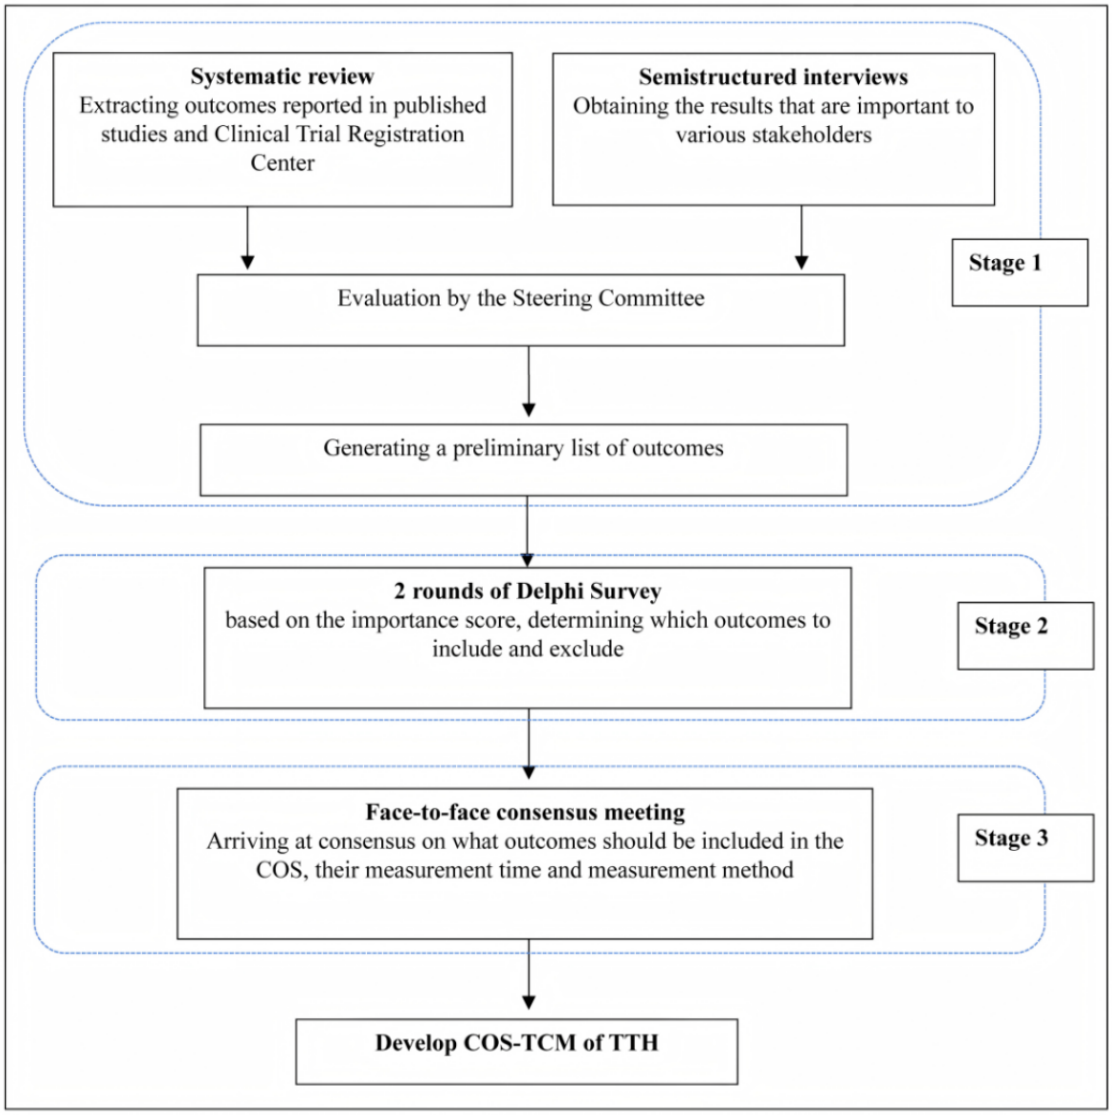
The scope of the COS-TCM encompasses several key areas. It focuses on the health condition of TTH and targets a population of patients with TTH who are aged 18 years and older. The types of interventions included are various TCM therapies, such as herbal medicine decoction, Chinese patent medicine, acupuncture, moxibustion, cupping, massage, Tai Ji, Baduanjin, Qigong, and other nondrug treatments. This scope applies to any type of clinical study.

Methods

Design

The study design is structured in 3 stages, providing a comprehensive framework for developing the COS-TCM. Initially, semistructured interviews and a systematic review will be conducted to identify potential essential outcomes. This will culminate in a preliminary list of outcomes, evaluated and finalized by the steering committee. The second stage involves selecting various stakeholders to participate in a 2-round Delphi survey, aiming to gather diverse opinions on the COS-TCM. Finally, a consensus meeting with key stakeholders will be convened to finalize the COS-TCM. Figure 1 illustrates the flowchart of the study process.

Figure 1. The flowchart of the study core outcome set (COS). TCM: traditional Chinese medicine; TTH: tension-type headache.



Steering Group

The steering group will consist of 5 individuals from various scientific fields, including 2 TCM clinical neurology experts, 2 Western medicine clinical neurology experts, and a methodologist. The group will examine and approve the study protocol, determine the preliminary checklist of the reporting outcome set, and take part in a consensus conference to advance the construction of the COS.

Working Group

The working group will consist of 20 members, including clinicians, methodologists, professors, and graduate students from Xiyuan Hospital, China Academy of Chinese Medical Sciences. The group will be responsible for conducting routine research tasks and related meetings, contacting experts, and seeking advice from the steering committee when disagreements need to be resolved.

Involvement of Stakeholders

Various stakeholders, including health professionals and patients, will be included in the COS development process. Health professionals will include TCM and Western medicine practitioners who specialize in cerebrovascular disease, methodologists who specialize in evidence-based medicine, and researchers. Core journal editors will select from journals focusing on neurological diseases, such as the *Chinese Journal of Neurology*, *Chinese Archives of Traditional Chinese*

Medicine, *Journal of Neurology and Neurorehabilitation*, *Chinese Journal of Evidence-Based Medicine*, and *Global Traditional Chinese Medicine*. Other relevant experts include clinical trial personnel, industry representatives, and policy makers. The study will invite patients with TTH to participate.

Patient and Public Involvement

Considering that patients' opinions are significant for the formulation of the COS, this study will involve semistructured interviews, 2 rounds of Delphi survey, and consensus meetings.

Stage 1: Identification of Potentially Significant Outcomes

Step 1: Systematic Review

According to the guidelines of the COMET Initiative [21], a systematic evaluation will be performed to screen the spectrum of critical potential outcomes. Previous COS-TCM studies will be used for systematic review as the research starting point [28-30]. This study will include all clinical studies (regardless of research type) that report TTH outcomes.

Search Strategy

PubMed, the Cochrane Library, Embase, Web of Science, SinoMed, Chinese National Knowledge Infrastructure, Chinese Citation Database, China Science Periodical Database, Chinese Clinical Trial Registry, and Clinicaltrials.gov will be systematically searched from inception to January 31, 2024. The search strategy for English databases is shown in Multimedia Appendix 2. The languages will be restricted to English and Chinese.

Inclusion Criteria

The inclusion criteria for the study encompass several key aspects. First, the study must be a clinical investigation, which can include randomized controlled studies, case-control studies, cohort trials, or case series. Participants should be patients diagnosed with TTH who are 18 years or older. The diagnosis must be made using any internationally recognized classification, such as those outlined in the International Classification of Headache Disorders, including the first edition (1988), the second edition (2004), and the third edition (2013) by the Headache Classification Committee of the International Headache Society. The intervention under consideration should involve TCM therapies for those included in the treatment group. In addition, if a study primarily investigates secondary TTH as a consequence of conditions such as mental disorders, infections, or endocrine diseases, a thorough review of the full text will be conducted to determine the presence of headache-related outcome measures. Studies that report such outcomes will be eligible for inclusion.

Exclusion Criteria

The exclusion criteria encompass several specific aspects. Clinical trials that investigate the outcomes of comorbidities related to TTH, such as nausea caused by TTH, are excluded. In addition, studies primarily focused on assessing pharmacodynamics or pharmacokinetics are not considered. A study involving fewer than 10 cases is also excluded.

Data Extraction

A data extraction table was designed and will be used to extract basic study information, including author information, year of publication, country, Western medicine diagnostic standards, type of TTH, TCM syndrome names and diagnostic criteria, interventional measures, study type, conclusions, outcomes and their definitions, time points, and method of outcome measurement. A total of 2 trained reviewers will be responsible for independent study screening and data extraction. Disagreements will be resolved by consulting with a third researcher. If any data is missing, the reviewers will contact the authors of the research by email or telephone to obtain the missing data.

Step 2: Semistructured Interview

A systematic review has been conducted to summarize the outcomes of existing clinical studies. However, this mainly represents the researchers' perspectives. According to the current guideline recommendations of the Core Outcome Set-STAndards for Development [25] and the COMET handbook (version 1.0) ADDIN [31], the opinions of clinicians and patients on the treatment of TTH with TCM can be obtained through semistructured interviews.

Participants

In this study, we will use heterogeneous and purposive sampling methods to recruit participants. Purposive sampling is widely used in qualitative and mixed-methods research because it enables researchers to select samples based on specific study objectives and criteria. This approach allows for the selection of more representative samples within a limited timeframe, thus conserving significant time and effort and reducing costs. Specifically, we will recruit patients diagnosed with TTH from the Xiyuan Hospital of the China Academy of Chinese Medical Sciences, as well as clinical doctors from 15 tertiary hospitals nationwide, to ensure the diversity and representativeness of the sample. The criteria for patient selection include age, gender, type of disease, duration of illness, and type of treatment, aiming to capture a broad range of patient experiences and treatment outcomes. For clinical doctors, the selection will focus on geographical diversity and professional background to obtain a wide spectrum of clinical perspectives. We plan to recruit 30 clinical doctors and 30 patients. Although no standardized method exists for determining the sample size for semistructured interviews, previous studies suggest that data saturation typically occurs when the sample size reaches 30 [24,30,32]. By adhering to these criteria and methods, we ensure that the selected sample adequately reflects the diversity and complexity of the research topic, thereby enhancing the quality and reliability of the study findings. Detailed inclusion and exclusion criteria for clinical doctors and patients in the semistructured interviews are provided in Table 1.

Table 1. Inclusion and exclusion criteria for clinicians and patients in semistructured interviews.

Category	Inclusion criteria	Exclusion criteria
Clinicians	• Senior titles in neurology or TCM[a], with more than 5 years of work experience. • At least a bachelor's degree. • Engage in headache treatment.	• None.
Patients	• Diagnosed with TTH[b], no limitations on status. • Aged 18 years and older. • Receiving TCM treatment. • Sign informed consent forms. • Capable of reading, understanding, and speaking Chinese or English.	• Severe diseases such as heart failure, cerebral infarction, cerebral hemorrhage, and tumors.

[a]TCM: traditional Chinese medicine.

[b]TTH: tension-type headache.

Data Collection

Considering previous studies and the characteristics of TTH, we designed a semistructured interview. The development of the interview questions involved a thorough review of existing literature and consultation with experts in the field to ensure content validity. The interview will be conducted by professional researchers in a specific consultation room or office, with face-to-face interactions with participants conducted as often as possible. All interviews will be recorded to facilitate comprehensive data analysis. Before the interview, participants will be informed of the study's purpose and content, and they will be required to sign an informed consent form.

For patients, the semistructured interview will explore several key areas. Participants will be asked about the duration of their headache experience or how long they have been diagnosed with TTH. They will describe their main symptoms and the treatment they are currently receiving. In addition, they will be queried about their satisfaction with the current treatment and any recommendations they have for its improvement. Further questions will address the areas they would most like to improve and the outcomes they hope to enhance after treatment.

For clinicians, the interview will focus on their professional experience and treatment approaches for TTHs. Clinicians will discuss how long they have worked in their field and their methods for treating tension-type headaches. They will be asked about the outcomes they believe the therapies will enhance for patients. Furthermore, they will identify which outcomes they prioritize in the treatment of TTHs, listing at least 5 indicators they are concerned with.

To evaluate the validity of the interview questions, we conducted a pilot test with a small group of participants and clinicians not involved in the main study. Feedback from this pilot test was used to refine the questions, ensuring clarity and relevance. In addition, an expert panel reviewed the questions to confirm that they accurately capture the dimensions of interest related to TTH.

Data Analysis

A total of 2 researchers will independently conduct the data analysis. Disagreements will be resolved through discussions or with the assistance of a third researcher. After sorting out the recorded text, the data will be analyzed using the frame analysis method, including familiarity, identifying thematic frames, indexing, charting, mapping, and interpretation to obtain essential outcomes for patients and clinicians [33].

Step 3: Merging and Collating Outcomes

After completing the systematic review and semistructured interviews, the results from these 2 components will be merged. Guided by the COS-TCM standard, 2 researchers will independently collect the outcomes, resolving any disagreements through consultation or with the input of a third researcher. The data collation process begins with importing the extracted indicators into a Microsoft Excel table for sorting. Outcomes are assigned and matched to the corresponding study numbers to facilitate tracing. Following this, the outcomes undergo preliminary sorting, during which duplicates are removed. All study numbers and amounts indicating the results and frequency of application for each outcome are recorded.

Subsequently, the original outcome measures are standardized. For example, the names of outcomes are standardized, and composite results are reduced to a single result without altering the original meaning of the index. Finally, the names and frequencies of all outcomes are counted. The outcome domains are then determined, with the collected outcomes further classified into 7 domains according to the COMET manual [31] and COS-TCM [26] standards: TCM syndromes, symptoms and signs, physical and chemical testing, quality of life, long-term prognosis, economic evaluation, and safety events.

Step 4: Generating a Preliminary List of Outcomes

A preliminary list of outcomes will be finalized after evaluation by the steering committee. If the number of results collected in the indicator pool is small (≤100), all the outcomes will be included in the outcome list. If the number exceeds 100, the steering committee will conduct an internal vote on the indicator pool. If 90% of the members do not agree to include an item in the original list, it will be removed. Outcomes added by the steering committee will also be included to form the initial outcome list.

Stage 2: Delphi Survey

Involvement of Stakeholders

Stakeholders, including health care experts and patients with TTH, will be invited to participate. Health care experts include

TCM and integrated Chinese and Western medicine practitioners who are engaged in the field of cerebrovascular disease, Western medicine clinicians in the field of cerebrovascular disease, methodologists in the field of evidence-based medicine, researchers, core journal editors, and other relevant experts.

As the project team's leading unit, the China Academy of Chinese Medical Sciences formed the Encephalopathy Project Team of the TCM Evidence-based Medicine Center with 15 hospitals from 15 provinces. Qualified health care experts from these 15 hospitals will be recruited to participate in the Delphi survey. Patients will be recruited from the Encephalopathy Department of Xiyuan Hospital. The inclusion and exclusion criteria for the health care experts and patients are listed in Table 2.

Table 2. Inclusion and exclusion criteria for health professionals and patients in the Delphi survey.

Category	Inclusion criteria	Exclusion criteria
Health professionals	• More than 1 year of work experience. • Bachelor's degree or above. • Experience working in tertiary hospitals. • Published at least one clinical trial on cerebrovascular disease.	• None.
Patients	• Diagnosed with TTH[a], no limitations on status. • Aged 18 years and older. • Receiving TCM[b] treatment. • Sign an informed consent form. • Capable of reading, understanding, and speaking Chinese or English.	• Patients with severe diseases such as heart failure, cerebral infarction, cerebral hemorrhage, and tumors will be excluded based on medical history, physical examinations, and auxiliary tests.

[a]TTH: tension-type headache.

[b]TCM: traditional Chinese medicine.

Sampling Strategy

Since there is no reliable method for estimating the required sample size, the sample size will be determined according to the needs and conditions of the study [34]. Based on the sample size of previous studies and the implementation specification for the Delphi survey in the COS-TCM [26,35,36], we aim to involve 100 stakeholders, including 30 TCM and integrated Chinese and Western medicine clinicians, 15 Western medicine clinicians, 45 patients, 5 researchers, and 10 methodologists. In total, 2 rounds of the Delphi survey will be conducted.

Round 1 of the Delphi Survey

Developing a Questionnaire for Round 1 of the Delphi Survey

A questionnaire for round 1 of the Delphi survey will be formulated based on a preliminary list of outcomes obtained from systematic reviews, semistructured interviews, and evaluation by the steering committee. The questionnaire will consist of 4 parts, including the description of the purpose of the study, personal information of the respondent, evaluation of the importance of outcome indicators, and open questions. Participants will need to provide arguments for the inclusion or exclusion of each outcome in a COS. These arguments can then be summarized and used to develop proposals for voting on the inclusion or exclusion of each outcome in the second round. The open questions will be mainly supplementary to the questions considered necessary by the participants but not included in the questionnaire. To improve the intelligibility of the questionnaire, different terms will be designed for different stakeholder groups. For example, for Western medicine experts, the interpretation of TCM terms can be translated into the Western medicine language in which they are proficient. A general explanation will be added for patients. Stakeholders will be involved in the design of the questionnaire in advance. Delphi survey items commonly use a 9-point critical or relevant outcome to score the importance of outcomes [26,31]. Scores of 1-3 indicate that the outcome is nonessential," 4-6 indicate that the outcome is "important but not vital," whereas 7-9 indicate that the outcome is "necessary for inclusion." If participants are unable to assess the importance of some outcomes, they will be able to select "uncertain."

Process of Round 1 of the Delphi Survey

The first round of the Delphi survey is expected to be completed within 3 weeks. We will email the electronic version of the questionnaire to health care experts. They will be required to complete the questionnaire within 3 weeks and will be reminded by text messages 1 week and 48 hours before the end of the survey. The working group will assess the number of participants at the end of the second week. If the response rate to the Delphi survey (number of respondents/number of invited participants) is less than 70%, the survey will be extended for another 2 weeks. To increase the awareness rate, the questionnaire will be distributed on workdays. We will recruit eligible patients from the Department of Encephalopathy at Xiyuan Hospital. The consulting doctor will be responsible for introducing the content of the questionnaire to the patient and obtaining their consent and signature on the informed consent form. Team members will then hand out questionnaires to patients for immediate completion. We will try our best to answer the patients' questions.

Data Analysis for Delphi Round 1

The working group will gather all submitted questionnaires and calculate the response rate, average score, score distribution among health professionals and patients, and the number of participants from various stakeholder groups for each outcome item. To ensure that the outcomes of Delphi round 1 are fully shown and can be rescored, all outcomes will be retained in subsequent rounds [31,35,36]. Newly added items can be

included in Delphi round 2 if the steering committee deems them to be different from the results of Delphi round 1.

Round 2 of the Delphi Survey

Process of Round 2 of the Delphi Survey

Participants who completed the first round of the Delphi survey will be invited to participate in the second round. Each participant will be shown their first-round results, the score distribution of other stakeholders, and a summary of arguments. Based on this feedback, participants will be requested to regrade and score the additional questions in the second round. If the score for an outcome changes significantly between rounds, for example, from "not important" (1-3 points) to "critical" (7-9 points), the rationale for the change will be asked to be mentioned. Participants will also be able to provide suggestions for each survey item.

The Delphi round 2 questionnaires will be distributed like that of round 1 and will be expected to be completed within 3 weeks. For health care professionals, we will provide an electronic version of the questionnaire. A week and 48 hours before the end of the survey, we will send text messages to participants who have not completed the questionnaire. We will recruit eligible patients from the Department of Encephalopathy of Xiyuan Hospital and send the questionnaires to them after obtaining their consent.

Data Analysis for Round 2 of the Delphi Survey

After completing the questionnaire, the working group will calculate the response rate, average score, and score distribution for each item. After analyzing all the data, the average scores for the 2 rounds will be compared, and the reasons for score changes will be analyzed to evaluate whether there was attrition. Considering the results of the second round, in combination with the consensus definition, the outcomes will be categorized as "consensus in," "consensus out," and "no consensus" (Table 3) [31].

Table 3. Definitions of a consensus.

Classification of consensus	Description	Exclusion criteria
Consensus in	Consensus that the outcome should be included in the COS[a].	≥70% of participants score the outcome as 7-9, and <15% score it as 1–3 in both stakeholder groups.
Consensus out	Consensus that the outcome should not be included in the COS.	≤50% of participants score the outcome as 7-9 in both stakeholder groups.
No consensus	Uncertainty about the importance of the outcome.	Anything else.

[a]COS: core outcome set.

Stage 3: Consensus Meeting

Stakeholder Selection

After the 2 rounds of the Delphi survey, we will conduct a consensus meeting. To ensure the quality of the meeting and enhance the credibility of the results, we will invite representatives of various interest groups who have completed all Delphi surveys, steering committee members, and other representative senior experts from various stakeholder groups, regardless of their participation in the previous research process. At the same time, senior clinical experts in the field of TCM, especially academicians, TCM masters, nationally famous TCM practitioners, and leaders of academic groups, will be invited. Patients who participated in both rounds of the Delphi survey will be invited to the consensus conference. The inclusion and exclusion criteria for health professionals who will participate in the consensus meetings are listed in Textbox 1.

The first and the second must be qualified, while the third and the fourth can be qualified by any one of them.

Textbox 1. The inclusion and exclusion criteria for health care professionals who will participate in the consensus meeting.

Inclusion criteria:

- Master's degree or above, with more than 10 years of work experience.
- Clinicians with experience working at tertiary hospitals and at least in the position of associate chief physician.
- Participated in or hosted clinical research projects related to headache.
- Familiarity with evidence-based medicine and methodological research.

Exclusion criteria:

- None.

Sampling Strategy

According to the current guideline recommendations of COS-TCM standards [26], we will invite 25 stakeholders from all over the country, including 9 TCM experts, 5 Western medicine experts, 3 researchers, 5 methodologists, and 3 patients, to participate in the consensus meeting.

Consensus Meeting Process

The consensus meeting to determine the final COS will be face to face, preferably in Beijing. In exceptional cases, a network video conference will be held. The meeting will last for 2 days.

We will report on our previous work, including the preliminary list of outcomes generated using a systematic review and semistructured interviews and the results of the 2 rounds of Delphi. We will focus on reporting the outcomes of the second round, with outcomes categorized as "consensus in" from all stakeholder groups being prioritized for inclusion in the COS, and outcomes categorized as "consensus out" being excluded. The outcomes categorized as "no consensus" will be discussed at the meeting, and all participants will rate their importance using a 9-point Likert scale. The final COS will be developed according to the consensus definitions [5]. If some outcomes are still considered "no consensus" after 2 rounds of grading, the steering group will determine their inclusion in the final COS.

After formulating the final COS, the measurement method for the outcome index will be determined. The questionnaire will be designed based on the results of the system evaluation. Participants will discuss and vote on the measurement time and methods of the outcome indicators. For the measurement time and method of each outcome indicator, we will select the indicator with the highest percentage recommended in the consensus meeting.

Ethical Considerations

This study received approval from the Ethics Committee of Xiyuan Hospital, China Academy of Chinese Medical Sciences (approval number 2021XLA003-1). We followed the committee's ethical guidelines rigorously to ensure compliance and safeguard participant rights. All participants provided informed consent after receiving comprehensive information about the study, and they were assured that their involvement was voluntary, with the option to withdraw at any time without repercussions. We are dedicated to maintaining participant privacy and confidentiality; all data were anonymized and securely stored, accessible only to the research team. The findings will be presented in a way that does not reveal individual identities. There are no conflicts of interest in this study, and while participants did not receive financial compensation, we extend our heartfelt thanks for their contributions. Data for the systematic review were sourced from publicly available literature, in line with ethical standards for data sharing. The outcomes from the Delphi survey and consensus meeting will contribute to the development of the COS-TCM and will be reported without identifying individual participants.

Results

The protocol for this study has been registered in PROSPERO. The literature search has been completed, and the analysis of the systematic review results is currently under review. The findings will be published once the review process is finalized. A total of 19,033 articles were retrieved from 8 databases. After merging Chinese and English records and removing duplicates, 8074 duplicate articles were identified. Through title and abstract screening, 8844 articles were excluded for irrelevance, and 45 articles were excluded for being in languages other than Chinese or English. Further full-text review led to the exclusion of 672 articles for irrelevance, 67 articles due to inaccessible full texts, and 5 articles due to single-author, noncore publications. This process resulted in 1335 articles related to TCM.

Among these, there were 52 guidelines and clinical pathways, 102 systematic reviews and meta-analyses, 590 RCTs (including 177 on acupuncture, 293 on Chinese herbal medicine, and 120 on other therapies), 66 nonrandomized controlled trials, 1 cohort study, 4 case-control studies, 27 protocol registrations, 113 case series, 28 case reports, 21 cross-sectional studies, 226 review articles, 91 expert opinions, and 14 animal experiments. After the abstract screening, 650 articles were excluded, and 24 articles were excluded after a full-text review due to a lack of reported outcomes. Finally, 626 articles were included for further analysis. The PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) checklist is provided in Multimedia Appendix 3 of the initial draft. The Delphi survey involving stakeholders is scheduled to begin on November 30, 2024, and will be followed by a face-to-face consensus conference on February 1, 2025.

Upon completion of the development of the COS, the study findings will be reported in adherence to the COS-STAR (Core Outcome Set–STAndards for Reporting) statement [37]. This study will be disseminated through publication in an international journal and presentation at national and international conferences focused on TTH to promote the adoption of the Clinical Outcome Scale. The COS findings will be distributed to all participants by email or courier to support its clinical use.

Discussion

Expected Findings

Given the differences among various headache types, it is essential to specify the headache type of study participants in the clinical research design to ensure study accuracy. TTH represents the most common primary headaches and are characterized by pressing or tightening (nonpulsating) sensations on both sides of the head, are of mild or moderate intensity, and are not exacerbated by activity [38]. The current research on COS for headaches mainly focuses on migraine, such as the guidance on the design of outcome indicators for clinical trials of medications, patient-valued indicators, and identification of meaningful migraine outcome measures [38-40]. Compared with migraine, TTH generally receives less attention but has a substantial impact on individuals and society, compromising the quality of life in terms of work, study, and sleep and causing a social burden that cannot be overlooked [2,41-43]. Currently, only 1 published COS is available for TTH, which was initially published in 1995 [22] and updated in 2010 [20]. The clinical research of TCM on TTH have been increasing over the past 10 years [17]. However, there is no COS for TCM clinical research on the treatment of TTH. TCM has a unique diagnosis and treatment mode, and there are significant differences between the evaluation outcomes of TCM and Western medicine

[44]. Thus, developing a COS for clinical studies on TCM for the treatment of TTH is necessary.

This study was designed according to standard procedures and developed in 3 stages [25,26,31], with each stage conducted under the guidance of the steering group. In designing the COS, special attention is given to several key aspects. In the systematic review, we aim to include the intervention methods of TCM as comprehensively as possible to ensure the thoroughness of literature retrieval. Given the prevalence of nonstandard outcomes in clinical trials of TCM, we will standardize the outcomes obtained from systematic reviews and semistructured interviews. This includes standardizing the names of outcomes, dividing composite outcomes into single outcomes, and classifying outcomes into specific domains to ensure the standardization of COS [37].

Given the limited number of clinical RCTs for TCM treatment of TTHs, we have included observational studies to enrich the core outcome set, increase the diversity of outcomes, and enhance the robustness of our core outcome set. This approach ensures a more comprehensive evaluation of the effectiveness and safety of TCM treatments. To address the differences between these 2 types of studies, we plan to establish different core outcome sets for experimental (RCT) and observational studies. For example, in RCTs, we may focus on factors such as treatment duration and cost, whereas in observational studies, we may emphasize long-term outcomes and the impact on quality of life.

In this study, we included various TCM treatment methods to evaluate their comprehensive impact on tension-type headaches. This diversity helps capture the broad efficacy and patient responses to different treatment methods. However, it also introduces complexity in interpreting the results. We believe this approach is beneficial. First, the inclusion of treatment diversity allows us to assess the overall impact of TCM treatments on tension-type headaches. This method enables us to observe potential synergistic effects and individual differences among different treatment methods, providing more comprehensive guidance for clinical practice. Second, to address the variability of treatment methods, we used standardized outcome measurement tools in the study design. These tools ensure the comparability of results between different treatment methods. In addition, we used stratified analysis and subgroup analysis to handle data heterogeneity, ensuring the robustness of the results. It must be acknowledged that including various TCM treatment methods may introduce a certain degree of heterogeneity, which could affect the interpretation of results. Therefore, we used mixed-effects models in the analysis to adjust for potential differences between different treatment methods.

The study will also comprehensively cover different stakeholders in the Delphi survey and consensus meetings. This includes TCM and Western medicine practitioners, methodologists, researchers, core journal editors, and other relevant experts, as well as patients with TTH, to ensure the representativeness and authority of the COS. In designing the questionnaire for the Delphi survey, we will focus on improving its intelligibility. For instance, TCM terminology will be translated into the language of Western medicine for specialists, while patients will receive a general explanation. The questionnaire distribution will be tailored to the characteristics of stakeholders: healthcare experts will receive a combination of email and electronic questionnaires for efficiency and better data statistics, while patients will complete the questionnaire face to face with a doctor to enhance compliance and understanding. These measures are intended to ensure a higher response rate.

Conclusion

There is a lack of COS for TCM treatment of TTH; therefore, developing one is essential. This study will solve problems posed by nonstandard outcome indicators and limited measurement time, maximize the value of individual trial data, and provide high-quality research evidence for treating TTH with TCM.

Acknowledgments

We thank the patient advisers for contributing to the research. This research was supported by the project “Development and Research of Chaiqiong Qiwei Granules, a Class 1.1 Innovative Traditional Chinese Medicine for the Treatment of Tension-Type Headache” (XYZX0303-12), the Fundamental Research Funds for the Central public welfare research institutes (ZZ13-024-3), the Scientific and Technological Innovation Project of China Academy of Chinese Medical Sciences (CI2021B006), Capital’s Funds for Health Improvement and Research (No. 2020-2-4173), the National TCM Leading Personnel Support Program (NATCM Personnel and Education Department (2018; 12), the Innovation Team and Talents Cultivation Program of National Administration of Traditional Chinese Medicine (ZYYCXTD-C-202007), and the China Academy of Chinese Medical Sciences Innovation Fund (CI2021A01301 and CI2021A00911).

Authors' Contributions

GF, YC, Liang X, JW, and YZ conceived the study. CG, JW, and YZ provided insight into the tension-type headache patient experience. GF, YC, XF, XG, and WC contributed to the systematic review, and Teng J, Tang J, and Liao X provided supervision for all aspects of the manuscript. GF, YC, Liang X, JW, and YZ wrote the protocol and manuscript.

Abstract

Background: The exact cause of penile curvature in hypospadias remains unknown. Resection of the dartos fascia has been observed to straighten the penis, indicating the involvement of the dartos fascia in the superficial chordee. However, the characteristics of dartos tissue in the distal territory of the ventral penile shaft may differ from those in the proximal aspect of the penile shaft.

Objective: This study aims to investigate the distinct histopathological profiles and expression of COL1A1 (collagen type 1), COL3A1 (collagen type 3), and ELN (elastin) in proximal and distal ventral dartos of patients with hypospadias compared to those without hypospadias.

Methods: This prospective case-control study compares the ventral dartos tissue of patients with hypospadias at different locations with that of patients without hypospadias. Dartos samples will be taken during surgery, with age matching. Histopathology examination uses hematoxylin and eosin and Masson's trichrome stain. The mRNA expression of *COL1A1*, *COL3A1*, and *ELN* will be quantified using a 2-step reverse transcription–polymerase chain reaction analysis.

Results: Previous studies have documented different characteristics of dartos tissue between patients with hypospadias and those without hypospadias. Some studies even suggest resection of the dartos tissue during hypospadias repair. However, this is the first study to compare the characteristics of ventral dartos tissue in patients with hypospadias based on its location along the penile shaft, suggesting potential differences between the distal and proximal locations. We have obtained ethical approval to conduct a prospective case-control study aimed at elucidating these differences in dartos tissue characteristics. The findings of the study are anticipated to be available by 2025.

Conclusions: Differences in the characteristics of dartos fascia based on its location may require tailored surgical strategies. If the properties of distal dartos tissue closely mirror those of typical dartos tissue, the possibility of avoiding its excision during hypospadias surgery could be considered.

Introduction

Hypospadias is a common congenital malformation characterized by the displacement of the urethral meatus on the ventral side of the penis, incomplete ventral prepuce development, and penile curvature known as chordee [1-3]. Hypospadias represents the most prevalent form of penile deformity, with data indicating its occurrence in 1 out of every 125-300 male births [4-6]. The severity of this anomaly varies, with meatus locations ranging from the glans to the scrotum [3].

Hypospadias is typically categorized as either distal or proximal, depending on the location of the meatus [7]. Approximately 70% of cases are classified as distal hypospadias, typically considered as less severe [3,8]. However, certain variants of distal hypospadias may present with severe chordee, necessitating more intricate reconstruction procedures [9]. Chordee, one of the triads of hypospadias, can be further classified as either superficial or deep [6,10]. Superficial chordee involves the superficial fascia, whereas deep chordee affects deeper structures such as the deep fascia, urethral plate, corpus spongiosum, and tunica albuginea, and may involve a disproportion of corpora [10].

The exact cause of the chordee remains unknown. However, resection of the dartos fascia during hypospadias procedures has been observed to straighten the penis, indicating the involvement of the dartos fascia in the superficial chordee [11]. Changes in the structure of collagen (predominantly collagen type 1), reticulin (collagen type 3), and elastin components within the dartos fascia could influence its elasticity and mobility in cases of hypospadias [12]. Previous research has indicated that dartos fascia in hypospadias tends to be thicker and less elastic [13,14]. Dartos fascia also exhibited lower concentrations of collagen types 1, 2, and 3 compared to the normal control group [15].

Studies exploring the association between dartos fascia and chordee remain limited, primarily consisting of qualitative studies [16]. Some studies have suggested the resection of dartos fascia during hypospadias reconstruction surgery [15]. However, there is a lack of studies comparing the characteristics of ventral dartos in patients with hypospadias based on their location towards the meatus, classified as proximal and distal dartos. Variations in dartos fascia characteristics according to location may necessitate different surgical approaches. Therefore, this study aims to investigate the distinct histopathological profiles and expression of COL1A1 (collagen type 1), COL3A1 (collagen type 3), and ELN (elastin) in proximal and distal ventral dartos of patients with hypospadias compared to those with a normal penis.

Methods

Study Design

This study is a prospective case-control study comparing ventral dartos in cases of proximal and distal phenotypic variants of patients with hypospadias with dartos of patients without hypospadias. Dartos samples will be collected during hypospadias repair surgery (cases) and circumcision (controls), with the matching of ages between cases and controls and random allocation. The protocol has been developed in accordance with the 2013 SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) checklist for reporting protocol studies [17].

Study Population and Recruitment

Patients will be recruited from our university-affiliated academic tertiary care hospitals in Jakarta, Indonesia. The inclusion criteria for the cases are as follows: (1) male patients with prepuberty from 6 months to 9 years; (2) a confirmed diagnosis of hypospadias, established through physical examination by a pediatric urologist; and (3) undergoing hypospadias repair at our hospitals during the recruitment period. Conversely, the exclusion criteria for cases are specified as follows: (1) a history of previous hypospadias repair, (2) inadequate tissue samples for analysis, and (3) undescended testis.

The inclusion criteria for the control group consist of (1) male patients with prepuberty from 6 months to 9 years, (2) confirmation of a normal penile condition through a physical examination conducted by a urologist, and (3) undergoing circumcision at our hospitals during the recruitment period. Conversely, the exclusion criteria for controls are outlined as follows: (1) a history of previous genital surgery, (2) insufficient tissue samples for analysis, and (3) undescended testis.

Participants meeting the inclusion criteria and not meeting any of the exclusion criteria will be invited to participate in the study as either cases or controls. According to the sample size formula (5% α and 20% β), each group requires approximately 50 patients (rounded up from 43.18). Considering our patient volume, we anticipate completing recruitment within a 9- to 12-month time frame.

Data Collection

The following data will be collected:

- Patient demographics: information such as age and socioeconomic status.

- Clinical variables: detailed medical history, associated comorbidities, family history, and birth weight.
- Phenotypic data being captured: location of the urethral opening, plate objective screening tool, urethral defect ratio, penile curvature assessment, and glans-urethral meatus-shaft hypospadias score.

Location of Urethral Opening

The location of the urethral opening is given in Figure 1 [18].

Figure 1. Location of the urethral opening.

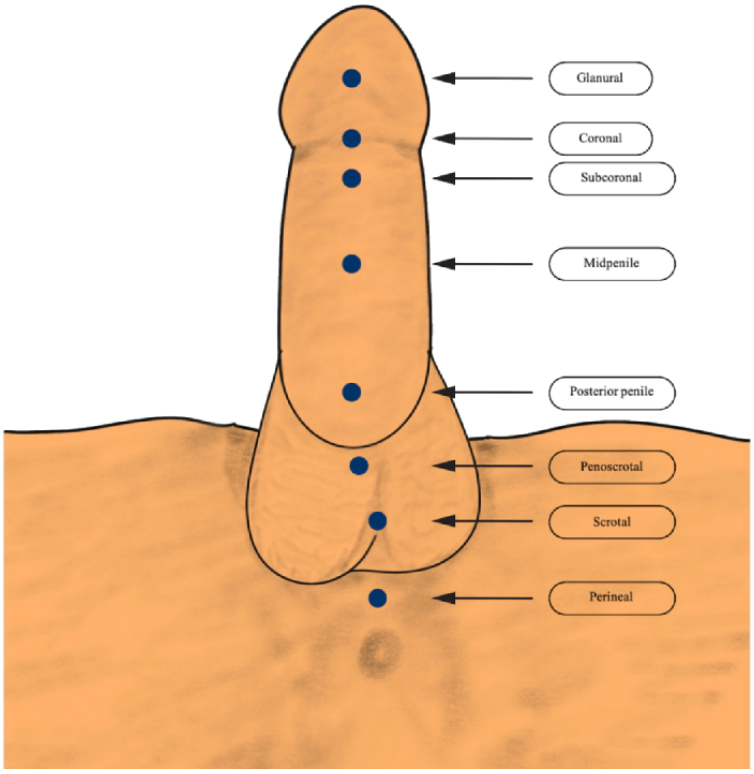

Plate Objective Scoring Tool

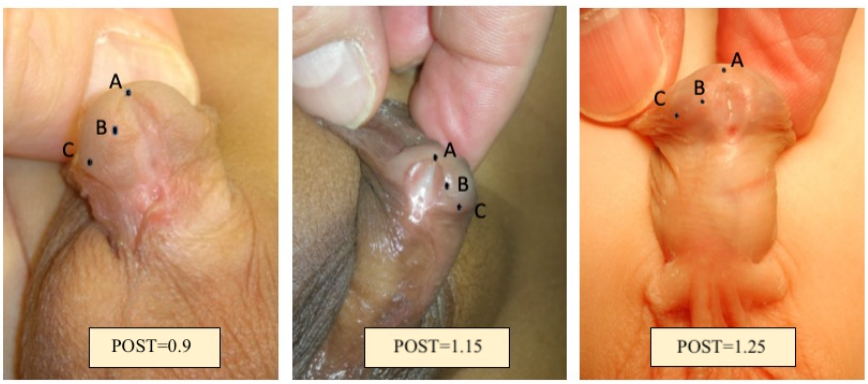
Plate objective scoring tool (POST) score is shown in Figure 2 [19,20]. The distal extent of the urethral plate at the midline is identified as point A. The glanular knob, where the mucosal edge of the plate changes direction, is marked as point B, while the glanular-coronal junction is designated as point C. The distance from point A to point B represents the neomeatal length, while the distance from point B to point C indicates the length of the prospective glanular fusion. The POST score has been used to quantify the urethral plate quality in distal hypospadias. This tool's correlation with postrepair complications underscores its relevance in optimizing surgical outcomes [20].

Figure 2. Plate objective scoring tool score calculation (AB/BC). POST: Plate objective scoring tool.

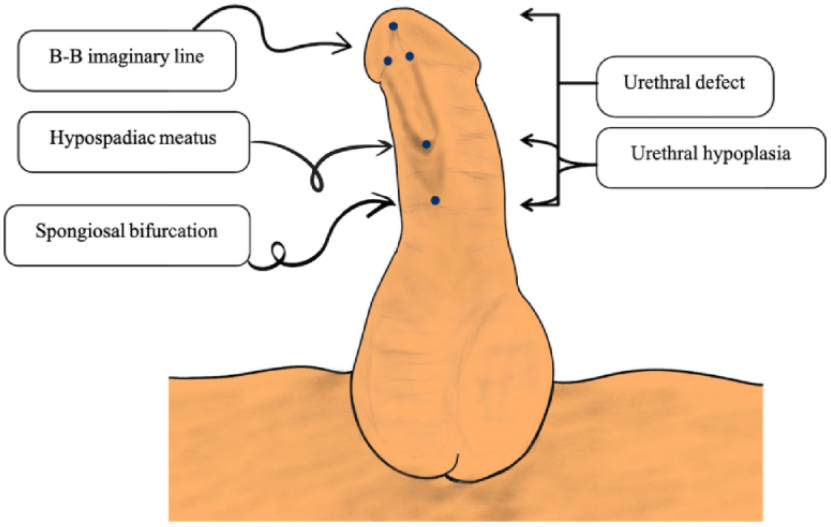


Urethral Defect Ratio

Urethral defect ratio (UDR), which is illustrated in Figure 3, is an objective hypospadias classification system [21]. The stretched penile length is measured along the lateral aspect of the penile shaft, extending from the tip of the glans to the superior border of the pubic bone. Stretching is facilitated using a stay suture in conjunction with a metal ruler. The bifurcation site of the corpus spongiosum penile curvature is evaluated following complete degloving of the penile skin. The distance between the glandular knobs (B–B imaginary line) and the bifurcation site of the corpus spongiosum penile curvature is

defined as the urethral defect, and the UDR is calculated by dividing UD by stretched penile length [21].

Figure 3. Urethral defect ratio. B–B: the distance between the glandular knobs.



Penile Curvature Assessment

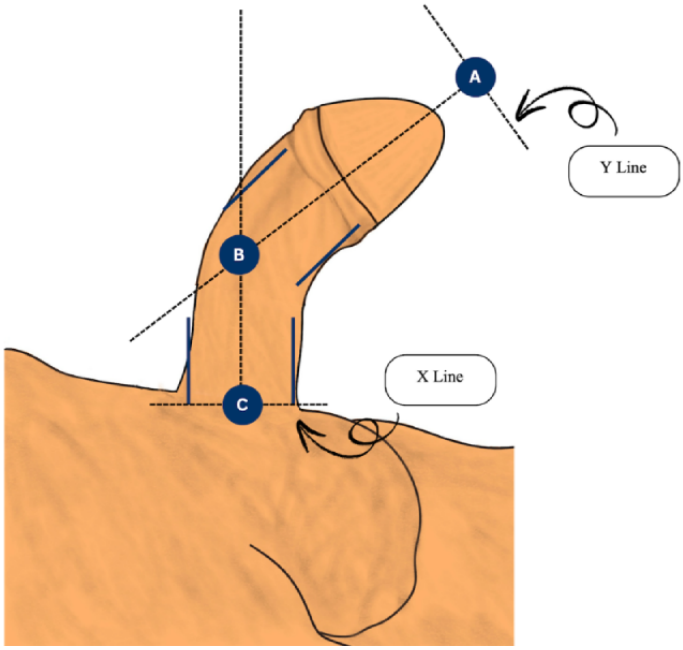
Penile curvature assessment is shown in Figure 4 [22]. To evaluate penile curvature intraoperatively, we have established a standardized protocol using mobile apps. This involves capturing a lateral photograph of the penis from a distance of 25-30 cm, ensuring alignment parallel to the penile shaft, and incorporating an upward oblique angle between 10° and 30° along the same vertical axis. The captured image is subsequently processed using specialized software, such as Angle Meter 360, where 3 critical anatomical landmarks are marked: the penile base, the point of angulation, and the distal midpoint.

In Figure 4, three key reference points are established for measurement: (1) corresponds to the intersection of the midline axis of the distal penile shaft with the Y-line, defined as a perpendicular line originating from the tip of the glans, (2) represents the intersection of the midline axes of the proximal and distal segments of the penile shaft, and (3) signifies the intersection of the midline axis of the proximal penile shaft with the X-line, a perpendicular line drawn at the level of the pubic bone. The degree of penile curvature is calculated by subtracting the measured angle from 180°.

Glans-Urethral Meatus-Shaft Hypospadias Score.

In the glans-urethral meatus-shaft (GMS) scoring system, each of its 3 components is assigned a numerical value ranging from 1 to 4 [23]. The total GMS score can range from a minimum of 3, indicative of very mild hypospadias, to a maximum of 12, representing severe hypospadias. Studies have demonstrated its predictive value for postoperative complications, highlighting its utility in guiding surgical decision-making [24].

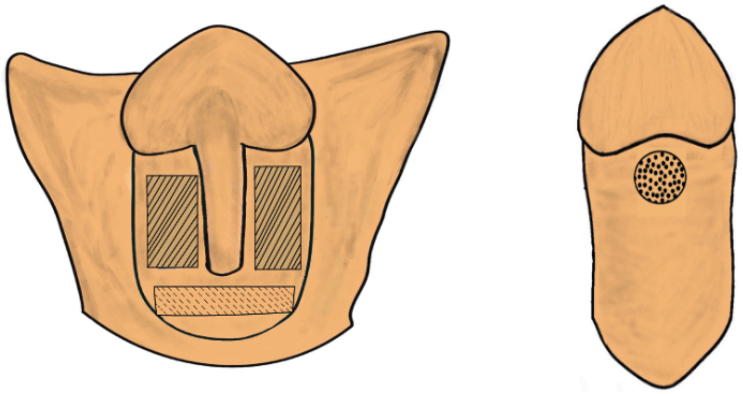
Figure 4. Penile curvature assessment. The distal midpoint (A); the point of angulation (B); and the penile base (C).



Dartos Fascia Sampling

Dartos fascia samples are obtained following penile degloving in the hypospadias group. The dartos tissue is collected from the ventral side at two distinct locations: distal to the urethral meatus (distal to spongiosa bifurcation) and proximal to the urethral meatus (proximal to spongiosa bifurcation). Conversely, in the control group, dartos tissue is acquired from the ventral side coronal area. The illustration of the samples' location is shown in Figure 5. The size of dartos tissue collected at each location ranges from 25 to 100 mm^2. To mitigate collection bias, all samples are obtained by a single surgeon.

Figure 5. Dartos fascia sampling in the hypospadias group (solid line: distal dartos, dashed line: proximal dartos) and control group (circle).



Histopathology Preparation

Dartos samples will be immersed in a 10% buffered formaldehyde solution for fixation. Subsequently, the fixed tissue will undergo dehydration, infiltration, and embedding in liquid paraffin to achieve solidification. The paraffin-embedded blocks will then be sectioned using a microtome at a thickness of 4-5 µm and mounted onto glass slides. Two distinct staining methods, namely hematoxylin and eosin and Masson's trichrome stain, will be used to assess the cross-sectional area and collagen percentage of the dartos tissue. All histopathological assessments and quantifications will be conducted in a blinded manner using the QuPath software.

Reverse Transcription–Polymerase Chain Reaction Analysis

Messenger ribonucleic acid expression levels of collagen genes (*COL1A1* and *COL3A1*) and elastin gene (*ELN*) will be quantified through a two-step reverse transcription–polymerase chain reaction analysis. Dartos tissue samples will be preserved with RNA later, followed by total RNA extraction using an RNA extraction kit. Subsequently, the extracted RNA will undergo reverse transcription to synthesize complementary deoxyribonucleic acid, which will then be amplified via PCR to detect the expression levels of the target genes.

Statistical Analysis

All data will undergo analysis using SPSS (version 24.0; IBM Corp) software. Descriptive statistics will be used, presenting frequency for categorical variables and mean or median for numerical variables. Comparative analysis of collagen percentage and expression of *COL1A1*, *COL3A1*, and *ELN* among proximal hypospadias dartos, distal hypospadias dartos, and normal dartos will be conducted using either 1-Way ANOVA or Kruskal-Wallis test, contingent upon the normality of data distribution. Post hoc analysis may use the Bonferroni test, Games-Howell test, or Mann-Whitney test as deemed appropriate. Subanalysis based on hypospadias classification (distal and proximal) and chordee severity (mild, moderate, or severe) will also be performed. Subanalysis based on the UDR and POST scores will also be performed [17].

Ethical Considerations

The Medical Research Ethics Committee at Universitas Indonesia approved our study protocol in March 2024 (KET-473/UN2.F1/ETIK/PPM.00.02/2024). Participants and/or their guardians will receive comprehensive information both verbally and in writing to ensure informed consent. Upon choosing to participate, they will be requested to sign the informed consent form.

Results

Previous studies have documented different characteristics of dartos tissue between hypospadias and patients without hypospadias [11,13-15]. Some studies even suggest resection of the dartos tissue during hypospadias repair [15]. However, no previous study has systematically compared the distinct characteristics of proximal and distal dartos tissue in patients with hypospadias. We have obtained ethical approval to conduct a prospective case-control study aimed at elucidating these differences in dartos tissue characteristics. The findings of the study are anticipated to be available by 2025.

Discussion

Anticipated Findings

The exact etiology of chordee in hypospadias remains unknown. Nonetheless, inadequate management of chordee during hypospadias repair may escalate the incidence of complications. Moreover, significant chordee can impede sexual function in later adulthood [10]. The aberrant curvature may result in ineffective insemination, painful erections, or hindered vaginal insertion. Therefore, meticulous management of chordee in hypospadias is imperative [18].

Numerous studies have indicated abnormalities in dartos tissue in hypospadias [11,13-15]. Surgical procedures involving penile

degloving and dartos tissue excision have been proposed to alleviate superficial chordee [15,18]. However, our preliminary observations during hypospadias surgery have revealed distinct characteristics between the dartos tissue located proximally and distally to the meatus. Specifically, we have noted that the proximal dartos tissue tends to exhibit greater thickness and reduced elasticity, potentially contributing to superficial chordee. Consequently, we aim to conduct a comparative analysis of the extracellular matrix properties of distal and proximal dartos tissue in this study. Variations in dartos fascia characteristics according to location may necessitate different surgical approaches. Should the characteristics of the distal dartos resemble those of normal dartos tissue, sparing its resection during hypospadias surgery may be feasible. Using the distal dartos as a secondary layer for neourethral coverage could potentially enhance surgical outcomes.

Conclusion

Differences in the characteristics of dartos fascia based on its location may require tailored surgical strategies. If the properties of distal dartos tissue closely mirror those of typical dartos tissue, the possibility of avoiding its excision during hypospadias surgery could be considered.

Acknowledgments

This research is funded by the Directorate of Research and Development, Universitas Indonesia under Hibah PUTI 2024 (grant number 635). Funding for the completion of this study will be pursued through additional noncommercial grant applications.

Abstract

Background: Rheumatoid arthritis (RA) is an autoimmune disease that affects joints and can have extra-articular manifestations. RA usually tends to be progressive and leads to substantial health care burdens, both in terms of disability and economic costs. Despite the various treatment modalities available, there is still an urgent need for safe and effective medicine based on the pattern of disease presentation. The increasing interest in complementary and alternative medicine has created a demand for extensive research in this area.

Objective: This clinical study is designed to evaluate the effectiveness and tolerability of a composite Ayurveda regimen in RA.

Methods: The study is a single-arm (pre-post design), community-based interventional study with a black box design being conducted at 6 study centers. A total of 240 participants aged between 18 and 65 years, diagnosed with RA as per the 2010 American College of Rheumatology and the European League Against Rheumatism criteria are recruited as per the selection criteria. All the participants received Ayush-SG and *Rasnasaptak Kashaya* for 84 days along with customized treatment as per the disease presentation and associated complaints. The outcome measures include the change in disease activity score (DAS)-28 with erythrocyte sedimentation rate, disease-specific biochemical and inflammatory markers, Disability Index score, change in the participant's assessment of pain and frequency of use of conventional analgesics or nonsteroidal anti-inflammatory drugs from baseline. The tolerability of interventions is assessed through the occurrence of adverse events. Categorical variables will be analyzed with McNemar chi-square test, and continuous variables will be assessed using the paired *t* test or Wilcoxon test for pre-post assessment. The level of significance will be 5%.

Results: The recruitment of participants was initiated in December 2023. The participant recruitment was completed in March 2024 and out of 240 participants enrolled, 222 (92.5%) completed the study up to the last follow-up. Data verification, compilation, and analysis are under process. After data analysis, the study's findings will be published in a peer-reviewed journal.

Conclusions: This interventional study that incorporates the black box approach may provide a strong framework for managing RA. This design is a more reliable method for evaluating the effectiveness and tolerability of the composite Ayurveda regimen in RA.

Introduction

Background

Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease that can damage joints and affect extra-articular organs. In 2019, 18 million people worldwide were living with RA. Women accounted for 70% of cases, and over half were older than 55 years [1]. The articular manifestation of RA includes symptoms such as musculoskeletal pain, swelling, and stiffness of joints. It is usually symmetric and initially manifests in small joints and progresses to larger joints. Over time, joint inflammation can lead to joint destruction, including loss of cartilage and bone erosion [2]. The symptoms of RA vary in patients; some patients have mild self-limited disease, while many experience joint destruction, severe physical disability, and multiple comorbidities. RA tends to be progressive in nature, involving a worsening of symptoms over time, and often begins for many people during the early or middle years of life, thus causing a heavy burden on society in terms of disability, health, and economic costs. The available evidence for pain management in RA involves the use of disease-modifying antirheumatic drugs and medications such as nonsteroidal anti-inflammatory drugs (NSAIDs) which play an important role in its management but may suppress the immune system and, lead to an increased risk of infections as well other side effects as gastrointestinal disturbances [3,4]. People from all over the world are also developing an interest in traditional herbal practices. It is reported that 60% to 90% of persons with arthritic conditions use complementary and alternative medicines [5-7]. In a study conducted in the United States, it was reported that around 60% of persons with arthritic conditions including RA use complementary and alternative medicines. Of these, 28% reported a history of herbal therapies, and 22% used diet supplements [8].

RA resembles the condition *"Amavata"* (rheumatism due to Ama) described in Ayurveda, where both the *Ama* (undigested or intermediate product of digestion or metabolism that act as a toxin in the body) and *Vata Dosha* (*Dosha* responsible for movement and cognition) become vitiated and located in the *Sandhi* (joints) leading to pain and inflammation in the joints. The causative factors of Amavata are described as *Viruddha Ahaara* (antagonistic food), *Viruddha Vihaara* (antagonistic lifestyle), *Mandagni* (subdued digestive power), a sedentary lifestyle, and exercising immediately after meals. Long-term adherence to these etiological factors causes vitiation of *Vata* along with impaired digestion and metabolism in the body leading to the formation of *Ama*. The gradual accumulation of *Ama* obstructs different *Srotas* (structural or functional channels) in the body and further vitiation of *Tridoshas* (3 regulatory functional factors of the body). The Ama and Vata along with other vitiated Doshas lead to the impairment of *Dhatus* (major structural components of the body) mainly joints causing the *Amavata* [9].

The Ayurvedic classics describe various treatment modalities and therapeutic formulations based on the condition and clinical presentation of the disease. The disease pattern of *Amavata* in a person depends on the extent of *Ama* association, *Dosha* vitiation, and the chronicity of the condition. In cases of *Amavata* with significant *Ama* association, there may be obstructions in the *Srotas*, leading to symptoms like severe pain, swelling, elevated temperature, and redness in the joints. The treatment for this scenario should prioritize digesting *Ama* and clearing the obstructions in the *Srotas* along with alleviation of vitiated *Dosha*. If there is only mild *Ama* association and less *Dosha* imbalance, symptoms may be limited to joint pain, stiffness, and minimal swelling, indicating medications that digest *Ama* and alleviate *Doshas* predominantly *Vata*. In chronic cases, patients may experience symptoms like mild aching stiffness, fatigue, or anemia. The choice of medicines varies according to each pattern of presentation and must be determined by the practitioner following a thorough assessment of the patient's condition. In a standard randomized controlled trial (RCT), it is not feasible to design a customized regimen that tailors medicine selection to specific conditions. In such instances, a specialized trial design should be considered to facilitate the prescription of medicines tailored to the clinical manifestations and disease stage of each individual. To address this issue, it is essential to consider modifying study designs, including exploring alternative approaches such as "black-box" designs [10].

The treatment plan for *Amavata* is focused on the digestion of *Ama* and the alleviation of *Vata*. For digesting the *Ama* and removing obstruction from the *Srotas*, drugs having *Katu* and *Tikta* Rasa (pungent and bitter tastes), *Pachana* (enhancing digestion), and *Dipana* (enhancing metabolic fire) properties have to be administered [11]. Ayush-SG, *Rasnasaptak Kashaya*, and *Guduci* (*Tinospora cordifolia*) have the above-said properties. Ayush-SG is a coded drug developed by the Central Council for Research in Ayurvedic Sciences (CCRAS) for the management of Amavata [12]. *Rasnasaptak Kashaya* is described in the context of *Amavata* treatment in Ayurveda classics [13]. *Brihat Saindhawadi Taila* and *Dashang Lepa* are used for local application to pacify pain and inflammation of the joints [14-16]. Considering the major patterns of disease presentations, a black box design has been planned for this study and the treatment has been tailored according to the accompanying symptoms.

Objectives

The primary objective of the study is to evaluate the effectiveness of a composite Ayurveda regimen on the disease activity score (DAS) in RA.

The secondary objective is to evaluate the effectiveness of the composite Ayurveda regimen on the disease-specific biochemical and inflammatory markers and assess the tolerability of Ayurveda regimen in RA.

Methods

Study Design

This is a single-arm (pre-post design), community-based interventional study with a black-box research design.

Study Setting

The study is conducted through 6 research institutes under CCRAS at New Delhi, Patiala, Guwahati, Gwalior, Vijayawada, and Chennai in identified areas predominantly dwelled by the scheduled caste population near the institute.

Inclusion Criteria

Participants aged between 18 and 65 years, diagnosed with RA as per the 2010 American College of Rheumatology and the European League Against Rheumatism criteria [17], and willing to give written informed consent for participation are enrolled in the study.

Exclusion Criteria

Participants presenting with complications of RA, for example, deformity of joints/bones, pleura-pericardial disease, participants with extra-articular manifestations of RA and gastrointestinal symptoms, those with joint prosthesis or unable to walk without support or confined to a wheelchair, participants with Hemoglobin <8 g/dL, diagnosed with other arthritis like osteoarthritis, gouty arthritis, tuberculous arthritis, psoriatic arthritis, spondyloarthropathy, active fibromyalgia, juvenile chronic arthritis, ulcerative colitis, or other systemic inflammatory conditions and autoimmune diseases, having blood pressure ≥ 160/100 mm Hg, or hemoglobin A_{1c} (HbA_{1c})>8%, on medication with corticosteroids, antidepressants, anticholinergics, etc or Ayush interventions/folk medicine or any other drugs that may influence the outcome of the study are excluded from the study. Participants with diagnosed concurrent neurological, pulmonary, or endocrine disorder, or unstable cardiovascular disease, with concurrent serious hepatic disorder (defined as aspartate aminotransferase or alanine aminotransferase, total bilirubin, alkaline phosphatase > 2 times upper normal limit) or renal disorders (defined as S Creatinine > upper normal limit); participants with alcohol use disorder (CAGE score >2) or any other substance abuse; and pregnant or lactating woman are not enrolled in the study.

Study Procedure

The participants have been screened from the out-patient departments, camps, or door-to-door visits in the identified areas. Before the initiation of the study, the head of the village or local administrative authority and the residents of the area were informed about the study in detail, in their regional language. Participants diagnosed with RA have been enrolled based on the defined inclusion and exclusion criteria.

Laboratory investigations such as complete blood count with an erythrocyte sedimentation rate (ESR), liver function test, renal function test, and C-reactive protein, RA factor (quantitative), serum immunoglobulin G, and serum immunoglobulin M have been conducted at baseline and the end of the treatment (84th day). HbA_{1c} levels are determined at baseline only (Figure 1).

Figure 1. Flow diagram depicting the study schedule for the assessment of the effectiveness of composite Ayurveda regimen for the management of rheumatoid arthritis. ADR: Adverse Drug Reaction; DAS: disease activity score; ESR: erythrocyte sedimentation rate; VAS: visual analog scale.

Intervention

The treatment regime was customized based on the major patterns of disease presentation in each participant. All of them have been given oral medication Ayush-SG one gram in tablet form twice a day with lukewarm water after meals and *Rasnasaptak Kashaya* 20 mL twice a day (80 mL water added in 10 g of course powder and boiled until remains 20 mL) before meals for 12 weeks. Along with this, *Brihat Saindhavadi Taila* has been given for local application in cases with only articular manifestations (joint pain, stiffness, and minimal swelling). Participants with severe pain and swelling (boggy swelling or affusion elicited by fluctuation test), elevated body or joint temperature, and redness of joint, have been administered *Guduchi Ghana vati* (*Sanshamani Vati*) orally in the dose of 500 mg twice a day with lukewarm water after meals and

Dashanga Lepa for local application. *Punarnavadi Mandura* has been given orally in a dose of 500 mg twice a day with lukewarm water after meals in participants with mild aching, stiffness, fatigue, and anemia.

Incidental medication has been given to the participants in case of any associated complaints. For constipation, *Triphala Churna* has been given in a dose of 5 g orally with lukewarm water at night before sleep. For *Mandagni*, *Vaishwanar Churna* has been administered in a 2.5 g dose orally with lukewarm water twice a day just after food. For the participants having insomnia/anxiety, *Ashwagandha Churna*, 3 g has been given orally twice a day. The duration of incidental medication is decided by the investigator as per the requirement.

The medicines were purchased from Ayurveda manufacturing pharmacies that are certified with good manufacturing practices. Ayush-SG was procured from the Central Ayurveda Research Institute's Ayurveda Pharmacy, Jhansi, Uttar Pradesh, India. All other medicines administered in the study were procured from the Indian Medicines Pharmaceutical Corporation Limited (Mohan, Almora, Uttarakhand, India).

Withdrawal Criteria

The participant has been withdrawn from the study if they have not been willing to continue, if there has been a worsening of RA symptoms, or if they have developed any other illness mentioned in the exclusion criteria. The decision to withdraw a participant from the study has been made solely by the Investigator, who has then had to provide a detailed justification and indicate the line of further management if needed.

In the case of any adverse event, serious adverse event, or adverse drug reaction, the Institutional Ethics Committee (IEC) and Data Safety Monitoring Board are to be informed and participants are to be withdrawn from the study.

Compliance

During the intervention period, compliance has been evaluated based on the amount of study medication that is consumed. This has been assessed using a compliance assessment form issued to the participants to fill up.

Concomitant and Rescue Medication

Concomitant therapy has been continued for diabetes mellitus, hypertension, or any other disease, that has not been specifically mentioned in the exclusion criteria**.** The investigators may prescribe any concomitant medications or treatments deemed necessary to provide adequate supportive care during the intervention period**.** The name, indication, dose, unit, frequency, start date, and stop date (if applicable) for all interventions (medicine/procedure/therapy) have been recorded on each participant's case record form (CRF)**.** Administration of any rescue medicines in case of any medical emergency has been documented in the CRF.

Outcome Measures

The primary outcome of the study is the change in the DAS-28 score (with ESR) [18] and it is assessed at baseline and the end of the treatment (84th day). Secondary outcomes include the change in disease-specific biochemical and inflammatory markers (RA factor, C-reactive protein, and ESR) and serum immunoglobulin levels (Immunoglobulin G and Immunoglobulin M), participants' assessment of Pain, Global assessment of disease activity, change in Disability Index score and frequency of use of conventional analgesic/NSAIDs medicines and occurrence of adverse events if any. The change in disease-specific biochemical and inflammatory markers and serum immunoglobulin levels are assessed at baseline and on the 84th day. The participants' assessments for pain and global assessment of disease activity are assessed using the visual analog scale [19] ranging from 0 mm (no pain) to 100 mm (worst possible pain) at baseline, 28th day, 56th day, and 84th day. The change in Disability Index score is assessed using the Indian Health Assessment Questionnaire [20] at baseline, 28th day, 56th day, and 84th day. The frequency of use of conventional analgesic/NSAIDs medicines and occurrence of adverse events are also assessed in a time frame of baseline, 28th day, 56th day, and 84th day (Figure 1).

Sample Size

Due to the low prevalence of RA (around 0.7% to 1%) [21], it is not feasible to recruit the participants based on the scientific line of sample size theory. Therefore, based on feasibility and the availability of resources, a total of 240 participants have been recruited from 6 institutes (40 participants at each center), within the given time frame.

Recruitment

The eligible participants have been screened for inclusion and exclusion criteria from the outreach out-patient departments/ camps/door-to-door visits conducted in the identified area/ village under the selected study sites. The participants have been informed about the study in detail (in their regional language) through banners and IEC materials.

Allocation

Since the study is conducted in a black box study design and the intervention is classified based on major disease patterns, allocation does not apply to this study.

Data Collection Methods

Demographic data, clinical history, details of concomitant medications, the score of 2010 American College of Rheumatology and the European League Against Rheumatism criteria, DAS-28, and other assessment parameters of the participants have been recorded in the CRF. The participants were followed up on the 28th day, the 56th day, and the 84th day**.** During follow-ups, the occurrence of any symptom and the need for any rescue medication have been recorded. The contact number of the investigator along with the address of the CCRAS institute have been provided to the participants at the time of enrollment**.** Participants have been instructed to inform about any adverse event that happens during the study period**.**

Besides a hard copy of CRF, the data have been recorded in e-CRF also. All source documentation supporting entries into the CRFs are maintained and will be kept readily available. To ensure the quality, the data are checked for consistency, omissions, and any apparent discrepancies. The reason for

withdrawal or dropping out of participation is recorded in the CRF.

Data Monitoring

A Data Safety Monitoring Board has been constituted to monitor the clinical study and to ensure the safety of the participants. The inspection of various records of the clinical study (CRFs and other pertinent data) will be done by the CCRAS representatives and regulatory authority to ensure strict adherence to the study protocol and correct documentation of the data. Any problems faced by the research staff at the participating site have been addressed timely. The Clinical Monitoring Committee is responsible for verifying the CRFs at regular intervals throughout the study to verify adherence to the protocol; completeness, accuracy, and consistency of the data; and adherence to local regulations on the conduct of clinical research.

Deviation From the Protocol

Any deviation from the study protocol is implemented in the study only after approval from the IEC.

Ethical Considerations

The study is conducted according to the national ethical guidelines for biomedical and health research involving human participants (2017) by the Indian Council of Medical Research; and Good Clinical Practice guidelines for clinical trials in Ayurveda, Siddha, and Unani Medicine, 2013. Approval from the IEC of all the concerned institutes has been obtained, and the study has been registered with the Clinical Trial Registry-India (CTRI/2023/06/054203 dated June 20, 2023). The participants have been educated by the investigator verbally and using a written patient information sheet in their regional language and have been asked to provide consent in writing regarding their participation in the study. The participants have been made aware that they are free to leave the study if they wish to discontinue without giving a reason, and without my medical care or legal rights being affected. All the information and records of the study participants including their names and identities are kept confidential in password-protected Microsoft Excel sheets. All the study participants are covered by a clinical trial insurance policy which included coverage for any adverse events occurring during the study.

Statistical Analysis

After data collection, verification of its accuracy and limits will be done. The filtered data will be used for additional analysis and interpretation. The Categorical variables will be reported in number (percentage) and analysis of pre-post-trial outcomes will be done by the Mc-Nemar chi-square test. The continuous variables (like scores and lab parameters) will be analyzed by paired *t* test/Wilcoxon test as per the distribution of data in the pre-post trial situation. The assessment parameters assigned in more than 2 follow-ups will be analyzed using the r-ANOVA/Friedman test/ Cochran Q test. The continuous data having normal distribution will be represented as mean (SD) and the data not having normal distribution as median (IQR). The 5% level of significance will be used throughout the analysis. The SPSS (version 26.0; IBM Corp) software will be used to conduct the analysis.

Results

The enrolment of the participants in the study was initiated in December 2023 and the final follow-up was completed in March 2024. Out of 240 participants enrolled, 222 (92.5%) participants have completed the study. Data verification, compilation, and analysis are under process. The findings from the study will be published in peer-reviewed journals after the completion of data analysis.

Discussion

Expected Findings

The selected composite Ayurvedic regimen is anticipated to reduce DASs in study participants with RA. This study was designed using a black box approach, which allows for the selection of medicine according to the pattern of disease presentation and associated symptoms instead of evaluating a specific medicine for a particular diagnosis [10].

Ayurvedic approach to treating a disease depends on the breaking of pathogenesis and alleviation of symptoms. The selection of medicines depends on different stages of pathogenesis that are usually assessed by the presentation of the disease. The available studies for the evaluation of Ayurvedic interventions in rheumatoid mostly used study designs such as single-arm studies, non-RCTs, and RCTs using controls from either Ayurveda or modern conventional drugs [22-25]. In these studies, the intervention was the same for all participants diagnosed with RA and did not consider differences in clinical conditions or the relationships with *Dosha* or *Ama*. Furst et al [26] have used modified RCT as a double-blind, randomized, double-dummy design to evaluate the efficacy of Ayurvedic medicines, both alone and in combination with the standard drug, methotrexate. In this study, 148 distinct Ayurvedic formulations with various dosage forms were used, allowing physicians to prescribe the appropriate combination of drugs based on the specific needs of the patient [26]. In our study, we have designed a single-arm black box design that allows the management of RA in different clinical manifestations on the basis of pathogenesis in terms of the association of *Ama* and *Dosha* along with the chronicity of the disease. For this, a predefined composite Ayurvedic regimen was used that is anticipated to reduce DASs in study participants with RA along with a change in disease-specific biochemical markers. Ayush-SG and *Rasnasaptak Kashaya* were given to all participants, while other medications were customized as per the form of disease presentation.

Ayush-SG contains 3 main ingredients as follows: *Shunthi* (*Zingiber officinale* Roscoe), *Guggulu* (*Commiphora wightii* Bhan), and *Godanti Bhasma* (Incinerated calcium sulfate/ gypsum) [12]. *Shunthi* is known to have anti-inflammatory, analgesic, immunomodulatory, and antioxidant activities [27]. Studies show that guggulipid, the oleo-gum resin of the plant *Commiphora wightii*, demonstrates significant antiarthritic and anti-inflammatory effects by targeting key molecular pathways involved in inflammatory responses [28,29]. *Rasnasaptak Kashaya* contains *Shunthi* along with other herbal ingredients such as *Rasna* (*Pluchea lanceolata* Oliver and Hiem), *Gokshura*

(*Tribulus terrestris* L), *Guduci* (*Tinospora cordifolia* [Willd] Miers), *Punarnava* (*Boerhaavia diffusa* Linn), *Eranda* (*Ricinus communis* Linn), *Devadaru* (*Cedrus deodara* [Roxb] Loud), and *Aragvadha* (*Cassia fistula* Linn). All these drugs possess anti-inflammatory activities and *Gokshura*, *Eranda*, and *Devadaru* have analgesic properties also. *Rasna* and *Guduci* have antiarthritic and *Aragvadha* has antirheumatic properties additionally [30-36]. A previous study on *Vatari Guggulu*, *Rasnasaptak Kashaya*, and *Brihat Saindhavadi Taila* has shown a significant change in DAS-28, disability index (Indian Health Assessment Questionnaire), and quality of life assessment (SF-36) scores when administered for 12 weeks [37].

Guduci Ghanavati contains an aqueous extract of *Tinospora cordifolia*, which possesses antiarthritic, anti-inflammatory, immunomodulatory, and antipyretic properties. The in vivo studies on aqueous extract of *T cordifolia* showed significant anti-inflammatory effects comparable with indomethacin and the mode of action is opined to be similar to that of a nonsteroidal anti-inflammatory agent [36].

Brihat Saindhavadi Taila is described as effective in pacifying pain in Amavata [37]. It is found effective in alleviating pain, swelling, and tenderness when administered locally in combination with other internal medications [14,38]. Most of the ingredients in this formulation possess anti-inflammatory properties [39-44]. *Eranda*, the base oil in the formulation, contains ricinoleic acid that has shown anti-inflammatory properties on peripheral application in an in vivo study in guinea pigs [45].

Dashanga lepa consists of 10 ingredients as follows: *Sirisha* (*Albizzia lebbeck* Benth), *Madhuyashti* (*Glycyrrhiza glabra* Linn), *Tagara* (*Valeriana wallichii* DC), *Raktachandanam* (*Pterocarpus santalinus* Linn), *Ela* (*Elettaria cardamomum* [Linn] Maton), *Jatamansi* (*Nardostachys jatamansi* DC), *Haridra* (*Curcuma longa* Linn), *Daruharidra* (*Berberis aristata* DC), *Kushta* (*Saussurea lappa* CB Clarke), and *Hrivera* (*Pavonia odorata* Willd). Most of the ingredients in this formulation have potent anti-inflammatory properties, and *Tagara* and *Jatamansi* have analgesic action too [46-54]. The anti-inflammatory and analgesic activities of *Dashanga Yoga/lepa* have been demonstrated in an in vivo study conducted on Wistar rats [55].

Anemia is one of the common comorbidities found in RA patients [56]. *Punarnavadi Mandura* contains ingredients such as *Amalaki* (*Phylanthus embelica* Linn), *Danti* (*Baliospermum montanum* Muell – Arg), *Pippali* (*Piper longum* Linn), *Punarnava*, *Kushtha* (*Saussurea lappa* C.B. Clarke) and *Daruharidra* (*Berberis aristata* DC) along with a mineral drug *Mandura bhasma* (incinerated iron oxide). An in vivo study conducted on *Punarnavadi Mandura* has shown significant hematinic activity against mercuric chloride-induced anemia in albino rats [57]. A previous clinical study on the drug also showed significant improvement in serum iron and serum ferritin levels with improvement in the symptoms of anemia such as fatigue, pallor, etc [58].

The pharmacological properties of the ingredients in the formulations and previous studies suggest that the selected composite Ayurveda regimen for the study will be effective in the management of RA. The findings from the study will be disseminated through reputed peer-reviewed journals after the completion of the data analysis. This research represents an initial effort using a black box design, which could lay the groundwork for customized interventions rooted in Ayurvedic concepts of pathogenesis and symptomatology.

Strength and Limitations

This study is planned using a black box design that will help in providing evidence-based data regarding the effect of personalized medications in Ayurveda for the management of RA. However, the study protocol has some limitations also. The study protocol does not include the assessment of inflammatory markers such as anticyclic citrullinated peptide. In this study, 3 distinct categories are considered for the composite Ayurvedic regimen. Future research could be designed to address a wider variety of disease presentations.

Future Scope

This study protocol could be extended to similar conditions that are presented with a wide range of symptoms that require a more individualized approach. Future RCTs may be planned to compare the Ayurveda treatment regimen with conventional standard treatment protocol.

Conclusions

This interventional study that incorporates the black box approach may provide a strong framework for managing RA. This design may be a more reliable method for evaluating the effectiveness and tolerability of the composite Ayurveda regimen in RA.

Acknowledgments

The authors wish to acknowledge the project team at the Central Council for Research in Ayurvedic Sciences (CCRAS) headquarters for their technical support during the drafting of the protocol. CCRAS, under the Ministry of Ayush, Government of India, New Delhi, has funded this study (CCRAS Headquarters, 61-65 Institutional Area, Opp. D Block, Janakpuri, New Delhi 110058). All authors declared that they had insufficient funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this article.

Conflicts of Interest

None declared.

Abstract

Background: The incidence of many common chronic childhood conditions has increased globally in the past few decades, which has been suggested to be potentially attributed to antibiotic overuse leading to dysbiosis in the gut microbiome.

Objective: This linkage study will assess the role of antibiotic use in utero and in early life in the development of type 1 diabetes (T1D), attention-deficit/hyperactive disorder (ADHD), and inflammatory bowel disease.

Methods: The study design involves several retrospective cohort studies using linked administrative health and social data from Statistics New Zealand's Integrated Data Infrastructure. It uses data from all children who were born in New Zealand between October 2005 and December 2010 (N=334,204) and their mothers. Children's antibiotic use is identified for 4 time periods (at pregnancy, at ≤1 year, at ≤2 years, and at ≤5 years), and the development of T1D, ADHD, and inflammatory bowel disease is measured from the end of the antibiotic use periods until death, emigration, or the end of the follow-up period (2021), whichever came first. Children who emigrated or died before the end of the antibiotic use period are excluded. Cox proportional hazards regression models are used while adjusting for a range of potential confounders.

Results: As of September 2024, data linkage has been completed, involving the integration of antibiotic exposure and outcome variables for 315,789 children. Preliminary analyses show that both prenatal and early life antibiotic consumption is associated with T1D. Full analyses for all 3 outcomes will be completed by the end of 2025.

Conclusions: This series of linked cohort studies using detailed, complete, and systematically collected antibiotic prescription data will provide critical new knowledge regarding the role of antibiotics in the development of common chronic childhood conditions. Thus, this study has the potential to contribute to the development of primary prevention strategies through, for example, targeted changes in antibiotic use.

early childhood; chronic childhood conditions; antibiotics; data linkage; study protocol; routine data

Introduction

The incidence of many chronic childhood conditions such as type 1 diabetes (T1D), attention-deficit/hyperactive disorder (ADHD), and inflammatory bowel disease (IBD) has increased globally in the last 2 decades [1]. The total global incidence of childhood and adolescent T1D is larger than previously estimated, with nearly 1 in 2 children currently undiagnosed, with most underdiagnoses occurring in low-income countries [2]. Current global incidence estimates range from 128,900 to 149,500 per annum [3,4]. For ADHD, although recent geographical estimates are unavailable, the highest incidence rates are reported in countries with a higher sociodemographic index [5]. The global incidence of IBD is increasing steadily and varies greatly by geographical areas, with the highest annual pediatric incidence of IBD reported to be 23/100,000 person-years in Europe, 15.2/100,000 in North America, and 11.4/100,000 in Asia/the Middle East and Oceania [6].

In New Zealand, the annual incidence of T1D is reported to be 23/100,000, and this is increasing by 4.1% annually [7]. It is estimated that 2%-5% of school-age children in New Zealand are affected by ADHD [8], with a recent study showing that the total ADHD medication dispensing prevalence had almost doubled from 516/100,000 in 2007-2008 to 996/100,000 in 2016-2017, with the highest dispensing prevalence reported for those aged 7-17 years [9]. In the case of IBD, recent New Zealand estimates have shown age-specific incidence rates of 39.5/100,000, which is 1.6-fold greater than what was measured 10 years earlier—this is among the highest in the world [10]. Research indicates significant ethnic differences in T1D and IBD, with European children having higher rates than Māori and Pacific children [7,11]. Furthermore, ADHD prevalence and treatment access vary by socioeconomic status [12].

The etiology of these diseases is not well understood, but environmental factors, genetics, immune-regulatory pathways, and microbial exposures are considered important [13,14]. Early life gut microbiome development is a critical window for immune and neurodevelopment. In early childhood, establishing a healthy microbiome is vital for shaping the immune system and influencing neurodevelopmental outcomes [15]. Microbial colonization begins at birth and evolves with a diverse gut microbiome linked to better health outcomes. Antibiotic use during this period may also be a risk factor that can disrupt the microbiome development by depleting beneficial bacteria, leading to dysbiosis [15,16], which may impair immune training and increase susceptibility to these chronic conditions [17].

Several studies have assessed associations between antibiotic use and the development of these chronic conditions during the prenatal period and early life years [18-20], but results have been inconsistent, with some showing positive associations [20] and others showing no association [21-23]. These inconsistencies may, at least in part, be explained by limitations in study design. For example, antibiotic use is often assessed through recall, which is vulnerable to bias. Moreover, studies often rely on short-term prescription history prior to disease onset, which may result in issues of reverse causality (if antibiotics were prescribed to treat early symptoms of the disease itself) [24,25]. Further, studies have often focused on only one specific class of antibiotics without considering the full spectrum of antibiotics used [25]. Importantly, most research has been conducted in Europe (particularly Scandinavia) and the United States, and it remains unclear whether results can be extrapolated to other parts of the world, including New Zealand, which, compared to other Organisation for Economic Co-operation and Development countries, including Scandinavia [26], is known to have a very high use of antibiotics among children [27].

The series of linked cohort studies for which the methods are described in this protocol paper will assess associations between prenatal and early life antibiotic use and the development of childhood T1D, ADHD, and IBD. These studies using detailed, complete, and systematically collected antibiotic prescription data will provide critical new knowledge regarding the role of antibiotics in the development of these common chronic childhood conditions. Thus, this study has the potential to contribute to the development of primary prevention strategies through, for example, targeted changes in antibiotic use. The central hypothesis of this study is that early life antibiotic use is associated with the development of childhood T1D, ADHD, and IBD.

Methods

Study Design, Setting, and Population

The study design involves several retrospective cohort studies using linked administrative health and social data from Statistics New Zealand's Integrated Data Infrastructure (IDI) [28]. Antibiotic use and T1D, ADHD, and IBD are defined as described below. To date, data for all children born in New Zealand between October 2005 and December 2010 (N=334,204) and their mothers have been extracted from the Department of Internal Affairs birth data in the IDI. Children's antibiotic use has been defined for 4 time periods (at pregnancy, at ≤1 year, at ≤2 years, and at ≤5 years). The development of T1D, ADHD, and IBD (which consists of Crohn disease and ulcerative colitis) has been measured from the end of the antibiotic use periods until death, emigration, or the end of the study in 2021, whichever came first, accumulating approximately 3,000,000 person-years. Children who emigrated overseas or died before the end of the antibiotic use period have been excluded from the analysis, as they cannot be followed up for the occurrence of these chronic childhood conditions. At the end of follow-up, children had reached the age of 11-16 years.

Data Sources

The IDI is a database of deidentified administrative and survey data about people and households in New Zealand [28]. It includes data about health, education, income, social support payments, migration, and other life events, which can be linked at the individual level. The IDI provides a longitudinal record of events and is a growing resource. As of September 2018, the IDI holds over 166 billion pieces of information from more than 14 organizations [28,29]. Table 1 lists the datasets that are being used for this study with a brief description of the data and the variables extracted from these datasets.

Table 1. Data collections available within the integrated data infrastructure for linking cohorts' demographic data with antibiotic use and selected health outcomes [30].

Data collections	Descriptions	Characteristics/variables extracted
Births (from 1840): This data collection was used to define the cohort and identify the mothers of the children.	This collection holds all births in New Zealand, including month and year of birth, sex, ethnicity, first and second parent as recorded on birth registration, and their sex, age, ethnicity, type of relationship, weight at birth, gestation, and their age.	Sex, date of birth, birth weight, ethnicity
Pharmaceutical data (from 2005): This data collection was used to analyze antibiotic prescription.	This collection holds claim and payment information from pharmacists for subsidized medicines, including Pharmaceutical Management Agency (PHARMAC[a]) identifier of primary active chemical ingredient, quantity, number of repeats, and date of dispensing.	Date of prescription dispensing, Anatomical Therapeutic Chemical codes for medicines, including antibiotics and treatments for T1D[b], ADHD[c], and IBD[d]
Maternity (from 2003): This data collection was used to calculate the gestational period and maternal age at birth and to identify the mode of delivery.	The National Maternity Collection provides statistical, demographic, and clinical information about selected publicly funded maternity services up to 9 months before and 3 months after a birth.	Mothers' date of birth, ethnicity, last date of menstruation, mode of delivery, maternal age at delivery
Mortality (from 1998): These data were used to identify the date of death.	This collection holds the underlying cause of death for all deaths registered in New Zealand using the International Classification of Diseases, Tenth Revision, Clinical Modification codes, including all registered fetal deaths and date of death.	Date of death
International travel and migration (from 1997): This data collection was used to identify children who emigrated from New Zealand.	This collection holds arrival and departure records and migration records.	Date of departure
Laboratory claims (from 2003): This data collection was used to obtain laboratory testing information.	This collection holds primary-care test subsidies.	Laboratory test(s) conducted (results of tests are not available), including testing for T1D, ADHD, and IBD
NNPAC[e] (from 2007): This data collection was used to identify any diagnosis procedure for nonadmitted patients.	NNPAC provides national consistent data on nonadmitted patient (outpatient and emergency department) activity.	Diagnosis for various health conditions, including T1D, ADHD, and IBD
Publicly funded hospital discharges (from 1998): This data collection was used to identify the principal and additional reasons for hospitalization and procedure performed during hospital stay.	This collection contains summarized information detailing publicly funded hospital discharges and procedures by New Zealand hospitals using the codes of the International Classification of Diseases, Tenth Revision, Clinical Modification.	Disease/procedure classification, diagnosis for various health conditions, including T1D, ADHD, and IBD.

[a]PHARMAC is a government agency in New Zealand responsible for managing the funding and procurement of pharmaceuticals and medical devices.

[b]T1D: type 1 diabetes.

[c]ADHD: attention-deficit/hyperactivity disorder.

[d]IBD: inflammatory bowel disease.

[e]NNPAC: National Non-Admitted Patient Collection.

Definition of Antibiotic Exposure

Antibiotic exposures in utero and for the first 5 years of life are identified for all cohort members born between October 2005 to December 2010 from pharmaceutical data. Dispensing dates and dose and number of purchases are identified, and each antibiotic prescription is categorized by (1) class, according to the Anatomical Therapeutic Chemical classification J01 "Antibiotics for systemic use" (eg, penicillins, cephalosporins, sulfonamides); (2) spectrum, that is, broad or narrow; and (3) whether antibiotics target Gram-positive or Gram-negative bacteria or both. These categorizations of individual antibiotics are provided in Table 2 [31].

Table 2. Antibiotics by class and spectrum of activity [31].

Class of antibiotics, chemical name of antibiotic used among the cohort	Spectrum of activity (narrow/broad)	Antibiotics targets Gram-positive/Gram-negative bacteria
Cephalosporins and cephamycins		
Cefaclor monohydrate	Moderate	Both
Cefalexin	Moderate	Both
Cefamandole nafate	Broad	Both
Cefazolin	Moderate	Both
Cefoxitin sodium	Moderate	Both
Ceftazidime	Broad	Both
Ceftriaxone	Broad	Both
Cefuroxime axetil	Moderate	Both
Cefuroxime sodium	Moderate	Both
Cephalothin sodium	Broad	Both
Cephradine	Broad	Both
Macrolides		
Azithromycin	Broad	Positive
Clarithromycin	Broad	Positive
Erythromycin	Broad	Positive
Erythromycin (as lactobionate)	Broad	Positive
Erythromycin estolate	Broad	Positive
Erythromycin ethyl succinate	Narrow	Positive
Erythromycin stearate	Narrow	Positive
Roxithromycin	Broad	Positive
Other antibiotics		
Aztreonam	Broad	Negative
Chloramphenicol	Broad	Both
Chloramphenicol sodium succinate	Broad	Both
Ciprofloxacin	Broad	Both
Clindamycin	Broad	Both
Colistin sulfomethate	Broad	Positive
Fleroxacin	Broad	Both
Framycetin sulfate	Broad	Both
Gentamicin sulfate	Broad	Both
Imipenem	Broad	Both
Levofloxacin	Broad	Both
Lincomycin	Broad	Both
Lincomycin hydrochloride	Narrow	Positive
Moxifloxacin	Broad	Both
Neomycin sulfate	Broad	Both
Ofloxacin	Broad	Both
Paromomycin	Broad	Positive
Pyrimethamine	Broad	Both
Sodium fusidate (fusidic acid)	Narrow	Both

Class of antibiotics, chemical name of antibiotic used among the cohort	Spectrum of activity (narrow/broad)	Antibiotics targets Gram-positive/Gram-negative bacteria
Spectinomycin hydrochloride	Moderate	Both
Spiramycin	Broad	Both
Sulfadiazine sodium	Broad	Both
Sulfadiazine	Broad	Both
Tobramycin	Broad	Both
Triacetyloleandomycin	Broad	Positive
Trimethoprim	Broad	Both
Trimethoprim with sulfamethoxazole (cotrimoxazole)	Broad	Both
Vancomycin	Narrow	Positive
Penicillins		
Amoxicillin	Broad	Both
Amoxicillin with clavulanic acid	Broad	Both
Amoxicillin clavulanate	Broad	Both
Benzathine benzylpenicillin	Narrow	Both
Benzylpenicillin sodium (Penicillin G)	Narrow	Both
Dicloxacillin	Narrow	Both
Flucloxacillin	Narrow	Both
Flucloxacillin magnesium	Narrow	Both
Penicillin G benzathine (Benzathine benzylpenicillin)	Narrow	Both
Phenoxymethylpenicillin (Penicillin V)	Narrow	Both
Piperacillin	Broad	Both
Pivampicillin	Broad	Both
Pivmecillinam hydrochloride	Narrow	Both
Procaine penicillin	Narrow	Both
Ticarcillin	Broad	Both
Tetracyclines		
Demeclocycline hydrochloride	Broad	Both
Doxycycline	Broad	Both
Lymecycline	Broad	Both
Minocycline hydrochloride	Broad	Both
Rolitetracycline	Broad	Both
Tetracycline	Broad	Both
Tetracycline hydrochloride	Broad	Both

Definition of Health Outcomes

The selected health outcomes of the study population are determined through linkage with the following data collections: (1) hospital discharges, (2) pharmaceutical data, (3) nonadmitted patient collection, and (4) laboratory claims, for the period starting from birth or end of antibiotic exposure period of each child to the end of 2021. The specific case definitions, including the International Classification of Diseases, Tenth Revision codes corresponding to the health outcomes under consideration, are provided in Table S1 of Multimedia Appendix 1 [32-35]. To ascertain the prevalence of T1D, we used 3 distinct algorithms to identify cases, facilitating a comprehensive comparison of results to ensure consistency. For IBD, the identification of cases, as outlined in Table S1 of Multimedia Appendix 1, will be subject to further validation against several cohorts of patients with IBD obtained from collaborating gastroenterologists. This validation will involve exploring various combinations of medications prescribed for IBD,

including those listed in Table S1 of Multimedia Appendix 1. The analysis aims to provide insights into the diversity of medication regimens associated with IBD cases. Any refinements or enhancements to the algorithms as well as insights gained from the medication combination analysis will be documented and incorporated into the final analysis.

Other Variables

Fixed covariates/confounders that will be considered in the analyses include sex, ethnicity, deprivation index (based on mesh block) [36], birth weight, gestation, mode of delivery, rurality, and maternal age. Time-dependent covariates include hospitalization for infections and other chronic diseases and selected prescription medications (eg, paracetamol, antivirals, antifungals).

Follow-Up of Vital Status and New Zealand Residency

Linkage to border movements and mortality data are used to determine whether cohort members are still alive and are based in New Zealand. Those who have emigrated or died prior to their fifth birthday are excluded from the analyses; the follow-up time for those who died or emigrated after the fifth birthday is censored up to that point, which means that the event of interest or health outcome being investigated may not be observed for some individuals.

Statistical Analysis

To date, the primary focus has been on data preparation that consisted of (1) constructing the cohort through data linkage; (2) identifying the antibiotic exposure variables for all cohort members; (3) identifying other variables, including confounders for all cohort members; and (4) identifying T1D, ADHD, and IBD cases within the cohort using the definitions described in Table S1 of Multimedia Appendix 1. The next stage involves analyses that focus on assessing associations between antibiotic use and the health outcomes described above. For this, we will use Cox proportional hazards regression, with attained age as the analysis time scale. As noted before, children have been followed up until the estimated date of diagnosis, emigration from New Zealand, death, or the end of the study period (December 31, 2021), whichever comes first.

For each health outcome, analyses will be conducted to measure associations with antibiotic use during specific early life periods (pregnancy, ≤1 year, ≤2 years, and ≤5 years, as well as combinations of these periods). Antibiotic use will be based on the number of prescriptions, which will enable the assessment of dose-response associations. In addition to considering all antibiotic classes combined, we will also conduct analyses where antibiotics will be grouped into different classes/categories (Table 2); this will provide insights into which specific groups of antibiotics may be most strongly associated with the 3 outcomes of interest. Analyses will be stratified by mode of delivery to assess whether associations may be different in different subgroups (effect modification) as has been shown for cesarean section births, with larger effect sizes shown for associations between antibiotic use and T1D for caesarean section births [20,37]. In addition to stratified analyses, we will also assess the role of potential confounders such as sex, prioritized ethnicity, deprivation index, and rurality by using multivariable analyses.

Nested case-control analyses will be conducted as an additional way to address potential bias and confounding. Controls will be matched to cases on year and month of birth, sex, ethnicity, and other potential confounding factors such as residence and deprivation. In addition, to address potential medical surveillance bias, matched controls that occur in the same data collections as the cases will be selected. Nested case-control analyses will also enable the evaluation of possible reverse causation (ie, the health outcome of interest resulting in the prescription of antibiotics rather than the other way around) by disregarding antibiotic use in the 6 months before diagnosis of the cases and the equivalent time point of the matched controls. Moreover, control for confounding by maternal factors will be achieved through within-mother analysis of disease-discordant pairs of siblings. Factors remaining constant between pregnancies could, for example, be the mother's attitude toward antibiotic prescriptions as well as the general practitioner's antibiotic prescription practices, which will influence the child's exposure to antibiotics; other types of analyses can typically not adjust for this. Further, confounding by indication, where the reason for prescribing antibiotics may be linked to the development of chronic conditions, will only be addressed once primary care data become available, enhancing the rigor of the study.

Study Power

Based on national and international data, we have assumed that at least half of the children will have been prescribed antibiotics within the first year of life (52% in a Finnish study, 15% for specific antibiotic classes [38]). Based on age-specific statistics of the Virtual Diabetes Register, which is an annually updated national register of all patients with diabetes mellitus from 2010 to 2015, we estimate that 400 cases of T1D can be identified within the cohort [39]. Furthermore, based on hospitalization data, as per the age-specific data, we estimate that at least 200 IBD cases (170 cases of Crohn disease and 30 cases of ulcerative colitis) can be included in the study based on hospitalization data. Finally, for ADHD, and as noted earlier, medication dispensing has doubled from 516 per 100,000 in 2007-2008 to 996 per 100,000 in 2016-2017 in New Zealand [9]. Although a breakdown by age group is not available, we estimate that at least 1000 cases can be identified in the cohort. This is a conservative estimate based on our experience with other IDI projects [34], and it is likely that this number is substantially higher (up to 3% of the study population). Thus, we assume that case sets will have a minimum size of 1000 for ADHD, 400 for T1D, and 200 for IBD. Hazard ratio (HR) estimates that are detectable with 80% power (P<.05, 2-sided) under different population size and exposure prevalence scenarios are summarized in Table 3. Assuming an exposure prevalence of 33%, this study has 80% power to detect an HR of 1.2 for ADHD, 1.4 for T1D, and 1.5 for IBD. Analyses of specific strata of the study population (eg, based on sex or ethnicity) will have sufficient study power to detect similar effect sizes (Table 3). Considering a lower exposure frequency of 10% (eg, for specific antibiotic classes), the study has 80% power to detect an HR of 1.3 for ADHD, 1.5 for T1D, and 1.7 for IBD. Assuming a further

reduction in exposure frequency of 5% (eg, for specific antibiotics), the study has 80% power to detect an HR of 1.5 for ADHD, 1.7 for T1D, and 2.0 for IBD (Table 3).

Table 3. Study power: hazard ratio detectable (power 80%, $P<.05$, 2-sided) under different population size and exposure prevalence scenarios.

Strata	Study population (N)	Scenarios for attention-deficit/hyperactivity disorder					Scenarios for type 1 diabetes					Scenarios for inflammatory bowel disease				
		Cases (n)	Exposure prevalence (hazard ratio)				Cases (n)	Exposure prevalence (hazard ratio)				Cases (n)	Exposure prevalence (hazard ratio)			
			50%	33%	10%	5%		50%	33%	10%	5%		50%	33%	10%	5%
All	300,000	1000	1.2	1.2	1.3	1.5	400	1.3	1.4	1.5	1.7	200	1.5	1.5	1.7	2.0

Ethnicity	60,000	200	1.5	1.5	1.7	2.0	80	1.8	1.8	2.2	2.5	40	2.2	2.2	2.7	3.2

Ethics Approval

This study was approved by Human Research Ethics Committee of the University of Otago (reference: HD21/053). Microdata access approval for the project was provided by Statistics New Zealand. To ensure confidentiality, all data are deidentified before access. Access to linked datasets is limited to authorized personnel, and data handling follows ethical guidelines. Sensitive data will be managed securely. Although the data within IDI are fully deidentified, there are several requirements that govern the use of IDI data that this study will adhere to. These are (1) statistical outputs can only be disseminated after outputs have been checked and approved by Statistics New Zealand, (2) the IDI confidentiality rules require the suppression of counts and associated results of analyses on samples smaller than 6, and (3) the random rounding of counts can be up or down to the next multiple of 3.

Results

As of September 2024, we have completed the data linkage, involving the integration of antibiotic exposure data with outcome variables and all relevant covariates for 315,789 individuals. Preliminary analyses show that both prenatal and early life antibiotic consumption is associated with T1D. Full analyses for all 3 outcomes, that is, analyses adjusted for potential confounders, stratified by ethnicity and sex, and further sensitivity analyses will be completed by the end of 2025.

Discussion

Antibiotics are widely used in human populations, particularly children. It is therefore important to assess and quantify potential adverse effects of this exposure at the population level so that they can be balanced against the many benefits of these therapies. We hypothesize that antibiotic use will result in a positive and significant hazard risk for the development of chronic childhood conditions. The unique data infrastructure established through Statistics New Zealand's IDI provides a robust way of assessing such relationships across a large cohort, consisting of the entire New Zealand population who can be followed up for many years. Findings will be of relevance both locally and internationally, particularly in regions with similarly low antimicrobial resistance rates, such as certain European countries [40]. Additionally, in areas with high pediatric antibiotic usage, such as parts of North America and Asia [41], these insights can inform public health strategies aimed at optimizing antibiotic stewardship.

The proposed series of studies, which are large by international standards and based on detailed, complete, and objectively collected antibiotic prescription data, will provide critical new knowledge regarding the role of antibiotics in the development of common chronic childhood conditions. As such, it will provide an important addition to the limited number of studies conducted in humans and has the potential to contribute to the development of feasible avenues for primary prevention, through, for example, targeted changes in antibiotic use in both quantity and type and targeted use of prebiotics or probiotics. Additionally, this study may be expanded to encompass other conditions such as asthma and allergies, which have also been associated with early life antibiotic exposure [42].

The focus of this study is on the effects of antibiotics on the host, but the results are also relevant to the broader issue of antibiotic overuse and its link with increased microbial resistance. New Zealand has comparatively low rates of antimicrobial resistance [43,44]. However, resistance has steadily increased, and experience gained from other countries suggests that this will become more common in New Zealand, raising patient risk and costs for the health system [45]. Antimicrobial resistance is considered one of the biggest man-made public health threats of modern times [43]. Clinicians and public health researchers have advocated that New Zealand needs to urgently institute a range of measures to significantly reduce antimicrobial consumption [46,47]. A systematic review of interventions aimed at reducing antibiotic prescribing for respiratory tract infections across several settings has led to substantial reductions [48], although efforts in New Zealand have not yet resulted in a decrease of antibiotic consumption [45]. This study may provide additional evidence for the need to reduce (unnecessary) antibiotic consumption both in New Zealand and internationally.

Acknowledgments

Funding for this study is provided by the New Zealand Health Research Council (reference ID: 18/509).

Data Availability

The datasets generated and analyzed for this study are not publicly available. Statistics New Zealand's integrated data infrastructure microdata are available for research purposes, and access is granted based on meeting the conditions set by Stats New Zealand through a secure laboratory environment.

Disclaimer

These results are not official statistics. They have been created for research purposes from the integrated data infrastructure, which is carefully managed by Stats New Zealand.

Authors' Contributions

JD, AtM, and MB conceived the original idea for this data linkage study. All authors contributed to the development of the study methodology. SR wrote the first draft of the manuscript, with assistance from JD, AtM, MC, AK, AE and MB. All authors contributed to the writing of the paper and read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Globally, women consume less alcohol than men, but alcohol consumption among women has declined less in recent years than among men. Drinking rates and alcohol-related harms vary substantially across population groups of women, and sexual minority women (eg, lesbian, bisexual, and queer) are at notably high risk. An emerging body of literature suggests that in addition to minority stress (eg, stigma, discrimination), drinking norms and drinking cultures likely influence sexual minority women's drinking. Almost no research has explored these factors as possible targets of interventions. Sober curiosity is a rapidly growing wellness movement that may be particularly salient for sexual minority women. It encourages individuals to be "curious" about the reasons they choose to drink and alcohol's effects on their life and health.

Objective: The aims of this research are to (1) explore the perspectives of the drinking social worlds of sexual minority women, their awareness of the sober curious movement, perceptions of their own and their peers' drinking and desire to drink less, and perceived barriers and facilitations to changing their drinking behaviors and (2) identify key elements of an alcohol reduction intervention tailored for sexual minority women.

Methods: We conducted a comprehensive review of the literature on alcohol interventions with sexual minority women. The handful of studies we found paid scant attention to drinking cultures, normative beliefs, or other key elements of sober curiosity. To address the study aims, we are conducting 2 descriptive studies with adult (>18 years) sexual minority women using mixed methods. One includes focus group interviews (n=24-36) and a national survey (n=100-120) with sexual minority women in Scotland. The other includes in-depth interviews (n=18-20) with sexual minority women in the United States. Data from the 2 countries and 3 sources will be analyzed using qualitative and quantitative methods to identify patterns and relationships across data to validate or corroborate findings.

Results: Each of the studies received ethics approval in August 2023 and is currently open for recruitment. We anticipate completing data collection in spring 2025. The results of qualitative analyses will be summarized as themes, and results of survey

data analyses will be summarized in tables. Findings will be presented to 2 panels of international experts who will assist in identifying critical elements of an alcohol reduction intervention tailored to the unique needs of sexual minority women.

Conclusions: With the assistance of the expert panels, we will use Acceptability, Practicability, Effectiveness, Affordability, Side-Effects, and Equity criteria to inform the development of a tailored intervention building on tenants of sober curiosity to assist sexual minority women in reducing harmful drinking.

Introduction

Background

Overview

Hazardous alcohol consumption is a pattern of alcohol use that increases the risk of harmful consequences [1]. As a leading risk factor for poor health outcomes worldwide, hazardous drinking is a global public health concern. According to the World Health Organization (WHO) [2], heavy drinking is a causal factor in more than 200 disease and injury conditions; it is also among the top 4 risk factors highlighted in the WHO global strategy for prevention and control of noncommunicable diseases. Efforts to reduce hazardous drinking are a major challenge because in many parts of the developed world, consuming alcohol at risky levels is widely socially acceptable and oftentimes viewed as preferable to abstinence, particularly within social worlds structured around heavy drinking norms [3].

The 2018 WHO Global Status Report on Alcohol and Health [4] suggests that women's drinking has decreased in most countries. However, this is not the case in some Western high-income countries including the United States [5], the United Kingdom [6], and Australia [7]. An increase in women's drinking is among the most prominent trends in alcohol consumption in the United Kingdom in recent history [8]. Further, alcohol consumption patterns and alcohol-related harms are not evenly distributed across population groups of women [9-12]. As described by Bloomfield's [13] "alcohol harm paradox", although different groups of women may drink similar quantities of alcohol, they often experience differential harms based on their level of social disadvantage. It is important to understand the contemporary determinants of health that contribute to hazardous drinking and make it more (or less) difficult for socially marginalized women to reduce alcohol consumption, particularly when alcohol is readily accessible and is used to facilitate or form social connections. In this paper, we review the literature regarding existing alcohol interventions for sexual minority women (eg, lesbian, bisexual, and queer), discuss barriers and facilitators to interventions that support sexual minority women who wish to reduce their alcohol use, and describe 2 studies, one in Scotland and one in the United States, that aim to support the development of an intervention designed to reduce alcohol-related harms among sexual minority women.

Sexual Orientation–Related Disparities in Alcohol Use

Hazardous drinking is among the most prominent health-related disparities when comparisons of heterosexual and sexual minority women are undertaken globally [14-16]. For example, findings from a US national sample found that compared to heterosexual women, sexual minority women were nearly 4 times as likely to engage in heavy episodic drinking [17]. A population-based study conducted in England found that lesbian, gay, and bisexual (LGB) adults (32%) were more likely than heterosexual adults (24%) to drink at harmful levels [18]. This sexual orientation–related disparity is hypothesized to be due to several factors: (1) minority stress related to discrimination and marginalization that impacts mental health and contributes to using alcohol as a coping strategy [14,19-21]; (2) sexual minority women are more likely than heterosexual women to have experienced lifetime trauma, including childhood sexual abuse, childhood physical abuse, adult sexual assault, and intimate partner violence [22-27], that also contributes to alcohol use as a means of coping [28]; (3) the predominantly alcohol-driven nature of the commercial lesbian, gay, bisexual, transgender, queer, and other sexual and gender minority (lesbian, gay, bisexual, transgender, queer or questioning [LGBTQ+]) scene, which facilitates connections and provides a key social environment for many LGBTQ+ individuals and communities [29,30]; and (4) the important role that alcohol plays in identity formation for LGBTQ+ people [14,30,31].

An emerging body of literature suggests that heavy drinking norms also contribute to the heavier drinking patterns of sexual minority women [32]. Drinking is primarily a social activity, often a central part of social occasions in a "social world" where members come together around something they have in common, such as an occupation or an identity [3]. In addition, research suggests that sexual minority women perceive the expectation to drink to be higher in LGBTQ+ spaces than in other contexts [33]. Understanding the drinking norms and drinking behaviors of sexual minority women is essential to informing the development of effective interventions to reduce heavy drinking and alcohol-related harms.

Alcohol Treatment and Sexual Minority Women

In the general population, women are less likely than men to seek help related to their drinking [34-36]. Women who drink heavily report experiencing gendered stigma that negatively impacts their desire or ability to access mainstream alcohol treatment services and their experiences when help is sought. Such stigma may be particularly salient for sexual minority

women who are already stigmatized based on their sexual identity [35,36]. For example, Dimova et al [37] found that sexual minority women (and sexual minority men) who accessed alcohol treatment were rarely asked about their sexual or gender identity, which precluded exploration of how these factors might impact their drinking or desire to reduce drinking. Both lesbian and bisexual women also reported experiencing heterosexist assumptions (eg, that they were partnered with a man) and feeling judged because of their drinking. Moreover, one recent study using data from the 2020 US National Survey of Substance Abuse Treatment Services found that only 2.4% of substance use treatment facilities offered LGBTQ+-tailored programming [38].

Compared to intervention studies aimed at reducing hazardous drinking among women in the general population, those that focus on the experiences of sexual minority women are more recent and more limited [14,39,40]. The small body of literature on interventions designed to reduce drinking among sexual and gender minority populations has focused predominately on sexual minority men [14,41]. A few studies have been conducted on sexual minority women's perceptions and experiences of alcohol treatment in the United States, but nearly all have focused on formal treatment or 12-step programs such as Alcoholics Anonymous (AA) [42-48]. Interventions that might be appropriate for heavy-drinking sexual minority women who are not accessing services or for whom alcohol use is not yet problematic enough to warrant formal treatment—but likely to worsen without early intervention—have not been explored.

Many alcohol treatment programs, especially 12-step programs such as AA, emphasize powerlessness, character defects, and making amends to those harmed by one's drinking—features that may be off-putting for sexual minority women who experience stigma, discrimination, and rejection based on their gender and sexual minority status. While AA is not affiliated with a religious organization, it uses a framework based on religious spirituality. Sexual minority women who do not identify with a particular religion or who have had negative experiences with religious institutions are less likely to access AA [43]. Access to nonreligious and affirming alternatives to AA is important, given research documenting low rates of endorsing religiosity and an absence of a protective effect of religiosity on heavy drinking among sexual minority women relative to heterosexual women [49,50]. Sexual minority women and sexual minority men are more likely than their heterosexual counterparts to express interest in accessible, nonstigmatizing alternatives to AA and traditional treatment approaches [51]. Sober curiosity, described in detail in "Potential Usefulness of an Intervention Based on Sober Curiosity" section, is an identity-affirming approach to alcohol reduction that offers such an alternative.

Existing Evidence Regarding Alcohol Interventions With Sexual Minority Women

In a large global scoping review of studies focused on alcohol and other drug use among sexual minority women, Hughes et al [14] describe the dearth of research related to substance use interventions as "a gaping hole." Although studies of alcohol treatment effectiveness sometimes report findings for sexual minority participants, they rarely report findings specific to sexual minority women. For example, Zajac et al [52] used data from 5 randomized clinical trials to compare the effectiveness of contingency management with financial incentives versus standard intensive outpatient care treatment among 920 LGB and heterosexual participants with a substance use disorder. Differences between LGB and heterosexual participants were compared across 3 substance use outcomes: treatment retention, the longest duration of abstinence, and percent negative substance use screens. Contingency management plus intensive outpatient treatment did not show statistically significant differences for any of the 3 outcomes. However, the LGB group means were higher than those of heterosexual participants for treatment retention and the longest duration of abstinence. Although not strong enough to reach statistical significance, these differences were considered potentially clinically significant. Unfortunately, analyses aggregated LGB participants, which prohibited specific examination of outcomes among sexual minority women.

In another study that combined sexual (and gender) minority participants, Gilmore et al [53] evaluated Positive Change (+*Change*) with 24 undergraduate students from a large university in the Southwestern United States. Of the 24 participants, most (n=17) identified as cisgender heterosexual; 7 identified as sexual minority, gender minority, or both sexual and gender minority. The intervention included content from an integrated alcohol and sexual assault risk reduction program developed for women and a web-based adaptation of a brief motivational interviewing personalized feedback protocol. +*Change* had high usability and acceptability ratings among both cisgender heterosexual and sexual and gender minority participants. Differences based on sexual and gender identity were not examined because of the small sample size.

In the only intervention study undertaken with sexual minority women prior to 2020, Fals-Stewart et al [54] evaluated the efficacy of behavioral couples therapy plus individual therapy compared to individual-based therapy only among lesbian and gay couples, in which at least 1 partner had an alcohol use disorder. Treatment intervention components included developing recovery contracts with partners, teaching partners communication strategies and strategies for reducing triggers and exposure to alcohol, and increasing shared activities. Results indicated that among lesbian couples, those who received the behavioral couples therapy condition reported fewer heavy drinking days at 12-month follow-up compared to those receiving individual therapy only.

Pachankis et al [55] conducted a small (N=60) sexual minority women–adapted cognitive behavioral therapy (CBT) intervention that focused primarily on mental health. This waitlist-controlled trial, Empowering Queer Identities in Psychotherapy, was designed to help sexual minority women understand emotion-driven behavior, reduce emotional avoidance, and learn behavioral skills and other resilience-building strategies. Pachankis et al [55] found that Empowering Queer Identities in Psychotherapy demonstrated preliminary efficacy in reducing sexual minority women's depression, anxiety, emotion dysregulation, and rumination in the intervention compared to the waitlist control group. The

effects of alcohol use were marginally significant, with the immediate intervention group outperforming the waitlist control group. Minority stress responses were not significantly affected by the intervention. In line with previous research, findings suggested that greater attention to sexual minority women's elevated rates of trauma and hazardous drinking is needed to enhance CBT interventions for sexual minority women.

Boyle et al [56] examined the feasibility and efficacy of reducing alcohol-related risks using personalized normative feedback delivered within a digital competition designed to challenge negative stereotypes and norms about sexual minority women's drinking. This study was the first to find that activities aimed at correcting sexual minority women–specific drinking and coping norms via personalized normative feedback reduced alcohol consumption among participants receiving this condition compared to those in the control condition who received information about nonsexual minority–specific topics.

In a study conducted with Australian same-sex attracted women, Bush et al [57] used SMS text messaging to examine the feasibility, acceptability, and efficacy of an alcohol intervention called the Step One program. In total, 97 same-sex attracted women who met the criteria for hazardous drinking by scoring ≥8 on the Alcohol Use Disorders Identification Test were randomly assigned to the Step One condition (n=47; mean age 37 years old)—which included a variety of SMS text messages about the health benefits of reducing alcohol intake—or a control condition of messages containing a link to a website with health information and support services for LGBTQ+ people (n=50; mean age 34 years). Participants in both conditions showed significant reductions in alcohol consumption and improved well-being over 4 weeks. The frequency of help-seeking was low; only 4 intervention group participants and 3 control group participants sought help. In total, 10 participants in the intervention group were interviewed about acceptability. Overall findings indicated that the intervention needed to be revised prior to its implementation.

Except for the study by Bush et al [57], all the intervention studies described earlier were conducted in the United States. Although a variety of approaches were used (eg, personalized normative feedback, couples therapy, and CBT), they were all based on individual behavior change models, which have limited effectiveness for heavier drinkers [58]. Efforts that target individual drinkers typically ignore the fact that most drinking is social, occurring in the company of others, and that how much one drinks is influenced by others (eg, pressure to drink more or less).

In summary, sexual minority women have seldom been the focus of intervention studies. When included as part of LGBTQ+ samples, outcomes are rarely reported separately by gender and sexual identity. Consequently, given this population's social and structural marginalization, it is unknown whether existing treatment options are suitable for sexual minority women. Because the drinking patterns of sexual minority women appear to be in large part motivated by seeking social connection and a sense of belonging, any intervention developed for sexual minority women must address these social and affective needs [59-61]. An intervention that incorporates these elements within sober curiosity, a wellness movement that challenges the centrality of alcohol in social life and questions the notion that alcohol is required on all social occasions [62], offers a potentially scalable approach to alcohol interventions suitable for sexual minority women. Supported by popular and well-known periods of nondrinking such as "Dry January" or "Sober October," sober curiosity is geared toward developing longer-term, sustainable lower-risk drinking practices.

Potential Usefulness of an Intervention Based on Sober Curiosity

There is evidence of substantive social change regarding alcohol consumption, including the exponential rise in the marketing and availability of no or low alcohol (referred to as "NoLo") content wines, beers, and spirits [63,64] and a growing number of sober venues and events, as well as proliferation of web-based support forums that are based on sober curiosity tenets. For example, Grace [65], author of *This Naked Mind* and founder of The Alcohol Experiment, reported on February 22, 2023, that in less than 1 year, more than 80,000 people globally had subscribed to the This Naked Mind web-based alcohol reduction program; notably, most subscribers are women. Similarly, Club Soda in the United Kingdom reportedly has helped "tens of thousands" of people reduce their harmful drinking.

The sober curious movement encourages individuals to question the centrality of drinking alcohol in their daily lives, to make a conscious decision to "be curious" about their reasons for drinking, and to consider if drinking alcoholic beverages is necessary in situations where drinking would typically occur. The growing popularity of sober curiosity provides support for a more positive identity for light or nondrinkers than has been previously available. It offers opportunities for both personal and social change, recognizing that individual alcohol consumption behaviors cannot be separated from their contexts. However, no research has examined how sober curiosity or similar interventions to reduce alcohol consumption are perceived by sexual minority women. An established literature on the links between minority stress and poor health [66-68] provides strong evidence that the contexts in which sexual minority women live and experience life differ in important ways (eg, marginalized identities and shame) from heterosexual women's life experiences, making it critically important that such experiences be considered in any intervention effort to reduce sexual minority women's alcohol consumption.

Drawing on several decades of our own and others' research investigating and seeking to understand sexual minority women's drinking, we believe that a sober curious approach may increase the desire of sexual minority women to reduce alcohol consumption and increase their self-efficacy to resist drinking. Sexual minority women typically participate in alcohol-centric social contexts (social worlds) to connect with other sexual minority people, establish inclusive friendships with like-minded people, and gain social supports that are limited in other contexts [59,60]. These social worlds, although contoured by heavy drinking norms, can be especially helpful during periods of transition or stressful events (eg, coming out, experiencing violence, or relationship dissolution), contexts in

which sexual minority women may be more likely to drink heavily [69].

Sober curious approaches could promote wider availability of alternatives that meet important personal and interpersonal needs but do not involve drinking alcohol. This alternative is promising, given research that has found social norms, particularly perceived peer-drinking norms, are strongly predictive of heavy drinking among sexual minority women [32,70,71]. Sober curiosity focuses on shifting cultural and subcultural heavy-drinking norms (not just individual behavior), and interventions that are shaped around the philosophy of sober curiosity may be an important way to address persistent sexual orientation–related disparities in hazardous drinking among women. Sober curiosity is nonjudgmental; it emphasizes alcohol and its addictive properties rather than the person as the "problem." Research across various domains of sexual minority women's health suggests that approaches that are nonpathologizing and nonstigmatizing, that focus on community norms and social connection, and that emphasize health, wellness, and mindfulness are likely to be most effective for sexual minority women [72]. Yet, no studies have been conducted that use these approaches in conjunction with sober curious principles to address sexual minority women's drinking.

Therefore, we are conducting 2 studies that combined to use a variety of methods to explore the feasibility, potential usefulness, and key elements of a tailored intervention based on sober curiosity for sexual minority women. One of the studies includes focus groups and a national survey with sexual minority women in Scotland; the other includes in-depth interviews with sexual minority women in the United States, followed by a review of findings by 2 international panels of experts. The aims of this research are (1) to explore the perspectives of the drinking social worlds of sexual minority women, their awareness of the sober curious movement, perceptions of their own and their peers' drinking and desire to drink less, and perceived barriers and facilitations to changing their drinking behaviors and (2) to identify key elements of an alcohol reduction intervention tailored for sexual minority women.

Conceptual Framework

The conceptual framework informing our work incorporates "social world" perspectives [58] and tenants of the health equity framework [73]. The social worlds of heavy-drinking sexual minority women are characterized by a connection point that can be thought of as a space where drinking alcohol is perceived to be an important aspect of shared activities or of a shared culture [3]. Research addressing heavy drinking social worlds is nascent; yet, this perspective can provide a unique lens for understanding and addressing harmful drinking in at-risk populations. The health equity framework builds on 3 foundational concepts: equity at the core of health outcomes; multiple, interacting spheres of influence; and historical and life-course perspectives. It illustrates how complex interactions between people and their environments affect health behaviors and outcomes. The importance of each of these concepts for LGBTQ+ people is highlighted in a 2011 landmark report on LGBT health [74].

Why Scotland and the United States?

Scotland

Most sexual and gender minority health research, especially research on alcohol use, has been conducted in North America [14,75-78]. We chose to collect data from sexual minority women in Scotland because the sober curiosity movement appears to be more prominent in the United Kingdom than in other European countries and in most other parts of the world [79,80]. Further, hazardous drinking in the UK general population is more prevalent than in other countries in continental Europe [81], and alcohol-related harm is disproportionately higher in Scotland than in the rest of the United Kingdom [82]. In 2018, as part of a raft of evidence-based strategies to tackle this "alcohol crisis," Scotland became one of the first countries in the world to implement minimum unit pricing with the aim of reducing alcohol-related deaths and decreasing health care use [83,84]. Although relatively little research on alcohol use among sexual and gender minority people has been conducted in Scotland, or in the United Kingdom, limited research has documented higher rates of hazardous alcohol use in sexual and gender minority people in the United Kingdom relative to their heterosexual counterparts [85]. Thus, although no studies have compared rates of sexual and gender minority drinking in Scotland and in the United States, there is reason to believe that sexual minority women in each country are at heightened risk of harmful alcohol use. Our research aims to understand similarities and differences in the cultural contexts of sexual minority women's drinking in the 2 countries and how such differences impact sexual minority women's drinking.

The United States

Because Scotland's population is predominately White (only 4% are Asian, African, Caribbean or Black, mixed, or members of other ethnic groups) [86] and because we wanted to include diverse sexual minority women's perspectives, we chose to also collect data in the United States. We created a sampling frame consisting of diverse sexual minority women in regard to age, sexual and gender identity, race or ethnicity, education, and geographic residence from participants enrolled in an ongoing longitudinal study of risk and protective factors for hazardous drinking among sexual minority women [87].

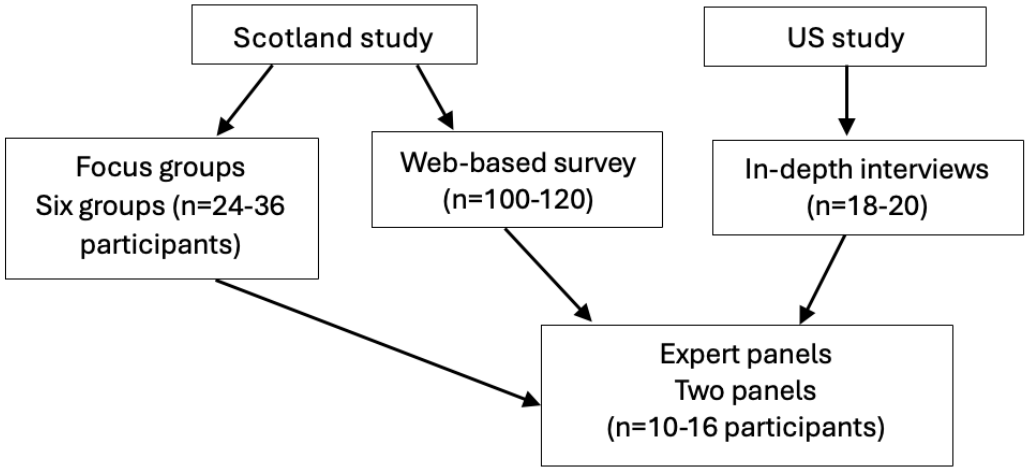
Methods

Study Design

We are currently conducting focus groups and a national web-based survey with sexual minority women in Scotland and in-depth individual interviews with sexual minority women in the United States. This mixed methods or triangulated approach, using both qualitative (focus group and individual interviews) and quantitative (web-based survey) methods conducted in 2 countries, was intentionally chosen to maximize understanding of similarities and differences in cultural contexts and influences on sexual minority women's drinking. Triangulation is commonly used in both qualitative and quantitative research and is especially helpful in understanding complex human behavior. Triangulating methods and data can enhance the

validity and credibility of findings, mitigate potential biases, and give more confidence in the findings [88]. Figure 1 summarizes the qualitative and quantitative components of the studies and includes the planned number of participants in each component of the studies.

Figure 1. Overview of research components.



Focus Groups

The Scotland study will include 5 to 6 focus groups, each with a purposive volunteer sample of 4 to 6 adult sexual minority women. Focus group interviews are conducted in person or via Zoom (Zoom Video Communications) and are led by team members (primarily LB and BM) who are experienced qualitative researchers with expertise in alcohol use among sexual minority women; some team members identify as part of the sexual minority women's community. Focus group discussions are organized around specific topics and include broad areas of inquiry [89] developed by the research team. The focus group interview guide was adapted following the first and second focus group sessions to improve clarity and more effectively address the study aims. Areas of inquiry include (1) perceptions of alcohol use in sexual minority women's "communities" in Scotland; (2) openness to reducing alcohol consumption (are they sober curious?); (3) factors and barriers that impact sexual minority women's decisions and preparedness to reduce consumption (eg, drinking norms and drinking behaviors of peers); (4) attitudes toward, perceived availability of, and experiences with NoLo alcohol beverage alternatives; (5) conditions that would support reducing their own and other sexual minority women's alcohol consumption; (6) messaging and framing about reducing alcohol consumption that sexual minority women would find appealing (or off-putting); and (7) the potential benefits and barriers to a successful sober curious alcohol reduction intervention with sexual minority women. The focus group interview guide is available upon request.

Web-Based Survey

We will complement data collected in focus groups with data collected from a larger convenience sample of Scottish sexual minority women (N=100-120) recruited to participate in a web-based Qualtrics survey. Our team developed the survey using existing literature and a previous study on sober curiosity conducted by Lunnay et al [90] with midlife women in Australia. We pilot-tested the survey with 10 sexual minority women in Scotland and the United States prior to its official launch. The survey includes approximately 80 questions (3-5 questions per page) and takes an average of 15-20 minutes to complete. Like focus groups, the survey includes questions about demographic characteristics, patterns of alcohol use (eg, frequency and quantity), drinking contexts, drinking companions, drinking motivations and perceived drinking norms of peers, as well as help-seeking, familiarity with the sober curious movement, or aspects of it (eg, Dry January, Sober October, and NoLo alcohol beverages), and perceived barriers and facilitators to reducing alcohol consumption. We also include a few open-ended questions to collect qualitative data that will be used to triangulate data from the focus groups (eg, participants' descriptions of barriers and facilitators to reducing drinking).

Scotland Study Recruitment

We are recruiting adult (age 18 years or older) sexual minority women who reside in Scotland and who report moderate (between 7 and 14 units per week) or heavy (>14 units per week) alcohol consumption. Although there is no agreed international definition of low- or moderate-risk drinking [91,92], researchers in the United Kingdom [93] have used 7-14 units per week to indicate "moderate" drinking. Efforts to support effective behavior change must consider local sociocultural contexts and build on existing community assets. In each country, we are working to recruit diverse samples of sexual minority women in terms of age, education, geographic location (eg, rural and urban), and identity (eg, lesbian, bisexual, queer, and nonbinary gender). In addition, because sexual minority women's "communities" are not homogenous, and distinct groups within it are more or less marginalized and have different levels of capacity and resilience than others, we are using recruitment strategies that attract sexual minority women across different sociodemographic statuses. We are posting advertisements in local LGBTQ+ publications, advertising the study via social media and relevant mailing lists, and conducting outreach through partnerships with LGBTQ+ organizations in Scotland (eg, *LGBTQ+ Health & Wellbeing*, *LGBTQ+ Youth-Scotland*, and *The Equality Network*) and LGBTQ+ sports groups. Interested individuals are directed to a web-based screener where

they answer several questions about their age, sexual identity, residence, and current drinking to determine eligibility. Prospective participants are informed that, in appreciation of their time and contributions, they will receive an Amazon gift card worth approximately US $38 for participation in a focus group or US $12.40 for completion of the web-based survey.

US Study

In-Depth Interviews

In a separate but complementary study, we are conducting in-depth interviews with a purposive, diverse sample of approximately 18-20 sexual minority women in the United States. Interviews lasting approximately 60 minutes are conducted via Zoom or phone by 2 researchers (LB and Ellen Riggle) with extensive qualitative training and research experience in sexual minority women's health. Questions explore the same areas of inquiry as the focus groups in Scotland. For example, sexual minority women are asked about their perceptions regarding alcohol use within sexual minority women's social worlds and about their personal experiences with drinking. During interviews, we ask if sexual minority women are aware of the sober curiosity movement, are interested in considering ways to reduce their alcohol consumption (are they sober curious?), factors and barriers that impact their decisions and preparedness to reduce consumption, alternatives to alcoholic beverages and alcohol-based events perceived to be available, attitudes toward and experiences with NoLo beverages, and perceptions of conditions that would support consideration of reducing their own and other sexual minority women's alcohol consumption. The US interview guide is available upon request.

Recruitment for US In-Depth Interviews

We are recruiting adult sexual minority women who participated in a longitudinal study of drinking among sexual minority women led by first author Hughes [14, 94]. This approach permits more efficient and accurate identification of sexual minority women who either drink at moderate or heavy levels (ie, at least 14 drinks per week on average) or reported that they were thinking of cutting down on their alcohol use. The sample will include sexual minority women with diverse demographic characteristics, such as age, race or ethnicity, sexual identity (eg, lesbian, bisexual, and queer), residence (urban or rural), educational level, and relationship status. Interviews last 60-90 minutes, and participants are given a US $50 Amazon gift card in appreciation of their time.

Ethical Considerations

The Scotland study received ethics approval from Glasgow Caledonian University (HSL NCH 22 040), and both the Scotland and the US studies received ethics approval from Columbia University (AAAU7672), the lead institution. The studies were reviewed and deemed to be exempt given that they were judged to pose little or no risk to the research participants. For the Scotland focus groups, informed consent is obtained by the researchers prior to commencing research procedures. An information sheet is provided to individuals who participate in the web-based survey with passive consent implied by virtue of survey completion. For the US study, verbal informed consent is obtained by the project manager prior to scheduling each participant's interview. Following a verbal review of the consent form, questions are asked of each participant to ascertain that they understand what is involved in their participation. Documentation of consent is maintained on a password-protected end-point device. Participants receive a copy of the consent form via email for their records. Scotland focus groups are conducted either in person or on Zoom (to accommodate the participation of sexual minority women who live in rural or other outlying areas). Participants are invited to provide a pseudonym to be used in focus group discussions, and any names or information that could potentially identify a participant are redacted from the transcripts. Each focus group participant is assigned a unique ID number linked to their demographic and contact details, which are saved separately on a password-protected system in a password-protected file. Audio files are destroyed after the transcripts are reviewed and verified. Deidentified transcripts will be available to members of the research team for analyses. Scotland survey participants are also each assigned a unique ID number and are asked to provide an email address in order to receive the link for the study incentive (Amazon gift card). The key that links ID numbers to email addresses is kept on a password-protected system in a password-protected file separate from the dataset with the survey responses. The ID numbers are used to keep track of who has been sent a gift card. Individual interviews in the United States are conducted by phone or Zoom. Audio files are coded with the participant's identification number but without any information that could be used to identify them. The list that links codes to names and addresses is kept on a password-protected end-point device in a password-protected file separate from the audio files. Once interviews are completed, the audio files of the interviews are saved on a secure electronic system (ie, Box). Once the interview transcripts are reviewed and verified, the audio files will be destroyed.

Data Analysis

Given the range of data sources used, it is essential to triangulate data to address the completeness, convergence, and dissonance of key themes. We will analyze data from each of the 3 sources separately.

Data from the focus groups (Scotland) will be analyzed using Krueger's framework analysis [95] for narrative focus group data that considers words, context, internal consistency, frequency of comments, extensiveness of comments, intensity of comments, specificity of responses, and big ideas. This process involves six interconnected steps: (1) data collection; (2) immersion in data; (3) memoing to identify ideas and concepts; (4) indexing descriptive statements; (5) formation of categories, drawing on within- and between-group comparisons; and (6) interpretation. In-depth interview data from the US study will be analyzed using inductive thematic analysis drawing on six phases described by Braun and Clarke [96]: (1) immersion through reading and rereading data and noting initial ideas, (2) generating initial codes, (3) searching for themes, (4) reviewing themes, (5) defining and naming themes, and (6) producing the report, including selection and use of extract examples. Thematic analysis is a method for identifying and organizing patterns of meaning, or themes, across a dataset to make sense of shared

meaning and collective experiences [97]. Analyses of the Scotland and US qualitative data will be guided by a social worlds' perspective, which aligns with constructivist and symbolic interaction theory and "supports identification and investigation of groups below the level of society but above the level of friendship groups, where relatively coherent heavy drinking cultures may operate" [3].

Although data will be analyzed separately, we will be particularly interested in comparing themes from the focus groups and the in-depth interviews to identify similarities and differences in the findings and to identify patterns and relationships across data to validate or corroborate findings. We expect that these comparisons will provide a more comprehensive understanding of factors that serve as facilitators or barriers to sexual minority women who wish to reduce their alcohol intake.

Several strategies will be used to enhance the trustworthiness of the qualitative findings [98]. These include prolonged engagement with the narrative data, researcher triangulation, with multiple researchers each bringing their perspective to analyses, and regular peer debriefing and reflexive meetings via Zoom with research team members (authors of this paper). The team members are part of a research collaboration among Columbia University School of Nursing, Center for Sexual and Gender Minority Health Research and international partners at Glasgow Caledonian University, Research Centre for Health, and Torrens University Australia, Research Centre for Public Health, Equity and Human Flourishing. The research team includes individuals from multiple disciplines (eg, public health, sociology, psychology, nursing, and social work). More than half of the team members identify as being part of either sexual minority or gender minority communities. As a check to ensure findings accurately reflect the experiences and perspectives of the participants, member checking will involve validating the findings with stakeholders involved in the research (eg, members of the research team) and with at least 3 focus group participants and 3 participants from the in-depth interview portion of the study.

Survey data will be analyzed using SPSS (version 29; IBM Corp). Analyses will initially screen for and correct outliers, data entry errors, or other inconsistencies. We will decide whether to use cases with incomplete data (eg, surveys that were only partially completed) based on the number and relevance of key questions that have valid responses. All statistical tests, for example, comparing rural versus urban sexual minority women, will be 2-sided (α=.05). Given the exploratory or descriptive nature of the study, we believe that data from 100 to 120 survey participants will provide sufficient information to inform our research aims. We will explore how findings from closed- and open-ended survey questions map onto key themes from the qualitative studies.

Comparisons of the perceptions and experiences of sexual minority women in Scotland and in the United States will identify thematic commonalities and differences and to formulate hypotheses about how drinking alcohol among sexual minority women relates to social contexts, group identity, and cultural norms. Although we expect to find similarities in the cultural contexts of sexual minority women across these 2 high-income countries, understanding differences and how they shape drinking norms and behaviors will elucidate key elements of a future tailored intervention aimed at helping sexual minority women reduce the risk of harmful drinking.

Results

The study was funded in July 2023, and data collection began in September 2023 after the study received ethics approval from the 2 lead institutions (August 2023). The Scotland study received ethics approval from Glasgow Caledonian University (HSL NCH 22 040) and from Columbia University (AAAU7672). As of December 2024, we completed 4 of the 6 planned focus groups (Scotland) and 18 of the 20 planned in-depth interviews in the United States. Data collection for the web-based survey in Scotland was paused in October 2024 for several months after discovering that about two-thirds of the approximately 150 responses were invalid (exhibited evidence of bot automation, eg, duplicate IP addresses). To address this, we removed the Amazon gift card incentive from recruitment advertisements and submitted the revised protocol to the 2 human participant review committees for ethical approval. As of December 2024, we have 64 valid survey responses. We expect to complete data collection in both Scotland and the United States by June 2025.

Results of qualitative analyses (data from focus groups and individual interviews) will be organized and summarized as themes, and results of survey data analyses summarized in tables. Findings from the studies will be presented to 2 international panels of experts; each panel will include 4-6 experts. Panel participants will consist of researchers with expertise in sexual minority women's use of alcohol, the development of alcohol interventions for women, or sober curiosity approaches. This will serve 2 purposes: peer review (having other researchers or experts review the findings to ensure their validity and to identify potential biases) and identification of key factors to be included in a planned intervention that will incorporate tenants of sober curiosity. We will use Acceptability, Practicability, Effectiveness, Affordability, Side-Effects, and Equity [99] criteria to consider important socioecological and cultural factors that provide an overarching understanding of key elements of an intervention tailored to assist sexual minority women to reduce harmful drinking.

Discussion

Principal Findings

To our knowledge, this project is the first attempt to investigate sexual minority women's openness and readiness to reduce alcohol consumption within a sober curiosity framework and with the view to designing an intervention tailored for sexual minority women. Understanding how sexual minority women might justify or rationalize their alcohol consumption in different contexts and social worlds, their interest in changing their drinking behaviors to reduce their alcohol consumption, and their perceived barriers and facilitators to doing so will provide new insights. We anticipate that findings will provide essential

preliminary data to develop (and subsequently evaluate) an intervention that incorporates tenets of the sober curious movement and is aimed at reducing harmful drinking among sexual minority women, with scalability to other high-income countries with similar drinking-related social norms. Such an intervention will respond to sexual minority women's reported need for social connection and will support alcohol reduction strategies while retaining social support.

Strengths and Limitations

First, the use of mixed methods to collect data, including both qualitative and quantitative methods, and the inclusion of 2 countries are strengths of this research. For example, while the perspectives of sexual minority women about alcohol use and sober curiosity in the web-based survey may be influenced by misunderstandings of the questions, focus group and individual interviews allow for such misunderstandings to be explored and corrected. However, relationships among drinking behaviors and patterns, sexuality, and gender are complex [5,30,60,100], and information to be gleaned from the current research may not capture these complexities. For example, qualitative research from Scotland and Australia highlights the ways in which drinking alcohol facilitates engagement with LGBTQ+ communities, aids in expressing sexuality and identity, and challenges heteronormative perspectives of women's drinking [30,100]. Our focus on sober curiosity and ways that sexual minority women might reduce their alcohol consumption does not consider the performative role that alcohol use, including heavier use, plays in "doing" gender and sexuality and in connecting with the LGBTQ+ community in pleasurable and meaningful ways. Future work should consider the complex meanings and social functions of alcohol in the lives of sexual minority women.

Second, because findings are from nonrepresentative samples of sexual minority women in Scotland and in the United States, they have limited transferability. Both countries are characterized by high income and relatively low levels of stigma (eg, compared to non-Western and low-income countries). There may be important cultural differences that shape alcohol use among sexual minority women who live in countries and cultural contexts where either same-sex sexuality or alcohol use among women is more stigmatized. Further, given limited time and resources, we may not be able to reach as diverse a sample as intended. For example, factors such as poverty and homelessness or disability influence sexual minority women's drinking. More research using mixed methods and larger samples across different cultural contexts is needed to further refine the understanding of factors that influence sexual minority women's drinking and perspectives about sober curiosity.

Third, although trauma is not a focus of the studies, it is well documented that experiences of lifetime trauma, particularly adverse childhood experiences, are more prevalent among sexual minority women [24] and are strongly linked with alcohol use among sexual minority women [14,101]. Thus, our failure to address trauma may limit important insights about key elements of an alcohol reduction intervention for sexual minority women.

Conclusions

The sober curious movement is gaining positive attention and momentum in mainstream society in many parts of the world. Now is an important time to leverage this momentum to address heavy drinking social norms and behaviors within sexual minority women's social worlds. An intervention developed and offered to sexual minority women within this growing movement may provide an acceptable and effective way to support sexual minority women to reduce alcohol-related harms. However, such interventions will likely need to recognize the positive aspects of drinking (eg, facilitating social connections) and the pervasive impact of trauma on sexual minority women's drinking as well as the linkages among connection, coping, and identity, if they are to be optimally effective.

Acknowledgments

The studies were funded by 2 pilot program grants from the Columbia University School of Nursing: the Elaine Larson Global Development Pilot Fund and the Center for Sexual and Gender Minority Health Research Pilot Program. The authors appreciate the time and contributions of the research participants. The authors acknowledge investigator Ellen Riggle (University of Kentucky), coinvestigator on the US study, Amy K McEwan (Glasgow Caledonian University), research assistant on the Scotland study, as well as Sergey Kisselev (Columbia University) for programming the Scotland web-based survey in Qualtrics.

Data Availability

The datasets generated and analyzed as part of this project will be available from the corresponding author on reasonable request after the research team has completed analyses related to the study aims.

Conflicts of Interest

None declared.

Abstract

Background: Type 2 diabetes is the fastest-growing chronic condition in Australia, with higher prevalence in disadvantaged groups. Logan Healthy Living by UQ Health Care is a proof-of-concept, interprofessional allied health clinic focused on supporting people with and at risk of type 2 diabetes in Logan, a region in South East Queensland, Australia, with high levels of health inequity. Logan Healthy Living is supported by the Queensland Government through Health and Wellbeing Queensland and a broader multisectoral alliance including primary health care; tertiary hospital and health services; and government, community, and university sectors.

Objective: This paper describes the establishment of Logan Healthy Living and outlines the evaluation protocol for the service's type 2 diabetes lifestyle management program.

Methods: The context and setting of Logan Healthy Living are presented, and the process for establishing the multisectoral partnerships, development and governance of the service, and the facility are described. The lifestyle management program is an 8-week, group-based program that includes 1 hour of education and 1 hour of supervised, individually tailored exercise each week. The theoretical underpinnings and the program are described in detail. The Reach, Effectiveness, Adoption, Implementation, and Maintenance (RE-AIM) framework will guide evaluation of the program and inform key questions regarding the number and characteristics of the clients (reach); diabetes-related distress, health behaviors (physical activity and diet), quality of life, self-management self-efficacy, loneliness, community involvement, anthropometric measures, hemoglobin A_{1c} levels, physical function, and health care use (effectiveness); referral pathways (adoption); fidelity, appropriateness, acceptability, and costs (implementation); and long-term effectiveness (maintenance). Data will be drawn from a purposefully embedded minimum dataset and data registry, with the process for designing and embedding data collection into practice (via surveys, in-person measures, and client management software) described in detail.

Results: Ethics approval has been obtained for the data registry. Logan Healthy Living is a 4-year proof of concept that concludes on December 31, 2024, with findings expected to be reported starting in 2025.

Conclusions: While multisectoral responses are needed for complex community health challenges, the processes for achieving these are rarely documented, and the description of the development of Logan Healthy Living has the potential to inform future partnerships. The findings of the evaluation will provide important new knowledge on the impact of a community-delivered type 2 diabetes program on individuals, the community, and the health system in an area of high health inequity.

type 2 diabetes; lifestyle management; allied health; evaluation; protocol

Introduction

Background

Type 2 diabetes is a chronic condition where the body becomes resistant to the normal effects of insulin and gradually loses the capacity to produce enough insulin in the pancreas [1]. The onset of type 2 diabetes is associated with both nonmodifiable (eg, genetic) and modifiable (eg, health and behavioral) risk factors [1]. Worldwide, in 2020, type 2 diabetes was the ninth leading cause of death, affecting 7% of the population, with prevalence rates only expected to increase [2]. In Australia, type 2 diabetes impacts an estimated 1.2 million people [1], with a further 2 million having prediabetes [2]. It is the fastest-growing chronic condition in Australia [1], with health system expenditure estimated at Aus $3.4 billion (US $2.1 billion) per year [3]. Type 2 diabetes has a significant impact on individuals. Along with the symptoms of the disease itself, many people experience diabetes-related complications (eg, retinopathy, peripheral vascular disease, and ischemic heart disease) and are at increased risk of multimorbidity (eg, cardiometabolic, vascular, and mental health conditions), which collectively impact their quality of life, impair functioning, and increase financial and economic burden [4]. Type 2 diabetes disproportionately affects disadvantaged groups. For example, people of a low socioeconomic status and with low levels of education [5], immigrants, and those from culturally and linguistically diverse backgrounds have increased risk of type 2 diabetes [6]. Furthermore, the intersection of disadvantage is likely to magnify risk and burden of disease [7].

Management of type 2 diabetes is primarily focused on achieving glycemic control through modification of health behaviors (typically physical activity and nutrition) and, where required, medication. Evidence-based management of type 2 diabetes emphasizes person-centered, team-based care with integrated long-term treatment approaches, as well as the involvement of social community support [8,9]. Self-management, where the person with type 2 diabetes works in partnership with their social supports and health professionals to understand, manage, and optimize their health, is the goal. Management of modifiable risk factors is a core component of self-management, with such strategies focused on building positive health behaviors, including physical activity and nutrition, and optimizing psychological well-being [9,10]. Multidisciplinary, group-based approaches to lifestyle modification have consistently been shown to positively impact a range of health and well-being outcomes for people living with type 2 diabetes [11]. To support this in practice, the Australian National Diabetes Strategy (2021-2030) has called for a multisectoral response by government and communities to provide the integrated care required [12].

UQ Health Care (a not-for-profit health care wholly owned enterprise of The University of Queensland) has established Logan Healthy Living as a specialist clinic designed to respond to this need [13]. Purposefully established in South East Queensland in the City of Logan, an area of Queensland with high burden of type 2 diabetes and intersectional disadvantage, Logan Healthy Living was designed with the aim of reducing the burden of disease on individuals, the community, and the health system [13]. The core service of Logan Healthy Living is a group-based lifestyle management program delivered by an interprofessional allied health team focusing on supporting people living with and at risk of type 2 diabetes in Logan. The program has 3 main foci: physical activity, healthy eating, and well-being [14]. Logan Healthy Living is a 4-year proof of concept delivered by a Queensland-first alliance among primary health care; tertiary hospital and health services; and government, community, and university sectors.

A key feature of the establishment of Logan Healthy Living was the integration of an outcome-based funding model—a model that prioritizes value-based care and patient-centered outcomes and leverages multisectoral partnerships. Critical to value-based care models is the collection and use of data to continually evaluate the impact of the service on the participants as well as the health system more broadly [15]. Moreover, leveraging this approach for practice-based evidence generated in “real-world” settings can add to the currently limited evidence on community-based, self-management programs for people living with or at risk of type 2 diabetes [16]. With dimensions at both the individual level and multiple ecological levels, the Reach, Effectiveness, Adoption, Implementation, and Maintenance (RE-AIM) framework [17,18] offers a balanced and pragmatic approach to the evaluation of applied community-delivered programs considering factors such as the characteristics of the participants who take up the program (reach) and participant satisfaction (implementation). The RE-AIM framework has been applied across multiple evaluations, including diabetes health coaching [19], diabetes prevention programs [20], and telephone-delivered type 2 diabetes support [21]. To simultaneously support reporting for the outcome-based funding model and evaluate the real-world

impact of a routinely delivered community program, a comprehensive continuous evaluation protocol informed by the RE-AIM framework was developed.

Objectives

The purpose of this paper is to describe the development of Logan Healthy Living and the protocol for program evaluation of this allied health care service. Specifically, we describe the context and setting of the service, the multisectoral partnership and co-design activities contributing to the service development, governance, and participants and recruitment channels. We then describe the protocol for the evaluation of the service according to the RE-AIM framework.

Methods

This protocol was prepared using the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) checklist [22].

Context and Setting

Logan Healthy Living by UQ Health Care is located in the City of Logan in South East Queensland, Australia. With an estimated population size of 345,098 [23], the City of Logan is identified as one of the most culturally and linguistically diverse and socioeconomically disadvantaged areas in Australia. The proportions of the population speaking a language other than English at home; being born overseas; identifying as Aboriginal or Torres Strait Islander, Māori, or Samoan; being unemployed; and having one or more chronic health conditions are above South East Queensland averages [23]. The region has also experienced rapid population growth and has an aging population [24]. The City of Logan has a strong focus on community services and fostering connection, with a wide range of no- and low-cost community social programs, including Logan City Council Libraries; arts, culture, and heritage initiatives; sport and recreation facilities (including the Active and Healthy program offering >100 weekly free and low-cost health and well-being activities); and parks and community gardens. Logan also has a diverse range of cultural groups and grassroots networks supporting community connection [25].

In Logan, estimates of the prevalence of type 2 diabetes and associated indicators of burden of disease are consistently higher than state-based estimates for Queensland. Almost 20% (18.5%) of people aged ≥75 years living in Logan have type 2 diabetes (12.4% for those aged 55-74 years and 1.7% for those aged 18-54 years) [26], with the third highest rate of insulin-treated type 2 diabetes in Australia (an indicator of advanced or nonresponsive progression of the disease) [24]. Type 2 diabetes accounts for 31% of potentially preventable hospitalizations in Logan, making it the leading cause of potentially preventable hospitalizations [24]. Those living with type 2 diabetes in the area are also disproportionately likely to die from diabetes-related causes, with the average diabetes-specific mortality rate in Logan being 32% higher than that for Queensland in general [24].

Development of Logan Healthy Living

The concept of a multisectoral, allied health–delivered lifestyle management program for people living with type 2 diabetes in Logan emerged from an existing partnership between UQ Health Care and Metro South Health (the region's public health care provider) [27]. In 2014, Metro South Health and UQ Health Care established an innovative, integrated primary-specialist model of care for the medical management of people with complex diabetes, the "Beacon" model [28]. The Beacon model saw complex diabetes management provided within a community practice by a multidisciplinary team consisting of an endocrinologist from Logan Hospital, 2 to 3 general practitioners (GPs) with a special interest in diabetes from UQ Health Care, and a diabetes nurse educator from the Metro South Health community team who provided 1:1 consultation (at times before the GP with a special interest in diabetes to assist in triage). The aim of the Beacon model was to build capacity in primary care for managing complex diabetes through advanced management plans and subsequently diverting people with type 2 diabetes from tertiary care. While the Beacon model demonstrated favorable outcomes in changes in hemoglobin A_{1c} (HbA_{1c}) concentration and the percentage of patients meeting combined clinical targets of HbA_{1c} concentration, blood pressure, and low-density lipoprotein cholesterol [29], key stakeholders acknowledged that the Beacon model alone was not sufficient to address the rising community need. Moreover, it lacked a health behavior change program focused on self-management—a critical component for the management of type 2 diabetes [11].

To address these needs, in approximately 2019, what would eventually be known as "Logan Healthy Living" was envisioned, expanding on the existing partnership between Metro South Health and UQ Health Care and integrating learnings from the Beacon model and UQ Health Care's experience in delivering interprofessional, allied health services at other sites. The first phase of service development was establishing an alliance of partners underpinned by a commitment to prevent chronic disease and keep people well and out of hospital in Logan. UQ Health Care and Metro South Health led the establishment of the alliance, which in turn also included the Brisbane South Primary Health Network, The University of Queensland, and Griffith University. By early 2020, the alliance had established a proof-of-concept model for a comprehensive lifestyle management program delivered by an interprofessional team of allied health professionals and infused with a student allied health workforce.

Concurrently, in 2019, the Queensland Government established the state's first prevention agency, Health and Wellbeing Queensland [30]. The concept of Logan Healthy Living, a service delivering comprehensive lifestyle management programs to support behavior change and self-management, was put to the board of Health and Wellbeing Queensland by UQ Health Care and Metro South Health on behalf of the alliance. The proposal was strongly aligned with the vision and strategic plan of the newly formed Health and Wellbeing Queensland, which included developing and trialing new models of care for the prevention and management of chronic disease.

Here, the intention was to reduce pressure on the tertiary health care system, address health inequities, and build multisectoral partnerships that drive system-level change for improved health and well-being outcomes. In 2021, Health and Wellbeing Queensland joined the alliance, with UQ Health Care and Health and Wellbeing Queensland entering into a 4-year agreement (2021-2024) to support the delivery of a tailored lifestyle management program. UQ Health Care secured additional revenue agreements and financial contributors to deliver on the commitment to reduce financial barriers for participants. The UQ Health Care and Health and Wellbeing Queensland service-level agreement outlined a comprehensive suite of deliverables and biannual key performance indicators. These key performance indicators were designed to evaluate the program according to the RE-AIM indicators across the 3 priorities identified previously (reduce the burden of disease on individuals, the community, and the health system). Examples of the agreed upon key performance indicators are summarized in Table 1.

Table 1. Examples of key performance indicators for Logan Healthy Living.

Evaluation domain	Key performance indicator
Reach	• Participant's type 2 diabetes status (at risk, newly diagnosed, complex, or chronic) • Participant's demographic characteristics • Participant retention • Participant attrition
Effectiveness	• Participant's knowledge, health literacy, and intention to change • Participant's healthy behavior action (health behavior change and anthropometric measures) • Health system impact
Adoption	• Referral pathways
Implementation	• Participant satisfaction • Staff satisfaction • Participant safety (adverse events) • Student training
Maintenance	• Participant sustained healthy behavior • Sustainable funding

The development and design of the service was community led and iteratively co-designed with key stakeholders, including consumers. Activities included participant journey mapping to inform program and resource development, consultation with student placement providers, and learning needs assessments for local GPs. A key event for consumer and stakeholder engagement was a half-day "design-jam" led by UQ Ventures and held on campus at Griffith University in Meadowbrook, where approximately 60 end users, delivery providers, academics, clinicians, community leaders, and representatives of other key stakeholders (eg, Metro South Health, Brisbane South Primary Health Network, and the Aboriginal and Torres Strait Islander Community Health Service) came together to progress their combined vision and implementation plan for the service. Subsequent planning days have also been hosted, which have similarly included Logan Healthy Living staff, key stakeholders, and consumers.

Simultaneously, the plan for routine collection of reporting and evaluation data was co-designed by key stakeholders, including researchers from The University of Queensland; the Logan Healthy Living Clinical and Operations Manager, administration team, and clinicians; and relevant content experts. Key to successfully collecting the range and breadth of data required was the intent to embed data collection into routine service delivery. Led by a researcher employed by the Health and Wellbeing Centre for Research Innovation (a research center jointly funded by The University of Queensland and Health and Wellbeing Queensland; SG), along with a senior academic experienced in evaluation (GH) and a data analyst (EW), a pragmatic data collection and consent process was co-designed and embedded into daily operations. Data are collected through both practice management software (Gensolve) and clinical trial software (REDCap [Research Electronic Data Capture]; Vanderbilt University) and facilitated day to day by the Logan Healthy Living clinical team, with technical and content support on an as-needed basis from The University of Queensland. Implementation of the data collection process was supported by on-site training sessions and a comprehensive manual developed by the data analyst. The Clinic and Operations Managers have been essential in establishing and building a culture for collaboration and prioritization of data collection.

Facilities

Logan Healthy Living went live for operations in July 2021. The service initially operated from Griffith University Logan Healthcare Centre, where it was intentionally colocated with the Beacon Clinic and Metro South Health Chronic Disease Diabetes Service (which included diabetes educators, nurse practitioners, and a podiatry service). In February 2023, Logan Healthy Living moved into its permanent, purpose-built location in a dedicated health and medical clinic, Meadowbrook Medical Centre, colocated with the UQ Health Care Meadowbrook GP clinic and the Logan Hospital endocrinology outpatient services (Logan Endocrine and Diabetes Service). The Meadowbrook Medical Centre is centrally located in the City of Logan and

positioned within the community's transport and retail hub, Logan Hospital, and the Logan Healthy Kids Club and Good Start programs operated by Children's Health Queensland. The site is also set to become part of a larger health precinct, with a planned staged expansion of Logan Hospital and an additional 2 private hospitals.

Logan Healthy Living occupies 400 m^2 at Meadowbrook Medical Centre and includes a gym floor, 5 curtained consultation spaces, 2 individual consultation rooms, 2 large private rooms (used for staff or student rooms or for group education sessions), and an integrated open space dedicated to delivering group education. The open gym includes a range of exercise equipment, including cardiovascular training equipment (treadmill and stationary bicycle), parallel bars, steps and stairs, and resistance and balance training equipment. UQ Health Care invested in state-of-the-art resistance training machines by HUR Australia [31] that use air resistance and SmartTouch software for automatically programming and tracking load and equipment position (eg, seat heights), with participants tapping on and off the equipment with a personalized radio-frequency identification wristband. HUR Australia equipment was selected to reduce the barriers and improve safety with resistance training for older adults and new exercisers; the HUR Australia equipment is fully automated and applies smooth and consistent resistance across the range of motion.

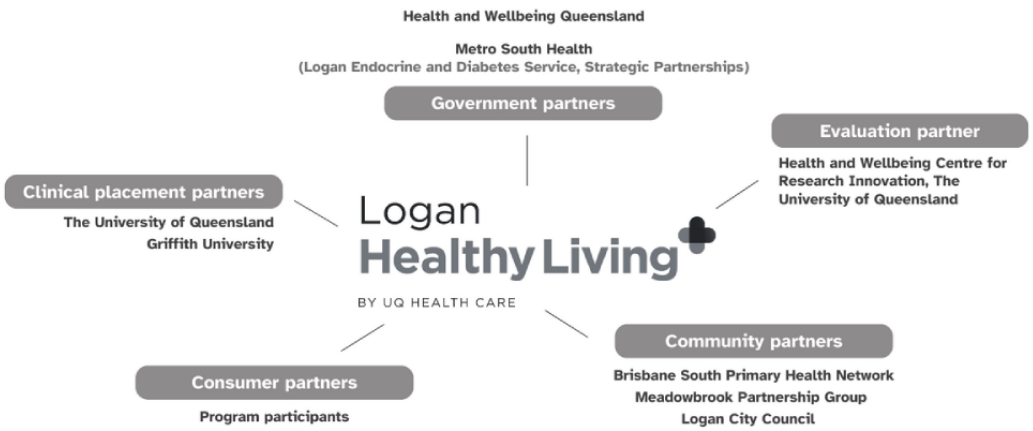
The clinic is staffed by a range of allied health professionals, including physiotherapy, exercise physiology, dietetics, diabetes education, and health psychology professionals. With its student-infused model, the service also provides clinical education and placements for students from Griffith University and The University of Queensland. These include clinical placements for physiotherapy, exercise physiology, dietetics, and psychology students (ranging from 4 to 20 weeks in length) and project placements in a wide range of health disciplines such as nutrition and dietetics, pharmacy, social work, and health service management. Students from a range of disciplines work together to provide an interprofessional model of care. Beyond providing health care services, Logan Healthy Living is also further embedding itself into the community by contributing to the development and career selection of a locally based workforce, with the aim to promote workforce sustainability in the region. Examples of these activities include facility tours with question-and-answer sessions and opportunities for work experience with the Logan Healthy Living team for local high school students with interest in health careers.

Governance

Logan Healthy Living is governed by a multisectoral steering committee that is cochaired by UQ Health Care and Health and Wellbeing Queensland. Beyond UQ Health Care and Health and Wellbeing Queensland, the steering committee includes representatives from The University of Queensland, Griffith University, Metro South Health, Logan Hospital, Brisbane South Primary Health Network, and Logan Healthy Living participants. Members of the steering committee are responsible for providing program leadership and direction (eg, understand strategic implications and outcomes and accept responsibility for program strategy and overall benefit realization) and governance (eg, risk identification and mitigation, stakeholder management, and monitoring of progress) and maximizing program benefits (eg, monitor program outputs and monitor implementation and evaluation). Additional stakeholders are also consulted by the steering committee, such as broader consumer groups, the Aboriginal and Torres Strait Islander Community Health Service, Children's Health Queensland, and Diabetes Australia.

Logan Healthy Living is connected to the broader community governance of the Logan region through the Meadowbrook Partnership Group. Established in 2018, the group comprises representatives from key organizations who are positioned to influence integration and impact in Logan. Membership includes Brisbane South Primary Health Network; Logan City Council; Metro South Health; Economic Development Queensland; Loganlea State High School; The University of Queensland; Griffith University; and the Department of State Development, Infrastructure, Local Government, and Planning. Collectively, the membership represents state, federal, primary care, education, and local government stakeholders. All members have strong community relationships and understanding of local issues. Logan Healthy Living (clinical and operations manager) and UQ Health Care (chief executive officer) are members of the Meadowbrook Partnership Group. Figure 1 shows the network of key stakeholders involved in the development and delivery of Logan Healthy Living.

Figure 1. Logan Healthy Living key stakeholder network.



Program Cost, Participants, Referral Pathways, and Intake Process

Logan Healthy Living delivers services at no cost to participants. Where possible, reimbursement for the lifestyle management program is sought through Medicare, Australia's universal health insurance scheme that provides free or subsidized health care (Medicare Benefits Schedule) and selected medication (Pharmaceutical Benefits Scheme, including diabetes medications) for Australian and New Zealand citizens, permanent residents, and some temporary residents. Specifically, Logan Healthy Living seeks reimbursement through the Medicare Benefits Schedule (group allied health service for type 2 diabetes), which funds 1 intake assessment (Aus $74.80 [US $46.99]) and 8 group sessions (Aus $18.65 [US $11.72] per session per person) per calendar year [32]. To claim Medicare benefits, the group sessions must include between 2 and 12 people; last at least 60 minutes; and be delivered by a credentialed diabetes educator, accredited exercise physiologists, or accredited practicing dietitian [32]. While the lifestyle management program is the primary service, participants are also able to access 1:1 consultations with health professionals on an as-needed basis.

To be eligible for the Logan Healthy Living lifestyle management program, participants must have a diagnosis of type 2 diabetes and be aged ≥16 years. While the program is intended for people living in the Logan region, no one is excluded from the service based on their geographical address. Participants may be excluded if it is identified by the clinical team that a group program may not be a feasible method of service delivery (ie, a participant requiring 1:1 education support). At Logan Healthy Living, services are currently delivered in English, and there is no access to free interpreter services (eg, through state or national government programs). However, clinical services have been delivered to participants who do not speak English when supported by a carer or support person.

Participants are primarily referred to the program by GPs using a referral form for group allied health services under Medicare for patients with type 2 diabetes. Participants are also able to self-refer through an expression of interest form on the service's website. Word of mouth and marketing activities support self-referrals, such as the service's website and newsletter, referrals from specialists (eg, the Logan Endocrine and Diabetes Service), and local advertising (eg, booths at local shopping centers, open days, and notice boards). Self-referrals may also be driven more broadly through the activities and promotion of the service by members of the alliance (eg, Metro South Health, Health and Wellbeing Queensland, Brisbane South Primary Health Network, UQ Health Care, Griffith University, and The University of Queensland). Where participants self-refer and do not have a GP referral, they are encouraged to obtain one so that the service can be reimbursed through Medicare; however, in cases in which there are barriers, this does not preclude admission into the lifestyle management program. For example, participants may experience financial barriers to primary care. While visits to GPs are subsidized by Medicare in Australia for some people, visits often attract a gap payment; services that provide no-gap primary care (bulk bill only) are limited; and some participants may not be eligible to enroll in Medicare and, therefore, ineligible for subsidized consultations. Participants can re-enroll in the program once per calendar year.

Upon presenting to Logan Healthy Living, participants are booked for an intake assessment, which is arranged over 2 appointments (appointments 1.1 and 1.2). The first appointment (1.1) is focused on medical history screening (using referral information where possible) and physical assessments. If it is identified at this first appointment that more information is required to safely prescribe exercise, the team may place the participant's referral on hold until medical authorization to exercise is provided by the referring GP or (if self-referred) the participant's usual GP. The second appointment (1.2) is focused on identifying barriers to participation in the lifestyle management program, goal setting, and an introduction to the exercise program. In between the 2 appointments, participants complete web-based, self-report surveys and are invited to indicate whether they agree or disagree to providing written informed consent for their data to be included in a research data registry (further details on ethics are described in the evaluation protocol in the Ethical Considerations section). Screening for completion of surveys and consent forms is conducted by the reception team, with face-to-face support for completion provided by the clinicians at the second appointment if required. After completion of the intake assessment, participants are allocated to the next available group according to their support needs and whether they are most suited for a "recently" diagnosed or "chronic" group allocation based on time since diagnosis.

Logan Healthy Living Lifestyle Management Program

Overview

The lifestyle management program is the primary service delivered by Logan Healthy Living. The program was developed and is delivered in line with the American Diabetes Association Standards of Care in Diabetes [33], which outline recommendations for a range of factors related to the management of people with type 2 diabetes. In particular, the Logan Healthy Living lifestyle management program follows the key recommendations for diabetes self-management education and support, medical nutrition therapy, routine physical activity, health behavior counseling, and psychosocial care. The program incorporates a range of behavior change strategies (as described in the Behavior Change Technique Taxonomy by Michie et al [34]), including goals and planning (eg, goal setting and action planning), feedback and monitoring (eg, biofeedback), social support (eg, unspecified, emotional, and practical), shaping knowledge (eg, instruction on how to perform the behavior), comparison of behavior (eg, demonstration of the behavior), repetition and substitution (eg, graded tasks), comparison and outcomes (eg, credible source), identity (eg, framing and reframing), and self-belief (eg, verbal persuasion about capability) [34].

Program Structure

The lifestyle management program is delivered face-to-face in groups over 8 weeks using an interprofessional model of care. Each week includes one 2-hour session that comprises a

60-minute education workshop and a 60-minute supervised exercise ("movement") session. Each group has a maximum of 10 participants and is assigned an education workshop and an exercise lead (either health psychologist and exercise physiologist or diabetes educator and physiotherapist, respectively) who supports and provides services to the group throughout the 8 weeks. "Recharge" sessions are offered at 1, 3, 6, 9, and 12 months following completion of the 8-week program to provide an opportunity for participants to reconnect with their health care team, review their goals, and participate in a follow-up assessment before being discharged at 12 months. The 1-month recharge is conducted face-to-face, with the remaining sessions conducted via telephone. The education workshops and supervised movement sessions are conducted on-site at Logan Healthy Living, with movement sessions conducted in the fully equipped, on-site gym.

Program Content

A week-by-week overview of the topics, key concepts, and resources provided in the education workshops is detailed in Table 2. The education workshops were designed to be patient centered and focus on diabetes self-management education with the clinical support needed to facilitate the knowledge, decision-making, and skill mastery necessary for diabetes self-care. Education workshop topics are integrated with social prescribing, where opportunities for community engagement related to that week's content are signposted to support longer-term behavior change and address the broader social determinants of health. In addition to being signposted to local programs, participants are signposted to Health and Wellbeing Queensland's suite of prevention programs, including 10,000 Steps and Deadly Choices [30]. The supervised movement session comprises an individually prescribed exercise program targeting combinations of cardiovascular fitness, strength, or flexibility depending on participant presentations. All participants are provided with the opportunity to have an individually prescribed home exercise program or access to Physitrack [35], an app that supports home exercise prescription and monitoring.

Table 2. Overview of the education workshop topics for the Logan Healthy Living lifestyle management program.

Week	Description	Key concepts	Handouts
1	Welcome and orientation	• Acknowledgment of Country[a] • Overview of the allied health team • Overview of program structure • Instructions and rationale for pre-exercise checks • Group introductions • Group activity: "What health behaviors impact my diabetes?"	• Pre-exercise checklist • Lifestyle management program journey plan • Opportunities for community engagement
2	Diabetes education	• What is type 2 diabetes • The role of insulin, insulin sensitivity, and insulin resistance • Key management strategies • Blood glucose testing, HbA_{1c}[b], understanding one's "normal," hypo- and hyperglycemia, and management strategies • Effects and complications of type 2 diabetes • Understanding the annual cycle of care • Identifying other support (family, friends, and community) • Introduction to self-management • Important services to connect with	• What is type 2 diabetes • Key management strategies • Instructions for blood glucose testing • Team of support and recommended review time frames • Services to find out more about type 2 diabetes—National Diabetes Services Scheme, DESMOND[c] Australia, Diabetes Connect by Diabetes Australia, and Logan Healthy Living Facebook page
3	Nutrition part 1	• Carbohydrates and how different types affect blood sugar • Healthy eating guidelines • Understanding what a diet looks like living with type 2 diabetes (5 main food groups) • Hydration • Healthy eating for diabetes • Meal timing and consistency	• A guide to a nourishing lifestyle—a breakdown of the 5 main food groups • How to build a healthy plate • Recommended meal timing • Tips for staying hydrated • Local services providing nutrition support
4	Nutrition part 2	• Understanding food labels • How food labels can help with diabetes management • Grocery shopping efficiently (saving money) • Modifying favorite meals to make them healthier	• Tips for reading food labels • Tips for enjoying home cooking and putting nutrition advice into practice • Local services providing food banks
5	Movement medicine	• The importance of enjoying movement • what is physical activity and exercise • What are the benefits of exercise • The importance of exercise for type 2 diabetes • Physical activity guidelines • Safely exercising with type 2 diabetes • Group activity: "Where can you find the motivation and inspiration to exercise?"	• Benefits of exercise • Pre-exercise checklist • Types of movement (aerobic, balance, flexibility, and resistance training) • Making exercise work for oneself • Exercise and blood glucose levels • Local services providing opportunities for movement
6	Stress management	• Understanding stress and what happens to the body when one is stressed • Understanding how stress impacts type 2 diabetes • The importance of social support • Group activity: managing stress—stress bucket analogy and brainstorming ways to manage stress	• What is stress • Identifying stressors • Sources of support • Local services providing well-being activities

Week	Description	Key concepts	Handouts
7	Healthy habits	• Understanding how to set goals effectively • Review of goals and progress • Planning for life after the program • Creating and sustaining healthy habits • Planning for future success and overcoming barriers • Group activity: building healthy habits (understanding prompts, habits, and rewards) • Group activity: identifying barriers and "helpers"	• Tips for changing behavior and the habit cycle • Ideas for goal setting related to type 2 diabetes • "Planning for the future" activity—identifying what success looks like, what support systems are needed, and what has worked so far and planning for healthy habits • Information on local organizations offering a range of services (eg, community centers and libraries) • "Active and Healthy" booklet by the City of Logan (free and low-cost activities in the area)
8	Wrap up—review and future planning	• Review of educational workshops • Review of action plans (movement, community connection, nutrition, support networks, and rewards and motivations) • Group activity: bingo (revision of each topic)	• Summary of key takeaways from each topic • How to stay connected with Logan Healthy Living (recharge session schedule, gym memberships, meet-ups, Facebook group, blogs, and allied health consultations)

[a]An Acknowledgment of Country is delivered at the beginning of each week.

[b]HbA_{1c}: hemoglobin A_{1c}.

[c]DESMOND: Diabetes Education and Self-Management for Ongoing and Newly Diagnosed.

Evaluation Protocol for the Logan Healthy Living Lifestyle Management Program

Guided by the RE-AIM framework, the evaluation protocol was developed in partnership with the Health and Wellbeing Centre for Research Innovation at The University of Queensland and the other members of the steering committee and was designed to inform the service-level agreement and key questions regarding the uptake, effectiveness, costs, and sustainability of the program.

Study Design

The evaluation is a single-arm intervention design where participants are evaluated at intake to the service (before the program); at the end of the supervised program (8 weeks); and at approximately 1, 3, 6, 9, and 12 months after the end of the supervised program. For participants who do not re-enroll in the program, annual follow-ups are conducted at 2, 3, and 4 years.

Measures

Overview

A summary of measures that are being collected from participants to describe contextual information, program effectiveness, and acceptability is provided in Table 3, with further details and outcomes from other data sources described in the following sections. All self-report surveys are administered using REDCap, service-level data are extracted from practice management software, and physical measures are administered by clinicians on-site.

Table 3. Outline of participant self-report measures and timing of assessments[a].

Measures	Structured program		Extended follow-ups				
	Intake	8 weeks	1 month	3 months	6 months	9 months	12 months
Contextual information							
Sociodemographic	✓						
Smoking and smoking changes[b]	✓	✓					✓
Digital health use	✓	✓					✓
Community involvement	✓	✓		✓	✓	✓	✓
Program effectiveness							
Diabetes-related distress	✓	✓		✓			✓
Health behaviors (physical activity, sitting, and nutrition)	✓	✓		✓	✓	✓	✓
Quality of life	✓	✓		✓	✓	✓	✓
Self-management self-efficacy	✓	✓		✓			✓
Loneliness	✓	✓		✓			✓
Anthropometry	✓	✓		✓	✓	✓	✓
Physical function	✓	✓					
HbA_{1c}[c] level	✓		✓				
Self-reported health care use	✓						✓
Acceptability							
Satisfaction		✓					

[a]All self-reported 12-month assessments (except smoking) are repeated annually at the 2-, 3-, and 4-year follow-ups.

[b]Smoking status is assessed at intake, and change in smoking status is assessed at 8 weeks and 12 months.

[c]HbA_{1c}: hemoglobin A_{1c}.

Reach Outcomes

Program Uptake

Program uptake will be described by reporting the number of participants who enroll in and commence the lifestyle management program compared to those considered ineligible. These outcomes will be tracked using appointment data from the practice management software, Gensolve. Withdrawals from the program and reasons for withdrawal will be tracked by clinicians using REDCap.

Sociodemographic and Other Contextual Characteristics

Demographic data are collected at intake on time since diagnosis of type 2 diabetes, age, sex assigned at birth, gender, postcode, First Nations status, country of birth, language spoken at home, highest level of education, occupation, and employment status. Other contextual information is collected at intake and tracked throughout the program. Smoking status is assessed at intake, and smoking changes are collected at the 8-week and 12-month follow-ups. Use of digital health technologies (eg, apps, wearables, and telehealth) is collected at intake, 8 weeks, 12 months, and then annually. Community involvement is collected at each of the assessments except for the 1-month follow-up by asking participants to report whether they take part in the following activities outside the home: social-based groups, exercise-based groups, combined social and exercise groups, and art and craft–based activities.

Effectiveness Outcomes

Diabetes-Related Distress

The primary effectiveness outcome for the evaluation is diabetes-related distress. Diabetes-related distress will be assessed using the Problem Areas in Diabetes scale [36]. The Problem Areas in Diabetes scale is a self-report, validated questionnaire that comprises 20 items assessing diabetes-related problems, with participants asked to indicate whether each item is “not a problem,” “a small problem,” “a moderate problem,” or “a somewhat serious problem.” Scores of ≥40 to 40 are considered “severe distress”; distress on specific items is considered when the total is not ≥40 but the score on one or more items is ≥3. Participants have “no evidence of distress” when both previous definitions are not met.

Health Behaviors

Physical activity will be assessed using the Active Australia Survey, a validated self-report measure [37]. The Active Australia Survey is designed to measure participation in leisure-time physical activity. It offers a short and reliable set of questions that can be easily administered via self-report or interview. Sitting time will be measured using an adapted version of the AusDiab multicontext sitting questionnaire, which

asks participants to recall weekday and weekend day sitting time over the previous 7 days [38].

Nutrition-related behaviors will be assessed using 14 self-report items sourced from the 13-item Diet Quality Tool by O'Reilly and McCann [39] and 4 items from the evaluation of the Get Healthy Service [40], with redundant items removed. The Diet Quality Tool [39] has been validated in an Australian clinical population and reflects overall dietary quality relative to national recommendations. The New South Wales Get Healthy Service items, derived from population surveys—daily servings of fruit and vegetables as per the National Nutrition Survey [41], as well as daily servings of sweetened drinks per day and takeaway meals per week from the New South Wales Population Health Survey [42]—are useful stand-alone items for comparing results to those of other interventions such as the Get Healthy Service.

Alcohol consumption will be assessed using the brief 3-item version of the Alcohol Use Disorders Identification Test. The Alcohol Use Disorders Identification Test provides both a continuous score that correlates with alcohol consumption and adverse drinking consequences and a valid screening tool for detecting alcohol use disorders and risky drinking with validity in numerous populations, including primary care samples [43].

Quality of Life

Quality of life will be assessed via self-report using the EQ-5D-5L. The EQ-5D-5L is a widely used and validated tool to measure health-related quality of life [44]. The questionnaire comprises 5 dimensions—mobility, self-care, usual activities, pain or discomfort, and anxiety or depression—and participants are asked to report their level of difficulty with each dimension: *no problems*, *slight problems*, *moderate problems*, *severe problems*, and *extreme problems*. It also asks participants to self-rate their health on a numerical scale from 0 to 100.

Self-Management Self-Efficacy

Self-management self-efficacy will be measured via self-report using the Patient Motivation Questionnaire [45]. The Patient Motivation Questionnaire comprises 10 statements related to patients' understanding and confidence in the self-management of their condition. The score is calculated as a total out of 10, with 8 items required to be completed.

Loneliness

Loneliness will be assessed via self-report using a valid and reliable scale that asks 4 questions to capture different aspects of loneliness [46]. The first 3 questions are from the University of California, Los Angeles, 3-item loneliness scale. Scores from the 3 items are used to determine whether the participants are lonely (scores of 6-9) or not lonely (scores of 3-5). The final question is a direct question on how often the respondent feels lonely.

Anthropometric Measures

A combination of directly measured and self-report methods will be used to assess weight (kg) and waist circumference (cm). Directly measured weight will be assessed during the 1.1 intake appointment, the 8-week group appointment, and any subsequent face-to-face recharge appointments (not including the 1-month follow-up). Where participants do not attend face-to-face follow-up appointments for direct measures, they will be asked to self-report their weight and waist circumference. Instructional videos will be provided on how participants can best self-administer these measures. The combination of self-report and direct measures is standard practice at the clinic to allow for flexibility in collecting the data in a timely way with respect to the measurement time points while also allowing participants to have measures directly taken if they are at the clinic at the time of their follow-up.

HbA_{1c} Measures

HbA_{1c} level will be collected using a combination of approaches. For all participants, data will be collected by state pathology laboratories, with the tests conducted closest to intake and the 1-month follow-up after the supervised program (ie, approximately 3 months after baseline) being requested from relevant data custodians. A subsample of participants will have their HbA_{1c} levels collected via finger prick at intake and at the 1-month follow-up, with the point-of-care protocol introduced in January 2024 due to availability of resources.

Physical Function Measures

The 2-minute step test [47], time to complete 5 sit-to-stand exercises [48], and grip strength [49] will be assessed at intake and at 8 weeks to evaluate physical function.

Health Care Use

Health care use will be assessed using a self-report measure of use of GP, hospital, and emergency services at baseline and the 12-month follow-up based on questions adapted from those used in the Household, Income, and Labour Dynamics in Australia Survey [50,51]. In addition, Queensland Health records will be used to quantify emergency department presentations, hospital admissions, bed days, and potentially preventable hospital admissions related to type 2 diabetes (according to the Queensland Health key performance indicator attribute sheets for diabetes-related potentially preventable hospital admissions).

Adoption Outcomes

Adoption will be described by estimating the number of referrals and their referral sources.

Implementation Outcomes

Fidelity

Fidelity will be assessed using adherence to the program, where adherence is the number of sessions attended. These data will be drawn from the practice management software.

Appropriateness

Appropriateness of the program will be assessed by continuing to monitor program adaptations. These will be tracked using a log similar to that in Table 3.

Acceptability

Acceptability will be determined by assessing participant satisfaction. Participant satisfaction will be assessed using a 4-point Likert scale at the end of the supervised group component of the program (8 weeks), where 1=*not at all satisfied*, 2=*somewhat satisfied*, 3=*satisfied*, and 4=*highly satisfied*. Participants will be asked to rate their overall service

satisfaction, satisfaction with the quality of the services, satisfaction with the first appointment being scheduled within a reasonable period, satisfaction with the staff providing the service, and satisfaction with the written information.

Costs

Cost of delivery will be assessed using appointment data collected using the practice management software and overall operating costs.

Maintenance Outcomes

Primarily, participant maintenance will be considered using their longer-term outcomes collected at approximately 12 months after the 8-week structured program. Additional perspective will be provided by the extent of re-enrollment after 12 months (or as early as 9 months if clinically indicated), as well as the long-term outcomes at the 2-, 3-, and 4-year follow-ups among those who do not re-enroll in the program.

Sample Size

The number of participants receiving treatment is not connected to an a priori sample size requirement as it would be in a traditional intervention study. Nonetheless, it is useful to consider how much evaluation data provide an adequate degree of power to detect changes in outcomes. These approximate requirements, based on simple bivariate tests and presented in Table 4, show that even a brief evaluation with few participants should be adequate for some outcomes (such as physical activity), whereas a long-running evaluation with many participants might be required to detect the expected changes in sitting time or potentially clinically meaningful changes in quality of life based on the EQ-5D-5L visual analog scale.

Table 4. Approximate number of evaluated participants required to detect 0- to 8-week changes in effectiveness outcomes with 80% to 90% power and 5% 2-tailed significance.

Measure	Effect size	Assumed values, *r* (SD)	Required number of participants[a]	
			80% power	90% power
Diabetes-related distress				
PAID-20[b] score	MCID[c]=5	0.65 (15)	52	69
Health behaviors				
Active Australia MVPA[d] (minutes per week)	Moderate effect (0.5 SD)	0.4 1)	40	53
Sitting time (minutes per day)	Expected effect=30	0.4 (340)	1212	1622
Fruit consumption (servings per day)	Small effect (0.2 SD)	0.5 (1)	199	265
Vegetable consumption (servings per day)	Small effect (0.2 SD)	0.5 (1)	199	265
Sweet drink consumption (cups per day)	Small effect (0.2 SD)	0.5 (1)	199	265
Takeaway meals (times per week)	Small effect (0.2 SD)	0.5 (1)	199	265
Quality of life				
EQ-5D-5L visual analog scale (0-100)	MCID=6	0.6 (65)	739	989
EQ-5D-5L index score	MCID=0.262	0.75 (0.2)	5	6
EQ-5D-5L visual analog scale (0-100)	Small effect (0.2 SD)	0.6 (1)	159	213
EQ-5D-5L index score	Small effect (0.2 SD)	0.75 (1)	101	134
Self-management self-efficacy				
Patient Motivation Questionnaire score	Small effect (0.2 SD)	0.5 (1)	34	44
Loneliness				
UCLA[e] Loneliness Scale score	Small effect (0.2 SD)	0.75 (1)	101	134
Anthropometry				
Weight (kg)	Very small change=1	0.99 (26)	427	571
Waist circumference (cm)	Expected effect=2	0.97 (17)	36	48
Physical function				
2-minute step test (steps)	MCID=11	0.65 (25)	31	40
Sit-to-stand test (seconds)	MCID=2.3	0.65 (5.5)	34	45
Grip strength (left hand; kg)	Expected effect=1.5 kg	0.9 (11)	87	115
Grip strength (right hand; kg)	Expected effect=1.5 kg	0.9 (11)	87	115
HbA_{1c}[f]				
HbA_{1c} level (%)	MCID=0.5%	0.7 (1)	21	28
Health care use				
Number of general practitioner visits	Small effect (0.2 SD)	0.5 (1)	199	265
Number of emergency department presentations	Small effect (0.2 SD)	0.5 (1)	199	265
Number of hospital visits	Small effect (0.2 SD)	0.5 (1)	199	265

[a]Number of participants with pre- and postevaluation data collected.

[b]PAID-20: Problem Areas in Diabetes.

[c]MCID: minimum clinically important difference.

[d]MVPA: moderate to vigorous physical activity.

[e]UCLA: University of California, Los Angeles.

[f]HbA_{1c}: hemoglobin A_{1c}.

Data Analysis

Reach, adoption, and implementation outcomes will be reported using descriptive statistics. The effectiveness of the lifestyle management program on effectiveness outcomes (all continuous) will be assessed by examining changes over time in linear mixed models accounting for repeated measures. Missing data in these mixed models will be handled through evaluable case analysis, with adjusted models including any characteristics that may differ between those providing data at different time points. The sensitivity of the conclusions to missing data handling will be evaluated using multiple imputation. All relevant time points will be reported, with the primary end point for effectiveness being 8 weeks (except for HbA_{1c} level and GP visits) and the primary end point for maintenance being approximately 12 months. The main evaluation will focus on all participants enrolled in the program, and a further per-protocol evaluation will consider outcomes for adherent participants only. Health care use in the 12 months before and the 12 months following enrolment in Logan Healthy Living will be compared using appropriate paired nonparametric tests (Wilcoxon signed ranks test and McNemar chi-square test). Costs will be estimated where possible. Sensitivity analyses will be conducted to explore whether health care use differs by a range of factors, including demographic and clinical characteristics.

Ethical Considerations

The data registry has ethics approval from the Metro South Health Human Research Ethics Committee (project ID 84062) and has received ratification from The University of Queensland Human Research Ethics Committee (2022/HE001421). At intake, participants are provided with the participant information and consent form for the data registry by the clinical team electronically and invited to opt in by providing written informed consent. Data for the data registry are collected in an identified manner, with data stored in REDCap and The University of Queensland Research Data Manager in password-protected folders. Participants are not provided with any compensation for taking part. Hospital use data will be drawn from centrally held medical records and obtained on request from relevant data custodians.

Iterative Adaptations to the Program

Since the opening of Logan Healthy Living in July 2021, several iterative adaptations have been made to the service delivery model to better meet the needs of the participants and the clinical team. Adaptations have been informed by stakeholder feedback (clinicians, students, and consumers) and biannual key performance indicator reports. Clinician and student reflections and feedback are discussed in regular team meetings, and participant feedback is openly encouraged through all interactions with Logan Healthy Living. Feedback from participants was sought more formally through qualitative focus groups conducted in the first years of operation that aimed to identify barriers to and facilitators of maintaining behavior change following the lifestyle management program [52]. In addition to identifying barriers that resulted in service changes (eg, ongoing access to resources such as Physitrack and the gym), participants reported that there was a sense of belonging and safety within the program, which facilitates an open dialogue for feedback on services. Key changes in response to consumer feedback are communicated to participants using a range of mechanisms, including “You said...we listened...” posters that outline feedback and corresponding changes to service delivery, which are displayed around the facility, and via clinic newsletters and social media posts. A summary of key service delivery model adaptations is provided in Table 5.

Table 5. Summary of key service delivery model modifications.

Year	Feedback or challenge	Modification
2022	Initially conducted as 1 appointment, the intake assessment took approximately 3 hours, and participants reported fatigue.	The intake assessment was split into 2 appointments (1.1 and 1.2).
2023	Participants wanted the opportunity to continue to attend Logan Healthy Living to exercise.	"Open" gym time was scheduled, where participants could independently use exercise equipment once they had finished the lifestyle management program.
2023	Participants had access to Physitrack during the lifestyle management program and for 3 months after, and feedback indicated that they wanted access for longer.	Participants are provided with access to Physitrack for up to 12 months after the lifestyle management program.
2024	Demand for access to the gym was increasing, and access times were unsuitable for a large number of participants.	"Open" gym concept was expanded to a full, low-cost gym membership model with expanded opening times.
2024	Recharge sessions were scheduled as a group, and attendance was poor.	To improve attendance, recharge sessions are individually scheduled and delivered face-to-face at 1 month and via telehealth (telephone) at 3, 6, 9, and 12 months.
2024	Participants expressed a desire to have ways to continue to connect socially with their peers after completion of the lifestyle management program.	A community engagement social group was started. This included a bimonthly scheduled opportunity for participants to engage with each other socially and to inform them of local community engagement activities. This activity is jointly supported by the community development team of Logan City Council.
2024	The time taken to complete the intake assessment (eg, time from referral to commencing the lifestyle management program) was resulting in high attrition and low rates of uptake of the program.	The intake process was streamlined so that appointments were booked concurrently (1.1 and 1.2) to minimize time between referral and commencing the program.
Ongoing	Feedback is continually sought on the program materials and resources from all stakeholders (participants, students, and clinicians).	Program materials and resources are iteratively adapted to respond to feedback and ensure that they are up-to-date (eg, that local services are current and still operating).

Results

The 4-year proof of concept concludes on December 31, 2024, with reporting of the results anticipated in 2025. Results will be reported in conference abstracts and publications and with stakeholders informed through reports (with authorship determined according to scientific authorship guidelines). Findings will be shared with Logan Healthy Living participants using a range of channels, including clinic posters, newsletters, and social media.

Discussion

Overview

This paper describes the development and evaluation protocol for Logan Healthy Living, an interprofessional, community-delivered allied health service for people living with or at risk of type 2 diabetes in Logan, a region in South East Queensland, Australia. Delivered by a multisectoral alliance including primary and tertiary health care, government, and university partners, Logan Healthy Living is a proof-of-concept service that will be comprehensively evaluated using the RE-AIM framework and drawing from data at the level of the participants, service, and health system.

In this project, the evaluation outcomes are continuously monitored and collected in partnership between researchers and clinicians, with data collection embedded into usual practice. This is driven simultaneously by a value-based funding model and the opportunity for evidence-generating practice, with the establishment of agreed upon key service performance indicators being a pivotal influence in the buy-in required to embed this into practice. While the benefit for research is obvious, what has also emerged is the potential of continuous monitoring to inform iterative adaptations to the program, with the ability to respond in real time to optimize the health care service to suit participant and health system needs. Ongoing findings have also been used to inform collaborative strategic planning between partners to drive further development and expansion of the program and services. These "ripple effects," such as establishing new networks, partnerships, and services to meet the needs of these adaptations, will be monitored and reported in detail in an attempt to capture the nontraditional impacts of the program on the community.

While there is a call for multisectoral responses to complex health system challenges [12], including chronic diseases such as type 2 diabetes, responses to these calls are rarely documented in detail, and the learnings from these processes are potentially lost. The detailed description of the alliance, establishment of the service, and protocol for the evaluation have the potential to inform future multisectoral partnerships and the development of community-delivered models of care for type 2 diabetes prevention and management, as well as for chronic diseases more broadly. For example, there were challenges experienced in streamlining referrals and data sharing between government health care providers and Logan Healthy Living. While they were partners within the alliance, formal pathways for these activities were not established, which meant that referrals were

limited to advertising and recommendations from health professionals and participants were required to replicate intake assessments that could have been avoided, thus reducing burden. Future programs can ensure that such details are determined as part of the establishment process. The limitations of the evaluation must also be acknowledged, including the lack of a comparison group; reliance on survey data due to practical considerations, which may introduce self-report bias; and the potential high rates of missing data given that the evaluation is within a service delivery rather than research context.

Conclusions

The implementation and evaluation of a community program within a culturally diverse region of a low socioeconomic status with rising rates of type 2 diabetes provides an opportunity to further understand the interplay of social determinants of health and chronic disease and the impact that a purposefully designed service can have on reducing the burden on the participants, the community, and the health care system. The outcomes of the evaluation will provide valuable insights into the impact of this model of care in practice, with the findings expected to inform potential scale-up through local, state, and national partnerships.

Acknowledgments

The authorship team wish to thank the participants, clinicians, and administrative teams at Logan Healthy Living for their ongoing contributions to the evaluation of the service. They also wish to acknowledge the Logan Healthy Living steering committee, who have governed and guided the service since its establishment. Those who consented to be named include Debbie Cowan, Metro South Health; Dr Rosy Dobrijevic, UQ Health Care Ltd; and Laura Casey, Brisbane South Primary Health Network. Finally, the authorship team would also like to thank the people who were in key positions of leadership during the development of the service who volunteered their time to help the authors understand the early beginnings of Logan Healthy Living. Those who consented to be named include Mika Hayward, Director of Health Partnerships and Major Projects at The University of Queensland. GNH is funded by an Australian National Health and Medical Research Council and Medical Research Future Fund Emerging Leadership Fellowship. SRG, TA, and EAHW are partly funded by the Health and Wellbeing Centre for Research Innovation, which is cofunded by The University of Queensland and Health and Wellbeing Queensland.

Data Availability

Data sharing is not applicable to this paper as no datasets were generated or analyzed during this study.

Conflicts of Interest

DG and WW are employed by UQ Health Care Ltd, who deliver and operate Logan Healthy Living. JC, JM, and RL are employed by Health and Wellbeing Queensland, who provide a financial and governing contribution to Logan Healthy Living. All other authors declare that they have no competing interests.

Abstract

Background: Although HIV pre-exposure prophylaxis (PrEP) has been proven to be an effective prevention tool in decreasing HIV transmission, achieving adequate PrEP uptake has remained a challenge among Black cisgender women living in the Southern United States. Gynecology clinics, which provide primary health care services for many cisgender women, have the potential to be an ideal setting for the integration of PrEP services.

Objective: We designed an intervention, PrEP4Her, which aims to implement PrEP service delivery at gynecology clinics in Alabama, the United States, as part of routine reproductive and sexual health care visits to improve PrEP engagement rates among Black cisgender women.

Methods: Guided by the information gathered on (1) factors impacting PrEP implementation at gynecology clinics, including key barriers and facilitators to PrEP implementation and potential strategies to address the identified barriers (in-depth interviews with the gynecology care team), (2) structural barriers and provider-level barriers to PrEP implementation (cross-sectional study among gynecologists), and (3) implementation strategies on how to integrate PrEP services into routine gynecology care (in-depth interviews and focus groups with Black cisgender women), a multicomponent implementation strategy, tailored for Black cisgender women, was developed to integrate PrEP in routine women's health visits (ie, PrEP4Her). To determine the efficacy of the program, we will measure implementation outcomes, reach (increase in the absolute number of Black cisgender women receiving PrEP prescriptions), effectiveness (increase in the proportion of PrEP prescriptions over time), and adoption (proportion of team members willing to implement PrEP4Her) using the RE-AIM (Reach, Effectiveness, Adoption, Implementation, and Maintenance) framework. In addition, acceptability (the extent to which providers and Black cisgender women feel PrEP4Her to be acceptable—in-depth interviews); Feasibility (appropriateness of PrEP4Her for a larger, full-scale trial—the Feasibility of Intervention Measure scale); and fidelity (the degree to which PrEP4Her program was implemented as designed—electronic survey with patients) will also be assessed.

Results: The qualitative and quantitative data from the gynecology care team and the qualitative data from Black cisgender women were collected from August 9, 2022, to April 19, 2023, and were integrated through joint displays to identify major themes. The combined findings provided a comprehensive understanding of factors that were fundamental in the development and refinement of PrEP4Her implementation. The PrEP4Her was implemented from January 29, 2024, to August 16, 2024. The information gathered is being used to assess PrEP4Her efficacy (based on reach, effectiveness, adoption, acceptability, feasibility, and fidelity).

Conclusions: Upon completion of our research, our interdisciplinary team, which includes experts in infectious diseases, implementation science, community-engaged research, and psychology, will be primed to lead a multisite type III implementation trial for PrEP service delivery at gynecology clinics across the Southern United States.

KEYWORDS

Black; cis-Gender women; PrEP; pre-exposure prophylaxis; South; HIV; gynecology

Introduction

Black people only constitute 13% of the US population but account for more than half of the new HIV diagnoses [1]. These disparities are more pronounced in the South [2], where the highest acquisition and mortality rates are documented among Black people [3]. In response to these inequities, the US federal agencies are working in a coordinated manner to end the HIV Epidemic with a mandate to focus on populations facing HIV inequities and geographic hot spots, with prioritization to increase utilization of effective biomedical prevention tools like HIV pre-exposure prophylaxis (PrEP), that reduces HIV transmission with consistent use [4-7]. The US state of Alabama has been prioritized for End the HIV Epidemic efforts due to high HIV incidence and prevalence rates. In Alabama, where the rate of HIV diagnoses in 2020 was 14.1 per 100,000 people, most new diagnoses occurred among Black men and women [8]. In addition, in 2021, Alabama had a PrEP-to-Need ratio of 5.55, with the highest unmet need for PrEP occurring among the Black community (PrEP-to-need ratio among Black vs White individuals: 2.94:11.30) [9].

When focusing on cisgender women, who account for approximately one-fifth of new HIV diagnoses in the United States, only 8% of the 227,010 women with a PrEP indication are currently receiving PrEP prescriptions [10-13]. This low PrEP uptake is similar in Alabama, where only 7% of the PrEP clientele comprised of cisgender women in a university-affiliated infectious diseases-led PrEP Clinic [14]. Among cisgender women, Black cisgender women are even more disproportionally impacted by the HIV epidemic, currently accounting for 54% of all new HIV diagnoses among cisgender women, nationally [15]. These disparities are mirrored in Alabama's HIV incidence, where Black cisgender women are 9 times more likely to be diagnosed with HIV compared with White cisgender women [16]. With Black cisgender women in the Southern United States being disproportionately impacted by the HIV epidemic, approaches to increase PrEP uptake among this population present an opportunity to ameliorate these inequities.

Previous studies among Black cisgender women have found PrEP uptake barriers to occur at multiple levels (ie, individual, interpersonal, and Meso levels) [17]. Some individual-level barriers include a lack of awareness of PrEP and concerns around PrEP-related stigma, including fear of being labeled as HIV-positive with PrEP use, limiting PrEP uptake in this population. In addition, some provider-level barriers have also been discovered, such as a lack of knowledge on current PrEP clinical care guidelines, misconceptions related to insurance coverage, and provider bias preventing culturally appropriate PrEP-related discussions [18]. In addition, providers' stereotypic beliefs or prejudices (ie, having higher levels of color-blind racial attitudes) lead to a decreased willingness to counsel and prescribe Black cisgender women PrEP [19]. As such, overcoming current inequities requires innovative strategies to engage Black cisgender women in PrEP service delivery tailored to their preferences.

Of the total HIV diagnoses among Black cisgender women, the majority occur in those of reproductive age [20]. There is strong evidence to support that 70% of women in the United States are seeking routine annual care for reproductive health and nearly half access contraceptive services [21,22]. Safety-net programs created for cisgender women to receive reproductive health care, like family planning clinics, have been evaluated in Southern states as sites for PrEP implementation [23,24]. However, a major barrier to PrEP uptake is low provider knowledge on the delivery of PrEP services. Interventions focused on improving provider knowledge alone have fallen short on seeing huge gains in PrEP uptake among women [25-28]. In Addition, previous studies have shown that even with increased PrEP access in clinical care settings that specialize in women's health care, PrEP uptake has been low and providers have struggled in optimizing these spaces for PrEP service delivery [22-27,29]. Gynecologists have been shown to be ideal PrEP service delivery candidates, as national data supports higher willingness to prescribe PrEP among gynecologists compared with general practitioners [30]. Furthermore, 81% of patients seen by gynecologists are of reproductive age (18-44 years old), which also reflects the age range among cisgender women more likely to acquire HIV [31]. In line with this, our previous work among Black cisgender women in the state of Alabama also revealed they preferred PrEP services to be delivered by gynecologists in a clinical care setting [32].

Informed by compelling preliminary data, we designed an implementation study to determine the requisite steps and strategies for the implementation of PrEP services into routine gynecological care visits at a university-affiliated clinic in Birmingham, Alabama, which provides services to women with low income across the state [33]. Our gynecological pilot site is a large center that sees over 17,000 patients (40% Black cisgender women) annually, with the majority being of reproductive age, who reside in both urban and rural areas of Alabama. This paper outlines the protocol for this multicomponent implementation strategy, which evaluated key individual-level, inner-setting, and process-level determinants for the implementation of PrEP service delivery in gynecology clinic settings. The intervention aimed to develop and refine a

multicomponent implementation strategy (PrEP4Her) that integrated PrEP in a gynecology clinic, which was then piloted to deliver PrEP for Black cisgender women attending routine gynecologic care visits. The PrEP4Her intervention is aimed at improving PrEP engagement among Black cisgender women in order to reduce the HIV disparity among this population.

Methods

Study Setting

The PrEP4Her was implemented at the University of Alabama at Birmingham gynecological Continuity clinic.

Development of the Protocol

To explore perceived barriers and facilitators for integrating PrEP into routine gynecological care, qualitative and quantitative data were collected. In-depth interviews were conducted with gynecologists, practice managers, medical assistants, nurses, and pharmacists at our gynecological clinical site via teleconference. The interviews covered topics, such as factors effecting PrEP implementation at gynecological clinics, key barriers or facilitators to PrEP implementation, potential strategies to address the identified barriers, and any emerging topic areas for subsequent exploration. In addition, existing PrEP coverage services and programs for uninsured Black cisgender women were discussed with medical service providers, case managers, and social workers. After each interview, interviewers documented field notes, including emerging topic areas for subsequent exploration. The qualitative data were analyzed by an expert qualitative researcher using the NVivo (Lumivero) qualitative data management software. First, a preliminary codebook was developed, which included inductive codes, that emerged from the data, and pattern codes, that connected concepts to one another. The lead qualitative analyst along with a team of 2 researchers applied these codes to a subset of interview transcripts and adjusted the code definitions until an adequate interrater reliability was achieved. The finalized codebook was then used to analyze the remaining transcripts, noting major themes. Finally, data matrices were created to visually represent associations between key concepts and patterns in the data.

In addition to interviews, a cross-sectional study was conducted in collaboration with the Alabama Section of the American College of Obstetricians and Gynecologists and the university's Center for Women's Reproductive Health in the Department of Obstetrics and Gynecology to understand barriers to future state-wide implementation that needed to be measured during this pilot study. Surveys were conducted with English-speaking, currently practicing gynecologists or advanced practitioners at gynecological clinics (n=39), to evaluate structural barriers to PrEP as well as any potential provider-level barriers. The surveys documented information on sociodemographic, HIV, and PrEP knowledge [34,35], HIV- and PrEP-related stigma [36,37], and questions ascertaining current routine testing and screening practices. The data from the surveys reported findings on willingness to prescribe PrEP by the independent variables (sociodemographics: race and ethnicity, clinic name, gender, years of practice, clinic resources, characteristics of populations served; knowledge: PrEP and HIV; stigma: PrEP and HIV; and practice: sexual history, sexual transmitted infections testing, and sexual transmitted infections treatment) as well as willingness to prescribe PrEP (primary outcome) and the capability of the clinical-setting for providing PrEP services (secondary outcome).

To explore the desired PrEP educational materials and communication strategies from gynecologic care teams, in-depth interviews, and focus groups were conducted with Black cisgender women. The inclusion criteria for the in-depth interviews and focus groups were the same and included (1) self-reported HIV-negative status, (2) being Black cisgender women, (3) ability to speak in English, and (4) age of 18 to <54 years (the choice of age range is based on the current HIV epidemiology reporting highest HIV incidence among cisgender women aged <54 years). An informed consent was signed by eligible Black cisgender women before the interview and focus group participation. The semistructured interviews covered topics such as sexual health, education needed to increase awareness and knowledge, stigma, and communication with the care team. The qualitative data were analyzed in a similar manner as described above by the expert qualitative data team.

To develop and refine a multicomponent implementation strategy (PrEP4Her) that aimed to integrate PrEP in gynecology clinics, an intervention mapping technique was used [38]. First, key barriers to PrEP implementation among Black cisgender women and providers were reviewed from the data collected with the PrEP4Her community advisory board (CABs, with the full description provided below). Next, using existing knowledge of components identified from studies that implemented PrEP at family planning clinics in the South, an initial list of components was created. Although family planning clinics may have differences from our gynecological setting in terms of the type of care providers and resources, they share a mission for providing reproductive and sexual health services, which may result in overlap with strategies needed for our research population. Using the knowledge gained through the reported findings, the team modified their list of components for PrEP4Her in a way that was more suited toward our gynecological clinics. Table 1 and Textbox 1 outline the preliminary name, definition, and operationalization of components based on current feedback from the PrEP4Her CAB, established by Proctor et al [39-41]. The team then mapped the implementation strategy and linked it to the desired implementation outcomes. This was followed by developing a content-specific implementation strategy. After implementation strategy materials were refined, appropriate operational steps needed to integrate PrEP into the clinical site were reviewed. JS, who has expertise in implementation science and has previously worked with family planning clinics in Southern settings to improve HIV prevention among Black cisgender women, also helped with PrEP4Her implementation.

Table 1. Specification of components of the implementation strategy ("PrEP4Her").

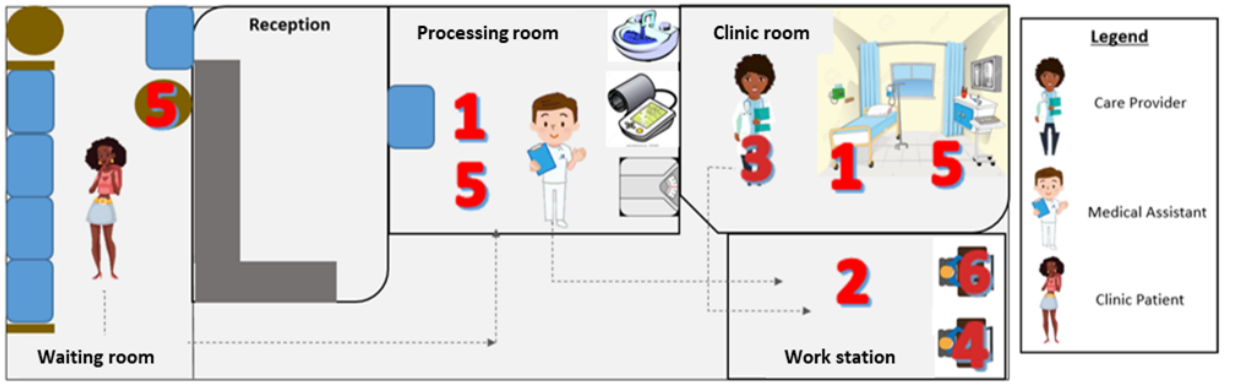
Implementation strategy	Number 1	Number 2	Number 3	Number 4	Number 5	Number 6
Actor	Medical assistant or care provider	Study staff or PrEP[a] expert	PrEP expert	PrEP expert and information technician	PrEP expert and graphic designer	PrEP expert
Action	Charts evidence-based sexual history questionnaire in the medical record	Provides 1.5-hour training on HIV, risk, and PrEP indications and care	Creates easily accessible pocket cards with indications for PrEP	Creates templates in electronic medical records for PrEP visits and order sets	Develops informational content to include in educational materials tailored to Black cisgender women	Develops 30-minute training tutorial on how to communicate with patients about sexual health and PrEP, tailored to Black cisgender women
Target	Patient	Providers or staff	Provider	Provider	Patient	Patient
Temporality	Medical assistant (before every patient encounter with a provider) or provider (beginning of every visit)	1 month before PrEP4Her being implemented at our pilot site	Continuously carried by providers and displayed in shared workspaces	1 month prior to PrEP4Her being implemented with instructions on how to access placed in shared workspaces and sent through email communications	Placed in waiting areas and private examination rooms, accessible during every visit and replenished by study staff members	1 month before PrEP4Her being implemented and presentation accessible in the shared workspace as well as emailed to all providers
Dose	5-minute screener at every visit	1.5-hour training occurring once before 6-month pilot	As needed by providers during clinical care	As needed by providers during charting	Available during the entire 6-month pilot for every clinic	Once before 6-month pilot and then available as needed

[a]PrEP: pre-exposure prophylaxis.

Textbox 1. Pre-exposure prophylaxis 4Her components and outcomes.

- Named pre-exposure prophylaxis 4Her components
- Universal sexual health screening for gynecological patients
- Synchronous training of gynecological care team on HIV, pre-exposure prophylaxis indication, pre-exposure prophylaxis care (for both daily and long-acting injectable regimens), and stigma
- Pre-exposure prophylaxis indication job aids
- Electronic medical record documentation aids, including pre-templated notes and order sets
- Educational materials for Black cisgender women on HIV and pre-exposure prophylaxis
- Asynchronous training on effective communication strategies with patients about sexual health and pre-exposure prophylaxis
- Implementation outcomes affected
- Figure 1. for detailed description of how each implementation strategy maps to implementation outcomes. In short, we will be evaluating the following proximal implementation outcomes: reach, adoption, fidelity, acceptability, and preliminary effectiveness. Distal outcomes will not be evaluated in this study.
- Justification
- Implementation strategy components selected for this study have been selected based on observed, researched, or hypothesized barriers based on a review of the literature. These components may be subject to change based on findings in Aim 1 and feedback from our community advisory board.

Figure 1. Pre-exposure prophylaxis implementation science research logic model. CAB: Community Advisory Board; GYN: gynecology; PrEP: pre-exposure prophylaxis.



PrEP4Her Components		
1. Universal Sexual History – Brief, gender-neutral sexual history screening assessment [42].	**2. Job Aids** – 2-sided pocket cards for white coats/scrubs that will include CDC guidance summary criteria for PrEP among cis-gender women and 5Ps [43,44].	**3. Educational Materials** – Pamphlets, tailored for Black cis-gender women that contain information about HIV and PrEP [45].
4. Synchronous HIV and PrEP Training – ~ 1.5-hour PrEP informational training (adapted from Sales et al. in family planning clinics) made available on UAB CFAR website.	**5. EMR Documentation/Order Aids** – Premade order sets within UABs electronic medical record for initial and 3-month PrEP visits as well as a PrEP note template.	**6. Asynchronous Training on Communication Strategies** – ~ 15 minute training on communicating empowering, "gain-framing" messaging, made available on CFAR website [46].

Conceptual Framework

This multiphase study will be evaluated using the RE-AIM (Reach, Effectiveness, Adoption, Implementation, and Maintenance) conceptual framework and will link our multicomponent implementation strategy to proximal implementation outcomes. Figure 1 depicts the research logic model for the implementation of the PrEP4Her study. The PrEP4Her components box shows the implementation strategies (A to F): A: carrying out the universal sexual health screening for gynecological patients in the medical record; B: providing training on HIV, PrEP indication, PrEP care, and stigma for the gynecological providers; C: creating job aids such as pockets cards to easily identify those with a PrEP indication; D: creating aids for electronic medical record documentation such as creating templates for PrEP-related visits and order sets; E: developing educational material tailored toward Black cisgender women; and F: developing training tutorials on communication methods with patients about sexual health and PrEP, tailored toward Black cisgender women. Moreover, the change of mechanisms box shows how the strategies in the PrEP4Her components box are anticipated to impact the implementation outcomes (the superscripts indicate the implementation strategies that are expected to cause the change). Finally, the proximal implementation outcomes box outlines the expected outcomes that will be assessed as per the RE-AIM framework; the superscripts again indicate the PrEP4Her components that will impact each of the outcomes. The project is expected to improve the conditions deemed as potential barriers to PrEP usage among Black cisgender women, ultimately achieving the desired outcomes of increased PrEP uptake among Black cisgender women. Our study describes the planning and piloting stages of the implementation research logic model, evaluated by the RE-AIM framework, in which we will work with key informants and Black cisgender women to assess the reach, adoption, and preliminary effectiveness of integrating PrEP services within a gynecological clinic in Birmingham, Alabama, with the ultimate goal of increasing uptake of PrEP.

The Role of CABs

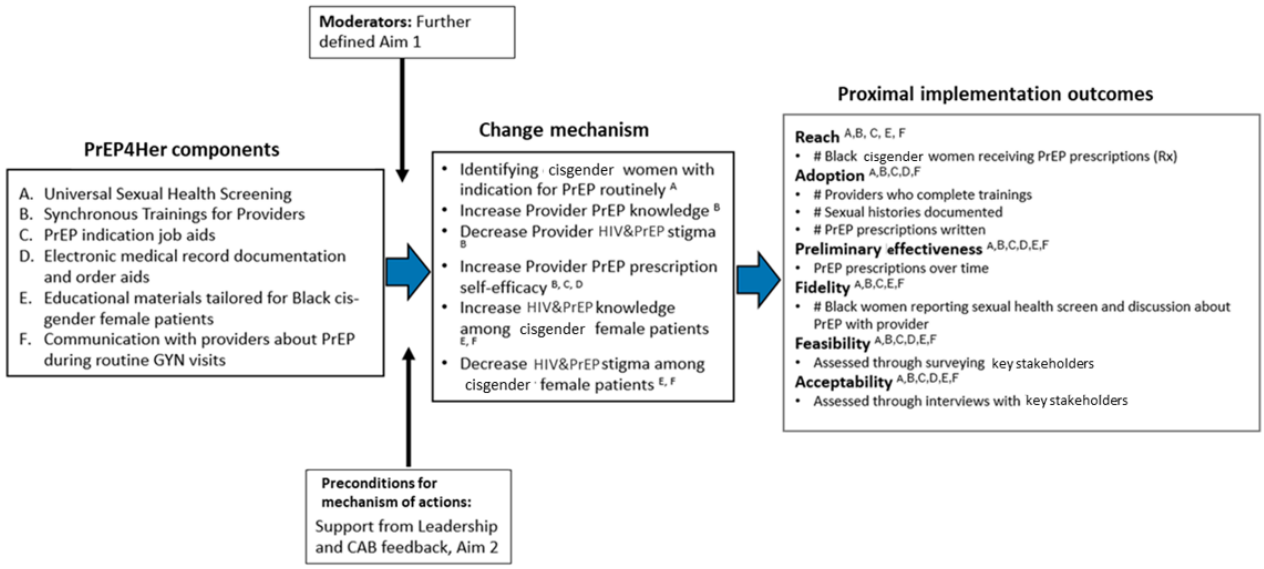
Two CABs, one for Black cisgender women (N=5) and one for gynecology practitioners (N=7), have worked and will continue to work with the study researchers. The CABs are led by a graduate-level researcher, who is also a part of this project. The CABs previously provided help with the interpretation of the qualitative findings and in selecting and refining components of the implementation strategy (PrEP4Her). Currently, the CABs meet monthly and advise on how to disseminate study results. At least 10 meetings were or will be held during the study, with a shared decision-making structure. Detailed notes will be documented to evaluate the meeting processes.

Piloting PrEP4Her to Deliver PrEP for Black Cisgender Women Attending Routine Gynecologic Care Visits

PrEP4Her is a multicomponent implementation strategy, which was evaluated through a 1-arm pilot at a university-affiliated gynecological clinic. We chose a 1-arm trial, as PrEP was not routinely offered at gynecological clinics in Alabama and there were only 3 Black cisgender women on PrEP at the university-affiliated PrEP clinic at the study start, which meant a comparison between other gynecological clinics or between our PrEP clinics would have had limited meaning. Upon completion of PrEP4Her development, gynecological staff members, practice managers, and clinicians received training as well as implementing job and documentation aids within the clinic. In addition, educational materials were placed in all areas where patients are seen within the clinic. Figure 2 outlines the

workflow for PrEP4Her along with the detailed description of each component. Implementation outcomes for PrEP4Her were monitored over a 6-month time frame (Jan-Aug 2024). Of the RE-AIM components, only reach, effectiveness, and adoption will be evaluated as a part of this study. In addition to the 3 components of RE-AIM, we will also evaluate the acceptability, feasibility, and fidelity of the trial.

Figure 2. Pre-exposure prophylaxis 4Her components [42-46]. Image created by LE. CDC: Centers for Disease Control and Prevention; CFAR: Center for AIDS Research; PrEP: pre-exposure prophylaxis; UAB: University of Alabama at Birmingham.



Reach Outcome

Reach in RE-AIM captures the ability to engage the target population in the intervention. In PrEP4Her, this will correspond to the absolute number of Black cisgender women who receive a PrEP prescription. In addition, the proportion of Black cisgender women prescribed PrEP among those who had a PrEP indication, will also be evaluated. PrEP indication will be based on the sexual risk screener (component 1 in Figure 2) documented in the chart during patient visits. For this study, PrEP indication will be defined based on the Centers for Disease Control's guidance summary criteria. According to this guidance, cisgender women not living with HIV meet at least one of the following criteria are considered to have a PrEP indication: (1) HIV-positive sex partner not virally suppressed, (2) bacterial STI in the past 6 months (ie, gonorrhea or syphilis), (3) more than one sex partner, (4) inconsistent condom use, (5) sex for exchange of goods, or (6) being in a high-prevalence network [44]. PrEP prescription data will be obtained from the university's electronic medical records visit data during the pilot period. Although measuring the number of PrEP discussions with Black cisgender women by electronic medical record audit was also considered an important aspect to examine reach, it was deemed to add little value due to the anticipated inconsistencies in documentation by providers in reporting PrEP discussion in their clinic notes. However, we have incorporated this element in our surveys with Black cisgender women, evaluating their experiences with providers in receiving PrEP health counseling.

Effectiveness Outcome

Effectiveness in RE-AIM evaluates the effect of the intervention on the primary outcome as well as effect modification. Effectiveness of PrEP4Her will be determined by the increase in PrEP prescriptions over time. In addition, patient factors associated with PrEP prescription will be evaluated [47]. PrEP prescription data from the electronic medical records will be extracted at baseline, at 3 months, and at 6 months of PrEP4Her implementation, to evaluate effectiveness. Moreover, information on patient demographics (ie, age, race, ethnicity, and insurance status) will also be obtained. Using this data, frequencies for PrEP prescription will be reported overall and for each independent variable at baseline, 3 months, and 6 months.

Adoption Outcome

Adoption in the RE-AIM determines the ability of the setting's staff members to adopt the intervention. This will be determined by measuring the proportion of key informants within the pilot site who were willing to initiate the PrEP4Her implementation strategy. This will be assessed by evaluating the training and sexual history documentation.

Training

A website will be created as a part of this study, to aid in easy access of training materials for providers and staff members. During initial training, the number of providers and staff members who attend the meetings will be documented. In addition, viewing training on the website will be captured through collecting para data (tracking clicks).

Acceptability Outcome

Acceptability is defined as the extent to which key informants felt PrEP4Her was acceptable (ie, providers delivering the intervention and Black cisgender women receiving the intervention). This will be measured by conducting key-informant interviews. The sample will include 15-20 participants, with at least 10 providers, and approximately 10-15

Black cisgender women seen during the 6-month pilot period. Recruitment of providers will be carried out directly from the pilot study, whereas recruitment of Black cisgender women will be done through flyers and direct referrals from clinical staff members. Interview guide questions will be grounded in a theoretical framework of acceptability by Sekhon et al [48]. Interviews will be conducted virtually to allow for flexibility, using a secure system. Interviews will be digitally audio recorded, professionally transcribed, and deidentified. A preliminary codebook will be developed consisting of a priori deductive codes (based on the theoretical framework), inductive codes (emerging from the data), and pattern codes (connecting concepts to one another). The analysis of these data will be carried out in a similar manner as described above by our expert qualitative team.

Feasibility

Feasibility of the intervention will determine if PrEP4Her is appropriate for a larger, full-scale implementation trial. This information will be captured using the validated scale, Feasibility of Intervention Measure [49], through surveys conducted before interviews among key informants. The survey will include straightforward items such as "[PrEP4Her] was appealing to me," "[PrEP4Her] seemed suitable," and "[PrEP4Her] seemed easy to implement," which respondents will rate on a 5-point Likert scale. Descriptive statistics will be calculated to determine feasibility.

Fidelity

Fidelity to the intervention protocol will be assessed as the degree to which the PrEP4Her implementation strategy was implemented as designed [50]. To measure fidelity, all patients seen during the 6-month pilot period will be given a flyer by the staff upon clinic checkout with information to take a brief 5-minute electronic survey. Recruitment will end once 300 surveys have been completed. While this intervention is tailored to Black cisgender women in terms of developed educational materials and provider communication, implementation strategy components are universal to all patients and, therefore, targeted sampling of only Black cisgender women will not be conducted. The brief electronic survey will include the following questions: (1) Did your provider (or other clinical staff members) take a history asking about your sexual activities and health? (2) Did you see educational materials during your visit about HIV prevention and a prevention method called PrEP (3) Did you speak with a provider about PrEP? (4) For those who spoke with a provider about PrEP, would you please describe the conversation and how you felt about communicating with your provider about this prevention strategy? As the survey contains both close-ended and open-ended questions, data will be analyzed both, quantitatively (descriptive statistics) and qualitatively (inductive and pattern coding).

The findings from the pilot will provide the necessary information to refine PrEP4Her for broader dissemination and future multisite implementation studies.

Ethical Considerations

Human Subject Ethics Review Approvals

The following study was approved by the University of Alabama at Birmingham's institutional review board (IRB#300008345) on December 2, 2022.

Informed Consent

An informed consent was collected and documented from all gynecological interview participants. The quantitative data used for this study was covered under the study's institutional review board and was secondary in nature that data was abstracted from available deidentified electronic medical records.

Privacy and Confidentiality

All data were deidentified before being analyzed.

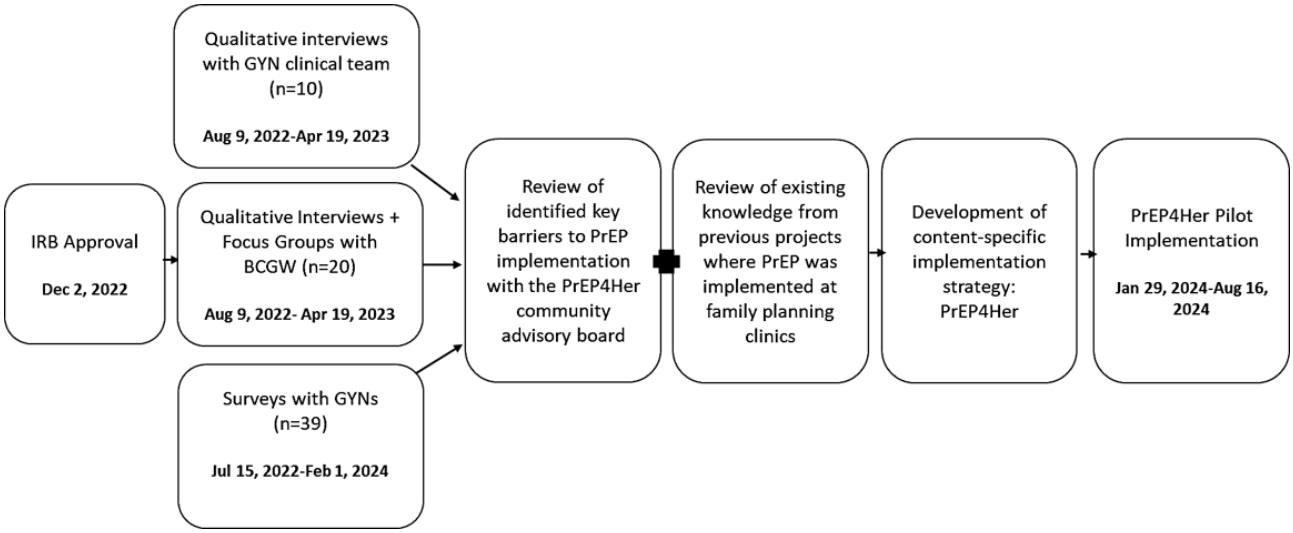
Compensation Details

All CAB members received a US $50 stipend per meeting. Each interviewee and focus group participant was compensated with US $50. Patients who will complete the electronic survey determining Fidelity will receive a compensation of US $20 after completion.

Results

Figure 3 outlines the PrEP4Her study timeline. The in-depth interviews with the gynecological care team were conducted between August 9, 2022, to April 19, 2023. A total of 10 in-depth interviews were conducted (40% were attending or training physicians). In addition, the cross-sectional study used data collected from surveys with gynecologists from July 15, 2022, to February 1, 2024 (n=39; 80% female). Moreover, the in-depth interviews and focus groups with black cisgender women (n=20) were conducted between Aug 9, 2022, to Apr 19, 2023. The qualitative findings from in-depth interviews with the gynecological care team (physicians, nurses, and medical assistants) and in-depth interviews and focus groups with women patients (64% black) highlighted a gap in care delivery for women (manuscript in the process of publication), suggesting additional training of providers may be beneficial. This was added as one of the strategies to improve PrEP uptake under the PrEP4Her implementation.

Figure 3. PrEP4Her study timeline BCGW: Black cisgender women; IRB: institutional review board; GYNs: gynecologists; PrEP: pre-exposure prophylaxis.



The qualitative and quantitative data were integrated through joint displays, bridging results using visual displays to connect major themes [51]. The combined findings provided an in-depth and granular understanding of key factors that were necessary to address in the development and refinement of PrEP4Her, as well as in the development of implementation strategies to support the integration of PrEP services into routine gynecological care. The PrEP4Her pilot was implemented from January 29, 2024, to August 16, 2024. The data gathered during the program are being used toward assessing the program's efficacy by measuring PrEP4Her's reach, effectiveness, adoption, acceptability, feasibility, and fidelity. The findings obtained would help guide the implementation of PrEP4Her at a larger scale.

Discussion

Anticipated Findings

The quantitative and qualitative data gathered to inform the development of PrEP4Her indicated a need to integrate PrEP services into an already existing and stretched gynecology clinic workflow by optimizing medical assistants and apps to aid in sexual history screening and provision of PrEP services. In addition, there was a gap in knowledge around PrEP as an HIV prevention option for cisgender women and the desire among Black cisgender women to have sexual health and PrEP services integrated into routine gynecology care. This information helped guide the PrEP4Her program implementation in the most effective manner.

PrEP is a highly effective method to decrease HIV acquisition among cisgender women. However, its impact to improve HIV outcomes among women has been hindered due to poor understanding of how to effectively identify strategies to improve uptake among cisgender women. Previous studies conducted at family planning clinics, aiming to improve PrEP uptake, found that although many cisgender women were willing to start PrEP, only a few obtained a prescription for PrEP, highlighting a gap between PrEP knowledge delivery and PrEP uptake. While cisgender women are disproportionately impacted by the HIV epidemic, Black cisgender women living in the Southern United States face heightened challenges such as decreased access to health care services and structural racism, which leads to medical mistrust and greater bias when engaging with providers [52]. Keeping these inequities in mind, the study aims to improve PrEP prescription in this population. We designed a novel intervention, PrEP4Her, which will be focused on increasing PrEP uptake as an effective HIV prevention tool among Black cisgender women by improving access and expanding provider options. Given the pilot site's Southern US location and the patient population served, preliminary results from this pilot will provide substantial guidance on the successful refinement and implementation of PrEP4Her in similar clinical-care settings across the South. In addition, sampling of gynecological providers across the Southeast United States allowed for greater generalizability of our implementation strategy to other Southern US states that have similar contexts (eg, access to medical resources, access to transportation, proximity to clinics, socioeconomic status, etc.).

PrEP4Her intervention is a novel approach hypothesized to significantly improve PrEP uptake among Black cisgender women. Completion of this study will result in the development of a culturally tailored strategy to improve uptake of PrEP among Black cisgender women. If PrEP4Her shows feasibility, acceptability, and preliminary efficacy in enhancing PrEP uptake for Black cisgender women, a subsequent R01 application will be prepared to conduct a fully powered implementation trial across multiple gynecology care sites across the South. Even in the absence of preliminary efficacy of the pilot, the knowledge gained around determinants and components to include in the PrEP4Her implementation strategy for integrating PrEP services into gynecological settings will provide novel insights to inform future HIV prevention research among this highly impacted group. The findings obtained from this study will be submitted to peer-reviewed journals for publication and presented at local and national conference meetings. Moreover, to disseminate these findings to the nonacademic community, we are currently in discussion with our patient CAB on the most appropriate method to do so. In addition, we are currently working with our institution's communication team to ensure that the patient

community is made aware of PrEP being offered at the gynecology continuity clinic.

Despite our efforts, our study has a few limitations. It is often challenging to engage clinical care teams to conduct interventions due to workflow demands and time constraints. This may impact the overall efficacy of PrEP4Her due to low adoption and lack of fidelity to PrEP4Her components. To overcome this barrier, investigators will work with leadership in identifying "champions" within the clinic setting to encourage PrEP4Her implementation. Inclusion of a physician practicing in the gynecology continuity clinic as part of our investigative team embeds a committed champion within our pilot site. In addition, recruitment of Black cisgender women will be carried out from our clinical site, to take part in both interviews and quantitative surveys throughout this proposal and this may pose a challenge. To overcome this, we will use well-established research advertising through the university and will also leverage provider referral and referral from our research staff to meet recruitment goals. There is a potential for selection bias, as Black cisgender women who are interested in participating in the study may experience less HIV and PrEP stigma than the general population. To overcome this, efforts will be placed to recruit participants via pamphlets at our clinical site with nonstigmatizing, health-promoting messaging to engage a representative sample. Finally, due to time and budgetary constraints, quantitative evaluation of PrEP adherence with drug level testing via blood or hair for those prescribed, will not be conducted. While this is not currently a primary end point for this study, we will measure PrEP adherence more objectively in a subsequent efficacy trial.

Conclusion

PrEP4Her intervention, by integrating PrEP services into existing gynecology clinic workflow, is aimed at improving PrEP uptake among Black cisgender women, a population disproportionately impacted by the HIV epidemic. Completion of the intervention will be followed by a multisite type III implementation trial for PrEP service delivery at gynecology clinics across the Southern United States.

Acknowledgments

Jessica Sales provided consultation in the development of the intervention.

This study was funded by the National Institute of Mental Health (R34MH128002).

We attest that generative artificial intelligence was not used for the generation of any portion of this manuscript.

Data Availability

The datasets generated during this study or those that will be generated or analyzed in the future will be available from the corresponding author on reasonable request.

Authors' Contributions

LE conceptualized the study and acquired funding for this project. LTM, AW, MCK, DP, HMG, and MJM advised on the project investigation and methodology. BJ performed activities associated with administration. MS wrote the manuscript. All authors provided feedback on the manuscript.

Conflicts of Interest

LE serves as an investigator on a Merck pharmaceuticals research grant.

Abstract

Background: Global concern for the mental well-being of university students is on the rise. Recent studies estimate that around 30% of students experience mental health disorders, and nearly 80% of these individuals do not receive adequate treatment. Brazil, home to around eight million university students, lacks sufficient research addressing their mental health. To address this gap, we aim to conduct a longitudinal mental health survey at 2 Brazilian universities.

Objective: This paper outlines the research protocol for a web-based mental health survey designed to assess the well-being of Brazilian university students.

Methods: The survey targets undergraduate students (N=8028) from 2 institutions: UniFAJ (Centro Universitário de Jaguariúna) and UniMAX (Centro Universitário Max Planck). Students will be invited to respond to self-reported questionnaires, including theSMILE-U (lifestyle and quality of life), the *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders* [Fifth Edition]) self-rated level 1 cross-cutting symptom measure, and a brief version of the Adult Self-Report Scale for attention-deficit/hyperactivity disorder. Students who exceed thresholds for conditions such as depression, anxiety, and attention-deficit/hyperactivity disorder will receive additional diagnostic instruments. The survey will be conducted annually, tracking individual and group trajectories and enrolling new cohorts each year. Data will be analyzed using cross-sectional and longitudinal methods, focusing on descriptive, associative, and trajectory analyses.

Results: The first wave of data collection began in February 2024 and is expected to conclude in December 2024. As of October 2024, a total of 2034 of 7455 (27.2 in 100) eligible students had completed the questionnaire. Cross-sectional statistical analysis is planned to commence immediately after data collection and is expected to be completed by June 2025.

Conclusions: This survey uses a scalable, cost-effective design to evaluate mental health conditions among Brazilian university students. The longitudinal framework facilitates the monitoring of mental health trends, supports the development of targeted interventions, and informs policy initiatives in higher education.

KEYWORDS

study design; university students; mental health screening; longitudinal survey; college students

Introduction

The mental health of university students is a widely recognized global concern. The transition to university life marks a crucial developmental phase characterized by individuation, the establishment of new social connections, and increased autonomy and responsibility [1]. This period aligns with continued, rapid brain development at a time when university students are exposed to multiple risk factors known to affect mental health, including psychosocial stressors, recreational drug use, alcohol binging, and disruptions in sleep patterns [2]. Mental health disorders typically present before or during young adulthood, often going unrecognized for years, resulting in significant delays in receiving treatment. Failing to adequately address mental health issues in a timely fashion can lead to the progression of more complex outcomes, such as school dropout, addiction, and self-harm. Indeed, the international prevalence estimates of mental health disorders reveal higher rates among college students compared to the general population. For example, a multicenter study involving 13,984 students from 8 countries, led by the World Health Organization (WHO), demonstrated that one-third met the clinical criteria for a psychiatric disorder in the previous year [3]. The most frequently reported were depressive disorders (18.5%) and anxiety disorders (16.7%-18.6%), followed by alcohol (6.8%) and other substance use disorders (3%). Moreover, approximately 22.6% of university students reported experiencing suicidal thoughts. Tragically, suicide stands as the second leading cause of death within this population [4].

The presence of psychiatric disorders is linked to numerous detrimental consequences both in the short and long term. In the short term, individuals may experience a decline in their quality of life, poorer academic performance, increased absenteeism, and a higher likelihood of course dropout [5-7]. In the long term, individuals endure lower quality of life, higher unemployment rates, and socioeconomic impairment [8,9].

Though the alarming data presented above were derived from studies conducted in countries with diverse income levels, to date, there is a disproportionately limited body of evidence addressing the mental health issues of young adults attending universities in low- and middle-income countries. The few studies that have been conducted in Brazil have tended to focus on medical students, also unveiling concerns about rates of mental distress in this population [10] with approximately 37% of them undergoing psychiatric treatment. In a study by Campos et al [11], the most prevalent diagnoses were depression (39.1%) and anxiety disorders or phobias (33.2%) and 4.5% declare previous suicide attempts. Severe mental health disorders such as psychotic disorders (3.7%) and bipolar disorder (1.9%) were less common [11].

In Brazil, there are approximately eight million students enrolled in 2714 higher education institutions [12]. Extrapolating from international prevalence estimates, over two million Brazilian university students may be struggling with mental health issues.

UniFAJ (Centro Universitário de Jaguariúna) and UniMAX (Centro Universitário Max Planck) are private university centers located in the medium-sized cities of Jaguariúna and Indaiatuba in the southeast of Brazil. Together, they serve approximately 8000 students enrolled in undergraduate programs spanning technical fields (eg, administration, accounting, architecture, law, or engineering) and health sciences (eg, medicine, nursing, psychology, biomedicine, or veterinary medicine). These institutions are representative of the broader Brazilian university population, as more than 75% of Brazilian students are enrolled in private universities.

To address the gaps in national and international literature, we propose to measure the mental health of all undergraduate students of UniFAJ and UniMAX. The survey will assess the prevalence of psychopathological symptoms and identify associated factors. The survey will also address another largely unexplored facet of mental health issues, namely the longitudinal course of mental health and quality of life. To achieve these goals, we designed a web-based mental health survey suitable for Brazilian students. This paper aims to describe the protocol and methods for conducting a web-based mental health cohort study in 2 private Brazilian universities. We hypothesize that, consistent with international studies, we will find high rates of common mental disorders, such as anxiety and depression. Furthermore, we expect to identify distinct patterns of mental health disorders unique to the low- and middle-income context of Brazil. By following students over time, we hypothesize that mental health disorders will correlate with poorer academic performance and quality of life, consistent with findings in the international literature.

Methods

Overall Design

This study will use validated self-report questionnaires delivered through an electronic web-based survey. The protocol will be repeated annually starting in 2024, allowing for the evaluation of mental health trajectories over time and the inclusion of new cohorts of incoming students to assess potential trends specific to these groups. This study of the university population is an arm of a large mental health project carried out by the National CISM (Center for Research and Innovation in Mental Health) [13]. CISM aims to study and expand, over the next 10 years, knowledge about mental health conditions in the State of São Paulo, the biggest one in Brazil.

Participants and Recruitment

All undergraduate students enrolled at UniFAJ and UniMAX will be invited to participate annually. Invitations will be sent via email, providing a brief explanation of this study's objectives and encouraging participation through the electronic survey link.

We have devised several strategies aimed at maximizing participation. First, we will conduct wide media campaigns in the university to promote awareness concerning mental health and discuss the importance of this study. Second, professors of all disciplines will be encouraged to remind students to engage in the survey. Third, nonresponders and survey noncompleters will receive at least 3 invitation reminders via email, followed by 3 reminders via text message (WhatsApp; Meta Platforms). Importantly, students will be informed that the time spent on the survey will count as an equivalent complementary academic activity. All these steps will be executed anonymously to ensure students' privacy.

Upon receiving the invitation, students are required to read and sign an informed consent form (ICF). The consent form will clearly state that the participation is voluntary and that declining will not affect their academic standing or relationship with the university. Additionally, students who opt out will not receive further invitations.

The exclusion criteria are being younger than 18 years of age and limitations in accessing or responding to the survey (ie, no access to electronic devices or internet connection or being illiterate). These exclusions are expected to be negligible within this study population.

Instruments

We selected empirically validated psychometric self-report questionnaires, all of which have been translated and validated for Brazilian Portuguese and can be administered electronically. A key challenge in designing this survey was balancing the need for a comprehensive assessment of the targeted phenotypes with the potential impact of a lengthy survey on participant engagement. To address this, we adopted a 2-step strategy aimed at minimizing survey duration while maintaining comprehensiveness (Figure 1). In the first step, in addition to collecting sociodemographic and overall lifestyle or quality of life information in Short Inventory Lifestyle Evaluation [14], we will screen for an array of mental health conditions using the *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders* [Fifth Edition]) cross-sectional adult symptoms scale level 1 [15] and a short version of the Adult Self Report Scale for attention-deficit/hyperactivity disorder [16] (Table 1). In the second step, participants scoring above predefined thresholds in any domain will be invited to complete domain-specific psychometric scales. These scales assess conditions such as depression, mania, generalized anxiety, sleeping disorders, borderline personality disorder, obsessive-compulsive disorder, attention-deficit/hyperactivity disorder, substance use (Multimedia Appendix 1). After completing the relevant scales, participants will have the option to answer a questionnaire on personality traits (the Big Five Inventory [17]). The total time required to complete the survey will vary depending on the domains assessed, ranging from approximately 20 to 40 minutes. This streamlined approach ensures a balance between thorough mental health assessment and participant engagement by limiting survey fatigue.

Figure 1. Initial data collection scheme: The figure illustrates the initial data collection scheme, and the scales applied according to the screening presented. ASSIST 2.0: Alcohol, Smoking and Substance Involvement Screening Test; ASRS-18: Adult Self Report Scale; BFI: Big Five Inventory; BPDS: Borderline Personality Disorder Scale; GAD-7: Generalized Anxiety Disorder Scale-7; HCL-32: Hypomania Checklist scale; OCI-R: Obsession and Compulsion Inventory; PHQ-9: Depression Patient Health Questionnaire-9; PSQI: Pittsburgh Sleep Questionnaire; QSD: Sociodemographic Questionnaire; SMILE-C: University Short Multidimensional Inventory Lifestyle Evaluation.

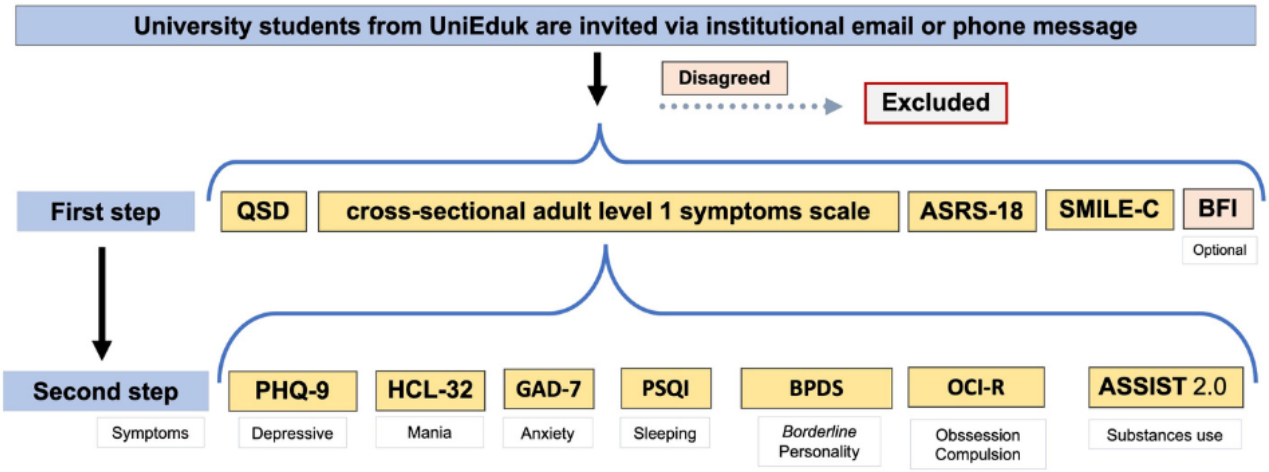

Table 1. Instruments used in step 1.

Instruments	Description
Sociodemographic Questionnaire (QSD)	The questionnaire was developed specifically for this study, including age, sexual identity and orientation, income, academic course, professional and career expectations, religiosity, use of social networks, and medical, psychiatric, or psychotherapeutic history.
The University Short Multidimensional Inventory Lifestyle Evaluation (SMILE-C)	Multidimensional assessment of lifestyle in 7 domains (diet, substance use, physical activity, stress management, social relationship, sleep, and screen time), along with an overall lifestyle score. The instrument comprises 24 questions that evaluate the frequency of behaviors considered healthy, with a response scale ranging from 0 to 4, where a higher score corresponds to a healthier lifestyle.
Adult Self Report Scale (ASRS-18)	Assesses symptoms of attention-deficit/hyperactivity disorder (ADHD) in adults, over the past 6 months, via 18 items divided into 2 domains: A (inattention) and B (hyperactivity-impulsivity). Responses for domain A vary as follows: 0=never, 1=rarely, 2=sometimes, 3=often, and 4=very often. As a screening measure, all participants will complete only the short version of this scale, which consists of 4 items (4, 5, 6, and 9) from part A and 2 items (1 and 5) from part B (hyperactivity). Those who score above 4 points on the short version will receive the complete version. Individuals are considered to have a possible diagnosis if they present at least 6 symptoms in at least 1 of the domains, or in both.
Cross-sectional adult level 1 symptoms scale (CSA) level 1 symptoms scale	Comprises 23 screening items that assess the frequency and intensity of symptoms across 13 domains of relevant symptomatology to frequent or severe psychiatric diagnoses. These domains include: sadness, irritability, mania, anxiety, somatic symptoms, suicidal ideation, psychosis, sleep disturbance, memory, repetitive thoughts and behaviors, dissociation, personality functioning, and substance use. Each item is rated on a 5-point scale (0=not at all; 1=very mild or rarely; 2=mild or several days; 3=moderate or more than half the days, and 4=severe or nearly every day).
Big Five Inventory (BFI)	The “Big Five” is an established model that analyzes 5 dimensions of personality: extroversion (tendency toward assertiveness and sociability), agreeableness (tendency toward reliability and altruism), conscientiousness (tendency to be careful and diligent), neuroticism (tendency toward negative emotions and sadness), and openness (tendency toward creativity and imagination). Likert-type scale with 44 items, where responses range from 1 (totally disagree), 2 (disagree a little), 3 (neither agree nor disagree), 4 (agree a little), to 5 (totally agree).

Data Collection Instruments

Data collection will be performed using REDCap (Research Electronic Data Capture; Vanderbilt University), a secure digital platform designed for data management and research studies. REDCap facilitates the deployment of standardized digital instruments while ensuring participant anonymity [18]. The platform provides a convenient “survey queue” for participants to access the survey questionnaires and a “to-do list” so they can keep track of their progress. This allows for the tracking of initial participation, completeness status, and longitudinal data collection for all participants. The REDCap feature best suited to address automation of the communication process and is, furthermore, better at data collection is the automated invitations. The participants receive an individual link, and we can choose how many reminders will be sent as well as their periodization.

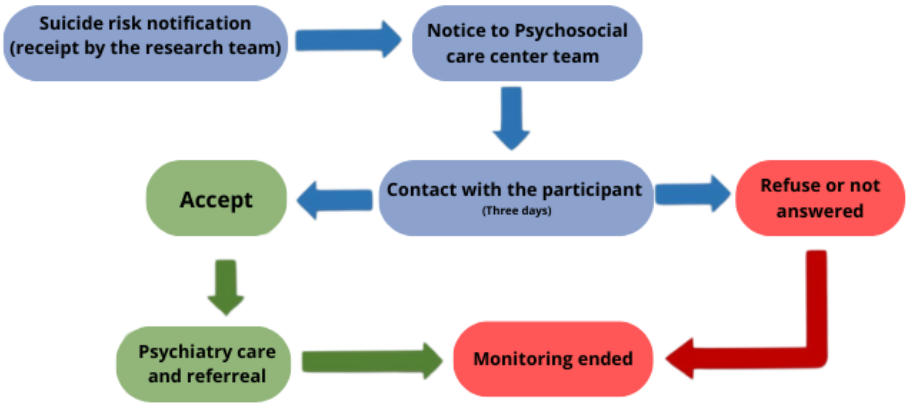
Survey Distribution Tools

We will upload student data straight from a file containing the emails of all enrolled students (provided by the university’s administration sector), in order to generate a unique individual ID link for each student. This will allow us to track the participants’ survey engagement or completion rate.

Reports and Alerts

The reports and alerts feature in REDCap will be used to monitor specific events and outcomes, particularly for suicide risk management (Figure 2). Suicide risk monitoring will rely on responses to the cross-sectional adult level 1 symptoms and PHQ-9 (Patient Health Questionnaire-9 depression) scales. The platform is programmed to generate immediate email alerts to this study’s team if participants affirmatively respond to either of 2 questions directly addressing suicidal ideation and suicide plans. This study’s team then immediately notifies a relevant health care team associated with our research group. Upon receiving this notification, the health care team will contact the participant to offer them appropriate psychiatric care. If the participant does not answer the first contact, the health care team will call again every day for 3 days. If the research participant accepts the offered care, they will be evaluated by psychiatry professionals and given necessary referrals. If they do not agree, this study’s team will register this nonagreement, and monitoring by the research team will end.

Figure 2. Suicide risk monitoring: The figure illustrates the monitoring protocol for participants identified as high risk of suicide.



Statistical Analyses

Given the annual assessments and longitudinal tracking of students throughout their university journey, we will use statistical methods suitable for both cross-sectional and longitudinal analyses. To enhance the representativeness of the sample, poststratification weights will be applied based on demographic data (eg, sex or age major) of the entire target sample provided by the university. All tests will be performed with a significance level of P=.05.

Descriptive Analysis

We will perform descriptive analyses to characterize this study's population. Summary statistics such as means, SDs, and medians will be computed for continuous variables (eg, age and quality of life) and frequencies and proportions for categorical variables (eg, gender or sexual orientation). Psychometric scales will be categorized into binary outcomes (absence or presence) based on established cutoff values.

Simple Cross-Sectional Analyses

We will explore associations between sociodemographic characteristics, quality of life scores, personality traits, and the prevalence of psychopathological symptoms using parametric and nonparametric statistical tests (eg, chi-square tests for categorical variables, *t* tests [2-tailed], or Mann-Whitney *U* tests for continuous variables). For significant associations, odds ratios will be calculated to identify predictors of psychopathological symptoms. Linear or logistic regressions will be used to adjust for potential confounders, depending on the distribution of the outcome variable. Leveraging this study's design and large sample size, we will use data to infer potential changes in mental health indicators throughout the students' academic programs. This will involve comparing data from students at different stages of their academic journey (eg, first-year vs final-year students). To achieve this, generalized estimation equations will be used, with the independent variable year as a proxy for time. Models will control for confounding factors such as gender, age, and socioeconomic status.

Longitudinal Analyses or Cohort Analyses

By tracking students longitudinally throughout their university journey, we aim to identify variations in mental health outcomes and analyze the evolution of symptomatology over time. Generalized estimation equations will be used, including time as an independent variable to model these changes and examine patterns at both individual and group levels.

Ethical Considerations

This study adheres to the Code of Ethics of the World Medical Association (Declaration of Helsinki). This protocol was reviewed and approved by the Ethical Board Committee of the UniFAJ and UniMAX University Center (decision 6.153.870, 2023). This study follows the ethical principles outlined in Resolution 466/2012 of the National Health Council [19], which sets the guidelines and regulatory standards for research involving human beings in Brazil and complies with Law 14,874 which specifically governs human research ethics in the country. This study is registered in the Brazilian national system used to manage and oversee research involving human participants (Plataforma Brasil, under CAAE: 67251922.4.0000.0191), ensuring adherence to national regulations for research registration and monitoring.

Participation in this study is entirely voluntary. They will receive comprehensive information about the research objectives, methodology, and their rights. To ensure informed consent, this study uses a digital ICF via the REDCap e-consent platform. The ICF is presented in a clear and accessible format, explaining the purpose of the research and the voluntary nature of participation, and guarantees confidentiality and anonymity. Participants will be instructed to read the ICF and confirm their consent by responding to a specific question: "Have you understood the guidelines, and do you agree to participate freely, knowledgeably and spontaneously in this research?" If they agree, they are asked to enter their full name so that it can be attached to their acceptance to take part in this study. Additionally, the participant's electronic signature will be collected, and a copy of the ICF will be provided via email. The participant will then be directed to a link to the digital survey. If they do not agree, the participant will receive a thank you note and the contact will be closed.

Participation in this study will be voluntary, with participants' time and autonomy respected at all stages of the research. Participants may withdraw from this study at any time without any negative consequences or impact on their academic standing. This study involves completing a digital survey, ensuring a noninvasive and risk-free process. Study data will be deidentified to protect participants' privacy and for data

protection risks. No monetary compensation will be provided to the participants.

Results

The first wave of data collection for this cohort began in February 2024 and is scheduled to conclude in December 2024. As of October 2024, a total of 2034 of 7455 (27.27%) eligible students had completed the questionnaire. Cross-sectional statistical analysis is planned to commence immediately after data collection and is expected to be completed by June 2025.

Discussion

Principal Findings

The psychological well-being of young adult college students is gaining significant attention, as it is one of the major determinants of their overall academic success, personal development, and prospects. A healthy lifestyle, access to mental health services, and the cultural relevance of mental health interventions are some of the themes that the university students consider relevant [20]. Meanwhile, the existing literature endures a dearth of evidence concerning the mental health of university students in low- and middle-income countries. We have presented the protocol of our cohort study, outlining the design of a web-based survey suited for Brazilian university students, aimed to improve our knowledge about the mental health of this population, mitigating an important literature gap.

In this way, we can address the hypotheses of this research. The prevalence of common mental disorders in the world is, as shown, high. A replication study for other universities in the country allows us to learn about the prevalence of these disorders and the risk factors in Brazil. The prior work of the WHO evaluated sociodemographic correlates of mental disorders among first-year university students. They also used web-based self-report questionnaires about *DSM-IV* (*Diagnostic and Statistical Manual of Mental Disorders* [Fourth Edition]) mental disorders: major depression, mania or hypomania, generalized anxiety disorder, panic disorder, alcohol use disorder, and substance use disorder. Their results show high rates, one-third of the students screened positive for 1 common mental disorder [3]. We had some similarities and differences with the study by Auerbach et al [3]. Our protocol is also a web-based self-report questionnaire that contains sociodemographic aspects and mental health scales. We access more sociodemographic aspects than the WHO study and, in the same way, we access more mental health disorders instead (Figure 1) of only common mental disorders. Finally, our research had been projected to follow these universities' students, identifying some risk factors and consequences of mental health disorders.

The studies conducted in Brazil are mostly cross-sectional and their focus is on medical students [10]. The study by Miguel et al [10] showed higher rates of common mental disorders when in comparison to the WHO study [3]. Our study protocol describes a proposal to systematically and longitudinally survey the mental health of a large population of university students in Brazil. Our plan was based on methodological decisions that balance quality, precision, scalability, cost, and the likelihood of participant engagement.

Among the challenges encountered during the design of this web-based mental health survey, we have highlighted the need to assess a large number of potential participants and assess most psychopathological symptoms while aiming to be concise to achieve a maximum response rate and increase generalizability. Although university students are the majority in the digital world, they usually do not seek support [21]; therefore, another challenge is to engage them in web-based mental health surveys, through the many incentives we have described, we have accomplished a response rate of 2034 of 7455 (27.27%), which is relatively high compared to other web-based surveys.

Ethical considerations addressed here are related to the importance of interaction with the local health care services to provide assistance if cases of psychiatric emergency (ie, risk of suicide) are detected, as well as ensuring data privacy. We have also strived for this longitudinal study proposal to be as cost-efficient as possible considering financial constraints.

Our proposed use of an internet portal improved participant engagement and data integration and reduced longitudinal data collection's time and expense [22,23]. Indeed, automated data capture minimizes the need for paid researchers to run participants and enter data, while also reducing data entry errors [24]; as our survey involves multiple questionnaires, the platform allows for easier and more engaging access for potential participants [25]. Our dissemination plan has internal importance for promoting and preventing mental disorders at UniFAJ and UniMAX universities. The results of the research can be shared with the students themselves and with the university coordinators, guaranteeing confidentiality. Another of our dissemination plans is to share this data and results with the media and with the governments.

Finally, we believe that this protocol could be useful for monitoring mental health cross-sectionally and longitudinally in thousands of universities across Brazil, either to assess their mental health in a cost-efficient manner or guiding interventions such as preventive mental health programs or even screening students with high risk of having mental disorder. This would allow a positive impact on the burden of mental health in university students and ultimately in our communities.

Limitations

There are disadvantages associated with digital research. For example, open-ended questions cannot be explored with immediate follow-up questions and participants are unable to seek clarification of ambiguous items [26]. To address this issue, in the present survey, participants can easily email the project team with any questions they may have.

Selection bias presents another challenge for digital research. Internet access is affected by myriad variables including income, geographical location, mental health status, and age [27,28]. We do not anticipate serious issues with internet accessibility. UniFAJ and UniMAX have free internet access for all students. In addition, there were 181.8 million internet users in Brazil at the beginning of 2023, which means it is 84.3% of the

population [29]; and the southeast, where UniFAJ and UniMAX are, has an even greater user concentration. Our plan to remind participants via WhatsApp to finish their questions is sound, as WhatsApp is the most used social media by Brazilians, around 169 million [29]. Thus, though we cannot fully account for all these possibilities, the present strategy maximizes accessibility in a way that will mitigate these potential confounding issues and, consequently, increase the response rate.

After identifying participants, the present protocol contains strategies to maximize the probability that participants will continue to engage with and complete the survey. For example, one way to increase engagement is to provide participants with information about this study that (1) knows their interests, (2) helps them understand the importance of their participation in mental health research, and (3) increases their confidence about participating. To this end, the research team will hold meetings with UniFAJ and UniMAX course coordinators to transmit detailed study information so that it reaches the students. Furthermore, a 2-minute video will be sent to all participants. This video contains information about the research team, the reason for the research and its objectives, details about the questionnaires (application time, confidentiality, or freedom to decline), and the opportunity to ask questions via email. We intend to demonstrate the importance of participation in promoting mental health among the university population.

The security of collected data is ensured by the REDCap platform, a trusted and secure data collection and storage platform [30] used throughout the scientific community. The platform allows for the long-term reduction of research costs, the possibility of use on many devices, and rapid data entry, review, and analysis [31].

As noted in the Introduction section, there is a paucity of data that have been collected from low- and middle-income countries. Existing studies were carried out mainly with students from specific courses [32]. The data analysis will summarize the data collected and integrate information about the mental health of this population. It will allow us to better understand the mental health of the Brazilian university population This survey is a structured means for assessing this population's mental health given that it has been well established that preventive actions are feasible, cost-effective, and efficient in improving overall mental health [33] and this period of life represents a hub that critically impacts their responsibilities, mental health, values, and outcomes [34]. We believe that the results of this survey could in the future guide policy makers in the design and implementation of preventive programs destined specifically for this public group and ultimately have a positive impact on the mental health of our communities.

Conclusion

College and university students have high rates of mental health issues. We have developed and described a web-based mental health survey that will allow us to evaluate and detect these issues with low cost and reasonable response rate in a university in Brazil. These efforts will allow us, soon, to monitor and test the efficiency and impact of mental health preventive programs. The accurate and representative data about mental health disorders, their risk factors, and the quality of life of these universities' students can lead the path for new policies to ensure mental health and quality of life for these populations.

This model could be scaled up across other universities in Brazil to easily assess the mental health status of their students and have a significant impact on the mental health of our communities.

Acknowledgments

This study was supported with grants from the National Center for Research and Innovation in Mental Health (CISM): Grant Fundação de Amparo à Pesquisa do Estado de São Paulo (FAPESP; 2021/12901-9) and Banco Industrial do Brasil S/A. FAPESP also provided a grant to this study (2021/05332-8). This study also received financial support from Conselho Nacional de Desenvolvimento Científico e Tecnológico (Coordenação de Aperfeiçoamento de Pessoal de Nível Superior; CAPES) through scholarships.

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed during this study.

Authors' Contributions

All authors contributed to this paper. TDS contributed to the conceptualization, formal analysis, project administration, review and editing of the writing, and supervision. AGN carried out the formal analysis, writing of the original draft, and supervision. PF handled the conceptualization, investigation, data curation, review and editing of the writing, and supervision. VM worked on the writing of the original draft and supervision. GCAdA, CFPV, LCdO, LOdC, EMMK, and LAZG assisted in the writing of the original draft, software, and methodology. LDFC aided with the resources and visualization. VCCJ conducted the visualization, software, and methodology. EdCH was responsible for the validation and visualization. ECMF was involved in the funding acquisition, supervision, validation, and visualization. AC did the project administration, resources, funding acquisition, supervision, validation, and visualization.

Conflicts of Interest

None declared. AC has served as a consultant for Knight Therapeutics and Libbs, but this work is not related to the topic of this manuscript.

Abstract

Background: The Global Burden of Diseases, Injuries, and Risk Factors Study (GBD) collects and calculates risk-outcome data for modifiable lifestyle exposures (eg, dietary intake) and physical health outcomes (eg, cancers). These estimates form a critical digital resource tool, the GBD VizHub data visualization tool, for governments and policy makers to guide local, regional, and global health decisions. Despite evidence showing the contributions of lifestyle exposures to common mental disorders (CMDs), such as depression and anxiety, GBD does not currently generate these lifestyle exposure-mental disorder outcome pairings. This gap is due to a lack of uniformly collected and analyzed data about these exposures as they relate to CMDs. Such data are required to quantify whether, and to what degree, the global burden of CMDs could be reduced by targeting lifestyle

factors at regional and global levels. We have established the Global burden of disease Lifestyle And mental Disorder (GLAD) Taskforce to address this gap.

Objective: This study aims to generate the necessary estimates to afford the inclusion of lifestyle exposures as risk factors for CMDs in the GBD study and the GBD digital visualization tools, initially focusing on the relationship between dietary intake and CMDs.

Methods: The GLAD project is a multicenter, collaborative effort to integrate lifestyle exposures as risk factors for CMDs in the GBD study. To achieve this aim, global epidemiological studies will be recruited to conduct harmonized data analyses estimating the risk, odds, or hazards of lifestyle exposures with CMD outcomes. Initially, these models will focus on the relationship between dietary intake, as defined by the GBD, and anxiety and depression.

Results: As of August 2024, 18 longitudinal cohort studies from 9 countries (Australia: n=4; Brazil: n=1; France: n=1; Italy: n=3; The Netherlands: n=3; New Zealand: n=1; South Africa: n=1; Spain: n=1; and United Kingdom: n=3) have agreed to participate in the GLAD project.

Conclusions: Our comprehensive, collaborative approach allows for the concurrent execution of a harmonized statistical analysis protocol across multiple, internationally renowned epidemiological cohorts. These results will be used to inform the GBD study and incorporate lifestyle risk factors for CMD in the GBD digital platform. Consequently, given the worldwide influence of the GBD study, findings from the GLAD project can offer valuable insights to policy makers worldwide around lifestyle-based mental health care.

KEYWORDS

mental health; depression; anxiety; diet; lifestyle; mental disorders; epidemiology; burden of disease

Introduction

Mental disorders rank among the top 10 leading causes of disease and economic burden worldwide. They account for 4.9% of global disability-adjusted life years [1] and it has been projected that by 2030 mental disorders will account for more than half of the economic burden attributable to noncommunicable diseases [2]. Given the recognized burden on individuals, communities, and economies [1,3], identifying risk factors for common mental disorders (CMDs), namely depression and anxiety disorders, is critical for early prediction, prevention, and treatment. While known risk factors such as genetics, childhood adversity, and family conflict have a significant impact on CMD risk [4], preventative efforts should also address potentially more modifiable factors that may have broader reach.

Over the past decade, evidence has emerged highlighting lifestyle behaviors as modifiable risk factors for CMDs. A recent meta-review, drawing from top-tier data such as meta-analyses of prospective cohort studies, Mendelian randomization studies, and randomized controlled trials, emphasized the significant role of lifestyle behaviors pertaining to diet quality, physical activity, smoking, and sleep in CMD risk [5]. Furthermore, current evidence indicates that targeting these lifestyle behaviors can ameliorate the risk of CMDs. For example, data involving adult participants from France estimate that 14% of incident cases of depression are attributable to a combination of unhealthful diet, weight, and smoking [6]. Promisingly, data from Norwegian adults show that 12% of de novo depression could be averted if an individual engages in at least 1 hour of physical activity per week [7]. Collectively, this evidence highlights the importance of lifestyle factors in mental health outcomes, which has implications regarding prevention and treatment.

Despite ample evidence supporting the inclusion of lifestyle-based mental health care in clinical recommendations and population-level strategies [8], exemplified by clinical practice guidelines from organizations such as the Royal Australian and New Zealand College of Psychiatrists [9], the global implementation of these strategies for addressing CMDs remains limited. Global nutritional recommendations focus largely on individual food groups or constituents, and not on the dietary patterns, such as the Mediterranean diet, that are commonly used in research. As such, the evidence regarding whether dietary components would be useful to the target population's mental health is unclear. Furthermore, it is widely acknowledged that numerous structural barriers hinder the improvement of lifestyle behaviors, including social, financial, and environmental determinants [10,11]. These barriers also exist in mental health treatment and care [12]. Therefore, there is merit in attempting to reduce the incidence of CMDs by improving lifestyle behaviors, not just at the individual level, but also through population and policy-level strategies. To inform such strategies worldwide, rigorous global data are required to quantify the contribution of lifestyle behaviors to the risk of population CMDs.

The largest epidemiological study worldwide, the Global Burden of Diseases, Injuries, and Risk Factors Study (GBD), provides important global health estimates that inform public health priority setting and policies. A critical tool used by the GBD to communicate the current state of health and disease for different countries is the digital platform, the GBD VizHub Data visualization tool [13]. This digital platform allows policy makers to quickly ascertain where the greatest improvements in public health could be achieved by targeting specific risk

factors. The GBD currently provides comprehensive estimates of lifestyle risks, such as diet, for a range of physical conditions, but has yet to incorporate estimates of these lifestyle risks for CMDs. This may be due to challenges in operationalizing and standardizing the measurement of lifestyle factors and CMD outcomes across studies, aligning them with GBD classifications and definitions, and establishing clear cause-and-effect relationships, particularly given the typical clustering of lifestyle risk factors [14-16]. In addition, studies investigating the associations between lifestyle risk factors and CMDs often face issues such as a lack of global representation, small sample sizes, inconsistent methodologies, residual confounding, and measurement error, particularly in regard to measuring dietary intake or ensuring adherence in intervention studies [17]. Consequently, while these factors are well-recognized risk factors for physical illnesses like heart disease and diabetes, the potential for lifestyle targets to be considered relevant to the population's mental health has historically been neglected [18].

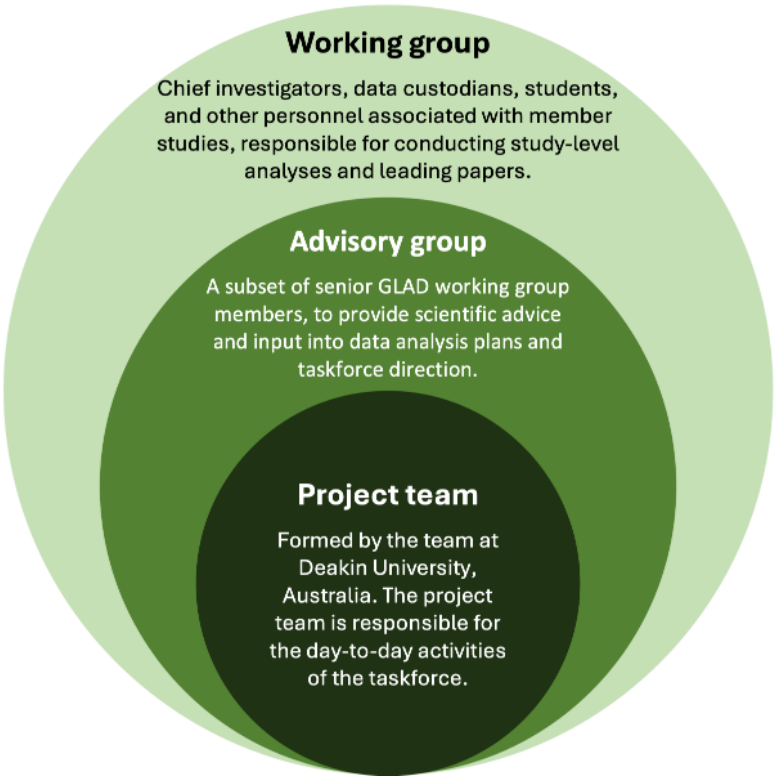
To include lifestyle exposures as risk factors for CMDs on the GBD digital platform, the Global burden of disease Lifestyle And mental Disorder (GLAD) Taskforce (a large-scale, coordinated, international collaborative effort) has been formed. The Taskforce comprises global epidemiological experts who will work with GBD representatives to oversee the comprehensive evaluation of the association of lifestyle risk factors with CMDs, starting with dietary intake as the exposure of interest (the GLAD project). These experts have developed a harmonized approach for individual studies to conduct analyses (the GLAD project) to enable the integration of lifestyle factors as a risk for CMDs in the GBD. This paper outlines the processes by which the GLAD project and participant member studies will execute this harmonized data analysis protocol on their own datasets and disseminate their results through peer-reviewed publications. The overarching aim of the GLAD project is to generate robust, comparable evidence on the global risk of CMDs attributable to lifestyle factors, ultimately enabling their inclusion as risk factors for CMDs within the GBD framework. We hypothesize that more healthful lifestyle factors, such as higher intakes of healthful dietary components (eg, fruits, vegetables, whole grains, and fiber) will be associated with a lower risk of CMDs. Conversely, we hypothesize that less healthful lifestyle factors, such as higher intake of less healthful dietary components (eg, processed meat, sugar-sweetened beverages, and sodium) will be associated with a higher risk of CMDs.

Methods

Recruitment

The GLAD project is a collective, multistudy initiative led by Deakin University's, Food and Mood Center, which is situated within the Institute for Mental and Physical Health and Clinical Translation, School of Medicine, Barwon Health, Geelong, Australia. The GLAD project will be completed by the GLAD task force, comprising the project team, the advisory group, and the working group containing all member studies (Figure 1).

Figure 1. The GLAD taskforce composition and responsibilities within the GLAD project. GLAD: Global burden of disease Lifestyle And mental Disorders.



To identify potential member studies for participation in the GLAD project, which would apply the harmonized data analysis protocol to their own datasets and contribute their results to the broader initiative, we used a multistep process. The first step was to identify epidemiological studies that had the necessary variables by which the study lead or representative could execute

our analysis plan (eg, food frequency questionnaires from which to derive GBD-defined dietary risks combined with mental health questionnaires to identify cases of depression or anxiety). This process involved a literature search to identify potentially eligible studies and key contacts to approach for invitation to participate in the GLAD project. To operationalize the dietary risk variables, we used previous GBD papers, which contained the definitions of each dietary exposure (Table 1) and depression and anxiety (Table 2) [1,19]. In addition to using the literature to identify potentially eligible datasets, we also drew on previous collaborations of the GLAD project team and researchers in the field of nutritional psychiatry (eg, via the International Society of Nutritional Psychiatric Research), as well as promoting the project on Food and Mood Center social media sites. Data custodians of identified studies were contacted, and those with relevant data and who had the capacity to participate in the GLAD project completed an expression of interest via the Food and Mood Center website.

To be eligible for inclusion, member studies must have dietary intake (Table 1) and depression and anxiety outcomes (Table 2) consistent with GBD definitions, or the ability to recode existing variables accordingly. Any deviations to these definitions must be reported and will be accounted for accordingly as reported below in "Future Directions: Meta-analyses." Any study design, in any location, with any sample size, is eligible to be a member study and can complete the required data analysis.

Table 1. Dietary exposure definitions and required coding for the GLAD project[a].

Dietary risk factor	GBD[b] exposure definition	Required coding[c]
Fruits	Average daily consumption of less than 310-340 g of fruit including fresh, frozen, cooked, canned, or dried fruit, excluding fruit juices and salted or pickled fruits.	grams/day
Vegetables	Average daily consumption of less than 280-320 g of vegetables, including fresh, frozen, cooked, canned, or dried vegetables and excluding legumes and salted or pickled vegetables, juices, nuts and seeds, and starchy vegetables such as potatoes or corn.	grams/day
Legumes	Average daily consumption of less than 90-100 g of legumes and pulses, including fresh, frozen, cooked, canned, or dried legumes.	grams/day
Whole grains	Average daily consumption of less than 140-160 g of whole grains from breakfast cereals, bread, rice, pasta, biscuits, muffins, tortillas, pancakes, and other sources.	grams/day
Nuts and seeds	Average daily consumption of less than 10-19 g of nuts and seeds.	grams/day
Milk	Average daily consumption of less than 360-500 g of milk including non-fat, low-fat, and full-fat milk, excluding plant derivatives.	grams/day
Red meat	Any intake of red meat including beef, pork, lamb, and goat but excluding poultry, fish, eggs, and all processed meats.	grams/day
Processed meat	Any intake of meat preserved by smoking, curing, salting, or addition of chemical preservatives.	grams/day
Sugar-sweetened beverages	Any intake of beverages with ≥50 kcal per 226.8-g serving, including carbonated beverages, sodas, energy drinks, and fruit drinks, but excluding 100% fruit and vegetable juices.	grams/day
Fiber	Average daily consumption of less than 21-22 g of fiber from all sources including fruits, vegetables, grains, legumes, and pulses.	grams/day
Calcium	Average daily consumption of less than 1.06-1.1 g of calcium from all sources, including milk, yogurt, and cheese.	grams/day
Seafood omega-3 fatty acids	Average daily consumption of less than 430-470 mg of eicosapentaenoic acid and docosahexaenoic acid.	milligrams/day
Polyunsaturated fatty acids	Average daily consumption of less than 7%-9% of total energy intake from polyunsaturated fatty acids.	total percentage of daily energy intake
Trans fatty acids	Any intake of trans fat from all sources, mainly partially hydrogenated vegetable oils and ruminant products.	total percentage of daily energy intake
Sodium	Average 24-hour urinary sodium excretion greater than 1-5 g.	grams/day
Ultra-processed foods (optional)	Any intake of ultraprocessed foods, as defined by the Nova system as any food item in Nova category 4 ("ultraprocessed food"), in grams [20].	grams/day

[a]Based on the GBD (Global Burden of Diseases, Injuries, and Risk Factors Study) risk exposure definitions (Pages 217-218 in Supplementary Appendix 1 in the study by the the GBD 2019 Risk Factors Collaborators [19]).

[b]GBD: Global Burden of Diseases, Injuries, and Risk Factors Study.

[c]Analyses using continuous exposures are required by the GLAD Taskforce. The units listed here are recommended, however, these may be rescaled to more meaningful units in papers (eg, per 10 g) provided the original units are available to the project team.

Table 2. Mental health definitions and recommended coding for the GLAD[a] project[b].

Mental disorder	Outcome definition	Diagnostic reference	Recommended coding[c]
Major depressive disorder	Involves the presence of at least one major depressive episode, which is the experience of either depressed mood or loss of interest/pleasure, for most of every day, for at least two weeks.	DSM-IV-TR[d]: 296.21–24; 296.31–34. ICD-10[e]: F32.0-9; F33.0-9.	0=no MDD[f]; 1= MDD
Anxiety disorders (any subtype)	Involves experiences of intense fear and distress, typically in combination with other physiological symptoms. Anxiety disorders will be modeled as a single cause for "any" anxiety disorder to avoid the double-counting of individuals meeting criteria for more than one anxiety disorder. Epidemiological estimates reporting an outcome for "any" or "total" anxiety disorders will be included if they reported on at least three anxiety disorders.	DSM-IV-TR: 300.0-300.3; 208.3; 309.21; 309.81. ICD-10: F40-42; F43.0; F43.1; F93.0-93.2; F93.8.	0=no anxiety disorder; 1=anxiety disorder

[a]GLAD: Global burden of disease Lifestyle And mental Disorders.

[b]The definitions and diagnostic references presented in this table are the current definitions used by the GBD (Page 4 in the Supplementary Appendix in the study by the GBD 2019 Mental Disorders Collaborators [1]). Since GLAD members may use alternative methods to ascertain disorder status, definitions or diagnostic references may vary slightly. For example, somatic forms of depression may be captured more by symptom scales, or studies using prescriptions may use Anatomical Therapeutic Chemical codes to determine incident depression and anxiety.

[c]Outcomes must be binary (condition present vs condition absent). For studies that only use symptom scales, validated cutoffs can be used to determine condition present versus condition absent (refer to Multimedia Appendix 1).

[d]*DSM-IV-TR*: *Diagnostic and Statistical Manual of Mental Disorders (Fourth Edition, Text Revision).*

[e]*ICD-10*: *International Statistical Classification of Diseases, Tenth Revision*.

[f]MDD: major depressive disorder.

Statistical Analysis

Overview

The GLAD project and the following methods have been prospectively registered on the Open Science Framework [21]. The methods outlined herewith are based on the most up-to-date definitions used by the GBD, at the time of writing this protocol. Given that the GBD is subject to change, future iterations may vary in accordance with such amendments. The initial iteration of the GLAD project will focus on dietary exposures, and the methods described within this protocol refer specifically to this first iteration. Subsequent updates to the protocol may be made when additional lifestyle risk factors are considered in future iterations of the GLAD project.

Exposure and Outcome Definitions

Definitions of dietary intakes and CMDs are based on definitions used by the GBD [1,18]. In addition to the 15 dietary intakes used by the GBD, ultraprocessed food intake will be included where practicable given the increasing literature in the field linking this dietary exposure to a wide range of health outcomes [22-25]. In doing so, we will use the most widely adopted food classification system based on the purpose and extent of industrial food processing, Nova, to define ultraprocessed foods [20]. Furthermore, we will follow best practice guidelines when categorizing foods according to the Nova food classification system [26].

CMDs can be measured differently across epidemiological studies. They are most commonly assessed using self-reported symptom scales with cutoffs for diagnosis, from medical records, or using diagnostic interviews. Multimedia Appendix 1 outlines some commonly used tools and their recommended cutoffs for identifying symptoms of depression and anxiety. The sensitivity, specificity, and diagnostic accuracy of these tools largely depend on the population. When undertaking meta-analyses, we may conduct a sensitivity analysis to determine if the magnitudes of associations change based on exposure and outcome measurement or ascertainment type.

Covariates and Confounders

To address the anticipated heterogeneity of member studies' available data, a set of core confounders are provided for the purpose of generating a consistent minimally adjusted analysis. The conduct of additional analyses (eg, using additional variables, fitting sensitivity models, or exploratory analyses) is at the discretion of the study author or authors based on available data and reviewer requests when studies are submitted for publication.

To be included in the GLAD project, member studies must adhere to the iteratively adjusted models (Textbox 1).

Textbox 1. The iteratively adjusted statistical models required for the Global burden of disease Lifestyle And mental Disorders (GLAD) task force.

- Model 1: Unadjusted model, with the dietary variable (as listed in Table 2) as the exposure and depression or anxiety as the outcome.
- Model 2: Minimally adjusted model, with the dietary variable of interest, depression or anxiety, and with baseline mental disorder status (or lifetime history of mental disorders for cross-sectional studies), age, sex, and a measure of socioeconomic status, such as household income, employment status, or education.
- Sensitivity model: Same as model 2, but with adjustment for total energy intake.

Of particular relevance in nutritional epidemiology are methods for adjusting for energy intake. Intake of specific nutrients are correlated with total energy intake, and so appropriate adjustment is required to disentangle the effect of the nutrient from the effect of energy. For example, an individual may alter intake of a specific nutrient by changing dietary composition, and not by changing total energy intake. As such, controlling energy intake can reduce confounding, and failure to appropriately control for total energy intake may nullify associations between nutrient intake and disease outcomes [27]. Given the correlation between nutrient intake and energy, the application of Willett's residual method is recommended to account for total energy intake [27]. This involves fitting a regression model with the dietary variable as the outcome and total energy intake as the exposure, predicting residuals from this model, and then using these predicted residuals in the analysis models [27].

Reporting Baseline and Demographic Characteristics

To describe participant characteristics, authors of member studies include a table containing descriptive statistics, given as n (%) for categorical variables, and mean (SD) or median (25th-75th percentile) for continuous variables. A column containing *P* values will not be included, as statistical tests do not meaningfully assess differences between samples or populations, nor should they be used as the basis for assessing confounders [28].

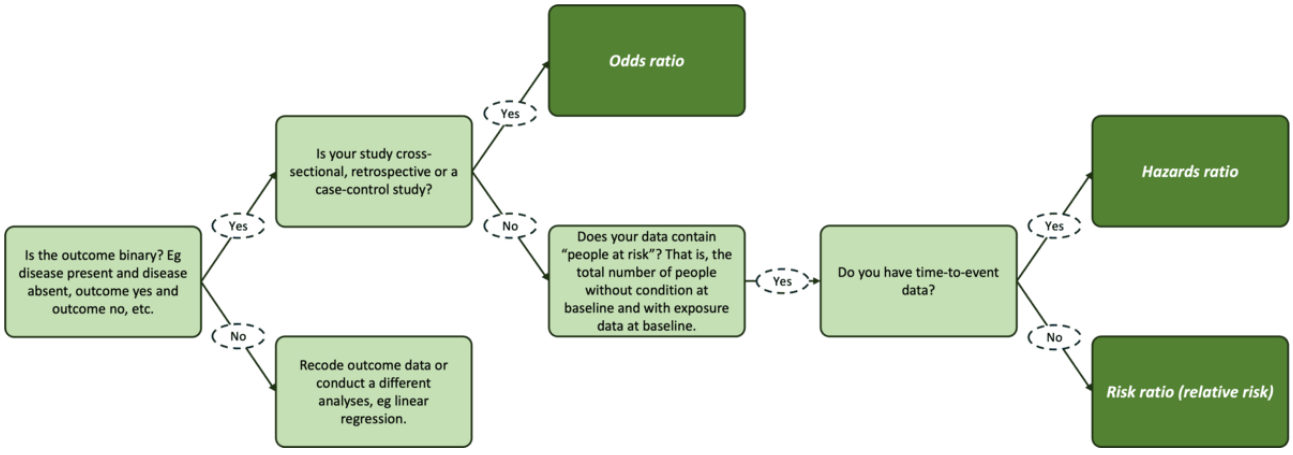
Estimating Risk Ratios, Odds Ratios, and Hazards Ratios

Each study is required to use risk ratios (estimated by Poisson regression with robust SE) as the primary means of assessing the association of dietary intake with CMDs. Risk ratios are based on incident cases, and so models will need to exclude participants with depression or anxiety at baseline. Furthermore, to determine incident risk, studies must have dietary exposures at baseline and depression, or anxiety measured at a subsequent time point. Where the estimation of a risk ratio is not possible (refer to Figure 2), for example, where the total number of people exposed at baseline is not available (such as for retrospective or case-control studies) [29], odds ratios are estimated using standard logistic regression techniques. Where only time-to-event data are available, hazard ratios are used, estimated by a Cox proportional hazards model. For rigor, all effect estimates will be accompanied by a 95% CI and exact *P* value [30].

Models can be fitted using any statistical analysis software, including R (R Core Team), SAS/STAT (SAS Institute Inc), Stata (StataCorp LLC), and SPSS (IBM Corp). Before fitting the relevant models, Member studies must assess model assumptions. Should any model assumptions be violated, an alternate approach to analysis may be selected. For example, the nonlinearity of continuous variables should be investigated, and transformations or nonlinear models fitted where necessary. Similarly, should any of the assumptions of Cox proportional hazards models be violated, alternative strategies will be deployed to account for these violations.

In addition to the models listed above, the following subgroups shall be fitted separately for each exposure-outcome pairing, where data allows: (1) sex, (2) age, (3) year (for longitudinal studies with multiple waves of follow-up), (4) country (for multicenter studies), and (5) all symptom scales and diagnostic measures (for studies with depression and anxiety measured via multiple measures. For age, studies should explore the relationship between the risk factors and mental disorders with age to see if a continuous measure is appropriate. Where a continuous measure is not appropriate, studies should generate appropriate age categories for their dataset by inspecting the frequency of outcomes by age groups. As a guide, the GBD currently uses 0-6 days (early neonatal), 7-27 days (late neonatal), 28-365 days, 1-4 years, 5-9 years, then 5-year intervals from 10-95 [31].

Figure 2. The types of ratio measures that can be obtained from binary outcome data. Odds ratios will be estimated using logistic regression, risk ratios will be estimated using Poisson regression with robust SE, and hazard ratios will be estimated using Cox regression.



Sensitivity Models

Multiple Testing

Given the need for multiple models to be fitted within each study, the GLAD Taskforce recommends a *P* value adjustment procedure, such as the Simes method, to minimize the chance of a type 1 error and determine whether multiple testing may be influencing results [32]. This should be applied to all models in a study where multiple models are required.

Outliers and Influential Data

Initial models include all available data points, with sensitivity analyses included for any influential or outlying observations. Influential observations are determined by predicting residuals, Cook's distance, or DFBETA after fitting the relevant model. Although several cutoff points have been proposed to identify influential observations, conventional cutoffs are applied: 3 for standardized residuals [33]; 4/(n-p) for Cook's Distance [34], where n=sample size and p=number of parameters in the model; and $2/\sqrt{n}$ for DFBETA [35].

Missing Data

Each study initially uses a complete-case model, whereby individuals with missing observations are excluded from the model. Member Studies with missing exposure, outcome, and covariate observations conduct a missing data analysis to determine the influence of missing data. While a multiple imputation approach is preferred, other methods such as k-nearest neighbor imputation or inverse probability weighting may be used where an imputation approach is not possible or appropriate [36-41].

Future Directions: Meta-Analyses

Upon completion of the analysis phase of the GLAD project (phase 2), the GLAD project team and advisory group will lead a meta-analysis (phase 3). A separate protocol will be created for this phase of the GLAD project. Briefly, the GLAD project team will conduct a systematic literature review to identify any relevant studies not already participating in GLAD. After screening abstracts and full text, data will be extracted from all identified studies and studies participating in GLAD. A random effects meta-analysis will be performed to pool results from all eligible studies. We will perform a meta-regression to quantify how the risk can vary by demographic factors, and methodological biases [42]. Where studies have used different assessment methods for mental health outcomes, different tools to ascertain dietary intake, any slight deviations to definitions, or where studies use different analysis strategies, we will perform cross-walking or sensitivity analyses to ensure comparability [43]. Papers using methods that deviate substantially from the methods described in this paper will be excluded from the meta-analysis. The resulting meta-analysis will be reported according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses).

Ethical Considerations

Each member study will have obtained informed consent from participants and had their study approved by institutional ethics review boards. Full details for ethics for each study can be found in previous studies [44-65] and a summary is provided below. This study is registered in the Open Science Framework (osf.io/zbg6x).

Results

As of August 2024, 18 longitudinal studies have agreed to participate in the GLAD project (Table 3). These studies have sample sizes ranging from 639 participants to 171,000 participants (Table 4).

The GLAD project comprises 3 essential phases, which will be repeated for other lifestyle exposures of interest: (1) conducting a systematic search to identify relevant studies and recruit study leads to contribute data, (2) generating estimates of study-level associations of dietary risk factors with CMDs using harmonized data analysis protocols developed by the GLAD Taskforce and approved by the GBD, and (3) pooling results from each study to provide the GBD with robust estimates to calculate the diet-CMD risk-outcome pairs in the first instance.

As of August 2024, phase 1 of the GLAD project has been completed, and phase 2 is due for completion in early 2025, at which time phase 3 of the GLAD project is due to begin (Figure 3).

Phase 1 includes searching for and recruiting studies with suitable data, harmonizing data definitions by ensuring member studies use the exposure definitions listed in Table 1 and the outcome definitions listed in Table 2, and harmonizing data analyses by ensuring member studies follow the statistical analysis plan presented in this paper.

Discussion

Anticipated Impact

The GLAD project is a global collaboration designed to estimate the risk of CMDs attributable to lifestyle risk factors, with this protocol focusing on dietary risk factors. The anticipated results will provide the GBD with the required threshold of evidence for lifestyle risks to be causally related to CMDs, thereby enabling lifestyle-CMDs risk-outcome pairs to be integrated into the GBD framework. Specifically, the GLAD project will demonstrate that GBD-defined lifestyle risks (eg, diets low in fruit) will be associated with increased risk of CMDs. The GBD study is the largest and most comprehensive global epidemiological health study, providing metrics for 369 diseases and injuries and 87 risk factors [19,66]. These health metrics, including estimates such as the burden of disease and disability-adjusted life years, are publicly available via the GBD digital platform [13] and provide critical information for clinicians, researchers, and policy makers worldwide. While lifestyle risk factors, including dietary intake defined as per GBD-specific definitions, have been considered in the context of chronic physical conditions in the GBD study, they have not yet been linked with mental health outcomes. As the first global collaborative study to link these lifestyle risks with CMDs, using the definitions and methods concordant with the GBD, the results of the GLAD project can be used to link these lifestyle factors as risks for CMDs in the GBD. This effort will allow us to quantify the potential reduction or elimination of the CMD burden by targeting these risk factors at regional and global levels, and to ensure these data are available freely online via the GBD VizHub Data visualization tool.

Risk factors for CMDs in the GBD are currently limited, and so, the inclusion of these additional lifestyle risk factors will represent a significant expansion in the scope of the GBD, which will have global policy implications. Our work builds upon the previous efforts of studies that have successfully integrated novel risk factors for CMDs in the GBD. For example, bullying victimization has been successfully incorporated into the GBD as a level 3 risk and is now routinely integrated into GBD papers [67,68]. By emulating the successful integration of these other risk factors into the GBD, our comprehensive, collaborative approach to harmonized statistical analyses across multiple, internationally renowned epidemiological cohorts has the potential to establish a basis for evidence-backed preventive strategies focused on lifestyle risk factors to reduce the burden of CMDs. Furthermore, by operationalizing the definitions to be in line with the GBD, which are used to inform global policy guidelines, and by capturing data from different regions, sexes, and ages, these results have the potential to bring benefits to individuals and communities on a global scale.

There is substantial observational [69-71], intervention [72-76], and meta-analytical [5,77-79] evidence linking these lifestyle factors to CMDs globally, which suggests that lifestyle factors are potentially suitable (and importantly, modifiable) preventive strategies. This has been recognized by the Royal Australian and New Zealand College of Psychiatrists, with lifestyle treatments integrated into the recent clinical practice guidelines for mood disorders, including depressive disorders [9]. A 2020 meta-review identified that targeting lifestyle variables like physical activity and smoking can be used effectively in the prevention and treatment of CMDs [5]. However, there was less evidence for the role of targeting diet in preventing CMDs, particularly as defined by international policy guidelines or as per the GBD framework. In order to incorporate additional lifestyle factors into guidelines globally, we need comprehensive epidemiological evidence, with a particular focus on dietary risks. The GLAD project will address previous methodological limitations through global collaborations and following a rigorous methodological framework informed by the GBD.

Although mechanistic evidence is currently limited, the causal role of lifestyle risks for CMDs has been supported by shared biological mechanisms between lifestyle factors and CMDs. These pathways include inflammation, oxidative stress, epigenetics, hypothalamic-pituitary-adrenal axis regulation, and the gut microbiome [80]. Inflammation has been linked to CMDs previously, and physical activity, diet, sleep, and smoking have all been shown to impact inflammation [5]. As such, improving dietary intake, increasing physical activity, improving sleep, and smoking cessation may improve mental health via anti-inflammatory properties. Another mechanistic pathway shared by CMDs and many lifestyle risk factors (including diet, physical activity, sleep, and smoking) is the microbiome [80,81]. Many of the dietary risks listed in the GBD, including fruit, vegetable, whole grain, and fiber intake, have pre- and probiotic potential which has been shown to beneficially influence the gut microbiome, and other GBD-defined dietary risks, such as processed meats and sugar-sweetened beverages (which are markers for a high-fat diet), Western-style diet (have been shown to increase anxiety and depression via gut microbiome alterations) [80]. Despite the evidence linking lifestyle risk factors with CMDs, including studies identifying potential mechanisms of action, studies assessing the relationship between lifestyle risks as defined by the GBD with CMD outcomes are lacking. Further, to integrate lifestyle risks for CMDs in the GBD, evidence needs to be generated globally, and not just from individual studies. As a global collaborative project, the results from the GLAD project will therefore provide the necessary evidence to incorporate lifestyle as a risk factor for CMDs in the GBD, which will enable policy makers around the world to make policy decisions regarding the potential public health benefit of population-level lifestyle improvements to mental health.

Strengths and Limitations

Currently, the GBD is unable to include lifestyle exposures such as dietary intake as a risk for CMDs due to the following: difficulties determining directionality and causality, inconsistency in dietary variables and methods, small sample sizes, and lack of global representation. A strength of the GLAD project is that it will address all these methodological considerations. We will (1) prioritize prospective studies using incident cases (ie, excluding those with baseline CMDs) to obtain risks of CMDs attributable to dietary intake, and not the other way around (to determine directionality or temporality), (2) include all study designs (including from experimental or randomized controlled trials to strengthen causal conclusions),

(3) conduct harmonized data analyses approved by the GBD (to improve consistency between studies and specificity of the diet-CMD relationship), and (4) pool data from multiple studies from around the world (to address sample size and global representation).

Despite the clear strengths of the GLAD project, there are some limitations. First, the GBD study is an ongoing and dynamic study, and definitions and methods are constantly evolving. Every effort will be made to ensure the taskforce are following GBD-approved methods, however, some changes from the GBD may be unavoidable. Second, since the GBD does not currently include ultraprocessed food as a dietary risk factor, the definitions and methods used by the task force may not reflect those used in future iterations of the GBD. Finally, although food intakes provide a general overview of diet quality, people do not eat food items in isolation. The current methods used by the GBD do not currently consider dietary patterns. This may limit interpretations to specific food items and not to an overall dietary pattern.

Conclusion

This multicountry, 5-year project has the potential to highlight the role of modifiable lifestyle risk factors in the prevalence and incidence of CMDs. Given the global burden of depression and anxiety, new approaches and targets for their prevention and management are of unprecedented importance.

Acknowledgments

We would like to acknowledge all GLAD members, including the GLAD project team based at Deakin University, the GLAD advisory group, and the GLAD working group comprised of all member studies.

MML is supported by a Deakin University Alfred Deakin Postgraduate Fellowship. RO is supported by a Deakin University Postgraduate Research Scholarship. LM is supported by the Italian Ministry of Health (Ricerca Corrente 34/2017) through funding made to the Institute for Maternal and Child Health - IRCCS Burlo Garofolo. CL is supported by a Ramon y Cajal fellowship funded by the Spanish Ministry of Science and Innovation (RYC2020-029599-I funded by MCIN/AEI /10.13039/501100011033 and the European Social Fund. DFS is affiliated with the Queensland Centre for Mental Health Research which receives core funding from the Department of Health, Queensland Government. AG is supported by the Italian Ministry of Health (Ricerca Finalizzata U40 2021, GR-2021-12375341 and Bando PNRR 2022, PNRR-MAD-2022-12375859). MB and SC are supported by the Italian Ministry of Health (Ricerca Corrente 2022-2024) through funding made to the IRCCS Neuromed; MB is supported by the Italian Ministry of Health (Bando PNRR 2022, PNRR-MAD-2022-12376167). SC is supported by the Italian Ministry of Health (Bando PNRR 2022, PNRR-MAD-2022-12376569).

Data Availability

The GLAD project is a multicountry collaborative effort for which individual collaborators apply a harmonized protocol developed by the task force to their own data. Data are not pooled in a shared repository or location, nor publicly available. The data custodians of each dataset may or may not make their data available upon request.

Disclaimer

The opinions, methods, and conclusions reported in this paper are those of the authors and are independent from the funding sources. This manuscript has been prepared in accordance with the requirements of the GLAD task force, as part of a global collaborative project to inform the GBD.

Authors' Contributions

AON and FNJ conceptualized the GLAD task force and project. AON acquired the funding for the project. DNA, RO, and MML contributed to the development of methodology, data curation, and project administration. DNA, RO, MML, FNJ, and AON contributed to the resources (provision of study materials), supervision of the project, and writing the original draft of the manuscript. All authors contributed to the validation of the methodology, and critically reviewing and editing the manuscript.

Conflicts of Interest

None declared.

Multimedia Appendix 1
Commonly used tools and scales for assessing common mental disorders, and their cut-offs for indicative diagnosis.

Abstract

Background: Patient safety is essential in pharmacotherapy, especially in surgical contexts, due to the elevated risk of drug-related complications. Vascular surgery patients are particularly susceptible because of their complex medication needs and underlying health conditions. Improved safety monitoring and targeted pharmaceutical care in collaboration with physicians are crucial to minimize these risks and enhance patient outcomes.

Objective: This protocol evaluates whether structured pharmaceutical care interventions—including medication reconciliation, medication review, and patient education—can reduce the prevalence of drug-related problems at hospital admission and discharge in vascular surgery patients.

Methods: This prospective, uncontrolled study was conducted over 1 year in the Vascular Surgery Department at the National Institute of Cardiovascular Diseases in Bratislava, Slovakia. The study included adult patients with carotid artery disease or lower extremity artery disease who were on 3 or more medications, with an estimated sample size of approximately 100 patients. The primary intervention involved 3 key changes in practice: medication reconciliation at both admission and discharge, where hospital pharmacists review and verify medication lists; medication review to identify and address drug-related problems; and patient education at discharge. Pharmacist-proposed interventions were documented and communicated to the physician for treatment adjustments. The primary outcome is the change in drug-related problem prevalence from hospital admission to discharge. Secondary outcomes include the acceptance rate of pharmacist recommendations and patient understanding of pharmacotherapy. Data collection involved documenting the number, type, and frequency of drug-related problems; the anatomical therapeutic chemical classification of medications associated with drug-related problems; and patients' social, demographic, and clinical characteristics, with a focus on factors related to drug-related problems, comorbidities, and medication use. Data analysis will use the paired Wilcoxon signed-rank test to compare the prevalence of drug-related problems and medication counts between admission and discharge. Continuous variables will be presented as means (SDs), while categorical variables will be reported as counts and percentages. Patient understanding of pharmacotherapy will be evaluated using a 3-point scale, classifying understanding as good (2-3 points per medication), modest (1-2 points), or poor (0-1 point).

Results: Recruitment began in September 2021 and concluded in August 2022. Data collection occurred continuously during hospital stays, capturing demographics, comorbidities, pharmacotherapy, and drug-related problems at admission and discharge. Important milestones included the initial data review, which began in August 2023 to assess recruitment and data quality, including

an early evaluation of drug-related problems. The primary analysis was completed in January 2024, focusing on the reduction in drug-related problems, intervention acceptance, and patient understanding. The final report was to be prepared by June 2024, disseminating the findings on pharmacist-led intervention impacts.

Conclusions: This study should demonstrate that pharmacist-led interventions in collaboration with physicians can reduce pharmacotherapy risks and optimize medicine management for patient safety.

Introduction

Background

Pharmaceutical care was first defined in 1990 by Hepler and Strand [1] as "the responsible provision of drug therapy for the purpose of achieving definite outcomes that improve a patient's quality of life." Worldwide, pharmaceutical care is currently considered a patient-centered approach, replacing the previous product orientation (dispensing medications) [2,3]. The pharmacist actively cooperates not only with the patient but also with health care professionals in health promotion, disease prevention, evaluation, monitoring, and adjustment and initiation of drug use in order to ensure an effective and safe drug regimen, achieve positive clinical results, and reduce the economic costs of care [2,4].

Currently, patient safety in health care delivery is at the forefront of interest worldwide [5,6]. Patient safety is the absence of preventable harm to a patient during the process of providing health care and reduction of the risk of unnecessary harm associated with health care to an acceptable minimum. Hospital pharmacists [4,7] can make a significant contribution to the safe, effective, and rational use of medicines by hospitalized patients, especially high-risk medication and look-alike and sound-alike medications, through their close surveillance as well as advising on the most appropriate use of medicines [7]. Identification of drug-related problems (DRPs) and proposal of solutions for DRPs by hospital pharmacists is a tool to ensure safe and effective pharmacotherapy for patients [8,9].

The Pharmaceutical Care Network Europe Association (PCNE) defines a DRP as a problem, event, or circumstance related to pharmacotherapy that affects or has the potential to affect a desired therapeutic effect [10]. An example is the arbitrary withdrawal of metformin by patients due to persistent diarrhea [11]. The PCNE has developed a classification system as a tool to accurately identify DRPs. The current version is V9.00 as of 2019 [10]. This classification tool is used throughout our study to ensure consistency in identifying and categorizing DRPs.

DRPs are generally all problems related to the use of a drug [10]. DRPs include adverse drug reactions (ADRs), an unintended reaction after medication administration [11-14], medication errors, and any phenomenon that may lead to improper use of a drug under the control of a health care professional or patient [15-17].

Although it is not common practice in Slovakia to report all DRPs, this is not an issue unique to the country. Many nations face similar challenges, especially where comprehensive pharmacovigilance systems are still developing [18]. In 2019, only 1128 suspected ADRs were reported, of which only 8% were reported from pharmacists. Overall, up to 26% of reports were classified as severe (ie, required hospitalization of the patient or caused permanent harm to the patient). Although state authorities have seen an increase in the number of spontaneous reports, their number probably does not correspond to their actual occurrence. Currently, we do not have statistically evaluated health care costs due to medication errors in Slovakia [18].

We distinguish between intentional and unintentional DRPs [10,19,20]. There is no uniform classification of the severity of DRPs. It is necessary to focus on the identification and elimination of unintentional DRPs.

At the same time, according to current statistics, the average age of the population is increasing worldwide, which is directly related to the higher prevalence of polymorbidity and polypharmacy in the population [21-23].

There are certain indicators on the basis of which an increased incidence of unintentional DRPs can be expected. In a hospital environment, these are the high number of drugs, which is related to low adherence, potential interactions, accumulation of medication errors, more frequent hospitalizations, and increased treatment costs [24-27]; a low level of understanding of the therapy being used among patients [28-30]; older age of patients [21-23,28]; and absence of caregivers for older adult patients [29].

These indicators may be associated with the incidence of treatment errors related to primary care.

Prior Work

Pharmacists use several strategies to reduce DRPs, including medication reconciliation (MedRec), medication review (MedRev), and patient education [30-34]. Prescription errors during hospital admission are common, with studies showing that these errors occur in up to 67% of patients [35]. MedRec has been shown to identify at least one DRP in 60% of patients, with 18% being clinically significant [36]. The incidence of drug discrepancies during hospital transitions, especially at discharge, is high, with some studies showing significant discrepancies upon patient discharge [37,38]. According to a

2020 Organization for Economic Co-operation and Development report, pharmacy-led MedRec before discharge reduces drug discrepancies and the associated risks to patient health [39]. A meta-analysis conducted by Mekonnen et al [40] in 2016 found that pharmacist-led MedRec reduces hospital readmissions by 67%, emergency admissions by 28%, and hospitalizations by 19%.

MedRec involves obtaining a best possible medication history (BPMH) from various sources, including medical records, community pharmacies, and patient interviews. This is compared with the patient's current medication list to identify discrepancies, which are then discussed with health care professionals and resolved [32-34,41,42]. MedRev further optimizes pharmacotherapy by eliminating unnecessary medications, adjusting dosages, or addressing drug interactions [43].

Studies on pharmaceutical interventions typically focus on specific patient groups, such as those with cardiovascular diseases, renal failure, or older adult patients. For example, Stemer et al [44] identified 487 DRPs in 138 visits, with a 54.7% acceptance rate for pharmacist recommendations. Hohn et al [45] found a rate of 0.41 unintentional medication errors per patient in vascular surgery patients. In patients with chronic renal insufficiency, pharmacist interventions improved renal function, particularly in more severe cases [46]. Older adult patients also showed positive outcomes, with pharmacist interventions reducing hospital readmissions by 16% and hospitalization rates due to DRPs by 80% [47].

Overall, pharmacist-led interventions are effective in reducing DRPs, improving pharmacotherapy, and enhancing patient outcomes. However, the types and numbers of DRPs detected vary across studies, indicating the need for standardized definitions in research on DRPs [19,33,48].

Trial Objectives

This study aims to assess the impact of pharmaceutical care in collaboration with physicians on the prevalence of DRPs at hospital admission and discharge in patients with carotid artery disease or lower extremity artery disease hospitalized in the Department of Vascular Surgery. These patients often experience polypharmacy, making them particularly suitable for pharmacotherapy optimization through pharmacist-led interventions. MedRec, MedRev, and patient education provided by pharmacists are new interventions at our hospital and were not part of the standard of care prior to the study.

The key focus area of this project is the identification of DRPs, their occurrence, and their type. As part of further research, we want to analyze the degree of acceptance of the proposed changes in pharmacotherapy by physicians, document the Anatomical Therapeutic Chemical Classification (ATC) groups of drugs with the highest incidence of DRPs, and identify patients at highest risk for DRPs taking into consideration their personal and health information.

Trial Hypotheses

The null hypothesis is that pharmaceutical care provided at hospital admission and hospital discharge does not reduce the prevalence of DRPs in patients with carotid artery disease or lower extremity artery disease hospitalized in the Department of Vascular Surgery.

The alternative hypothesis is that pharmaceutical care provided at hospital admission and hospital discharge reduces the prevalence of DRPs in patients with carotid artery disease or lower extremity artery disease hospitalized in the Department of Vascular Surgery.

Methods

Study Design

This study is a single-center, prospective, uncontrolled biomedical clinical trial conducted over 1 year. The study took place in a hospital setting, specifically in the Department of Vascular Surgery at the National Institute of Cardiovascular Diseases in Bratislava, Slovakia. The intervention included MedRec, MedRev, and patient education, all performed by a trained pharmacist following the High 5s Project Standard Operating Protocol for Medication Reconciliation [24] and PCNE guidelines [10]. All pharmacist recommendations and proposed changes to therapy were documented in writing, recorded in the patient's medical record, and communicated to the attending physician.

Our study followed the Standards for Quality Improvement Reporting Excellence (SQUIRE) guidelines [49].

Study Population

Adult (≥18 years of age) vascular surgery patients with carotid artery disease or lower extremity artery disease admitted for hospitalization at the study setting during the course of the study were recruited.

Inclusion Criteria

To participate, patients needed to be ≥18 years old at the date of admission for hospitalization, taking at least 3 medications administrated systematically, and have carotid artery disease or lower extremity artery disease.

Exclusion Criteria

Patients were excluded for any of the following reasons: admitted for an acute condition; transferred from other hospitals or wards; not willing to sign the informed consent form for the study; not understanding the Slovak language; had any mental disorder affecting memory and recall ability (such as Alzheimer disease); any other reason, at the investigator's discretion, why he or she deemed the participant not eligible for study participation (all such reasons were recorded); or participating in another clinical study.

Study Sample Size

To calculate the sample size, we aimed to accept a type I error rate with a P value ≤.05. The study seeks to achieve 80% power to detect a small effect size of 0.3 using the Wilcoxon signed-rank test. Based on these assumptions, the required sample size was calculated as 94 patients. To account for potential dropouts, the sample size was increased to 120 patients. The sample size calculation was performed using G*Power

software version 3.1 [50]. Similar studies published in this field have comparable sample sizes [51].

Data Sources and Measurements

Data were drawn from the hospital information system (HIS), medical and nursing reports, patient interviews, and contacting outpatients.

Primary Outcomes

The primary outcome is a change in the prevalence of DRPs at hospital admission versus hospital discharge.

Secondary Outcomes

The secondary outcomes are the acceptance rate of the pharmaceutical intervention by physicians and patient understanding of their pharmacotherapy.

Variables

The variables collected include the number, type, and frequency of DRPs; ATC of drugs causing DRPs; medical, social, and demographic characteristics of patients; health condition of patients; comorbidities; and patient understanding of their pharmacotherapy assessed on a 3-point scale at hospital admission.

We assessed the patients' basic social, demographic, and clinical characteristics, with a particular emphasis on evaluating their pharmacotherapy and the incidence of DRPs. Additionally, we examined the degree of acceptance of pharmacists' recommendations by physicians and the outcomes of DRP resolutions. Our analysis will also identify the medications most frequently associated with the occurrence of DRPs. Patients' understanding of their pharmacotherapy was also be evaluated.

Time Points for Intervention

At Hospital Admission

Current Condition at Patient Admission

A vascular surgery patient with carotid artery disease or lower extremity artery disease comes for a planned hospitalization with a report from the attending physician, with or without an internal preoperative examination. The physician, in cooperation with the nurse, examines the patient on admission, draws information from the patient's medical records, and in the case of rehospitalization, from the HIS and internal preoperative examination. The physician will prepare an admission report, which will record the patient's previous illnesses, the current state of health, the reason for hospitalization, and all associated illnesses. Patients often bring a list of medications they are taking; the physician will consult with the patient on the completeness of this list. He or she detects then records possible allergies to drugs and food and other forms of intolerance or allergic manifestations. He or she is interested in the use of addictive substances, alcohol, and drugs of abuse and the frequency of their use. The patient signs informed consent that he or she consents to hospitalization and treatment. The admission report, which also includes the drug course (current drug record, which is updated once a day; if necessary, it is possible to insert notes, consultation examinations, orders for laboratory tests, and other information), will be prepared both in the HIS and in printed form. Each hospitalized patient has a printed medical record that is more comprehensive and contains more detailed information than the HIS records. It contains all the patient's health results, required examinations, daily drug courses, all daily updated nursing records, records of the patient's diet, and more. Based on the prescription of medications in the course, the nurse prepares and administers medications to the patient, and a sudden change in pharmacotherapy by the physician is reported to the nurse orally then recorded in the course. Some patients keep some of their medication with themselves and dose it themselves according to the physician's instructions.

MedRec by Pharmacists at Patient Admission

The patient is normally admitted to a planned hospitalization by the physician in cooperation with the nurse, as aforementioned. If the patient is older than 18 years, takes more than 3 medicines, speaks and understands the Slovak language, and has signed informed consent to participate in biomedical research, after being placed in a bed, a pharmacist comes to the patient's bedside and performs a MedRec. During the MedRec, the pharmacist creates a record of the patient's therapy, the original of which is placed in the patient's medical record, and a copy is placed in the pharmacist's records.

The steps in the MedRec involved the following. As part of the invitation for the hospitalization (by telephone or in writing), the patient was asked to bring all their medications and a complete medication list, which was used in consultation with the pharmacist regarding their proper use. The BPMH was completed.

The source of information can be a drug record, an admission report, hospital records, historical records from the HIS, or information from the patients or their family member. A BPMH is different and more complex than the routine history of primary treatment (which is often a rapid history of patient treatment). The BPMH includes the name of the medicine, dose, and frequency and administration route of the medicines that the patient is currently taking, although it may differ from what was actually written in the drug list.

The types of drugs that need to be recorded in the BPMH include prescription drugs, over-the-counter drugs, nutritional supplements, herbal medicines, medicinal teas, recreational drugs, and regular consumption of certain foods (eg, grapefruit). Special emphasis should be placed on specific forms of medicines, such as inhalers, eye drops, topical semisolid medicines, or medicines taken every few weeks (bisphosphonates).

One of the recorded parameters is patient understanding. This is evaluated in 3 steps and scored as 0 or 1: The patient knows (1) or does not know (0) the name of the drug, the patient knows (1) or does not know (0) the indication of the drug, and the patient knows (1) or does not know (0) the dosage of the drug. The 3-point scale was based on previously published studies by Cline et al [52], Boonstra et al [53], and Marfo et al [54], who evaluated patients' knowledge based on their understanding of the drug name, dosage, duration of treatment, indication, relationship of the drug to food, duration of therapy, or route

of administration. If the patient was unable to attend the interview, other sources were used to obtain a medical history or to clarify conflicting information. Other resources should never be a substitute for a thorough conversation with the patient or family members.

Regarding verification and documentation of the BPMH, the BPMH list should be verified by more than one other source. Sources for the initial acquisition of an overview of pharmacotherapy are the admission report, the history of hospitalization, outpatient reports, HIS, and the course at admission.

According to the World Health Organization standard operating procedure, a retroactive MedRec model was used for our biomedical research. In a retroactive model, in accordance with the aforementioned method, the patient is admitted by a physician in cooperation with a nurse by default, and a drug course—a daily prescription of drugs for the patient – is created. In this case, the BPMH is determined after admission by a physician or nurse.

The result of the MedRec is a comparison of medicines prescribed to and actually used by patients (BMPH) with marked discrepancies.

During the process of obtaining the BPMH, the pharmacist informs patients to always share their doubts about the correct use of the medication with the medical staff.

MedRev With Pharmaceutical Intervention at Patient Admission

The basis for patient therapy optimization is the acquisition of the BPMH and patient factors, such as the reason for hospitalization, current health status, comorbidities, height, weight, heart rate, blood pressure, and the results of examinations of biochemical and hematological parameters.

The detected BPMH is written in the case report form. It is then analyzed in the context of the patient's overall health condition, and DRPs are identified. Each detected discrepancy is assigned an alphanumeric code according to the PCNE V9.00 classification. The patient's personal data are anonymized.

Discrepancies in therapy should be consulted with the treating physician within 24 hours of admission.

Evaluation of Therapy Based on DRPs and PCNE Classification

After receiving the BPMH and a detailed study of the reason for hospitalization, current medical condition, and any patient comorbidities, the pharmacist collects information about the patient's weight, height, heart rate, and blood pressure from the admission report. Subsequently, the results of biochemical and hematological examinations are studied. The pharmacist focuses on the results of examinations related to pharmacotherapy and the determination of the function of elimination organs. These are mainly the levels of serum potassium, serum creatinine, serum uric acid, liver transaminases, lipidogram, and C-reactive protein. Renal function is calculated based on the Cockcroft and Gault creatinine clearance estimate.

Duplicate Treatment

The pharmacist controls duplication in the drugs used, considering the use of the same substance in 2 drugs, use of the same substance in 2 dosage forms, use of 2 substances from the same pharmacological group, and double inhibition of the renin-angiotensin-aldosterone axis by angiotensin-converting enzyme inhibitors and angiotensin II receptor blockers.

Duplicity is recorded in written form in the final evaluation of the patient's pharmacotherapy; duplication is discussed with the patient, who confirms or refutes the actual use of the duplicate drugs, and the most appropriate procedure is proposed in collaboration with the attending physician.

Indications of Used Drugs and Contraindications

The pharmacist checks the indications of the drugs used according to the patient's comorbidities. The pharmacist checks whether all comorbidities are treated according to evidence-based medicine and according to treatment procedures developed by local, national, or international authorities. The result of this step is the identification of missing drugs in the patient's pharmacotherapy.

Furthermore, drugs whose use has no clear indication are identified. In older adult patients (≥65 years), the pharmacist also considers the use of potentially inappropriate drugs. The pharmacist follows the EU (7)-PIM list [55], which was designed for patients aged 65 years and older. The result of this step is the identification of drugs that do not have a clear indication or are inappropriate due to the patient's age.

The pharmacist also checks whether the prescribed drug is appropriate for the specific patient.

Drugs that the patient should and should not take, drugs whose indications are not clearly known from the available data, and contraindicated drugs are recorded in the final evaluation of the patient's pharmacotherapy, in cooperation with the attending physician; subsequently, the most appropriate procedure is proposed.

Drug Management

The pharmacists verify compliance with maximum recommended doses, considering patient-specific factors, and records any excess in the pharmacotherapy evaluation. They assess the suitability of dosage forms, administration practices (including infusion components, timing, and food interactions), and screen for potential drug interactions using LexiComp and other resources, documenting any clinically significant findings. All observations and recommendations are reviewed with the attending physician to determine the appropriate course of action.

Adverse Drug Reactions

If a newly manifested ADR not documented in the patient's medical history is suspected, the pharmacist evaluates the degree of causality between the drugs used and the manifestations of the ADR, which is proven on the basis of laboratory parameters or the patient's subjective complaint. The pharmacist reports suspicions of ADR to the State Institute of Drug Control via an electronic form available from [56].

ADRs are recorded in the final evaluation of the patient's pharmacotherapy.

The individual DRP findings shall be entered in the form as an appropriate code according to the PCNE classification [10].

The result of the pharmacist's intervention at patient admission is the completion of the MedRec form at admission and creation of an accurate list of medicines taken by the patient. All comments on pharmacotherapy with the proposed solutions are written in the form of a summary report and undergo consultation with the physician.

At Hospital Discharge

Current Condition at Patient Discharge

When discharging a patient, the attending physician evaluates the patient's state of health and prepares a discharge report with complete information about the procedures that the patient underwent during hospitalization. The discharge report also includes the current results of the patient's laboratory examinations, an overview of current pharmacotherapy, and recommendations to the patient's general practitioner. The nurse explains the regimen measures in relation to his or her state of health to the patient and gives the patient medication for the 3 days following discharge.

MedRec by Pharmacists at Patient Discharge

The pharmacist performs MedRec when discharging a patient from the hospital, similar to the process at admission. When evaluating a patient's pharmacotherapy on discharge from hospital, the BPMH obtained at the patient's admission will be used as a source of information. The BPMH is then compared with the list of medicines that are recorded in the release report. The pharmacist will compare 2 lists of medicines, focusing on the identification of DRPs with special regard to the re-introduction of the chronic therapy the patient was taking before hospitalization. As part of this research, the pharmacist met with the patient during his or her discharge from the hospital and discussed with him or her the management of further pharmacotherapy. Pharmacists provided an understandable summary list of a patient's medicines explaining the importance and the correct use of the medicine.

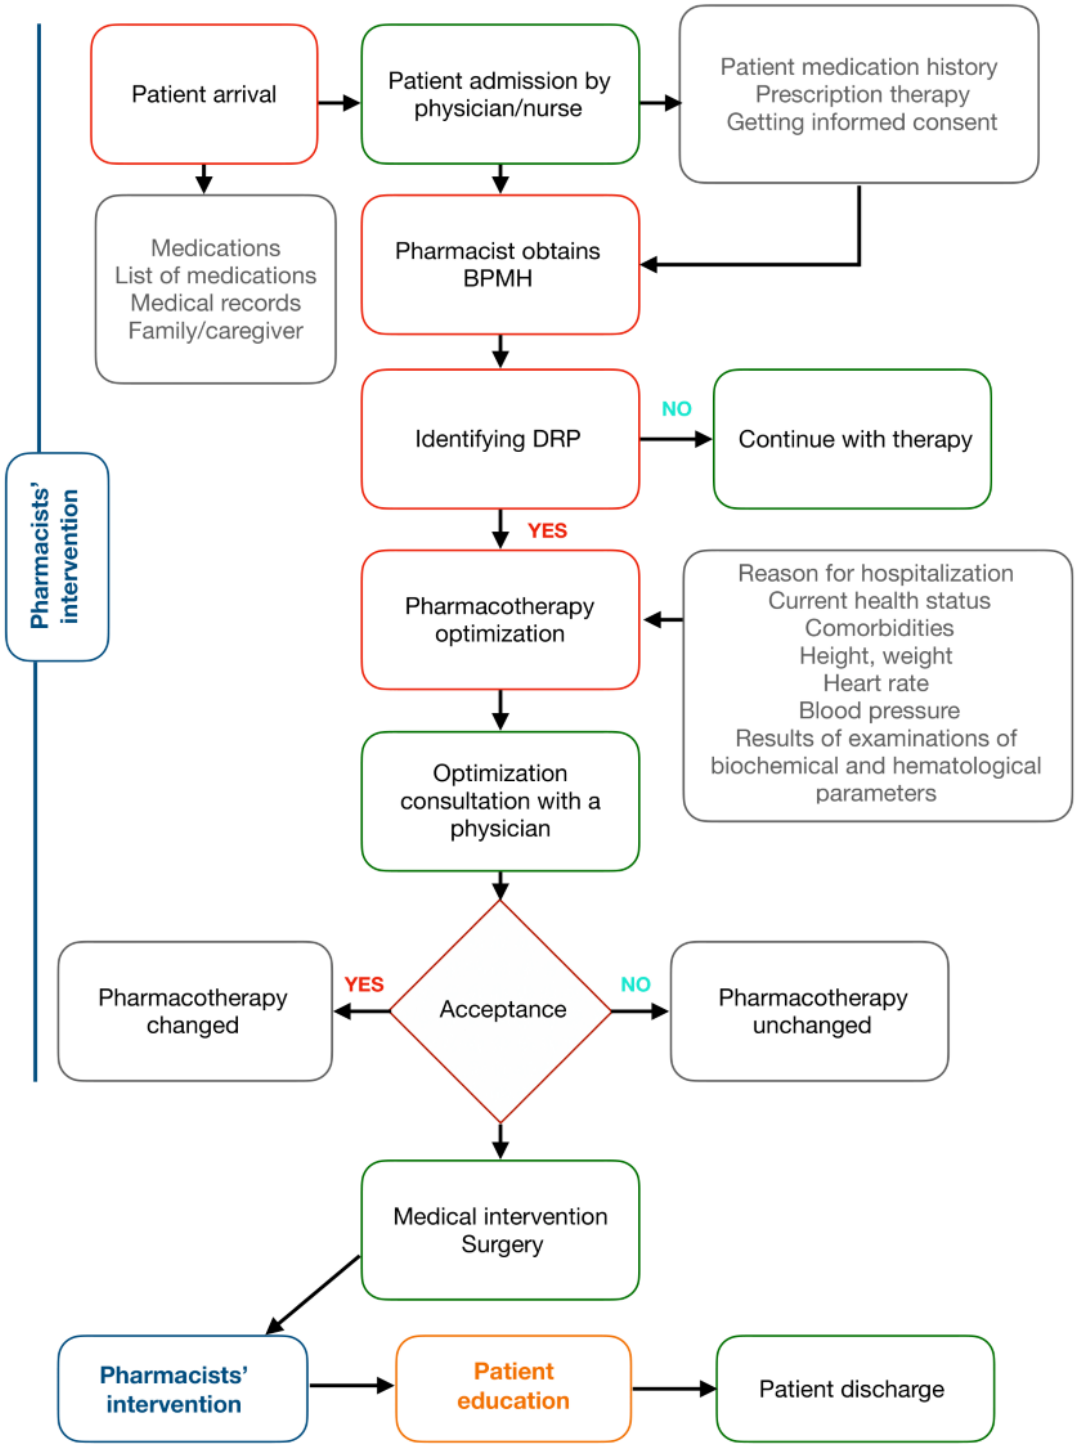
MedRev With Pharmaceutical Intervention at Patient Discharge

The pharmacist analyzes the pharmacotherapy in the context of the patient's state of health and the results of laboratory tests, similar to the patient's admission, as described in the previous sections. Detected DRPs are then consulted with the treating physician and recorded in the case report form.

The result of the pharmacist's intervention at discharge is the completion of the MedRec form for discharge and the documentation of all comments on pharmacotherapy in the form of a summary report. Discrepancies and comments are consulted with the physician.

The complete scheme of the procedure can be seen in Figure 1.

Figure 1. Procedure scheme.



Ethical Considerations

Human Subject Ethics Review Approvals

The study was approved by the Ethics Committee of the National Institute of Cardiovascular Diseases (approval number 1625/21; May 26, 2021) and registered on ClinicalTrials.gov (trial registration number NCT04930302; June 16, 2021). All research procedures adhered to the ethical standards of the institutional and national research committees and were conducted in accordance with the 1964 Helsinki Declaration and its later amendments or comparable guidelines.

Informed Consent

Written informed consent was obtained from all participants before any research-related activities were initiated. The consent form, approved by the Ethics Committee, was provided in Slovak to ensure participants' understanding. By signing the consent form, participants consented to the publication and presentation of their pseudonymized data.

Privacy and Confidentiality

Patients' personal data were anonymized to ensure confidentiality. The Participant Identification Sheet was securely

stored at the study center, alongside other documentation. Anonymized data were entered into the case report form in the MIA DMS online database, which operates within Europe.

Compensation Details

No compensation was provided to participants for their involvement in this study.

Results

This protocol outlines the planned study design and anticipated timeline for the PHAROS trial, aimed at evaluating the impact of pharmacist-led interventions on DRPs in patients undergoing vascular surgery. The key stages of the trial and their anticipated completion dates are described in the following sections.

Study Initiation and Recruitment

Patient recruitment began in September 2021 and was completed in August 2022. The target sample size of 100 patients was reached.

Data Collection

Data collection occurred continuously during each patient's hospital stay, including assessments at admission and discharge to document patient demographics, comorbidities, pharmacotherapy details, and DRPs. These data will help evaluate the prevalence and types of DRPs, intervention acceptance rates, and changes in patient understanding of pharmacotherapy.

Analysis and Reporting Milestones

For the initial data review, preliminary data analyses began in August 2023 to assess recruitment efficacy and data integrity. This phase includes an initial assessment of DRPs and intervention types recorded during patient admission.

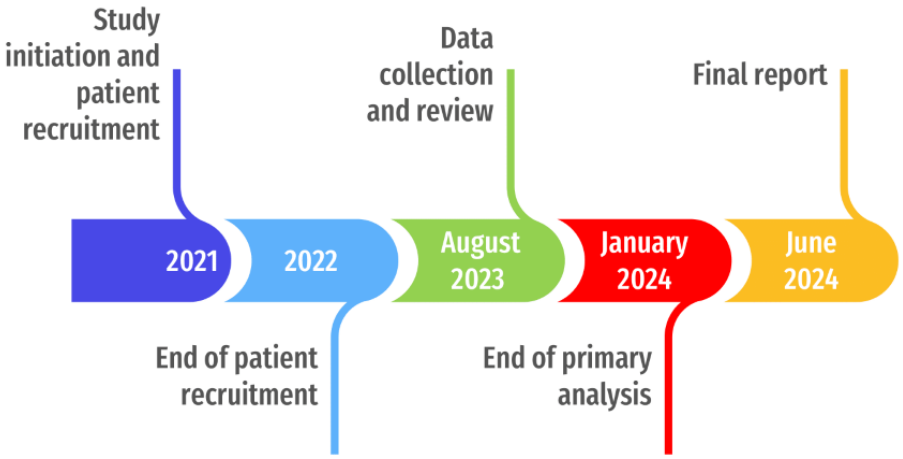
The primary analysis, including full data analysis encompassing outcomes related to DRP reduction, intervention acceptance, and patient pharmacotherapy understanding, was completed in January 2024.

For the final report and dissemination, the study findings, including the impact of pharmacist interventions on patient outcomes, were compiled and prepared for dissemination by June 2024.

A timeline of the PHAROS trial (Figure 2) illustrates each phase of the study, from patient recruitment through final analysis and reporting.

These timeline indicators and progress markers will enable ongoing tracking of study completion and ensure that each stage of data collection and analysis aligns with the study's objectives.

Figure 2. Timeline of the PHAROS trial.



Statistical Methods

Continuous variables will be characterized as the mean with standard deviation. Categorical variables will be expressed as numbers and percentages.

To compare the number of drugs, active substances, and DRPs at hospital admission and discharge, the paired Wilcoxon signed-rank test will be used due to the non-normal distribution of differences between the 2 time points. Normality will be assessed with the Shapiro-Wilk test. To determine the effect size of the intervention, Cohen *d* will be calculated and categorized as small, medium, or large based on established intervals. Patients' understanding of their pharmacotherapy at hospital admission will be evaluated using a 3-point scale. The average score per medication will be calculated, categorizing patients into groups based on their understanding: good (2-3 points per medication), modest (1-2 points per medication), and poor (0-1 point per medication).

Discussion

Importance

The PHAROS study is the first prospective clinical trial in Slovakia to evaluate pharmacist-led interventions on DRPs in vascular surgery patients. Our findings add to the growing body of evidence that pharmacist involvement can reduce the prevalence of DRPs, improve patient understanding of medications, and enhance overall pharmacotherapy outcomes for hospitalized patients.

Comparison With Prior Work

Several studies have examined the role of pharmacists in preventing and managing DRPs across various clinical settings [57], including vascular surgery. Hohn et al [45] and Martínez López et al [51] documented a decrease in DRPs due to pharmacist-led interventions, reporting an average of 1.3 and 1.7 DRPs per patient, respectively. These studies support the role of pharmacists in reducing DRPs and improving medication safety in hospitalized patients. Findings from Schmelzer et al [58] and other international studies also demonstrated a significant reduction in DRPs at discharge.

The impact of pharmacist-led interventions on vascular surgery patients specifically has not been extensively studied. However, studies in other settings, such as those by Hohn et al [45] and Rychlíčková et al [59], have shown positive outcomes from pharmacist interventions. Singh et al [60] highlighted the underprescription of statins in patients with peripheral artery disease, attributing this to clinician-related barriers such as concerns about adverse effects. The PHAROS study aims to contribute to this literature by demonstrating that pharmacist involvement in MedRec and MedRev supports DRP management and optimizes pharmacotherapy, underscoring the importance of pharmacist intervention in promoting guideline-adherent care.

An important aspect of the PHAROS study is its focus on patient education. Based on the prior literature, educating patients about their medications is strongly associated with better adherence and a reduction in DRPs [31,32,61,62]. Including patient education as part of the pharmacist's role is intended to support informed patient participation in their treatment.

Challenges and Barriers

Despite the promising outcomes of pharmacist-led interventions, challenges remain in their implementation. One significant barrier is resistance to change among health care professionals, especially in settings where the role of pharmacists in medication management is not well established. As noted by Hohn et al [45], physicians may be hesitant to accept pharmacist recommendations, particularly in complex cases involving polypharmacy and comorbidities. Successful pharmacist-led interventions require clear protocols, comprehensive training, and effective collaboration with other health care professionals. The lack of legislative requirements for MedRec and MedRev in Slovakia demonstrates the need for policy changes to integrate pharmacists systematically into patient care transitions. This is particularly important, as international guidelines, such as those from the European Association of Hospital Pharmacists [63], emphasize the role of MedRec in ensuring safe and effective care.

Future Directions

Building on the results of this pilot study, future research should seek to validate these findings through a larger, randomized controlled trial, which would allow for a more rigorous assessment of pharmacist-led interventions on DRPs. Such studies could incorporate a control group, a larger sample size, and postdischarge follow-up to evaluate long-term effects. Expanding research to diverse health care settings and patient demographics could provide insights into optimizing pharmacist interventions across various clinical contexts.

Limitations of the Study

Our study has several limitations. First, it was conducted as a single-center trial and performed in specific departments and with specific indications; therefore, the results may not be applicable under different conditions. Second, the study did not include a control group. Although all investigators were trained in all study processes, some degree of subjectivity is possible in the assessment of DRPs. Moreover, the number of patients was limited. However, trained hospital pharmacists strengthened the methodology used in our trial.

Conclusions

The study should determine that pharmaceutical care provided at hospital admission and at hospital discharge could reduce the prevalence rates of DRPs in our study setting. The pharmacist-led interventions upon hospital admission and discharge, followed by patient education, might be implemented in daily practice in health care in our hospital.

Acknowledgments

This study would not have been possible without the support of the Chief of the Vascular Surgery Department, Ján Tomka, MD, PhD, as well as the cooperation of the physicians from this department.

Data Availability

Only investigators from the National Institute of Cardiovascular Diseases have access to all patient data. They maintain an accurate and comprehensive list of biomedical research participants, along with the alphanumeric codes assigned to them, all documented in the "Participant Identification Sheet." Both the completed Participant Identification Sheet and all research data are securely stored. Anonymized personal data are entered into the case report form in the online MIA document management system (DMS) database and are accessible only to investigators. The data sets used and analyzed during the study are available from the corresponding author upon reasonable request.

Authors' Contributions

All authors contributed equally to the study conception and design. All authors read and approved the final manuscript. TT is responsible for the overall content as the guarantor.

Conflicts of Interest

None declared.

Abstract

Background: The tobacco industry has a history of targeting minority communities, including Hispanic individuals, by promoting vaping through social media. This marketing increases the risk of vaping among Hispanic young adults, including college students. In Texas, college enrollment among Mexican Americans has significantly increased over recent years. However, little research exists on the link between social media and vaping and the underlying mechanisms (ie, outcome expectations, attitudes, and beliefs) explaining how vaping-related social media impacts vaping among Mexican American college students. Moreover, there is limited knowledge about how acculturation moderates the association between social media and vaping. Hispanic individuals, particularly Mexican Americans, are the largest ethnic group in Texas colleges; thus, it is crucial to understand the impact of social media and acculturation on their vaping behaviors.

Objective: We outline the mixed methods used in Project Vaping, Acculturation, and Media Study (VAMoS). We present descriptive analyses of the participants enrolled in the study, highlight methodological strengths, and discuss lessons learned during the implementation of the study protocol related to recruitment and data collection and management.

Methods: Project VAMoS is being conducted with Mexican American students attending 1 of 6 Texas-based colleges: University of Texas (UT) Arlington, UT Dallas, UT El Paso, UT Rio Grande Valley, UT San Antonio, and the University of Houston System. This project has 2 phases. Phase 1 included an ecological momentary assessment (EMA) study and qualitative one-on-one interviews (years 1-2), and phase 2 includes cognitive interviews and a 4-wave web-based survey study (years 2-4) with objective assessments of vaping-related social media content to which participants are exposed. Descriptive statistics summarized participants' characteristics in the EMA and web-based survey.

Results: The EMA analytic sample comprised 51 participants who were primarily female (n=37, 73%), born in the United States (n=48, 94%), of middle socioeconomic status (n=38, 75%), and aged 21 years on average (SD 1.7 years). The web-based survey cohort comprised 1492 participants self-identifying as Mexican American; Tejano, Tejana, or Tejanx; or Chicano, Chicana, or Chicanx heritage who were primarily female (n=1042, 69.8%), born in the United States (n=1366, 91.6%), of middle socioeconomic status (n=1174, 78.7%), and aged 20.1 years on average at baseline (SD 2.2 years). Of the baseline cohort, the retention rate in wave 2 was 74.7% (1114/1492).

Conclusions: Project VAMoS is one of the first longitudinal mixed methods studies exploring the impact of social media and acculturation on vaping behaviors specifically targeting Mexican American college students. Its innovative approach to objectively measuring social media exposure and engagement related to vaping enhances the validity of self-reported data beyond what national surveys can achieve. The results can be used to develop evidence-based, culturally relevant interventions to prevent vaping among this rapidly growing minority population.

Introduction

Background

The tobacco industry has a history of targeting marketing campaigns toward specific minority groups [1,2]. In particular, Hispanic individuals, especially young adults and college students, are increasingly subjected to effective vaping promotions on social media, which raises their risk of e-cigarette use, commonly referred to as vaping [1,2]. Hispanic individuals are the largest and fastest-growing ethnic minority in the United States, comprising 19.1% of the total population, with 58.9% of this demographic being of Mexican heritage, primarily identifying as Mexican American [3]. In Texas, a majority-minority state with the second-largest Hispanic population in the United States, Hispanic individuals are the largest ethnic minority group, nearly 90% of whom are of Mexican heritage [4]. Moreover, the youthful profile of the Hispanic population, with approximately 50% aged <29 years, makes them a particularly appealing target for e-cigarette marketing [5,6]. One limitation of previous research is the study of Hispanic individuals as a homogeneous group. Despite variations in tobacco use behaviors by country of origin, there is a lack of ethnic-specific studies on Mexican Americans [7]. Moreover, little research has explored the link between social media and vaping among Hispanic college students even though national data show that they vape at rates comparable to those of their White peers and their use of social media is high [8].

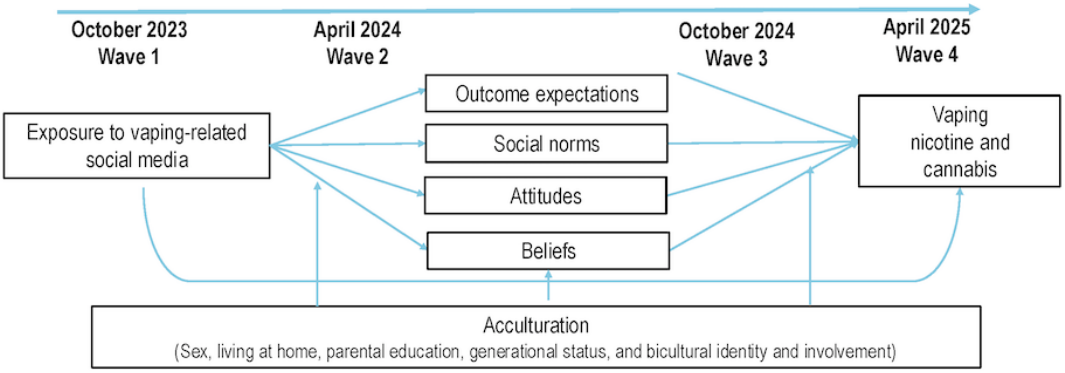
Social media plays a crucial role in the acculturation process as it provides a platform for language practice, information seeking, and social interaction, all of which are integral to acculturation [9]. Social media facilitates cultural exchange by enabling users to connect, share content of cultural significance, and influence each other's perspectives, thereby playing a pivotal role in shaping evolving cultural norms, beliefs, and identities within communities [10]. Of concern, Mexican American college students who are less acculturated yet use English-language social media might be more prone than their more acculturated peers to adopt the intrapersonal outcome expectations (eg, "e-cigarettes help me look cool and stay slim"), social norms (eg, perceived peer and family use and e-cigarettes being socially acceptable), and attitudes and beliefs (eg, e-cigarettes are safer and more convenient than cigarettes) promoted on social media, which elevates their risk of vaping [10]. Therefore, it is crucial to understand how social media influences intrapersonal mechanisms and mediators and, in turn, vaping behavior among individuals with varying levels of acculturation. This knowledge is important to developing evidence-based, culturally relevant interventions aimed at preventing vaping among this rapidly growing, vulnerable minority population.

Objectives

The primary goals of Project Vaping, Acculturation, and Media Study (VAMoS) are to (1) identify mechanisms underlying vaping-related social media exposure and engagement and vape use among Mexican American young adults and (2) examine the role of acculturation as a moderator of these mechanisms. Project VAMoS has 3 aims, which will be implemented in 2 phases and addressed using multiple methods. Aim 1 seeks to characterize vaping-related social media and vape use from the perspective of Mexican American college students using ecological momentary assessments (EMAs) and one-on-one qualitative interviews and was completed in years 1 and 2 (phase 1). Aim 2 seeks to identify intrapersonal mediators of the relationship between exposure to vaping-related social media and subsequent vaping, and aim 3 seeks to determine the moderating role of acculturation on the direct and mediated paths of aim 2. Aims 2 and 3 are addressed using a 4-wave, biannual web-based survey in years 2 to 5 (phase 2).

Guided by social cognitive theory [11,12], we hypothesize that outcome expectations, social norms, and attitudes and beliefs will mediate the association between social media and vaping. Guided by acculturation theories [13,14], we further hypothesize that these mediated associations will be moderated by acculturation such that they will be stronger for those who use English-language media and for less acculturated students, including first-generation college students and female individuals [15,16]. Figure 1 presents the conceptual framework used to guide this study as well as the data collection timeline.

Figure 1. Data collection timeline and conceptual model.



Methods

Overview

Project VAMoS is a 5-year study examining the independent and combined influences of social media exposure and engagement and acculturation on the vaping behaviors of a longitudinal cohort of Mexican American college students aged 18 to 29 years in Texas. VAMoS is a study that is conducted entirely on the web, including participant recruitment, data collection, and incentive delivery to participants. In this paper, we describe the protocol and present the planned mixed methodologies to be used in Project VAMoS. We present descriptive analyses of the participants enrolled in the study, focus on methodological strengths, and discuss lessons learned during the implementation of the study protocol related to recruitment and data collection and management.

Sampling

Sampling frames were constructed by requesting names and email addresses of full- or part-time undergraduate students through Texas's Public Information Act from the public information officers at 6 universities (University of Texas [UT] Arlington, UT Dallas, UT El Paso, UT Rio Grande Valley, UT San Antonio, and the University of Houston System). These 6 universities were selected because they are designated as Hispanic-serving institutions and all have large proportions of Hispanic students [17].

We received 100% of the requested information from all 6 colleges. Simple random samples using probability-based sampling frames of student names were drawn from each of the 6 colleges to minimize self-selection bias and improve generalizability [18]. The EMA study, qualitative interviews, and web-based surveys were and will be conducted in English, consistent with the cross-sectional web-based survey we conduct annually at Texas colleges as part of the tobacco prevention program [19]. However, participating students had the option to submit vaping-related social media content in Spanish, and our team had expertise to analyze such data.

Study Procedure and Participants

Phase 1: EMA Study (Years 1-2; March 2023 to May 2023)

An introductory invitation email explaining the study's objectives was sent to random samples of 5000 students at 5 of the 6 universities in the study (UT Arlington, UT El Paso, UT Rio Grande Valley, UT San Antonio, and the University of Houston), totaling 25,000 students, between March 24, 2023, and May 3, 2023. Eligibility criteria for the EMA study included (1) self-identifying as Mexican Americans, (2) being a degree-seeking college student, (3) being aged between 18 and 25 years, (4) being an active user of at least 2 social media platforms in the previous 30 days, (5) vaping in the previous 30 days, and (6) owning a smartphone and being willing to download the LifeData RealLife Exp mobile app.

Those who met the eligibility criteria were guided to a web-based consent form, and those who consented completed a baseline survey administered using the Qualtrics platform (Qualtrics International Inc). After completing the baseline survey, participants were invited to download the EMA app onto their smartphones via a QR code granting them access to the EMA study. Participants were provided with detailed study instructions that explained data collection procedures and offered step-by-step tutorials on how to use the app's features to complete the daily EMAs.

In total, 2 types of EMA data were collected over the 14-day-period: daily diary and event-based assessments. Daily diaries were delivered at 10 AM each day on weekdays and at noon each day on weekends. In both cases, participants had 8 hours to complete the survey, with up to 3 reminders delivered every 2 hours. The mobile EMA system alerted participants to complete the surveys through an in-app push notification, which rang and made the phone vibrate. Event-sampling assessments were initiated by participants and were available via a button on the app home screen. Participants were instructed to initiate an event-based assessment when they (1) encountered a vaping-related post on social media or (2) vaped. For the vaping-related social media post assessments, participants had the option to upload a screenshot or photo of the post. All assessments were date and time stamped.

Qualitative Interviews (Years 1-2; May 2023 to November 2023)

A total of 37% (19/51) of the students who participated in the EMA also completed a 1-hour, one-on-one qualitative interview that occurred between May 2023 and November 2023. The purpose of the qualitative interviews was to more deeply understand how vaping-related social media to which participants were exposed and with which they engaged during the 14 days shaped their outcome expectations, social norms, and attitudes and beliefs (ie, mediators) and, in turn, their vaping behaviors. For example, we showed participants a set of three screenshots of vaping-related content, which was in both English and Spanish and included (1) an advertisement for various flavors of vapes, (2) a video outlining tips to quit vaping, and (3) a humorous skit about locating a friend based on the scent of their vape.

We probed their reactions to the intended message of the content; its appeal to both the interviewee and other e-cigarette users; and whether, how, and why the content enticed vaping. Findings from the qualitative interviews also provided the basis for the measures and items in the web-based survey, ensuring culturally relevant content and terminology. For example, we identified and verified the terminology used for social media concepts and vaping products and verified that the vaping products and social media platforms that we planned to assess (eg, Instagram, TikTok, and YouTube) were appropriate. If participants identified other platforms or newly emerging tobacco products, our plan was to also assess those.

The interviews were conducted in English by trained bilingual staff (to capture "Spanglish" terminology) who were either college students attending one of the participating colleges (ie, UT Rio Grande Valley) or recent graduates of the University of Texas Health Science Center (UTHealth) Houston School of Public Health. The interviews were digitally recorded and transcribed, and transcripts were analyzed using a thematic

approach. Several members of our team audited the themes to ensure appropriate inferences. Each of the 19 participants was assigned a code number so that data from the EMA study and qualitative interviews could be deidentified. The code number was used to link data across the 14-day EMA study and the qualitative interviews.

Phase 2: Cognitive Interviews (Year 2; July 2023 to September 2023)

While designing the web-based survey, we conducted 1-and-a-half–hour cognitive interviews with 10 participants who had completed both the EMA and qualitative interviews. The purpose of the cognitive interview was to refine and finalize all measures and items for the web-based survey [20,21]. All cognitive interviews were conducted by trained staff through Microsoft Teams (Microsoft Corp) and were digitally recorded. We directed participants to complete the survey while on Microsoft Teams with both their own and project staff's cameras off and then let us know when they finished the survey; following completion, the staff walked through each question and the participants' answers, asking them to use the "think-aloud" method articulating their thought processes as each question was reviewed. Furthermore, the cognitive interviews incorporated specific, customized questions or "probes" regarding the survey questions. These probes yielded more detailed information than the think-aloud responses. This approach provided clarity on how participants formulated their answers as well as an estimate for approximate completion time.

4-Wave Web-Based Survey Study (Years 2-5; October 2023 Until 2025)

Following the incorporation of changes and recommendations from the cognitive interviews, we began to recruit for the web-based survey. An invitation email was sent to 165,966 undergraduate students across the 6 schools describing the study and providing a link with a brief eligibility screener survey between October 2023 and December 2023. Eligibility criteria for the survey included (1) self-identifying as Mexican American, (2) being a degree-seeking college student, and (3) being aged between 18 and 29 years. Those who met the eligibility criteria were guided to a web-based consent form that included the purpose and timeline of the study and described the incentive structure. Those who consented completed a baseline survey and established the cohort for Project VAMoS.

The survey was programmed in Qualtrics and was distributed using the built-in Qualtrics Mailer. Each participant received a unique link to the survey, which could only be completed once [22]. During data collection, participants' names, emails, and other information from the contact list were automatically saved to a secure server. Each participant was assigned a unique ID number, which allowed us to track student progress on each survey and match their data across waves without inclusion of personally identifying information in our survey database. Thus, we were able to track responses in progress and send reminders and thank-you messages to participants. In addition, this link automatically saved participants' data as they progressed through the survey. If they needed to leave the survey before finishing, a participant could return to it at any time before the survey closed. Participants who did not complete the baseline or wave-1 survey after receiving the initial email invite received up to 4 follow-up reminders to their school email addresses.

Measures

Phase 1: EMA Measures

Daily EMA measures captured data across 3 main constructs: acculturation, social media use, and vaping. For acculturation, participants provided information on their language preferences, engagement in cultural practices, and sense of ethnic identity. Regarding social media use, participants detailed how often they accessed social media per day, the time spent daily (in hours) on social media, the platforms they engaged with, the type of social media interactions they had (eg, comments, follows, likes, and shares), and their encounters with vaping-related content or advertisements. Participants also reported daily vaping behaviors, including frequency of use; device features; nicotine concentration; flavor preferences; use of other tobacco products, cannabis, and alcohol; and social contexts in which they vaped. All EMA questions were structured to capture participants' behaviors and experiences specifically for the previous day, allowing for a comprehensive understanding of their activities over a 24-hour period. Multimedia Appendix 1 shows the constructs assessed and example measures.

Qualitative Interview Guides

To provide a general outline for the qualitative interviews, we drafted a qualitative interview guide consisting of questions and follow-up probes to prime participant responses. The qualitative interview guide was informed by responses obtained from the EMA study. Participants were asked about vaping and use of social media. Probes sought to determine exposure to and engagement with vaping-related social media content over the previous 14 days and how this influenced their outcome expectations, social norms, and attitudes and beliefs (ie, mediators), subsequently affecting their vaping. After conducting 10 qualitative interviews, we observed that many participants disclosed vaping not only nicotine but also cannabis or tetrahydrocannabinol (THC), with some exclusively using cannabis or THC. Therefore, we revised the guide to explore the differences that participants perceived between vaping cannabis or THC and vaping nicotine. Specifically, these questions served to tease out distinctions in use patterns, contexts, and perceptions between the 2 substances. For example, we asked questions such as the following—"Are there places where and/or times when you use nicotine versus THC?"—to better understand the situational and behavioral differences in vaping these products.

Phase 2: 4-Wave Web-Based Survey Study

At wave 1 (baseline), participants completed a self-report survey consisting of 142 measures. Measurement selection was guided by the conceptual model in Figure 1, informed by the EMA and qualitative interviews, and refined through the cognitive interviews. Vaping measures were selected or adapted from national surveys, including the Population Assessment of Tobacco and Health Study, the Behavioral Risk Factor Surveillance System, the Youth Tobacco Survey, and the

National Survey on Drug Use and Health [23-26] (Multimedia Appendix 1).

The constructs assessed included sociodemographic characteristics, susceptibility to vaping, patterns of nicotine and cannabis or THC use, symptoms of dependence, cessation, outcome expectations from vaping, prevailing social norms, attitudes and beliefs, exposure to and engagement with social media, social media use patterns, and potential problems with social media [27]. We also assessed acculturation using proxy measures such as country of birth [28] and scaled measures such as the American Identity Measure [29-31] and included correlates of quality of family interactions and relationships [32]. Covariates assessed confounders and included use of other tobacco products and alcohol, experiences of racial or ethnic discrimination [33], and symptoms of depression [34] and anxiety [35].

At wave 2, we made several revisions. First, we shortened the survey by removing all items that would not change over time, such as sex at birth. We also did not ask participants to respond to "ever use" items at wave 2 (eg, ever used e-cigarettes) if they responded affirmatively at wave 1. Second, we included a limited number of new items; for example, we collected participants' race as defined by the US Census Bureau and intrapersonal measures of impulsivity, sensation seeking, and social anxiety [36-39]. Third, we asked participants to provide their personal social media handles or usernames for YouTube, Instagram, X (formerly known as Twitter), and Reddit to objectively assess the vaping-related social media content to which participants were exposed. We also asked participants to share 3 subreddits to which they subscribed and with which they frequently engaged also for objective assessment of vaping-related social media content. Consistent with our previous research [40,41], these data will be collected via the YouTube application programming interface (API) and web scraping for Instagram and X [42]. We will search for publicly available posts, videos, and hashtags with which our participants engage. We will not have access to the posts that participants see in their feeds or "for you" pages as these are not publicly available data and, thus, are outside the scope of our institutional review board (IRB) protocol.

Before analysis, all personally identifying information will be replaced with a unique ID number that matches the participants' ID number for the web-based survey, allowing us to link all the data for analysis. Custom-developed Python scripts (Python Software Foundation) will be used for API data collection from YouTube, and the Selenium toolkit [43] or Zeeschuimer [44] will be used for all browser-based web scraping (Instagram, YouTube, and X). The Python Reddit API Wrapper [45] will be used to collect data from Reddit. Depending on the platform, the date range of available posts will vary. We will scrape as much publicly available data as possible. The collected social media data will be studied computationally (with manual content analysis used to check validity). In terms of the former, we will use topic modeling, a computational natural language processing technique that we have successfully used in previous work [46], to identify statistically significant themes from (1) the posts of each user, (2) the aggregated posts of all users, and (3) the posts from subreddits that users follow and that they provided to us. Particularly for the latter, the data will be voluminous. Previous work has established the utility of generative artificial intelligence as a topic modeling tool to discover latent themes in large volumes of unstructured textual data [47]. We will adapt prompts developed and tested by others for topic modeling using ChatGPT (OpenAI) [48] to provide up to 5 themes for each user, 15 themes for all aggregated users, and 15 themes for each subreddit. We will then conduct a manual content analysis of a random sample of 150 posts from the aggregated posts of all users and the posts from subreddits that users follow to evaluate the robustness of the ChatGPT-based results. Our use of generative artificial intelligence will provide objective assessments of vaping-related social media content, which will allow us to characterize content that appeals to and entices Mexican American college students to use vapes**.**

Ethical Considerations

Human Participant Ethics Review Approvals

The IRB at UTHealth Houston (HSC-SPH-19-0796) approved all aspects of the study protocol. UT Austin approved the reliance on the UTHealth Houston IRB.

Informed Consent

All eligible participants in this study provided electronic informed consent before their participation in the 2 phases. Participants were informed about the study's objectives, procedures, potential risks, and benefits. They were informed that their participation was voluntary and that they could withdraw from the study at any time.

Privacy and Confidentiality

All collected data were deidentified to protect participants' privacy at the baseline wave. Personal information is removed before analysis, and the data are securely stored, with access restricted to authorized personnel.

Compensation Details

Phase 1

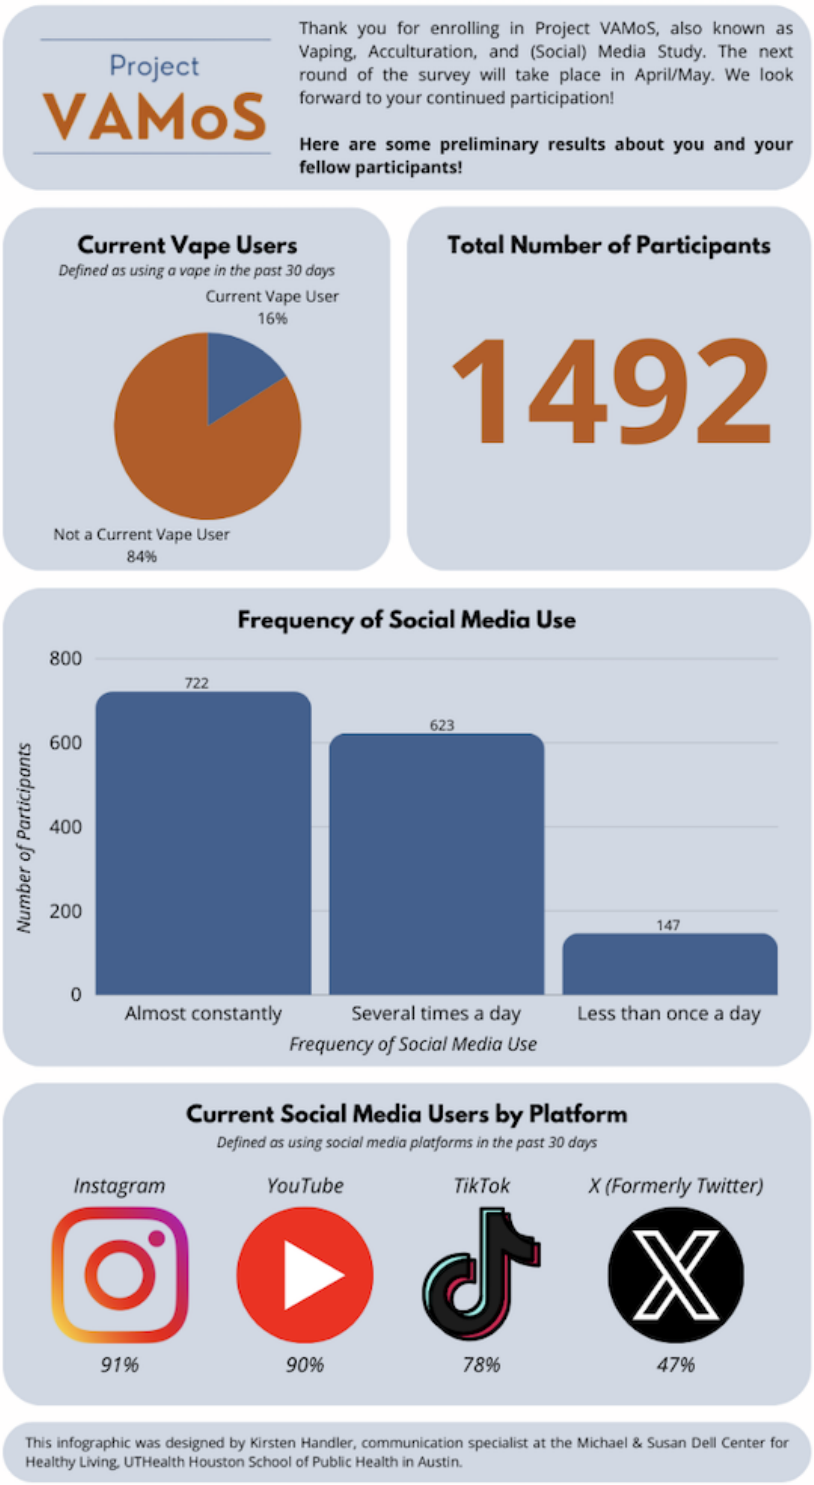
Participants who completed the EMA study were compensated with e-gift cards (US $10-$50) based on the percentage of daily diary assessments completed over the study period, with a minimum requirement of 50% of assessments completed to receive an incentive. Those who completed at least 7 daily diaries over the 14-day period received US $10 in e-gift cards (5/51, 10% of the participants), those who completed at least 10 daily diaries received US $35 in e-gift cards (13/51, 25%), and those who completed ≥13 of their daily diary EMAs received US $50 in e-gift cards (28/51, 55%). Participants were not compensated for event-based EMAs so as not to encourage false reporting of vaping or encounters with vaping-related social media content. Participants who completed the qualitative interviews were compensated with a US $50 e-gift card. Individual incentives were distributed within 2 weeks of completing the EMA and qualitative interviews.

Phase 2

Participants who completed the cognitive interviews were compensated with a US $50 e-gift card, which was distributed within 2 weeks of completing the interview. Individual

incentives were and will be offered at each of the 5 waves of the web-based survey. Students receive a US $25 e-gift card for completing each of the first 4 waves (totaling US $100) and a larger e-gift card of US $30 for completing the fifth and final wave. In addition, to maximize retention, we send an infographic with preliminary results between each survey (see Figure 2 for the infographic distributed between waves 1 and 2). Individual incentives are distributed within 2 weeks of survey completion.

Figure 2. Infographic distributed between baseline and wave 2 of the web-based survey.



Data Integrity and Security

We used rigorous protocols and advanced security measures to protect the integrity of the web-based survey data against bots and fraudulent respondents. First, we created a contact list with email addresses provided by each college and then distributed the survey using a unique, 1-time-use link for each participant in Qualtrics [22]. This setting prevented multiple survey completion attempts from the same individual by placing a

cookie on the participant's browser when they submitted a response. Participants are only able to complete the survey once; if the respondent clicks on the survey link after completing it, the presence of the cookie will prevent them from beginning a new survey. In addition, we incorporated a Completely Automated Public Turing Test to Tell Computers and Humans Apart (CAPTCHA) to ensure that surveys are completed by humans, not automated bots. Other strategies used to maximize the validity of the web-based survey data include the use of skip patterns within and across waves, which minimize participant fatigue and eliminate inconsistent responses; the use of "soft prompts" in most survey pages so that participants who skip questions are asked to verify their intent to leave the question blank; and the display of a limited number of items per screen or page [49,50]. In addition, participants are given the option to review and modify their responses using a Back button to enhance data accuracy. At wave 2, we added a human and attention check item to further ensure data validity and reliability [49].

Data security in Qualtrics is supported through advanced technological measures and robust policy enforcement. Qualtrics uses transport layer security encryption (also known as HTTPS) for all transmitted data. Qualtrics services are hosted by trusted data centers that are independently audited using the industry standard Statement on Standards for Attestation Engagements 18 method [49]. Access to datasets containing personal or identifying information is strictly limited to authorized members of the research team. These individuals undergo training in data privacy, confidentiality, and security protocols. Furthermore, they must use secure, complex passwords to access the Qualtrics data servers.

Final Data Quality Checks

Additional data quality checks were and will continue to be implemented to ensure the highest-quality survey data. Our team thoroughly reviews the survey responses for evidence of poor data quality. For example, we search for discrepancies in responses, such as participants providing contradictory answers to questions that should logically correlate or displaying a potentially problematic pattern of responses (eg, straight lining or selecting the same answer option several times in a row and a completion time of <10 minutes). Despite the exclusion of 0.2% (4/1824) of the participants at wave 1 due to these quality concerns, these participants received their incentive for taking part in this phase of the survey after we verified that a proper email address had been provided.

Maximizing Retention

To optimize retention across all waves of data collection, our team (1) fosters participant identification with the study by using our project name on all materials and correspondence [50-52]; (2) makes participation convenient by allowing participants to respond to the survey on a computer, smartphone, or other personal devices anywhere and at any time during the survey period [50]; (3) shares key study results via an infographic every 6 months; (4) sends multiple reminders (starting at wave 2, we sent reminders via email and SMS text message); and (5) keeps the survey open for up to 6 weeks to accommodate students' school and work schedules.

Results

Overview

Funding for Project VAMoS began in August 2022 and will conclude in March 2027. Data collection for phase 1 (EMA and qualitative interviews) was completed by June 2023. Phase 2, wave 1, was completed between November 2023 and December 2023; wave 2 was completed between April 2024 and May 2024. Wave 3 was completed between October 2024 and November 2024, and wave 4 will be completed between April 2025 and May 2025 (Table 1).

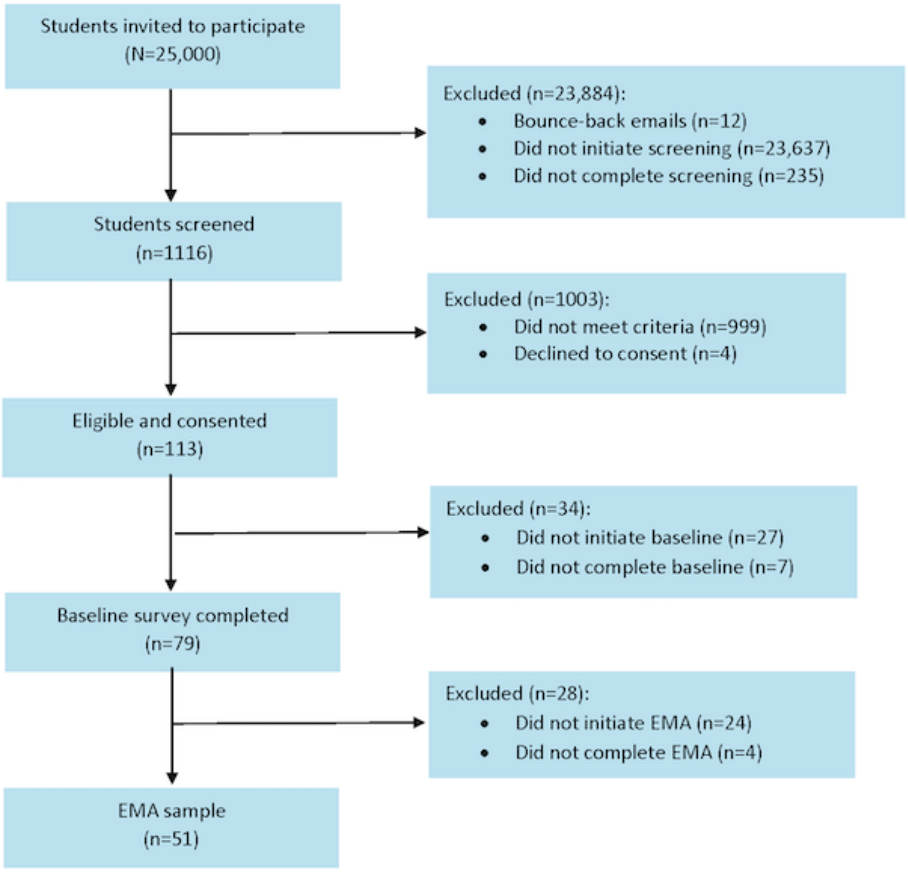
EMA Eligibility and Completion Rates

In spring 2023, a total of 25,000 invitations were sent to potential participants, and 1116 (4.5%) students were screened to participate in the EMA study, of whom 113 (10.1%) were eligible and 79 (7.1%) completed a baseline survey that collected information on their demographics, social media use, and tobacco use behaviors. Of the 79 eligible participants, 24 (30%) did not proceed with the EMA study, and 4 (5%) were dropped due to inactivity (ie, did not complete the daily assessments). Thus, 45.1% (51/113) of the participants took part in the 14-day EMA study to address aim 1 (Figure 3). Completion rates were calculated to determine the feasibility of EMA as a means of obtaining daily data among Mexican American college students. Of a possible 714 prompts, a total of 608 (85.2%) were sent to participants over 14 days; this discrepancy is due to some participants disabling the LifeData app before the study concluded, meaning that they were not able to receive further prompts. Of the 608 prompts sent, we received 583 (95.9%) complete responses. Of the overall sample of 51 participants, 5 (10%) completed at least 10 daily diaries, 13 (25%) completed at least 11, and 28 (55%) completed ≥13 of the daily diary EMAs. The average completion rate was 83.2% (SD 24.9%; range 7%-100%).

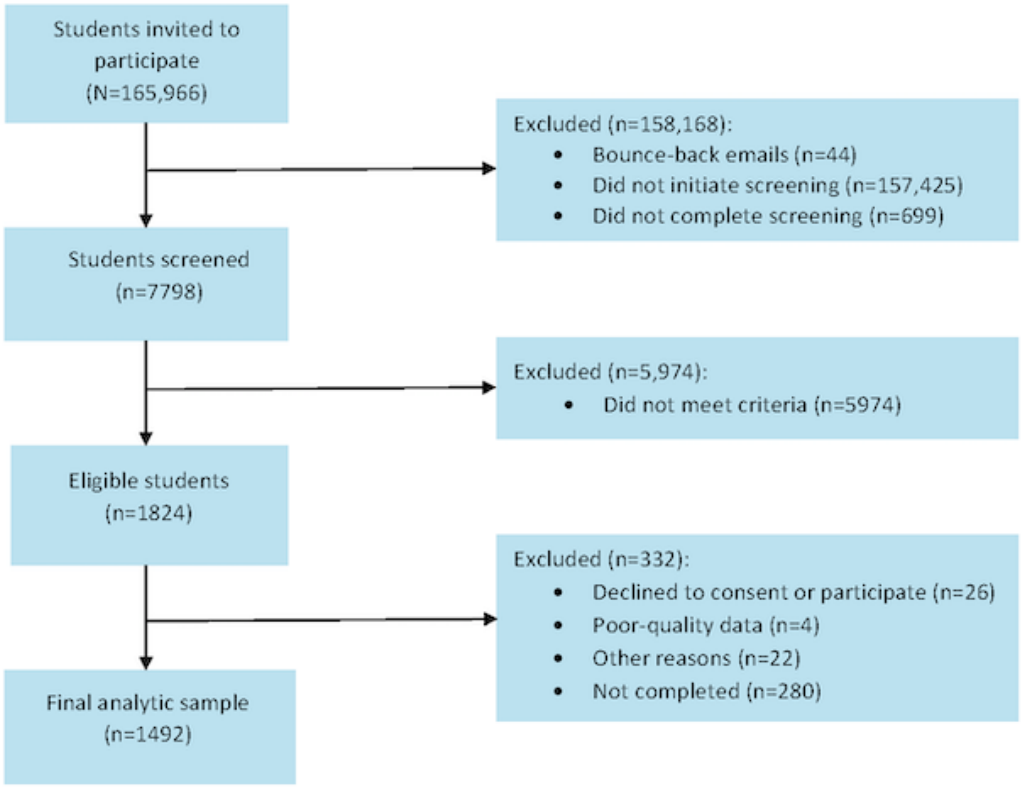
Figure 3. Flow diagram of ecological momentary assessment (EMA) participant recruitment.



4-Wave Web-Based Survey Eligibility and Retention Rates

In fall 2023, a total of 165,966 invitations were sent to potential participants, and 7798 (4.7%) students were screened to participate, of whom 1824 (23.4%) were eligible (Figure 4). Of those 1824 eligible participants, 26 (1.4%) declined to consent, 4 (0.2%) were excluded due to poor-quality data, 22 (1.2%) did not meet the age criteria and were excluded, and 280 (15.4%) did not complete the survey. Thus, 81.8% (1492/1824) of Mexican American students were recruited from all 6 participating universities to establish our cohort and address aims 2 and 3 (Figure 4). Of the baseline cohort, the retention rate in wave 2 was 74.7% (1114/1492).

Figure 4. Flow diagram of web-based survey participant recruitment.



Sample Characteristics

For the purposes of this paper, descriptive statistics were used to summarize the characteristics of the EMA study participants (Table 2) and the baseline characteristics of the participants who form the cohort for the web-based survey (Table 3). The final EMA analytic sample comprised 51 current vaping and social media users who were of Mexican American heritage. Participants (Table 3) were primarily female (37/51, 73%), born in the United States (48/51, 94%), of a middle socioeconomic status (38/51, 75%), and aged 21 years on average (SD 1.7 years). The final sample for the web-based survey included 1492 participants who were of Mexican American; Tejano, Tejana, or Tejanx; or Chicano, Chicana, or Chicanx heritage. Participants (Table 3) were primarily female (1042/1492, 69.8%), born in the United States (1366/1492, 91.6%), of a middle socioeconomic status (1174/1492, 78.7%), and aged 20.1 years on average (SD 2.2 y).

Discussion

Expected Findings

Project VAMoS is one of the first longitudinal mixed methods research projects to explore the influences of social media and acculturation on vaping behaviors focusing exclusively on Mexican American college students. The results of this project will provide evidence for the roles of intrapersonal mediators (eg, outcome expectations and social norms) in the associations between vaping-related social media content and subsequent vaping. The results will also determine the moderating role of acculturation in the association between vaping-related social media content and subsequent vaping, as well as in the mediated paths between vaping-related social media content and subsequent vaping. In turn, results can inform the tailoring of culturally relevant interventions and the development of countermarketing policies to prevent vaping among Mexican American college students [53].

Project VAMoS is innovative in 3 key areas. First, unlike many studies that consider Hispanic individuals as a homogeneous group, this project specifically focuses on Mexican Americans, acknowledging the diversity within this population, particularly in tobacco use patterns related to country of origin and acculturation levels [54]. Second, the project delves into the underlying mechanisms or mediators—such as outcome expectations, social norms, and attitudes and beliefs—that influence how exposure to vaping-related social media content affects vaping behavior. These mediators are identified through an EMA study and one-on-one qualitative interviews and are empirically examined in a comprehensive, 4-wave survey study. Finally, in addition to subjective assessments, the project conducts objective assessments of the social media content that participants actually view and engage with on popular platforms

such as Instagram, TikTok, and YouTube. This approach minimizes the biases often associated with self-reported data [55].

Refining and Finalizing the Web-Based Survey

Some items were developed or refined based on findings from the EMA study and one-on-one interviews and then tested through cognitive interviewing to ensure their appropriateness for the study population [11,12]. For example, given the diverse range of substances that can be vaped, we incorporated options such as cannabis, THC, or delta-9; delta-8 THC; cannabidiol; caffeine; essential oils; vitamins; and more to include more potential vaping choices. In addition, we refined survey questions to ensure that they specifically addressed the substances that participants are vaping by including the terms "with nicotine" or "with cannabis/THC" without assuming exclusive consumption of either substance. As another example, we added response options such as "I do not know" or "neutral," along with time frames such as "When you were younger?" or "currently" to some acculturation measures. Moreover, we amended and will continue to amend items that are and are not included in subsequent waves in response to findings from the baseline survey wave. We will also add items in response to changes in the marketplace, such as the introduction of a new vaping device type, or in the policy landscape, such as a state or federal ruling regarding vapes or the marketing and promotion of these products.

Items were also added in response to the 2023 Surgeon General Report titled Social Media and Youth Mental Health [56], which concluded that there are gaps in current knowledge related to "the mental health impacts posed by social media" and that, currently, we cannot conclude that social media is sufficiently safe for young people. Accordingly, at wave 1, we assessed symptoms of depression, suicidal ideation, and anxiety [34,35]. At wave 2, we added measures to assess sensation seeking and impulsivity [38,39]. Symptoms of depression and anxiety increase risk of vaping both nicotine and cannabis or THC [57,58], whereas sensation seeking is associated with the uptake of vaping nicotine [59,60] and impulsivity increases risk of current vaping [61]. Therefore, the inclusion of these mental health and personality constructs complements existing measures assessed in Project VAMoS and will enable us to examine their role as potential mediators and moderators of the association between social media use and vaping.

Lessons Learned

Recruiting participants to join the EMA took more time than planned. Thus, we revised the eligibility criteria from vape use in the previous week to use in the previous 30 days. Similarly, recruiting participants to join the web-based survey took longer than planned; thus, we expanded the age range eligibility criteria from 18 to 25 years to 18 to 29 years and expanded recruitment from freshman students to all undergraduate levels, and we sent up to 4 email reminders rather than just 3. However, recruitment for the EMA study was completed in 6 weeks, and recruitment for the web-based survey was completed in 8 weeks. These adjustments broadened our participant pool, thereby creating a more representative cohort of college students. These challenges might be due to the specific nature of the inclusion criteria, such as being Mexican American [62]; potential hesitancy among young adults to participate in substance use research studies [62-65]; or the omission of incentive details from the invitation emails sent to participants to comply with IRB requirements.

This project provides an opportunity to better understand how Mexican American college students self-identify across racial categories. In wave 1, a total of 78.2% (1167/1492) of the participants identified solely as Hispanic when responding to a combined race and ethnicity question, whereas only 20.2% (301/1492) specified their race (data not shown). In response, at wave 2, we adopted a best practice approach aligning with the US Census Bureau's guidelines [66,67]. Specifically, we separated the race and ethnicity question into 2 items on the survey to allow participants to identify with a specific race while also recognizing their Hispanic ethnicity. Such an approach ensures that our data more accurately reflect the diverse racial backgrounds within the Mexican American population, enhancing our understanding of the associations among race, ethnicity, and social factors in the Mexican American community [66,67].

Strengths and Limitations

This project has many strengths. A major strength is the focus on Mexican American college students. Most studies have examined Hispanic populations as a single group, overlooking the differences in vape use patterns influenced by country of origin and acculturation levels. In addition, the Mexican American population in Texas is on the rise, with an increasing number of young individuals from this group enrolling in college annually [68]. Another major strength is the innovative approach in objectively measuring both exposure to and engagement with social media related to vaping. These objective assessments optimize the validity of self-reported social media exposure and engagement data and represent a distinct advantage that cannot be replicated by national surveys such as the Population Assessment of Tobacco and Health Study [23]. Furthermore, our EMA study and in-depth semistructured interviews enhance our research by enabling us to uncover culturally pertinent terms and concepts for evaluation in our web-based survey. Finally, the longitudinal design of our web-based survey allows for mediation tests to identify the intrapersonal factors that explain whether and how baseline levels of vaping-related social media content impact subsequent vape use at follow-up [69].

The project is not without limitations. First, we focused on college students, which limits generalizability. Nonetheless, this drawback is somewhat mitigated by the rapidly growing rate of college enrollment among Mexican American young adults. Second, we only recruited participants from Texas. However, Texas is a majorly minority state with the second-largest Hispanic population in the United States, predominantly consisting of Mexican Americans [4]. Moreover, Texas has the second-largest population of Hispanic college students in the United States [68]. This demographic profile enables us to concentrate on the largest Hispanic subgroup in the country.

Implications

The results of this research will offer unique insights into the prevalence, patterns of use, and determinants contributing to vaping among Mexican American college students. This information will inform the development of evidence-based, culturally relevant prevention interventions and policies specifically for the growing population of Mexican American college students. Moreover, results from mediation analyses will pinpoint the most effective intervention targets (namely, significant mediators), and the outcomes of such analyses will highlight which subgroups (namely, significant moderators) are most at risk from the impacts of exposure to and engagement with vaping-related social media content.

The results gathered from the EMA study, in-depth semistructured interviews, and objective assessment of social media content will reveal the vaping messaging that attracts Mexican American college students to vaping and influences them to vape. These insights will then serve as a foundation for developing economical counteradvertising and health messaging strategies. These strategies can be effectively disseminated through social media platforms to reduce vape use among Mexican American college students, thereby lowering their risk of tobacco-related morbidity and mortality. Finally, research in this area contributes to the broader goal of health equity by ensuring that the health needs of ethnic minority groups are adequately addressed. By understanding and addressing the specific health behaviors and their determinants within minority communities, public health initiatives can move toward reducing health disparities.

Acknowledgments

The research protocol described in this publication was supported by the National Institutes of Health under award R01MD017280 to AL and AVW.

Abstract

Background: Climate change is affecting public health and well-being. In 2016, Swiss emergency departments (EDs) treated 1,722,000 cases, with 4718 daily admissions. In 2023, the ED of Sion Regional Hospital recorded 75,000 consultations. The links between climate change and health are complex, necessitating urgent research on its impact on cardiopulmonary health in Valais, Switzerland. Raising awareness among frontline professionals is crucial for developing health promotion and disease prevention strategies.

Objective: This study explores the preliminary effects of climate change on cardiopulmonary health in Valais and assesses adult patients' knowledge of its health consequences. Findings will inform adaptations in patient care, health promotion, and disease prevention at Sion Hospital's ED. The feasibility of patient selection and data collection will also be evaluated.

Methods: Using a convergent, parallel, mixed methods design, data will be collected from September 21, 2024, to September 20, 2025, with a target sample of 60 patients. The quantitative phase will examine patient recruitment feasibility, consultation reasons, and triage levels, correlating them with climate variables (temperature, nitrogen dioxide, particulate matter, sulfur dioxide, and ozone). It will also analyze sociodemographic profiles. The qualitative phase will explore patients' knowledge of climate change and its potential links to their ED visits. The feasibility and acceptability of the study process will be assessed. The protocol follows the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) Extension for Pilot and Feasibility Trials.

Results: Data collection started on September 21, 2024, following the approval by the ethical commission. Data collection will take place over 1 year, until September 20, 2025.

Conclusions: This study will test the feasibility of a larger investigation and examine potential associations between Valais' changing microclimate and population health. Findings will establish patient profiles and explore their perceptions and knowledge of climate change, informing future health interventions.

Introduction

The planet's climate crisis is directly damaging human health. Globally, 3.6 billion people live in areas highly sensitive to climate change. Rising temperatures, extreme weather events, air pollution, and the spread of infectious diseases are just some of the major health threats exacerbated by climate change [1]. Climate change has many other direct and indirect effects on human health, including physical and mental disorders. Projections for 2025 estimate that climate change will be responsible for 250,000 additional deaths per year between 2030 and 2050 [2,3]. Worldwide, 9 out of 10 people breathe poor-quality air, and more than 7 million people die every year because of this pollution [4]. Greenhouse gas emissions, particulate matter (PM), nitrogen dioxide (NO_2), tropospheric ozone (O_3), and sulfur dioxide (SO_2) are the pollutants with the most significant impact on human health. There has been a concurrent 57% increase in heatwave episodes since 2010. Heat-related deaths among people >65 years of age have risen by 70% in 2 decades [5].

In recent years, several studies have been conducted on the various components of the relationship between health and climate change in Switzerland, particularly via the Swiss Study on Air Pollution and Lung and Health Diseases in Adults cohort [6]. A review of 22 studies by Cicci et al [7] highlighted positive associations between high temperatures and ischemic heart disease, acute myocardial infarction, the risk of congestive heart failure, and the number of emergency department (ED) consultations. Indeed, increasing numbers of ED admissions [7,8] hospitalizations for respiratory and cardiovascular diseases have been linked to nonoptimal temperatures and exposure to pollutants and unconventional natural gas development, while more cases of decreased lung function or chronic obstructive pulmonary disease have been linked to exposure to SO_2, NO_2, and PM_{10} [9-11]. Finally, climate change is leading to global warming, that is, the phenomenon of increasing average air temperatures near the Earth's surface [12]. This prolongs plant growth and pollination seasons and often increases the overall amount of pollen produced. This phenomenon can lead to increased respiratory allergies, rhinitis, and asthma in sensitive patients with immunoglobulin E–mediated allergic reactions [13,14].

In addition to its impacts on health, climate change can compromise many social determinants of good health, exacerbating the inequalities in morbidity and mortality that particularly threaten vulnerable populations. Indeed, environmental risk factors, such as demographics, geography, biology, health, sociopolitical and socioeconomic status, health system capacity, and overall equity, are responsible for 80% of common illnesses and 25% to 33% of the total disease burden [15]. Vulnerability has 4 primary features: integrity (a person's sense of soundness), challenge (vulnerability is experienced when there is a perceived challenge to one's integrity and uncertainty about how to respond to it), capacity for action (the perceived ability to withstand, integrate or cope with the challenge), and multidimensionality (how vulnerability varies from one person to another and from one experience to another) [16,17]. Older adults, infants from the age of 0-1 year, people with chronic diseases, those living in urban environments with low socioeconomic status or experiencing social isolation [5,18], and people living at higher altitudes [7] are all considered to be population groups vulnerable to climate change. Finally, regarding biological sex, Bayentin et al [19] and Gebhard et al [20] found that hospitalizations for ischemic heart diseases and myocardial infarction were higher among younger women than among younger men. Women have a higher core temperature, skin temperature, heart rate, and blood pressure than men, which can lead to decreased heat tolerance. However, men have a 33% higher incidence of stroke and a 41% higher prevalence of stroke than women [7].

EDs are gateways to the health care system. Their mission is to provide immediate specialist care to patients with urgent or life-threatening needs. Despite their heterogeneous profiles, EDs must provide patients with efficient, high-quality care, which the Institute of Medicine defines as the ability of a health service to increase the likelihood of achieving desired health outcomes in line with current professional knowledge [21]. Quality of care is a multidimensional concept that implies safe, responsive, effective, efficient, equitable, and patient-centered care [21]. In Switzerland, the National Ordinance on Quality of Care and Patient Safety sets out how health care facilities, institutions, and health care professionals must be actively committed to ensuring the quality of care and promoting patient safety. Moreover, through their collaboration, patients contribute to achieving the defined objectives of high-quality care and safety.

Ever more attention is being paid to the relationship between the environment and health. Climate change is causing health problems that did not exist before, leading to new health care needs. It is, therefore, essential to explore preliminary associations between climate variables and sociodemographic and health variables. Specifically, the primary outcome of the quantitative phase is the systematic assessment and analysis of the feasibility of patient recruitment, the reasons for their consultation, and their triage level. This first outcome will be correlated with climate variables (maximum and minimum temperature and concentrations of NO_2, PM, SO_2, and O_3) to investigate whether climate variables influence hospital admissions. The secondary outcome is an exploration of the sociodemographic profiles of adult patients consulting at Sion Hospital's ED. For the qualitative stage, the primary outcome is evaluating the level of acceptability of an interview guide to explore patients' knowledge about climate change and its potential links with their ED visits, and the secondary outcome is an exploration of patients' knowledge about climate change. Given the nature of the study, we decided to focus solely on cardiorespiratory comorbidities. As part of a larger study, other comorbidities should be explored, such as metabolic comorbidities (metabolic syndrome; type 2 diabetes, often associated with cardiovascular disorders; hypercholesterolemia; and hyperuricemia or gout), psychiatric comorbidities (depression, anxiety disorder, schizophrenia, and bipolar disorder), musculoskeletal comorbidities (osteoarthritis, fibromyalgia, and osteoporosis), endocrine comorbidities

(hypothyroidism and hyperthyroidism), or gastrointestinal comorbidities (celiac disease and inflammatory bowel disease).

Nurses are pivotal in recognizing and addressing the direct health impacts of climate change. They are uniquely positioned to promote overall health with their sensitivity to patients' vulnerabilities and emerging health needs. This includes identifying how climate change affects health in their daily practice, educating patients and communities about related risks, and fostering environmentally sustainable behaviors [22]. To achieve this, studies must be conducted on climate change and its health consequences. The first step is to assess the feasibility of the methods and procedures for a future large-scale study.

Methods

Design

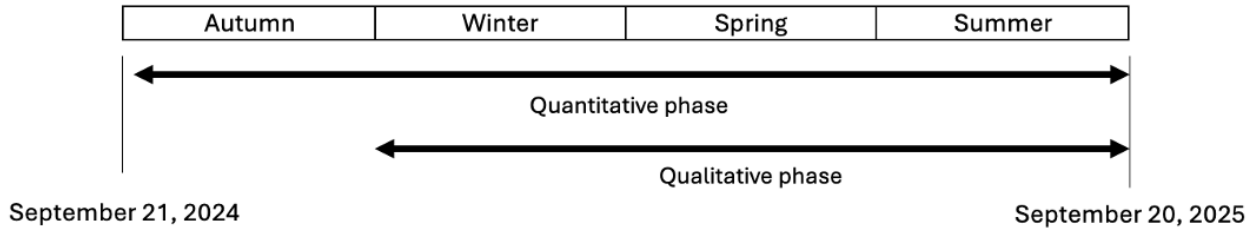
Achieving this development and usability pilot study's objectives requires a convergent, parallel, mixed methods design. Pilot studies are commonly used in health-related research in disciplines such as nursing and medicine [23], frequently to generate data for sample size calculations. This seems especially relevant when there are no data from previous studies to inform the process [24-26].

Quantitative Phase

Overview

Data collection will occur from September 21, 2024, to September 20, 2025 (Figure 1).

Figure 1. Pilot project's quantitative and qualitative phases.



The quantitative phase's objectives are to assess and analyze patient recruitment's feasibility, the reasons for adult patients' consultations at Sion's ED, their triage level, and their sociodemographic profiles. These variables will be analyzed with climate variables (maximum and minimum temperatures and concentrations of NO_2, PM, SO_2, and O_3) to investigate potential associations between hospital admissions and various climate variables. The secondary outcome is an exploration of the sociodemographic profiles of the adult patients consulting at Sion's ED.

A sample size of 40 to 60 adult patients is planned, that is, 15 per season. Pilot studies are often conducted to generate data for sample size calculations. This seems especially sensible when there are no data from previous studies to inform this process. This is the case in the context of this study. It is the first time such a study has been carried out in the canton of Valais. A general rule of thumb is to take 30 patients or greater to estimate a parameter [24,26]. During the triage process, the triage nurse recruits patients for the quantitative phase. Then, the nurse in charge collects the variables of interest.

Inclusion Criteria and Data Collection

We will include all adult patients aged 18 years and older, who consulted at Sion's ED and have cardiopulmonary comorbidities (ischemic heart disease, hypertensive heart disease, heart arrhythmias, heart failure, chronic obstructive pulmonary disease, asthma, obstructive sleep apnea, pneumonia, pulmonary fibrosis, and pulmonary cancer) sorted into levels 3, 4, or 5 according to the Valais triage scale. According to the Valais Swiss sorting scale, level 3 is considered semiurgent with a maximum response time is 60 minutes. Levels 4 and 5 are nonurgent, with a waiting time of 120 and 180 minutes, respectively (nonurgent). The patient must be able to speak, understand, and read French and sign the informed consent form with full knowledge of the facts. Eligible participants who sign this form but die during or after their ED consultation will be included in the study. The exclusion criteria are patients classified at levels 1 or 2 on the triage scale or who do not possess the capacity for discernment (as diagnosed by an ED physician). A level-1 classification on the Valais triage and severity scale implies a life-threatening condition. The patient's pathological situation could lead to death or the loss of an organ or a limb if care is not provided immediately. The patient must be transferred to an emergency care unit immediately. A level-2 triage classification requires urgent treatment since the pathological situation is not life-threatening but is susceptible to rapid deterioration. The patient must be transferred to an emergency care unit and assessed by a physician as quickly as possible. We believe it is, therefore, inadvisable to involve patients triaged at levels 1 and 2 in the pilot study as their rapid care is vital. Finally, Sion's ED does not accept patients under 18 years of age, as they are referred directly to the pediatric ED.

The variables to be analyzed can be divided into two categories: (1) sociodemographic data such as sex, age, place of residence (commune and postal code) and marital status (single, married, divorced, widowed, separated, or in a couple); and (2) medical and clinical data collected during ED visits, such as triage level, reason for the consultation, diagnosis based on the *ICD-10(International Statistical Classification of Disease, Tenth Revision*) classification, medical or surgical history, smoking status, and ED readmissions in the last 6 months. All these questions, except for ED readmissions in the last 6 months, will be collected by the nurse in charge during history taking and other exchanges with the patient. In this way, the data collection

process for the study's variables of interest will not prolong emergency care or diminish its quality.

Sociodemographic, medical, and clinical data will be analyzed in conjunction with climate data, for example, O_3 concentrations and air pollution data (Table 1). Data come from MétéoSuisse, Switzerland's official meteorological service, under the Federal Office of Meteorology and Climatology, and from RESIVAL, the Valais network collecting information on local climatic parameters.

Table 1. Databases and variables of interest for meteorological data.

Databases	Variables of interest								
	T_{max}	T_{min}	T_{mean}	NO_2[a]	PM_{25}[b]	PM_{10}	SO_2[c]	O_3[d]	Pollen
MétéoSuisse [27]	✓	✓	✓						✓
RESIVAL [28]			✓	✓	✓	✓		✓	

[a]NO_2: nitrogen dioxide.

[b]PM: particulate matter.

[c]SO_2: sulfur dioxide.

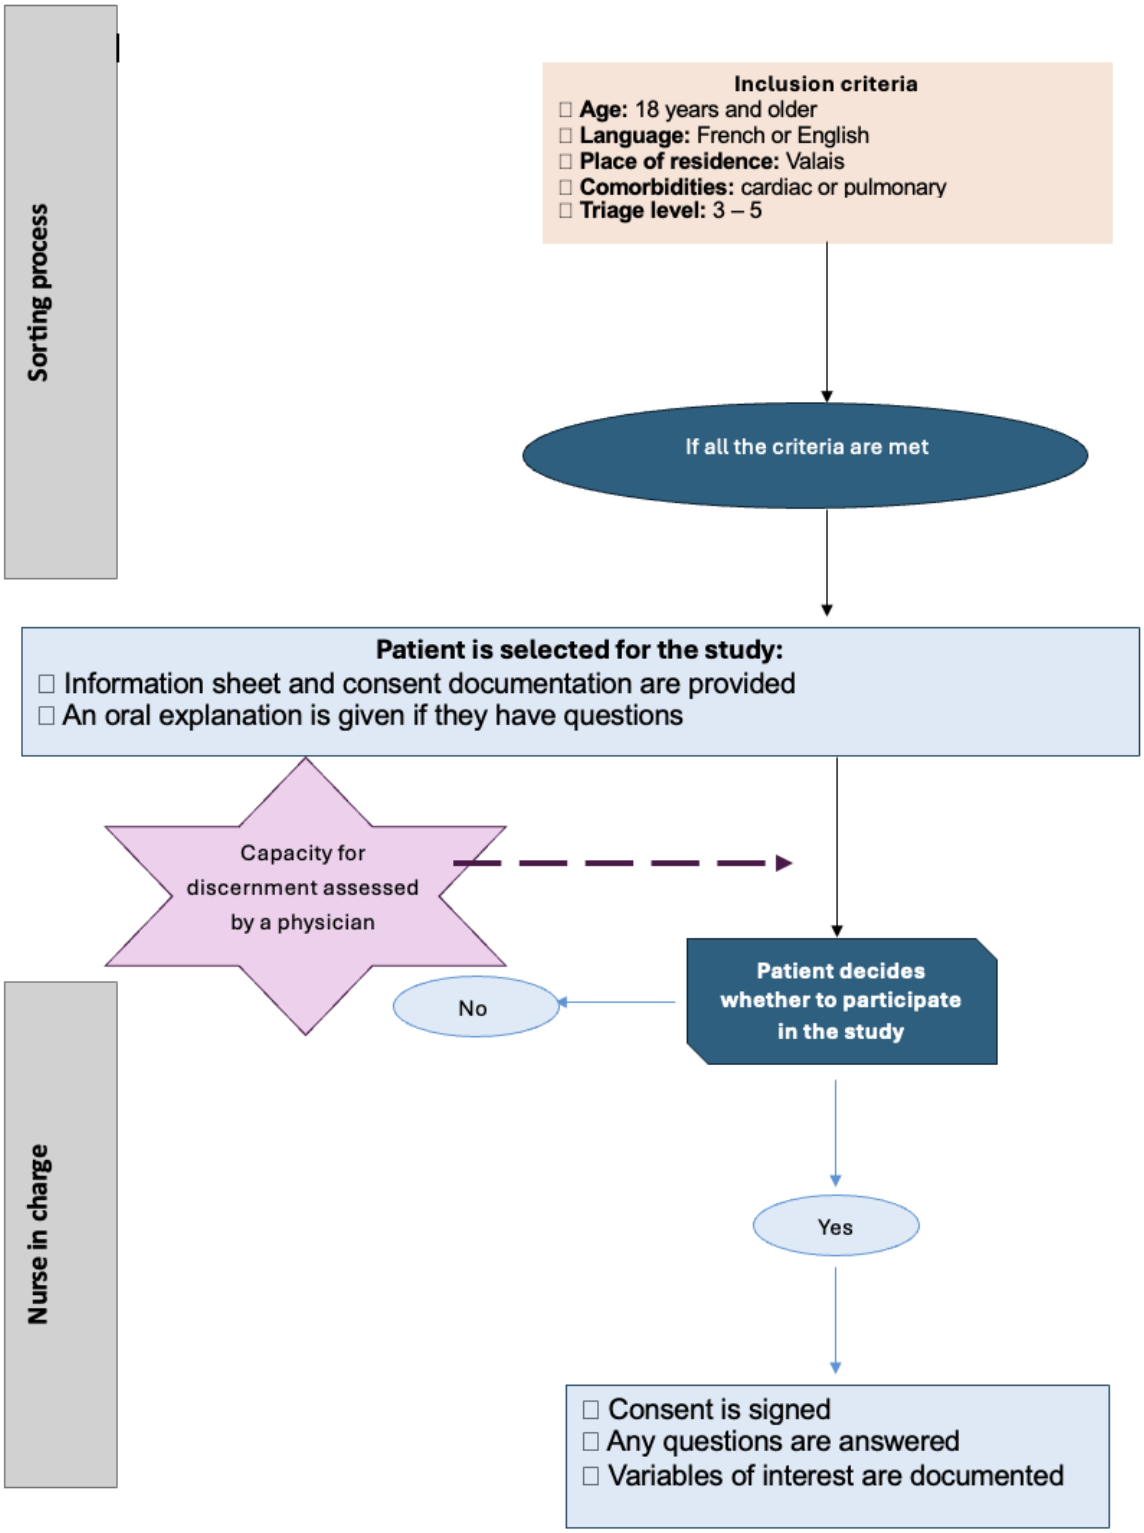
[d]O_3: tropospheric ozone.

Recruitment Procedure in Triage

The procedures for participant recruitment will be carried out by triage nurses—the first nursing staff patients meet when they arrive at the ED—and the nurse in charge. The principal investigator will explain the participant selection process to all the ED nurses at 2 team meetings (each 45 minutes long at the ED) and through an email containing a Microsoft PowerPoint presentation with a voiceover that will be sent out before those meetings. This will enable nurses to ask pertinent questions about their understanding of the recruitment algorithm. The triage nurses' role is to prioritize the patient's health status for their ED stay. They will be responsible for identifying whether patients meet all the inclusion criteria and, thus, for initiating the selection process. The nurse in charge or the triage nurse will then ask the patient whether they consent to participate in the study. If they agree, the nurses will collect the signed consent form. If the patient wishes, they can be given a 24-hour period to reflect. In this case, a stamped addressed envelope with the consent and information sheet will be given to them. As a reminder of the process and to ensure that it is carried out homogeneously, the participant selection algorithm (Figure 2) will be posted in every triage station and at the door of each cubicle. Indeed, nursing care in emergency contexts is often represented using an algorithm, so it is a visual tool that professionals in this field are familiar with. This will promote adhesion to and understanding of the algorithm.

The triage nurse or the nurse in charge will explain the study's purpose and the patient's contribution. They will then provide the patient with the study information document and the consent form. These additional explanations will not significantly lengthen triage time nor compromise the quality of care. The patient will have time to read the documents before entering the cubicle. When patients are given their discharge papers home (eg, a prescription, a follow-up appointment, a potential sick note for their employer, or other recommendations), the nurse in charge and the charge nurse, who oversees the operations of their specific nursing unit during a set period while working alongside the team, will ascertain the patient's decision to participate in the study. If the patient agrees, they will collect the signed consent and the document with the variables of interest. Their primary role is to ensure that all nursing functions within the department run smoothly and efficiently, verify whether they have decided to participate in the study, and collect their signed consent form if this is the case. They will answer any patient questions and remind them that their data will be coded and that they may receive a telephone call from the principal investigator.

Figure 2. Patient selection algorithm.



Measuring Temperatures and Pollution

In Valais, the RESIVAL measurement station network monitors and analyzes air pollution levels and calculates mean daily air quality parameters (24 hours from 0 Coordinated Universal Time to 0 Coordinated Universal Time) all across the canton [28]. Daily temperature variables (T_{min}, T_{max}, and T_{mean}) and pollen variables will be taken from MétéoSuisse, Switzerland's official federal national weather and climate service that operates under the Swiss Federal Department of Home Affairs. It is responsible for weather forecasting, climate monitoring, meteorological research, data collection, and public weather-related services [27].

Qualitative Phase

Overview

The qualitative phase's primary outcome is to explore patients' knowledge about climate change and its potential links with

their ED visits. The secondary outcome is an exploration of patients' knowledge about climate change. Indeed, factors outside of medical care, such as health beliefs, knowledge, attitudes, and behaviors such as smoking, are categorized as social determinants of health [29].

The inductive approach will guide the qualitative phase. A thematic analysis will be carried out independently by 2 researchers (OPS and PJPA). The level of theme identification will be latent or interpretative. During the pooling, disagreements will be settled by the intervention of the third researcher (HV).

Criteria and Data Collection

A nonprobability sample of patients participating in the study's quantitative phase will be selected for inclusion in the qualitative phase. The exclusion criterion established is the patient's incapacity for discernment, according to the patient's family doctor or family, or having a severe psychiatric disorder. The qualitative phase will be documented through individual interviews of 30-45 minutes until data saturation is reached. Data saturation will be reached when the data collected no longer yields any new significant or thematic information relevant to answering the research question. The theoretical number of interviews required is approximately 10-15. At least 6 weeks after the ED consultation, the principal investigator will contact participants on an aleatory basis by telephone to ask them to participate in a 30-45-minute interview. Six weeks were chosen so as to be far enough removed from any potential hospitalization that followed the index ED consultation. More information will also be collected and explored regarding the social determinants of health, categorized into five domains: (1) neighborhood and environment (where patients live, work, and play), (2) health and quality of access to health care (patients' use of health services to achieve the best health outcomes), (3) the social and community context (people with whom patients communicate and connect), (4) patients' access to education, and (5) economic stability (patients' financial resources). These domains can affect wellness, illness, and disease conditions [30]. By recognizing how social determinants impact health outcomes, nurses can play a key role in addressing health disparities and promoting health equity. Indeed, health disparities—variations in health linked to social, economic, and environmental disadvantages within a society [31], are pressing issues that demand immediate attention. Each area will be explored through a question and a follow-up question. Thus, the semistructured interview guide (Multimedia Appendix 1) consists of 5 questions and 5 follow-up questions. The aim is for the patient to share information about their daily life in relation to these 5 areas.

Withdrawal and Discontinuation

In the event of the patient's withdrawal from the study's quantitative phase, their data will not be included in the analysis. However, if the patient withdraws from the qualitative phase, their data will still be incorporated into the analysis of the quantitative phase. Participants withdrawing from the qualitative phase will be replaced in order to maintain the estimated number of interviews required. Participants can withdraw from the qualitative phase at any time, which could be due to a change of mind or to any complication resulting in a loss in their capacity for discernment or ability to understand and speak French (eg, an altered state of consciousness, intubation, tracheostomy, and tracheotomy).

Statistical Analysis

Statistics calculated in a pilot study are used to assess the feasibility of the full-size study and refine its methodology. A variety of methods can be used to address the objectives established for a pilot study, and these need not be statistical [23,26]. Indeed, statistical uncertainty must be taken into consideration before any of the pilot study's findings are generalized. The goal of publishing results from pilot studies is not to focus on their statistically significant findings but rather to provide their estimated effects on all the measures of interest and to describe the lessons that have been learned and will be informative in planning subsequent studies [23,32].

Factors such as the population's sociodemographic characteristics, economic conditions, and access to outpatient and hospital care facilities may confound the relationship between climate variables and hospital admissions.

More specifically, numerical and qualitative data will be analyzed according to good clinical research practices. Statistics will be generated from the raw data collected from the ED's patient records and the appropriate meteorological and air pollution websites (MétéoSuisse and RESIVAL). A database gathering sociodemographic variables (sex, age, place of residence, and marital status), health variables (triage level, reason for the consultation, diagnosis based on the *ICD-10* classification, medical or surgical history, smoking status, and ED readmissions in the last 6 months), meteorological (maximum and minimum temperature), and air pollution data (NO_2, $PM_{2.5}$, PM_{10}, SO_2, O_3, and pollen concentrations) will be prepared on a Microsoft Excel spreadsheet. They will be imported into and analyzed using SPSS software (version 29.0; IBM Corp). Descriptive statistics such as mean and SD (for quantitative variables) and frequency and percentages (for qualitative variables) will be calculated. Parametric statistical tests will be applied to normally distributed variables. Nonparametric statistical tests will be used for variables with non-Gaussian distributions. This data analysis will enable us to better describe the study participants' profiles. To estimate the effects of meteorological, sociodemographic, and health data, we will calculate a conditional quasi-Poisson regression and distributed lag nonlinear models. The model will estimate the association between hospital admissions and predictor variables (sociodemographic, health, meteorological, and air pollution variables). One advantage of the Poisson pseudomaximum likelihood estimator is that the scale of the dependent variable does not affect the parameter estimates [10]. In this type of regression model, a pseudolikelihood is applied to properly scale the SD of the coefficients proportionally to the potential overdispersion. We will use overdispersed generalized additive models with random effect meta-analysis to investigate the associations between variables [8]. ANCOVA models will also be developed to compare the means of a continuous dependent variable (hospital admissions) across multiple factor variables (autumn, winter, spring, and summer) and to determine

covariates' effects (sociodemographic, health, meteorological, and air pollution variables). This approach ensures a more nuanced understanding of how various factors and covariates collectively influence hospital admissions. Finally, the participant inclusion rate and study retention or drop-out rates will also be estimated, as will the total sample size required for the full-scale study.

The statistical significance threshold will be set according to the number of variables and the size of the database developed (2-sided *P* values<.01 will be considered statistically significant, with 95% CIs and Bonferroni adjustments for multiple comparisons).

Feasibility and Acceptability Phase

Feasibility refers to the practicality and appropriateness of the processes involved in patient selection and data collection within the pilot study. It evaluates the ability to recruit and retain participants, the functionality of inclusion and exclusion criteria, the adequacy of recruitment methods, and the efficiency, reliability, and acceptability of data collection tools and procedures [33,34]. Acceptability refers to the extent to which the study recruitment and data collection procedures, and interventions are considered appropriate, satisfactory, and appealing to participants, and other stakeholders. It evaluates the willingness of participants and involved personnel to engage with and adhere to the study's requirements [33,34]. The acceptability will be explored through an inductive approach. Three focus groups, each consisting of 4-6 ED nurses, will be conducted to explore variables such as time, objectives of the pilot study, implications, satisfaction, potential barriers, and facilitators to collect data, and ease of the process through open-ended questions. Finally, patients' level of acceptability of the interview guide will be explored through an open-ended question at the end of the individual interview "Do you feel that the guide enabled you to share meaningful insights?"

Feasibility will be assessed through 2 different approaches. The first approach will assess feasibility through the same focus groups used to assess acceptability. On a scale of 1="don't agree at all" to 5="completely agree," nurses will rate the process of the communication and training process to which they have been subjected (study protocol, mentoring, printed selection algorithm, principal investigator's feedback, and communication about the project). The second approach will consist of the proportion of expected data and data collected.

Ethical Considerations

The research protocol (2024-00900) for this pilot project was presented to its different partners. A request for authorization to proceed was presented to Swiss Ethics. The cantonal ethical commission for research on human beings, represented by Jean-Marie Annoni, gave its final approval on October 23, 2024. The support of the University of Applied Sciences and Arts Western Switzerland is assured. Participation in the study will be voluntary and pose no risk to the patients. In the context of this study, it is highly unlikely that participants will be exposed to any inconvenience or risk. Whether they participate in the study will in no way alter their care pathway or the quality of the care and follow-up they receive. Should the participant request them, the principal investigator will send them the pilot study's results by email or post. Participation in this study will be of no direct benefit to the patient. However, the results may help improve the overall delivery of care by providing emergency medicine that is better adapted to the patient's health status and needs. Finally, the preliminary results of the development and usability pilot study will enable the research team to propose a larger-scale study.

Given the nature of the variables to be collected, personal data will be coded to protect the life, health, dignity, integrity, right to self-determination, privacy, and confidentiality of the people participating in the research. The coding process will be based on the best-practice recommendations found in Article 29 of the Working Group on Data Protection (the independent European advisory body on data protection and privacy). A collaboration agreement has been drawn up with Hôpital du Valais in the canton's French-speaking area. The principal investigator will be granted access to data obtained with patient consent for the duration of the study. The data collection process will be carried out in compliance with the appropriate data protection, human research, and ethical principles, thus ensuring respect for patients' rights and the confidentiality of their medical information. The coding key will be kept separate from the study data.

For the purposes of this development and usability pilot study, data will be stored on the Haute École de Santé Valais-Wallis' OneDrive server. The coding key between personal data and the numerical code, as well as the transcripts of each individual interview, will be kept by the principal investigator.

Results

Data collection started on September 21, 2024, following approval by the ethical commission. Data collection will take place over 1 year, until September 20, 2025. After 1 season of data collection, that is, between September 21, 2024, and December 21, 2024, a total of 60 patients were screened. The quantitative phase will begin in February 2025.

Discussion

Principal Results

The results of this development and usability pilot study will enable us to assess the feasibility of its methods and procedures with a view to carrying out a larger study. Indeed, it is important to adapt the patient selection algorithm to the clinical field's requirements and frontline carers' needs. By definition, the flow of patients coming to EDs cannot be predicted. The selection algorithm must be simple and not significantly delay a patient's treatment or slow its commencement. Our assumption is that we will have to make changes in 2 stages. These will still be communicated to managers and the entire care team. Concerning sociodemographic profiles, the hypothesis is that cardiovascular disease, active smoking, previous smoking, and diabetes are factors of vulnerability to climate change. In conjunction with the qualitative part, we hypothesize that vulnerable patients are aware of reduced quality of life during extreme temperatures or pollution peaks. However, little, if any, action is taken to

anticipate and prevent this. Patients' levels of technical literacy are, therefore, potentially low. Finally, we hypothesize that the qualitative interview guide's acceptability level is high. The interview guide has been pretested, and the exchange lasts no more than 45 minutes [32].

The results of the present development and usability pilot study could constitute a first step toward developing sustainable, ecological care. Indeed, today's duality of a health care system that provides benefits to patients and the population but has deleterious environmental consequences is becoming less and less acceptable. Finally, this development and usability pilot study will establish guidelines for a future larger-sized study.

Limitations

Data will be collected over 1 year so that all 4 seasons and their particularities—especially regarding climatic variables—can be studied. This development and usability pilot study is a single-center study and will only represent results from the Hôpital du Valais' ED in Sion. Finally, its objective is to assess and analyze the potential for adult patient recruitment, the reasons for patients' consultations, and their level of triage. It will also test the acceptability of an interview guide to explore patients' knowledge of climate change and its links with their ED visits. These preliminary results will constitute the first milestone in the assessment of the practicality of recruiting and retaining participants and in the determination of the most appropriate participant selection process to ensure stakeholder adherence for a full-scale study.

Conclusions

Climate change is a central concern for the discipline of nursing. Nurses are strategically placed to respond to the impacts of climate change through their practice, research, and training in developing, implementing, and sustaining innovation for climate change mitigation and adaptation. To do so, they must be given the tools to come to grips with the global health emergency, that is climate change. Taking stock of the current situation, particularly in the alpine canton of Valais, in Switzerland, will require a thorough assessment. This development and usability pilot study's preliminary results will be used to inform a future large-scale study whose findings we may be able to generalize and identify climate change's impact on the environment and the health of Valais' population.

Acknowledgments

HV is thanked for his valuable help in developing this protocol. The authors thank Amélie Borgeat, a specialist in Internal Medicine and Allergology and Clinical Immunology at the Hôpital du Valais, and Vanessa Azzi Virgini, allergist and pneumonologist, for contributing to the selection of the 16 pollinic variables best suited to this research. The authors also thank Jean-March Fracheboud, air specialist, Department of Mobility, Territory and Environment, for his contribution to the selection of variables proposed by RESIVAL.

Data Availability

All data generated or analyzed during this study are included in this published article.

Conflicts of Interest

None declared.

Abstract

Background: Heart failure (HF) remains a disease of notable disparity for rural veterans, despite recent advancements in clinical treatment. Managing HF in the home is stressful and complex for rural veterans who experience unique barriers to optimal physical and mental health, necessitating adequate support and problem-solving skills.

Objective: This study aims to (1) adapt, to the rural sociocultural context, a culturally sensitive, tailored, telephone support and problem-solving intervention (CARE-HF [Supporting Physical and Mental Health in Rural Veterans With Heart Failure]) using findings from preliminary qualitative research and (2) evaluate the effects of CARE-HF on problem-solving and physical and mental health outcomes among rural veterans with HF.

Methods: This study involves a repeated-measures, single-group design. The intervention content was adapted and tailored to the rural sociocultural context using preliminary qualitative data and guided by the Theories of Social Problem-Solving and Stress, Appraisal, and Coping. Veterans are recruited from Veterans Administration home-based cardiac rehabilitation clinics, cardiology clinics that serve veterans, veterans-based community resource centers, and social media campaigns. Veterans with HF (N=100) receive the CARE-HF intervention. This nurse-led intervention comprises 8 telephone sessions that use a five-step, problem-solving process to manage common HF problems in the home: (1) identifying the problem and viewing it in a positive manner, (2) goal setting, (3) generating potential strategies for problem management, (4) choosing and implementing strategies to manage the problem, and (5) evaluating strategy effectiveness. Veterans receive initial problem-solving training during the first session, with follow-up sessions focusing on problem-solving skill reinforcement and assisting veterans in applying these principles to manage self-identified, HF-related problems experienced in the home. Data are collected at baseline and 3, 6, 12, and 18 months from baseline on problem-solving and outcomes of interest (ie, HF self-care; HF symptoms; health care utilization; depressive symptoms; anxiety; HF-specific, health-related quality of life; stress; resilience; and coping). Demographic data will be analyzed using descriptive statistics and multilevel growth curve modeling with restricted maximum likelihood estimation to compare a series of models using Akaike information criteria and Bayesian information criteria fit indices while controlling for covariates.

Results: Recruitment started in April 2023. As of December 2024, we have enrolled 56 veterans. Recruitment is anticipated to end in June 2025, with data collection continuing until all enrolled veterans have completed the 18-month follow-up period.

Conclusions: Adapting and testing a culturally sensitive, tailored, telephone intervention to aid support and problem-solving in the home has the potential to provide individualized care to rural veterans where they reside, thereby reducing travel burden while also increasing access to evidence-based care programs. If effective, telephone support and problem-solving interventions could be a low-cost, accessible method to improve physical and mental health in rural veterans with HF.

Introduction

Background

Heart failure (HF) is a chronic, progressive disease of notable disparity for rural veterans despite recent advancements in clinical treatments [1] and overall improvements in HF-related outcomes [2]. Incidence, hospitalization, and mortality rates continue to be highest in rural versus urban individuals with HF [2,3]. In rural veterans, specifically, HF is the second leading cause of cardiovascular-related hospitalization, accounting for about 30% of total hospitalizations [4]. Lower levels of health literacy, higher rates of food insecurity, the presence of food deserts, the lack of community support services, poverty, and limited health care access contribute to the disparities in HF-related outcomes in rural veterans [5-7] and influence physical and mental health [7].

Rurality impacts patients' ability to maintain optimal HF self-care and disease management in the home. Specifically, rural veterans with HF experience unique challenges, which are stressful, such as difficulties in obtaining fresh fruits and vegetables and low-sodium foods, which are a vital component of the HF dietary regimen [8]. The lack of local health care services and pharmacies, as well as public transportation, adds to the complexity of managing HF in a rural area [8] and increases the travel burden for veterans associated with receiving medical care [9]. In fact, only 9% of physicians practice in rural areas, which is significant given that 20% of the population in the United States lives in rural areas [6]. These rural-related social determinants of health play a crucial role in the ability to maintain optimal HF self-management and influence patient outcomes in rural veterans with HF [7].

Likewise, depression and anxiety are influenced by the progression of HF [10], with increased symptoms and decreased physical functioning contributing to poor mental health [11,12], and are associated with higher mortality and hospitalization rates [10,13]. Notably, depression and suicide rates are highest in rural patients compared to their urban counterparts, yet only 10% of mental health professionals practice in rural areas, leaving many rural veterans without access to mental health care [14] and placing them at even greater risk for poor HF outcomes [10,13]. Thus, rural veterans living with HF lack substantial support in aiding disease management and mitigating the negative emotions that often accompany living with HF, necessitating the development of novel interventions to support physical and mental health in the home.

Social support and problem-solving are essential coping resources that aid stress management, support resiliency, and enhance coping processes [15,16]. In rural veterans with HF, social support and problem-solving skills are critical to maintaining physical and mental health [8,17,18]. Patients with HF need to appraise and manage diverse symptomatology, adhere to dietary restrictions, cope with negative emotions, and negotiate daily activities [11,12]. Rural veterans with HF also need to successfully address rural-related challenges and barriers that undermine overall health [7]. Previous research suggests that the use of rational, systematic problem-solving strategies to manage HF-related problems is associated with better HF self-care [8,17] and may reduce HF symptom severity [18] and mental distress [17]. However, rural veterans often lack access to support and problem-solving interventions in their communities. Furthermore, when such services are available, they typically are not tailored to the rural sociocultural and educational context, nor are they able to address the specific emotional needs of veterans [19].

Culturally sensitive, tailored interventions that provide support and focus on enhancing problem-solving skills [16] hold considerable promise for increasing uptake in rural veterans with HF. Tailored support and problem-solving programs may be beneficial for veterans who need more assistance outside of a "standardized, one-size-fits-all" disease self-management program. Furthermore, the use of telephones allows for an easy-to-access, cost-effective, and successful modality for delivering such interventional programs to rural areas where access to broadband internet may still be problematic [20-22].

Our previous research assessed the preliminary efficacy of a 12-week, nurse-led, tailored, telephone-based, problem-solving and support intervention (Coping in Heart Failure [COPE-HF] Partnership) for patients with HF on changes in self-care, HF symptoms, depressive symptoms, and health care utilization in a three-arm randomized clinical trial [17,18]. Participants in the COPE-HF Partnership were all recently discharged from an acute care facility for issues related to HF and resided primarily in urban areas. A trained nurse interventionist partnered with the patient to manage HF-related self-care and disease management problems encountered in the home. Data were collected at baseline and 5, 9, and 13 weeks. The intervention was associated with improvements in self-care management;

notably, patients had less health care utilization over the intervention period versus the other groups [17]. Patients who received the intervention also reported fewer HF symptoms, with a significant decrease in HF symptom severity over the intervention period [18]. Although not significant, improvements in depression were also found in the intervention group [17].

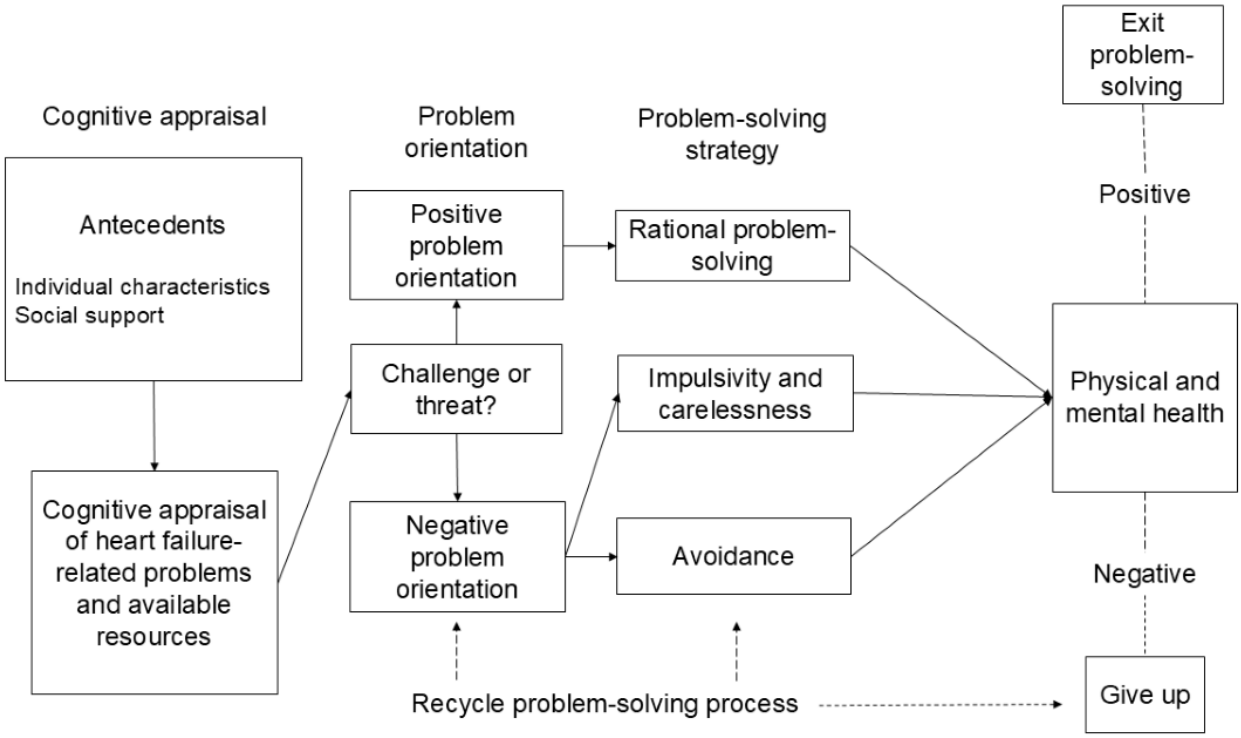
To prepare for the sociocultural adaptation of the CARE-HF (Supporting Physical and Mental Health in Rural Veterans With Heart Failure) intervention to the rural population, we conducted a qualitative study with rural patient–care partner dyads living with HF (n=11) to identify and describe the problems experienced in the home related to HF and associated management strategies [8]. The findings of this study showed that rural residents with HF experience significant problems related to self-care and disease management adherence due to the rural environment and lack of resources, as well as differences in cultural and personal values and beliefs related to health care. These problems resulted in a variety of physical and mental health sequelae and strained interpersonal relationships. However, most dyads developed effective workarounds and management strategies to overcome these challenges [8]. The problems and management strategies identified in this study provide the basis for the adaptation of intervention content for the rural population included in the CARE-HF intervention.

The CARE-HF also builds upon the COPE-HF Partnership intervention, in that it includes self-care and disease management components [17,18]. However, it differs in that the CARE-HF intervention is more holistically focused, also incorporating mental health, interpersonal, and social components. In addition, all components of the CARE-HF intervention are adapted to the rural sociocultural context and include specific problems and management strategies pertaining to physical and mental health drawn from the rural setting [8]. Because of the expanded focus of the CARE-HF intervention, additional study outcomes, not examined in the parent intervention, are included in the CARE-HF study.

Conceptual Framework

The Theories of Social Problem-Solving [16] and Stress, Appraisal, and Coping [15] provide the foundation for the CARE-HF intervention (Figure 1). Rural veterans with HF encounter a unique variety of problems that require cognitive appraisal and appropriate problem-solving to successfully cope with HF-related challenges. The two-fold cognitive appraisal process is influenced by individual characteristics and consists of primary appraisal (determination of the significance of the problem) and secondary appraisal (evaluation of available resources) [15]. Effective problem-solving requires a positive problem-orientation approach which elicits rational problem-solving versus avoidance, impulsivity, and carelessness. Problem-solving involves accurate problem identification, generation of appropriate strategies, active decision-making, and strategy implementation and evaluation [16]. The goal of the CARE-HF intervention is to move rural veterans with HF toward a positive problem orientation and use of rational problem-solving strategies, thereby supporting a more adaptive problem-solving style and enhancing physical and mental health [15,16].

Figure 1. Conceptual model based on the Theories of Social Problem-Solving and Stress, Appraisal, and Coping.



Purpose, Aims, and Hypotheses

The overall purpose of this study is to adapt to the rural sociocultural context and test the efficacy of a tailored, telephone-based intervention (CARE-HF) to support the physical and mental health of rural veterans by enhancing disease self-management and coping processes. To accomplish this goal, our research aims are to:

1. Adapt the CARE-HF intervention content to the rural sociocultural context using findings from preliminary qualitative research.
2. Examine the effectiveness of the CARE-HF intervention on study outcomes (HF self-care, HF symptoms, health care utilization, depressive symptoms, anxiety, health-related quality of life, stress, resilience, and coping), process (problem-solving), and antecedent (social support) in a sample of rural veterans with HF (N=100) at baseline and 3, 6, 12, and 18 months from baseline.

Our hypotheses are as follows:

- Hypothesis 2a: Increases in HF self-care, health-related quality of life, resilience, coping, and problem-solving will be noted at 3 months from baseline and sustained throughout the 18-month follow-up period.
- Hypothesis 2b: Decreases in HF symptoms (frequency, severity, and interference with physical activity and enjoyment of life), health care utilization, depressive symptoms, anxiety, and stress will be seen at 3 months from baseline and sustained throughout the 18-month follow-up period.

Methods

Cultural Adaptation

To address aim 1, before recruitment and study initiation, steps were taken to adapt the CARE-HF intervention content to the rural sociocultural context using some aspects of the ADAPT-ITT (Assessment, Decision, Adaptation, Production, Topical Experts, Integration, Training, and Testing) model [23]. Specifically, qualitative findings from preliminary research in rural patients with HF [8,12] guided the context of problems and potential strategies included in the program materials and telephone intervention sessions. The problems presented during the card sorting task, a component of the sessions, are drawn directly from this preliminary rural research [8,12]. In addition, during the telehealth sessions, veterans' values and beliefs are assessed and inform the potential strategies identified in the problem-solving process to enhance adherence and tailor the program to the unique needs of each rural veteran.

Ethical Considerations

This study was approved by the Florida State University Institutional Review Board (protocol STUDY00003764) to collect verbal consent via the telephone according to the principles of the Declaration of Helsinki, with potential participants maintaining the opportunity to opt out of the study. Telephone sessions are recorded to monitor intervention fidelity. However, all participant data are deidentified and stored in accordance with the General Data Protection Regulation Rules to maintain privacy and confidentiality. Veterans enrolled in the study receive compensation in the form of US $20 gift cards to a superstore following each completed data collection point, for up to a total of US $100 in gift cards if the entire study is completed. No identifiable information or images of research participants will be included in research reports. The CARE-HF protocol is registered at ClinicalTrials.gov (NCT05839067).

Design and Sample

This study includes a repeated-measures, single-group design. Veterans are recruited from Veterans Administration home-based cardiac rehabilitation clinics, cardiology clinics that serve veterans, veterans-based community resource centers, and social media campaigns using study flyers. Veterans with HF (N=100) will be recruited over 3 years, with the anticipated enrollment of 5 or more veterans per month. The desired sample size was based on a power analysis for repeated-measures ANOVA with 5 time points, α=.05, a medium effect size (f=0.25), and 80% power, plus oversampling for potential attrition (20%) estimated from studies involving patients with HF [17,18]. Veterans are eligible for participation if they (1) have a diagnosis of HF; (2) are aged 18 years or older; (3) have New York Heart Association functional class II-IV HF; and (4) can read, write, and communicate verbally in English, and excluded if they have a history of cognitive impairment.

Data Collection

Telephone data collection is conducted by a trained research assistant who verbally asks each item and records participants' responses in an online HIPAA (Health Insurance Portability and Accountability Act)–compliant Qualtrics database. Data are collected at baseline and 3, 6, 12, and 18 months from baseline. In addition to a sociodemographic and clinical survey (age, gender, comorbidities, education, and HF class), a set of self-report surveys is used to measure the study variables (Table 1). We also collect data on standard Veterans Administration Office of Rural Health metrics.

Table 1. Study variables.

[a]HF: heart failure.

Study Measures

Social Support

The 12-item Interpersonal Support and Evaluation List measures perceived belonging, tangible, and appraisal support. The 3 subscales will be combined to obtain a single index of perceived support, in addition to the evaluation of the individual subscales. Scores range from 0-36, with higher scores suggesting a higher perception of available support [24]. Previous studies support its construct validity using the original 40-item version [24] and its internal consistency reliability (α=.90) [25].

Problem-Solving

The 25-item Social Problem-Solving Inventory Revised-Short measures problem orientation and problem-solving style using 5 subscales: positive and negative problem orientation, rational problem-solving, impulsivity and carelessness, and avoidance styles. The 5 subscales will be combined to provide a total score, with higher scores representing more of an adaptive problem-solving style and lower scores suggesting more of a maladaptive style. Higher scores on the individual subscales suggest more of the problem-solving characteristics [26]. Research supports its validity [16,26] and its reliability (α=.91) [25].

HF Self-Care

The 39-item Self-Care of Heart Failure Index v 7.2 measures HF self-care across 4 subscales: self-care maintenance, symptom perception, symptom management, and self-efficacy (α=.73-.88 across all subscales) [27,28]. Scores are standardized (0-100), with higher scores on each subscale suggesting better self-care principles. Scores ≥70 on each subscale are considered adequate; improvement of ≥8 is considered clinically significant [27].

HF Symptoms

HF symptoms are measured using the Heart Failure Symptom Survey. This survey contains 14 common symptoms of HF, which are rated on an 11-point scale (0–10) across 4 domains (frequency, severity, interference with activity, and interference with quality of life) based on the last 7 days. Higher scores indicate more of the respective domain in relation to the specific symptom [29]. Empirical evidence supports its content validity [29] and reliability (α=.96) [25].

Health Care Utilization

Health care utilization is determined by the frequency of emergency department visits and readmissions for HF and assessed via self-report. There are acceptable levels of agreement between self-report and medical record data [30].

Depressive Symptoms

Depressive symptoms are measured using the 20-item Center for Epidemiological Studies—Depression Scale. Overall scores range from 0 to 60, with higher scores indicating the presence of more depressive symptoms. A cutoff score of 16 indicates an individual is at risk for some degree of depression. Previous studies support its validity (Radloff [31]) and reliability (α=.90) [25].

Anxiety

The Generalized Anxiety Disorder-7 scale is a valid and reliable (α=.92) 7-item scale that assesses the presence of anxious symptoms over the past 14 days, using a Likert scale to rate the frequency of the symptoms (0=not at all, 1=several days, 2=more than half of the days, and 3=nearly every day). Total scores range from 0 to 21, with higher scores indicating more severe anxiety symptomatology [32]. In this study, the following recommended anxiety severity categories will be used: none or

normal (0-4), mild (5-9), moderate (10-14), and severe (15-21) [32].

Health-Related Quality of Life

The multidimensional 21-item Minnesota Living with Heart Failure Questionnaire measures the physical, socioeconomic, and emotional dimensions of HF-specific, health-related quality of life. This self-report survey asks respondents to evaluate the way they have felt in relation to the specific dimension over the last 4 weeks. Scores for the individual dimensions, as well as a total score, are obtained by summing the individual items. Higher scores suggest worse health-related quality of life relative to the specific dimension or overall. A change of ≥5 points is considered clinically meaningful [33]. Previous studies support its validity [33] and reliability (α>or=.80 across dimensions) [34].

Stress

The valid and reliable 10-item Perceived Stress Scale measures stress and includes questions relative to feelings and thoughts experienced during the last month using a Likert scale with scores ranging from 0 (never) to 4 (very often). Higher scores indicate higher levels of acute stress [35].

Resilience

The 25-item Five-by-Five Resilience Scale has 5 subscales that measure adaptability, emotion regulation, optimism, self-efficacy, and social support on a 5-point Likert scale (1=very inaccurate to 5=very accurate). Higher scores represent higher levels of resilience relative to the specific facet. Previous research shows adequate validity and reliability (α=.81-.93 across subscales) [36].

Coping

The Brief Coping Orientation to Problems Experienced is a 28-item scale that measures 14 coping strategies over 3 subscales (active emotional coping, avoidant emotional coping, and problem-focused coping) on a 4-point scale ranging from 1 (I haven't been doing this at all) to 4 (I have been doing this a lot). Higher scores on the subscales suggest more use of the specific type of coping strategy [37]. Previous research has indicated the measure is valid [37] and reliable (α=.78) [38].

Procedure and Intervention

CARE-HF

Veterans are trained to use social problem-solving skills to manage common HF-related problems in the home during 8 telephone sessions led by a trained registered nurse interventionist (NI).

Initial Telephone Session

Before the first session, veterans are mailed program materials and a manual presented at a sixth-grade reading level. To start the first telephone session, participants receive an overview of the program manual, tailored to the rural context, which includes information about social problem-solving principles. The manual also includes detailed real-life examples drawn from the rural setting of how to use the five-step, problem-solving process to evaluate and manage HF-related problems based on previous research (Table 2) [8]. Each example includes a positive problem-orientation approach and rational problem-solving strategies to address these HF-related problems. The NI uses fatigue as an example when discussing how to apply the iterative five-step, problem-solving process to manage actual HF-related problems. The five-step, problem-solving process is based upon the "Theory of Social Problem-Solving" and rational problem-solving principles and includes (1) identifying the problem and viewing it in a positive manner, (2) setting a goal related to problem management, (3) generating potential strategies to address the problem, (4) choosing and implementing one to two strategies to manage the problem, and (5) evaluating the effectiveness of chosen strategies [16].

Veterans are then asked to participate in a card-sorting task. Veterans are given a set of cards portraying HF-related problems identified in previous research (Table 2) [8,12] and asked to prioritize the cards from the highest priority problem to the lowest. Then, the NI will guide veterans in applying the problem-solving process to the HF-related problem identified as the highest priority. Next, the NI describes the benefits of reframing the problem in a positive manner and facilitates the selection of preliminary strategies to manage them. In doing so, the NI explores through discussion with the participants how their values and beliefs can be incorporated into potential strategies. Participants then choose one to two strategies on which to focus, the results of which are reviewed at the next session. The five-step, problem-solving process is reinforced throughout the intervention period in the follow-up telephone sessions.

Table 2. HF[a]-related problems and examples.

Problem categories	Examples
Monitoring and managing HF symptoms	• Fatigue (tiredness) • Forgetfulness • Edema (swelling) • Activity intolerance • Difficulty breathing (shortness of breath)
Staying on your special diet program	• Access to suitable foods • Shopping for and cooking correct foods • Limiting fluids (if recommended) • Barriers to eating foods with less salt • Personal food likes and dislikes • Not sure how to read and understand food labels
Staying on your HF treatment program	• Take daily weights • Exercise regularly (as recommended) • Keep regular health care visits • Get immunizations (flu, RSV[b], pneumonia, and COVID-19) • Use oxygen (as directed) • Stop smoking
Dealing with unhelpful emotions	• Sadness • Anxiety • Decreased quality of life • Depression • Anger • Negative life changes
Social isolation and loneliness	• Unable to do normal activities (community, church, family, and friends) • Fewer or no invitations to social events with friends and family • Feeling as if you have no one to turn to for support • Feeling alone
Medicine management	• Difficulty in obtaining medicine • Unable to pay for medicine • Problems in preparing medicine • Trouble in taking medicine on time • Taking several medicines for other health problems
Health beliefs	• How you view your health and wellness (accept, do not accept, positive, or negative) • How well you think you can do health activities for yourself (good, ok, or not well) • Your view of how well the heart medicine and treatment works (works well, no change, or does not help)
Caring for yourself (self-autonomy)	• You want to do everything for yourself and or make health care decisions whether you can or not • Family or friends want to do everything for you and or make health care decisions whether you can or not
Social support and community resources	• Family or friends who live close by • Church members and social group friends • Neighbors • Local senior center • Home health • Grocery store or grocery delivery programs nearby • Food pantry • Pharmacy nearby • Public transportation
Managing HF and other health issues	Managing HF and: • Diabetes • Neurological disorders

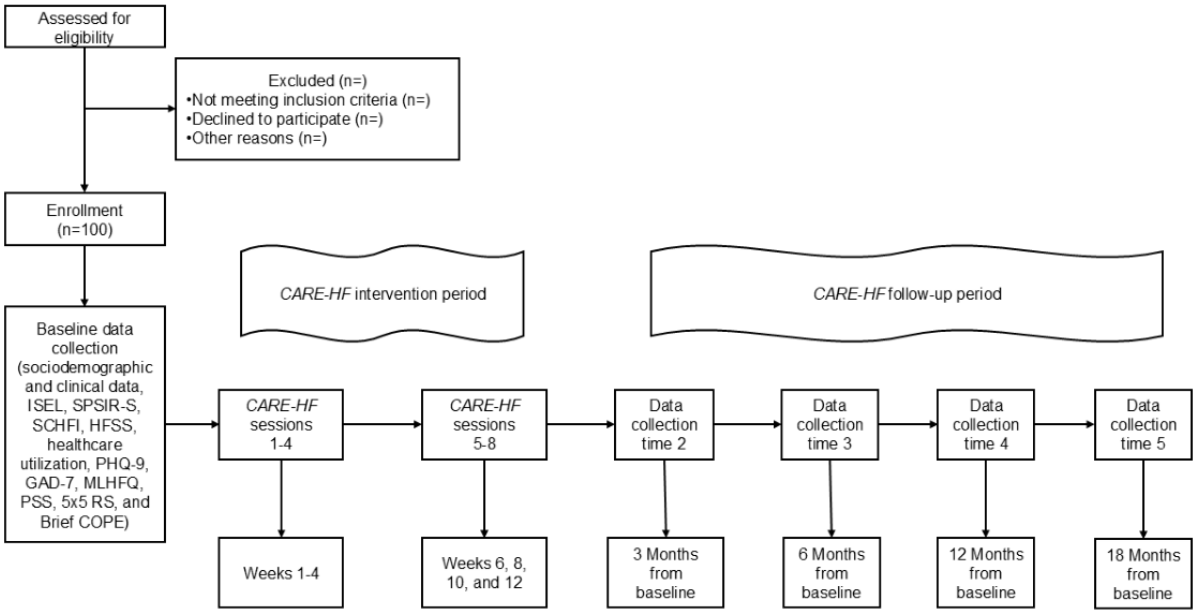
[a]HF: heart failure.

[b]RSV: respiratory syncytial virus.

Follow-Up Telephone Sessions

Seven follow-up telephone sessions occur weekly for the first month (sessions 2-4) and then biweekly for the second and third months (sessions 5-8). Each session begins with an evaluation of the previous week's problem, including the veterans' perceptions of the effectiveness of the strategies used. If needed, problem-solving guidance is provided or reinforced via verbal feedback from the NI. If the problem improves and no further problem-solving is required, the NI works with the veterans to establish a maintenance plan using rational problem-solving strategies. Veterans then repeat the card sorting task to identify new problems and the iterative five-step, problem-solving process starts over. Both current and new problems are identified by the veterans and examined during each follow-up telephone session. Each follow-up session lasts approximately 30 minutes. Figure 2 provides an overview of the study and associated major activities.

Figure 2. Study overview.



Intervention Fidelity

Strategies to enhance intervention fidelity are based upon the National Institutes of Health Behavior Change Consortium recommendations [39]. Standardized training for research staff who are conducting inclusion and exclusion screening, data collection, and intervention sessions occurred before study implementation to ensure adequate skill acquisition for the defined roles. The primary investigator trained staff initially until a minimum of 90% accuracy was achieved in covering the key elements of the defined role using role-playing, scenarios, and scripts. Fidelity checks of eligibility screening and informed consent, data collection contacts, and intervention sessions are also performed by the primary investigator every three months using a checklist of key elements for the specific activity to ensure that 90% of core elements are being consistently performed. Retraining of research staff occurs as needed to ensure that they meet the 90% criterion.

Data Analysis

Preliminary Analyses

Descriptive statistics will be computed on all time-invariant and time-varying study variables. Cronbach α values will be calculated for all measures containing multiple items to assess internal consistency. In the case that internal consistency is low ($\alpha<0.6$), an if-item-deleted analysis will be performed, and items that are not a good indicator for the underlying construct will be excluded.

Main Analyses

Multilevel growth curve modeling will be used for the testing of aim 2 or the evaluation of the effectiveness of CARE-HF. For each outcome variable, a series of models will be estimated and compared using incremental fit indices, including the Akaike information criteria and the Bayesian information criteria. The first model is an intercept-only model. Then, a growth curve model with a linear growth component will be estimated. Finally, a model with a quadratic growth component will be tested. The multilevel modeling and restricted maximum likelihood estimation method will be used in R (R Foundation for Statistical Computing) [40]. This method can deal with dropouts and missing data without excluding incomplete cases. In addition to fixed effects, random effects will be estimated.

Covariates

Several covariates will be considered for inclusion: age, biological sex, race and ethnicity, and educational attainment. Only covariates that are statistically significant predictors of at least one outcome will be included. That is, the same covariates will be used in all analyses for the primary aim.

Expected Outcome

We anticipate that the CARE-HF intervention will improve problem-solving, HF self-care, health-related quality of life, resilience, and coping and decrease HF symptoms, health care utilization, depressive symptoms, anxiety, and stress across all time points from baseline.

Results

Funding for this study was received in October 2022, and recruitment started in April 2023. As of December 2024, a total of 56 veterans have been enrolled, 4 veterans have completed the study, and the remaining veterans are in varying phases of intervention or follow-up. Recruitment is anticipated to end in June 2025, with follow-up data collection continuing until all enrolled veterans have completed the 18-month follow-up data collection period. Data analysis is forthcoming and will be conducted after the study completion.

Discussion

Significance of This Study

In recognition of the extraordinary challenges that rural patients encounter in maintaining optimal health, the American Heart Association [22] recently recommended the use of telehealth to increase health equity and provide vital access to cardiovascular supportive care in this population. Although mobile apps and virtual platforms are popular telehealth modalities for intervention delivery, their use in rural populations is plagued by technological challenges [22]. However, the use of telephones to deliver support and problem-solving interventions to rural patients with HF eliminates these technological issues and has been effective in optimizing HF self-care [17,18] and reducing depressive symptoms [41].

With an increasing focus on innovative methods to support physical and mental health and enhance health equity among rural veterans with HF, this study will provide important evidence on the effectiveness of an innovative, telephone-based, support and problem-solving intervention on HF self-care, HF symptoms, health care utilization, depressive symptoms, anxiety, health-related quality of life, stress, resilience, and coping. The CARE-HF intervention has the potential to improve the clinical care of rural veterans with HF, as well as be expanded to other populations. If this novel intervention is found to be effective and sustainable, it can be further tested in a larger randomized clinical trial, with the long-term goal of translating this intervention into clinical care for veterans with HF to enhance HF disease self-management and mental health.

Limitations

This study has some limitations. First, enrollment is restricted to rural veterans with HF; therefore, generalization of findings may be limited. Second, this is a single-group study that lacks a comparison group, reducing our ability to make meaningful comparisons across outcomes. Third, a lengthy follow-up period is included to examine the sustainability of the intervention effect and assess the need for booster sessions, but this may also contribute to a higher-than-desired attrition rate. Despite these limitations, this study will provide valuable insights for program evaluation and improvement, as well as intervention adherence and sustainability of effect to inform future research.

Conclusions

This study adapts to the rural sociocultural context and tests a tailored, telephone-based, support and problem-solving intervention designed to help rural veterans manage HF-related problems experienced in the home. If the intervention is effective, it will provide support for a highly accessible, low-cost method to aid rural veterans in maintaining optimal physical and mental health. This study fills an important research gap but, more importantly, provides the basis for future work to evaluate potentially effective and accessible services for rural veterans living with HF.

Acknowledgments

The authors would like to thank the following members of the research team: Rachel Abbott, RN, BSN; Armita Amiri, research assistant; Erik Rawls, PhD; and Kimberly Mattox, MS, research coordinator. The authors of this study would like to acknowledge the Veterans Administration Office of Rural Health, Gainesville Veteran Health Resource Center (VRHRC-GNV) (#008927), and the Florida Blue Center for Rural Research and Health Policy for the funding to conduct this study. We confirm that the protocol was subject to independent peer review as part of the review process conducted by the VRHRC-GNV.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

Abstract

Background: In the United States, Black women are 3-4 times more likely to experience maternal near miss (MNM) or severe maternal morbidity (SMM) than non-Hispanic White women. However, there is a limited narrative-based investigation into Black and other marginalized women's MNM experiences. Additionally, limited extant research on the impact of MNM and SMM on birthing women's families or support persons and health care providers precludes the development of multilevel, patient-centered methods to eliminate these racial or ethnic disparities.

Objective: This paper presents the protocol for a study that aims to draw insights from the experiences of racially and socioeconomically diverse mothers with MNM and SMM, their family or support persons (eg, partners), and health care providers to inform legislation, clinical practice, and infrastructure for optimal social support using PRISMA-P (Preferred Reporting Items for Systematic review and Meta-Analysis Protocols) guidelines. Using a storytelling approach to assess participants' risk factors, document underlying causes, and research clinical causes of MNM, researchers hypothesize these data will inform policies to improve maternal conditions and provide safe and effective prevention and treatment options for birthing persons.

Methods: Morehouse School of Medicine (MSM) will partner with health services and community-based organizations to promote inclusive participant recruitment for this multiphase study. In phase 1, qualitative interviews were conducted with birthing women (n≤87) who have experienced MNM and SMM. In phase 2, we will conduct qualitative interviews with the following groups: birthing women's partners or support persons (n≤50), health care providers serving birthing women (n≤50), and adults who lost their mothers to pregnancy-related complications (n≤50). In each phase, the total number of participants interviewed will be based on theoretical saturation, that is, the point in iterative data collection and analysis when all important insights have been exhausted from the data already available.

Results: Recruitment for phase 1 started in July 2021. As of March 2024, we have recruited 87 racially and socioeconomically diverse birthing women. Of those, 74% (64/87) self-identified as Black or African American, 20% (17/87) as Hispanic or Latina, and 9% (8/87) as Native American or Alaska Native. Severe preeclampsia accounted for 46% (40/87) of participants' pregnancy-related adverse experiences. Qualitative interviews grounded in narrative-based medicine are ongoing. Recruitment for phase 2 will occur between July 2023 and December 2024. Study results will be published in peer-reviewed scientific journals.

Conclusions: The findings from this research will deepen the understanding of how severe obstetric complications (1) are experienced by birthing women; (2) are perceived by their partners, support persons, and health providers; and (3) impact the lives of bereaved family and community members.

Introduction

Maternal health encompasses the well-being of both mothers and their newborns during pregnancy, childbirth, and the postpartum period. Despite advancements in medical technology and health care systems, there remain persistent challenges with maternal mortality (MM) and morbidity. The Centers for Disease Control and Prevention reports that the MM rate for the United States in 2021 was 32.9 deaths per 100,000 live births, compared to a rate of 23.8 in 2020 and 20.1 in 2019—statistics that suggest MM is increasing [1]. Likewise, severe maternal morbidity (SMM) is also on the rise in the United States [2]. SMM involves unforeseen birth outcomes that cause short-term and long-term health effects for birthing persons, including hemorrhage, cardiac arrest, organ failure, major surgery, and other life-threatening complications that require interventions [3]. Sadly, disparities in adverse pregnancy-related outcomes are widening. Research shows women of color experience disproportionate rates of MM and SMM in comparison to their non-Hispanic White counterparts [4,5]. This issue is perpetuated by racism embedded within the maternal health care infrastructure to the extent of which social determinants, such as higher income and education, no longer serve as protective factors for health [5-9].

The World Health Organization (WHO) contends that maternal near miss (MNM), defined as "a woman who nearly died but survived a complication that occurred during pregnancy, childbirth or within 42 days of termination of pregnancy," is a more useful indicator for studying the evaluation and improvement of obstetric health care than MM [10]. To date, little is understood about the contributors to MNM, especially for women and birthing people of color. Public health's tendency to rely on medical records and statistics often renders those most affected by health disparities unseen, unheard, and unnoticed in the discourse [11]. As Silverio et al [12] wrote, "it is not uncommon for quantitative approaches to be unable to detect the nuances of the experiences we seek to understand." Social context is needed to conceptualize the intricacies of health inequity as a means for developing effective and sustainable solutions [13]. Therefore, using a narrative-based medicine (NBM) model [14], this study centers on women of color's lived experiences [15] with surviving life-threatening pregnancy complications. Additionally, we are collecting a multistakeholder perspective by interviewing health care providers and partners or support persons who have witnessed an MNM experience and gathering narratives from adults and caretakers of adults, who lost their birth mother due to maternal causes. Using this approach, we hope to obtain an understanding of these stakeholders' perceptions and the impact of their experiences. Our goal is to uplift participants' stories as data points for influencing maternal health legislation, clinical practice, and health care strategy.

Methods

Study Design and Conceptual Framework

This study explores the burden of MNM and SMM using a narrative or storytelling approach recognizing birthing persons' experiences as legitimate sources of data. We used the Three Delays Model [16] to inform data collection and analysis. This model posits that MNM and SMM are largely the result of three critical delays, that are, first, delayed decision to seek care—barriers to making this critical decision include underestimation of the severity of the problem and its potential complications, poor understanding of danger signs and the potential scope of complications, cultural beliefs, customs, and attitudes (eg, distrust) regarding seeking care, and lack of social supports, among others. Second, delayed action or delay in reaching an appropriate site of care—getting to care, by definition, requires adequate transportation. A notorious problem in the developing world, transportation is also a challenge in many US states. Many states lack a sufficient number of perinatal providers; for example, half of Georgia's 159 counties lack a maternity provider [17]. Barriers like health care insurance enrollment and coverage, provider network limitations, as well as financial constraints can also be difficult to navigate. Further, lack of social support and lack of personal agency may hinder a woman's ability to act. Third, delayed diagnoses and appropriate treatment once a facility is reached—lack of facility resources (ie, equipment, blood, and drugs), a deficit of appropriately trained personnel, and systems that are poorly organized to manage obstetrical and medical emergencies are among the factors which can contribute to this delay.

Eligibility and Recruitment

In phase 1, to be eligible for the study, participants had to meet the criteria of (1) self-identity as Black or African American, Indigenous, or Latinx; (2) older than 18 years of age; (3) meet WHO near miss criteria, that is, experience with severe postpartum hemorrhage, severe preeclampsia, eclampsia, sepsis or severe systemic infection, and ruptured uterus during pregnancy; and (4) can speak and read English. Additionally, the screener survey was modified to include specific questions about medical interventions participants may have experienced to differentiate between MNM and SMM experiences. Recruitment occurred from July 2021 through April 2022. States originally chosen for recruitment included Georgia, Louisiana, New Jersey, and the DMV area (Washington, DC; Maryland; and Virginia) due to their high rates of MM. In September 2021, New York, Connecticut, South Carolina, and Mississippi were added to increase recruitment, followed by the addition of Alabama, Texas, and Oklahoma in December 2021. After numerous inquiries from birthing persons outside the previously included states, the study was expanded to include the entire United States in March 2022.

In phase 2, health care providers must meet the criteria of (1) self-identify as a physician, nurse practitioner, physician assistant, midwife, pediatrician, psychologist, or doula; (2) over 50% of their patient population identifies as a racial or ethnic minority; and (3) had a patient that experienced an MNM or witnessed an MNM. Support persons or partners will be considered eligible if they meet the criteria of (1) self-identify as a support person for a birthing person who experienced an MNM; (2) self-identify as Black or African American, Indigenous, or Latinx; (3) older than 18 years of age; and (4) can read and speak English. For adults whose mothers died due to maternal causes and caretakers of adults whose mothers died due to maternal causes, participants are considered eligible if they meet the criteria of (1) the death of the mother must have occurred within 1 year of the adult's birth; (2) self-identify as Black or African American, Indigenous, or Latinx; (3) older than 18 years of age; and (4) can read and speak English. An eligibility screener survey was created via REDCap (Vanderbilt University) for both phases of the study to identify participants.

Data Collection

All internal and external team members were required to complete the basic Collaborative Institutional Training Initiative course. Team members were also trained in research interviewing techniques, including how to ask additional questions that may be relevant to each specific interview.

Before the interviews, each participant completed the screening survey to verify their eligibility. Participants also completed a voluntary survey collecting sociodemographic data in addition to data surrounding the structural determinants that may have contributed to their MNM experience. These factors include age, parity, marital status, place of residence, education level, income, neighborhood characteristics, food insecurity, and so forth. Scheduling for interviews took place over email or messages via the technology platforms provided by Optum. Interviews were conducted virtually over the Zoom platform (Zoom Video Communications), included both audio and video, and typically lasted between 1 and 2 hours.

Birthing persons were identified through contacts with Morehouse School of Medicine (MSM) partner organizations, including our national community partner Reaching Our Sisters Everywhere (ROSE). ROSE was founded to address breastfeeding disparities in Black communities and works to normalize breastfeeding by providing resources and networking opportunities for individuals and communities. As a national expert, and in partnership with communities, ROSE builds equity in maternal and child health and fatherhood initiatives through culturally appropriate training, education, advocacy, and support. This partnership served as an opportunity to combine our advocacy and support of the community. ROSE used its network to recruit participants and assisted in conducting interviews. MSM and ROSE team members closely supported one another in debriefing some of the challenging and emotionally charged conversations held with participants about their MNM experiences [12]. This study was supported by Optum, the health services business of United Health Group, through grant support and research participant recruitment. Screening criteria were the same across all tools, and participants were cross-referenced against past and scheduled participants to avoid duplication of data.

Consent for interview facilitation and recording and transcription of interviews in addition to the demographic information were all collected via REDCap. A detailed informed consent form was developed by the research team and approved by the MSM institutional review board (IRB). The consent form was completed during the Zoom session with a team member present to answer any questions prior to beginning the interview. After determining that mental health effects were a common theme during several interviews, the consent form was modified in the event that emergency professionals needed to be contacted. The adjusted language stated, "This certificate does not stop Morehouse School of Medicine from giving out information to prevent harm to you or others." Any participants who mentioned suicidal ideation were also sent a Patient Safety Plan Template. This template, completed by individuals in their own time, collects warning signs, coping strategies, crisis contacts, and other material for participants to reference as needed [18]. Acknowledging that reliving traumatic experiences may have an effect, all participants received a detailed list of mental health resources located in their indicated state of residence.

Folders containing information about interviews and data analysis, including recruitment tracking, team interviewer availability, interview scheduling, and progress, were securely stored in an encrypted drive. Access was restricted to certified team members via password. Regular biweekly meetings were set up for the internal team to discuss updates and recruitment strategies. Additionally, separate biweekly working sessions were held with the funder.

As aforementioned, this study uses the power of storytelling, particularly NBM, which applies the narratives of patients or participants to medical practice [14]. We sought to understand participants' interactions with health providers, perceptions of quality of care, the circumstances of their "near miss," social support received, and their lived experiences prior to becoming pregnant. The interview guide was developed using the Three Delays Model and the International Consortium for Health Outcomes Measurement Set of Patient-Centered Outcome Measures for Pregnancy and Childbirth. These measures, including survival, morbidity, patient-reported health and well-being, and patient satisfaction with care were developed for providers to assess to improve patients' health outcomes and well-being [19]. The interview guide was submitted to and approved by the MSM IRB. In total, the interview guide contained 12 main questions and 13 probing questions.

For example, 1 key question of the interview guide used the Three Delays Model:

> *How was the process when you arrived at the hospital and how was your complication resolved? Take me through this part. What was said to you? Did you know what was going on? What was communication like? How did you feel at that moment?*

- Who/what were obstacles or facilitators to timely care?
- What was the wait time for care?
- Reasons for any delays

- Perceptions of quality of care

Furthermore, most of the interviews were spent answering the "near-miss" question:

> *Tell me about your birth experience. Tell me the story, all the way from beginning to end, describe the setting, who was involved, do you have any pictures you would like to share, please address important timelines...*

After the completion of the interviews, each participant received an email with a US $100 gift card as compensation. Also included in the email was the list of mental health resources and a link to the screener if any participants wanted to share the study with others.

Ethical Considerations

All Collaborative Institutional Training Initiative certificates were submitted and approved by the MSM IRB (ID number 1754465-15). Informed consent and the ability to opt out were provided to every participant. Participant data were deidentified. All participants who completed an interview were compensated with a US $100 gift card.

Data Analysis

After interviews were transcribed using a transcription service, transcripts were uploaded into Dedoose, a web-based qualitative data analysis program developed by SocioCultural Research Consultants, LLC [20]. A qualitative analysis training session was conducted and recorded for all Optum and MSM team members involved in the process. Our team used an open coding approach in which the codes identified emerged from the data itself, also known as inductive coding [21,22]. Once codes were found, they were classified under larger themes to establish a codebook. Research team members met periodically to refine and collate codes. Each coded transcript was reviewed by another team member to ensure the consistency of the code application. If there were any disagreements regarding codes, team members were informed to bring it to the attention of the principal investigator, and a final code would be decided via a team discussion. Additionally, any suggestions for new codes were brought to the attention of the principal investigator. Data analysis began in May 2022 and was completed in March 2023. Coding included about 12-15 team members per round.

Our research question is qualitatively focused, though we will collect and analyze quantitative data in a few ways. We will use demographic and quantitative data first to comprehensively describe the study population. Second, we will use these data to explore whether qualitative themes vary across participant characteristics such as race, age, income, education, and the presence or absence of social support. As we iteratively review the interview data throughout the analysis process, we will also examine thematic differences across other relevant factors that may emerge. Finally, given there are adequate data to support these analyses, we will assess whether factors including demographic (eg, race, age, income, and education); psychosocial; and clinical (eg, receipt and timing of prenatal care) factors are associated type of pregnancy-related complications experienced. We will perform qualitative analyses with SAS (version 9.4; SAS Institute) and SPSS Statistics (version 29; IBM Corp) [23,24].

Results

This study was funded in 2021 and recruitment for phase 1 started in July 2021. As of March 2024, we have recruited 87 racially and socioeconomically diverse birthing persons for phase 1. Of those, 74% (64/87) have self-identified as Black or African American, 20% (17/87) as Hispanic or Latina, and 9% (8/87) as Native American or Alaska Native (Table 1). Given the relatively low representation of some racial or ethnic groups, we will tailor ongoing recruitment efforts for phase 2 to improve inclusivity.

Table 1. Demographics of participants who completed an interview about the maternal near miss or severe maternal morbidity experience (N=87).

Variable	Values, n (%)
Race and ethnicity	
Black or African American	64 (74)
Hispanic or Latino or Latina	17 (20)
Native American, Alaska Native	8 (9)
Asian	4 (5)
Middle Eastern	1 (1)
Indian	1 (1)
Hawaiian or Other Pacific Islander	0 (0)
White	0 (0)
Other	4 (5)

Severe preeclampsia accounted for 46% (n=40) of participants' pregnancy-related adverse experiences (Table 2). Qualitative interviews grounded in NBM are ongoing.

Recruitment for phase 2 is scheduled to occur between July 2023 and December 2024. Findings from each phase will be published in peer-reviewed scientific journals.

Table 2. Pregnancy-related complications that participants indicated experiencing (n=86).

Variable	Values, n (%)
Severe preeclampsia	40 (46)
Severe postpartum hemorrhage	22 (26)
Eclampsia	3 (4)
Ruptured uterus	2 (2)
Sepsis or severe systemic infection	1 (1)
Other	18 (21)

Discussion

Principal Findings

Collecting stories from our participants' unique birthing experiences, as they relate to severe pregnancy-related complications, has allowed us to investigate the contributors to MNM and SMM and seek opportunities for improvement. Additionally, the majority of this study's participants completed college or a graduate or professional degree and reported an annual household income of $50,000 or more. Therefore, gathering demographic data from participants provides insight into whether socioeconomic "protective" factors, including income and education, have a significant impact on a birthing person's likelihood of experiencing MNM and SMM.

Sharing narratives from women of color who have experienced an MNM and SMM not only provides an opportunity to amplify the voices of those who have been historically silenced; but also, the evidence needed to advance maternal health justice. These perspectives are imperative in guiding the development of health priorities, policies, and strategies that drive optimal experiences for all birthing people. Some of our recommendations include equitable and respectful health care training, workforce diversification promotion, and health system disparity dashboards. Gathering stories from additional stakeholders will allow us to use their perspectives to refine our recommendations.

Strengths and Limitations

Initially, the interviews conducted were determined to be experiences of SMM and MNM. Using the WHO near-miss approach, the screener survey was edited to include questions regarding critical interventions [10]. Participants were asked which critical interventions were performed to save their lives, including cesarean section, blood transfusion, and intensive care unit admission. After implementing these changes, the following interviews were determined to be the experiences of MNM. All SMM interviews were noted as such, and they were organized separately from the MNM interviews. Additionally, we noted many completed screener surveys were fraudulent. There was an influx of emails, in both the internal email account and our funder's email account, that were spam and fraudulent. Screeners and emails were determined to be fraudulent if there were multiple screeners completed with different answers under the same email, the email addresses provided were invalid, and the open-ended answers or email communication did not grammatically make sense. To combat this issue, we incorporated a reCAPTCHA (Google) into our survey. Campbell et al [25] explain that humans and advanced bots can successfully avoid these mechanisms; this was consistent with our findings, given that reCAPTCHA did not seem to reduce the number of fraudulent screeners completed.

Future Directions

At this time, the study has expanded to include partners and support persons of those who have experienced an MNM, health care providers who have witnessed an MNM, and adult children and their caretakers who lost their mothers due to maternal causes. Garnering a multistakeholder perspective about MNM, SMM, and maternal deaths will allow us to examine the impact that severe obstetric complications may have on family members, survivors, and health care providers.

Acknowledgments

The authors would like to thank Reaching Our Sisters Everywhere (ROSE) for recruiting participants and conducting interviews. The authors would also like to thank all the birthing persons who shared their stories for this project. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health and the Department of Health and Human Services.

Funding

This study is supported by the Eunice Kennedy Shriver National Institute of Child Health and Human Development of the National Institutes of Health under award number U54HD113292. This project was also funded in part by the Health Resources and Services Administration (HRSA), U.S. Department of Health and Human Services, under grant number UR6MC50349. This study was supported in part by Optum through grant support and assistance in developing this protocol (as of publication of this study protocol, the grant mechanism is no longer active).

Data Availability

The datasets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

NHG was the principal investigator and performed the conceptualization, project administration, supervision, and writing (review and editing). KHS coordinated the submission and performed writing (review and editing). OF contributed to the supervision and writing (review and editing). LC performed supervision and writing (review and editing). TL performed the writing (review and editing). AS contributed to writing (review and editing). Abstract

Background: Norgestimate (NGM) is a progestin with negligible androgenic activity that is available in combination with ethinyl estradiol (EE) as a monophasic combined oral contraceptive (COC). It has been more than 30 years since a clinical study evaluated the effects of monophasic NGM/EE on menstrual cycle characteristics in healthy women, and in the interim, there has been growing recognition that clinical trials of contraceptives should evaluate a wide range of potential positive and negative impacts for users.

Objective: The aim of this study is to investigate menstrual cycle control during the use of a monophasic COC formulation containing NGM 0.25 mg and EE 0.035 mg (Effimia; Italfarmaco SpA), using established methodologies as well as patient-reported outcomes.

Methods: This is a prospective observational study being undertaken in a target population of 228 healthy Italian women aged 18-35 years who are starting oral contraception for the first time or switching from another COC. The participants are asked to complete a diary for 6 cycles recording information about their menstrual cycles (frequency, duration, regularity, estimated flow volume, and breakthrough bleeding), any unscheduled bleeding, and an evaluation of dysmenorrhea, using a 100-mm visual analog scale from 0=no pain to 100=very severe pain, and any adverse events. Compliance is assessed after 3 and 6 months via returned medication. The primary end point is the change from baseline in the rate of intermenstrual bleeding during the sixth cycle. At baseline, 3 months, and 6 months, acne will also be assessed using the Global Acne Grading Scale, and participants will complete a Profile of Mood State to assess premenstrual syndrome and the Female Sexual Function Index to evaluate the quality of their sex life. A subgroup of 28 participants at 1 site (Genoa) is also providing a blood sample for the assessment of metabolic, endocrine, and coagulation parameters.

Results: Study enrollment began in July 2023 and is expected to be complete by December 2024. Data analysis is expected to be complete by October 2025.

Conclusions: This study into the effects of monophasic NGM/EE 0.25/0.035 mg on menstrual characteristics in healthy Italian women will provide up-to-date data on these effects and includes assessments of a range of other parameters, such as acne severity and patient-reported outcomes, in line with recent international consensus recommendations.

Introduction

Combined oral contraceptives (COCs) are the most commonly prescribed form of hormonal contraception in Italy and in other European countries [1]. These contraceptive pills contain a combination of estrogen and progestin to suppress ovulation (the primary contraceptive effect) and to change endometrial and cervical secretions, hindering the passage of sperm [2]. COCs may be monophasic or multiphasic. Monophasic COCs contain the same dose of estrogen and progestin in each pill, whereas the ratio of these hormones varies over the course of a cycle in multiphasic COCs.

Since the first development of COCs in the 1960s, formulations have been modified to reduce the risk of undesirable adverse events (AEs) and cardiovascular health risks [3]. The early progestins used in first- and second-generation COCs were chemically related to testosterone and caused androgenic AEs such as acne, hirsutism, and oily skin, which could undermine adherence as well as negative effects on high-density lipoprotein cholesterol [4]. Newer progestins have been structurally modified to be less androgenic or are structurally related to spironolactone [5,6]. In addition, estrogen doses have been progressively lowered, and most COCs in use today contain ≤0.035 mg of ethinyl estradiol (EE) [3]. COCs containing the first- and second-generation progestins were associated with a markedly higher risk of venous thromboembolism (VTE) compared with COCs containing the newer-generation progestins [7].

One such newer-generation progestin is norgestimate (NGM). NGM is a third-generation progestin derived from 19-nortestosterone [8]. It is rapidly hydrolyzed in vivo to norelgestromin, the primary active metabolite (75% to 80%), and levonorgestrel (20% to 25%) [9]. Both NGM and its metabolites have activity similar to endogenous progesterone but have a very poor affinity for androgen receptors and are therefore less androgenic than earlier progestins such as norgestrel, gestodene, or levonorgestrel [9,10]. In addition, unlike levonorgestrel, NGM increases levels of sex hormone–binding globulin in plasma, but does not bind to sex hormone–binding globulin, and is associated with reduced levels of free testosterone [11]. Data show that COCs containing NGM carry a lower risk of VTE than COCs containing cyproterone acetate, desogestrel, dienogest, drospirenone, or gestodene [12,13]. On the other hand, contraceptive patches containing norelgestromin are associated with a slightly higher incidence of VTE compared with levonorgestrel-containing COCs, presumably because of the high cumulative dose of EE that accompanies the transdermal route of administration [9].

Women want their contraceptives to be effective in preventing pregnancy, convenient, safe, and well tolerated, and with excellent cycle control [14]. Unscheduled bleeding has a number of negative impacts on a woman's life, in addition to the inconvenience, including the potential for a negative effect on their sexual life and confusion about the status of their cycle [14]. Some women may interpret unscheduled bleeding as an indication that the COC is not working or interrupt use because of it [14]. Monophasic COCs containing 0.030-0.035 mg of EE offer women the greatest likelihood of a regular bleeding pattern with a low risk of estrogen-associated risks as well as the option of fewer periods by reducing or eliminating the placebo period altogether [15]. As well as preventing pregnancy and potentially providing better cycle control (increased regularity and reduced intermenstrual bleeding), COCs may also offer improvements in acne and premenstrual or menstrual symptoms, such as mood changes, headaches, and pelvic pain [16]. However, effects on these parameters vary between COCs [16].

A large German study (N=59,701) demonstrated that the use of a monophasic COC containing 0.25 mg of NGM and 0.035 mg of EE reduced the rate of breakthrough bleeding in healthy women compared with the rate before they started taking NGM/EE [17]. Similar results were seen in an Italian study among 92 women receiving NGM/EE [18]. However, both of these trials were conducted more than 30 years ago, and there has been no recent research in Italy to confirm the effects of monophasic NGM/EE in healthy women. Moreover, since then, there has been growing recognition that clinical trials of contraceptives should evaluate a wide range of potential positive and negative impacts for users [19].

Thus, this study is being undertaken to investigate menstrual cycle control during the use of a monophasic COC formulation containing NGM/EE 0.25/0.035 mg (Effimia; Italfarmaco SpA), using established methodologies as well as patient-reported outcomes (PROs).

Methods

Recruitment

This prospective, open-label study is being conducted at 6 centers in Italy in healthy women aged 18 to 35 years who are starting oral contraception for the first time or planning to switch to a new COC for the purpose of contraception and not for therapeutic reasons. No specific tests are performed before enrollment, consistent with Italian guidelines that such tests are not indicated in women without individual or family risk factors [20]. Patients who are switching need to undergo a 1-month washout phase prior to entry by discontinuing their previous COC 1 month prior to starting NGM/EE 0.25/0.035 mg. The participants must be residents of Italy and be sufficiently proficient in Italian to understand the informed consent form and the instructions for COC use. The key exclusion criteria are contraindications to the COC according to the current summary of product characteristics, concomitant conditions that place users at risk of AEs, or the use of COC for indications other than contraception, such as polycystic ovarian syndrome, endometriosis, or recurrent menometrorrhagia. Complete inclusion and exclusion criteria are shown in Textbox 1. Certain concomitant medications are not permitted for the duration of the study to minimize the potential for drug interactions or confounding of end-point assessment (Textbox 1).

Textbox 1. Complete inclusion and exclusion criteria.

Inclusion criteria (all must be met)

- Healthy women aged between 18 and 35 years (inclusive) in need of contraception.
- Residing in Italy and having a good knowledge of the Italian language, such as to correctly understand the informed consent form and the instructions for use and to ensure potential adherence to the study.
- Willing and able to understand and complete the written informed consent form.
- Willing to comply with the study protocol.

Exclusion criteria (any 1 of these disqualifies an individual from participating)

- Any contraindications to the use of combined oral contraceptives (COCs) according to the current summary of product characteristics of Effimia, that is, women presenting (or having ever presented) with myocardial infarction, transient ischemic attack, stroke, angina pectoris, deep vein thrombosis, pulmonary embolism (or presence of blood clots in organs other than legs and lungs), any blood clotting disorder (such as protein C deficiency, protein S deficiency, and antithrombin-III deficiency), or who need to undergo surgery or lie down for a long period of time (including the risk of previous deep vein thrombosis, arterial thromboembolism, hypertension in the course of treatment, and diabetes). If any of the listed conditions should appear during the use of the tested COC, the product must be stopped immediately, and the participant withdrawn from the study.
- Severe diabetes with blood vessel damage, heart valve disease with complications, severe hypertension, severe hypercholesterolemia or hypertriglyceridemia, hyperhomocysteinemia, migraine with aura, hepatitis C (and taking medications for this condition), endometrial hyperplasia, or unexplained vaginal bleeding.
- Women who are breastfeeding or pregnant or suspect they are pregnant.
- Current or history of any liver disease not yet recovered (liver function not yet normalized), any benign or malignant tumor of the liver, any breast or genital organs cancer (even suspected), or jaundice during pregnancy or while using hormonal contraceptives.
- Galactose intolerance, total lactase deficiency, or glucose-galactose malabsorption syndrome.
- Hypersensitivity to the active substances or to any excipients of the tested COC (eg, norgestimate, ethinyl estradiol, or lactose).
- Use of any of the following during the study period (according to the summary of product characteristics of Effimia): treatments for tuberculosis (eg, rifampicin), epilepsy (eg, primidone, phenytoin, barbiturates, carbamazepine, or oxcarbazepine), HIV and hepatitis C virus infection (protease inhibitor drugs and nonnucleoside reverse transcriptase inhibitors such as ritonavir, nevirapine, efavirenz, and also ombitasvir, paritaprevir, or dasabuvir), fungal infections (eg, griseofulvin), arthritis, osteoarthritis (etoricoxib), or pulmonary arterial hypertension (bosentan), and St John's wort used as an antidepressant. Medicines containing cyclosporine, antiepileptic lamotrigine, tranexamic acid, theophylline (used to treat respiratory problems), and tizanidine (used to treat muscle pain or cramps) should not be taken as well.
- Use of hormonal contraceptives in the previous month.
- BMI ≥30 kg/m^2 (class I obesity).
- Smoking >15 cigarettes per day.
- Off-label use of COC (eg, for polycystic ovarian syndrome, endometriosis, or recurrent menometrorrhagia).
- Currently taking part or who took part in clinical studies with experimental products in the previous month.
- Incapacity or inability to comply with the study protocol (unreliability in the intake of the product or in the completion of the diary) according to the investigator's opinion.

Ethics Approval

The study protocol and amendments were approved by the ethics committee at the coordinating center (Territorial Ethics Committee—Liguria; application 202100302715-003), with the latest version approved on June 17, 2024. The study is being conducted in accordance with the Declaration of Helsinki (seventh revision, 2013), the Convention of Oviedo in April 1997 and the additional protocol in January 1998, and the national laws, regulations, and applicable guidelines of Italy. In addition, the study is consistent with the International Conference on Harmonization Tripartite Guidelines for Good Clinical Practice requirements. Prior to any procedures, participants are given information about the study and asked to sign an informed consent form. Their personal data are deidentified before being stored and protected according to the current European General Data Protection Regulations. The women do not receive any financial compensation for participating in the study.

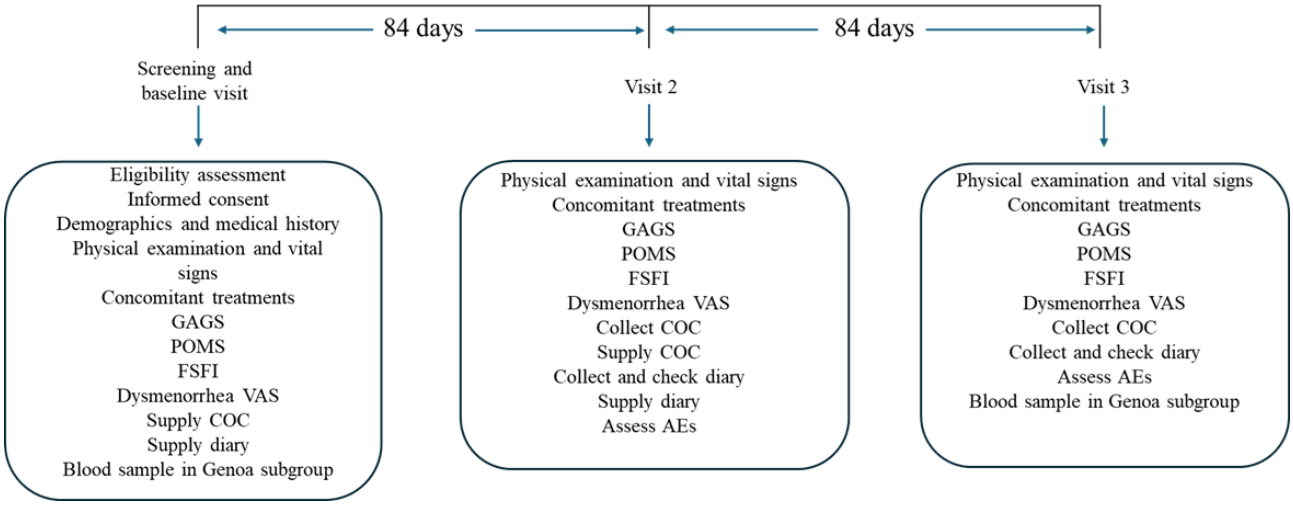
Procedures

During the baseline visit, participants have a physical examination, including an assessment of acne severity (using the Global Acne Grading Scale [GAGS] [21]), and provide a complete medical and menstrual history (Figure 1). They are asked about the characteristics of their menstrual cycle (frequency, duration, regularity, estimated flow volume, and breakthrough bleeding), any unscheduled bleeding, and an evaluation of dysmenorrhea, using a 100-mm visual analog scale (VAS) from 0=no pain to 100=very severe pain. Participants are also being asked to complete a Profile of Mood State (POMS) to assess premenstrual syndrome and the Female Sexual Function Index (FSFI) to evaluate the quality of their sex life, using the validated Italian language versions of these questionnaires [22-24]. At 1 site (Genoa), 28 participants are also providing a blood sample for the assessment of metabolic, endocrine, and coagulation parameters (Textbox 2).

At the baseline visit, participants are provided with NGM/EE 0.25/0.035 mg for the first 3 cycles and a diary, in which they are asked to record cycle evaluation parameters (Table 1), their medication-taking behavior, concomitant medications including over-the-counter medications (start and stop dates and dose), and any AEs.

Study participants are asked to return to the study site for 2 further visits, at day 84 and day 168 (Figure 1), and to bring their diaries and medication with them (whether used, partially used, or not used). At visit 2, researchers check the diaries to verify that participants are completing them correctly and provide them with new diaries and another 3 cycles of NGM/EE 0.25/0.035 mg. At both visits 2 and 3, the same assessments are conducted as at the baseline visit (physical examination, GAGS, POMS, FSFI, and dysmenorrhea VAS), and participants are asked about concomitant treatments, adherence, and AEs. At visit 3, the diaries are collected for final verification, and the subgroup of participants from Genoa provides another blood sample. In the case of an early withdrawal before the end of the sixth cycle, the investigator asks the participant to return for a final visit and records the reasons for the participant's decision to discontinue the study.

Figure 1. Study design. AE: adverse event; COC: combined oral contraceptive; FSFI: Female Sexual Function Index; GAGS: Global Acne Grading Scale; POMS: Profile of Mood State; VAS: visual analog scale.



Textbox 2. Parameters evaluated in blood samples in the subgroup of participants from Genoa.

Metabolic

- Glucose
- Insulin
- Total cholesterol
- High-density lipoprotein cholesterol
- Low-density lipoprotein cholesterol
- Triglycerides

Endocrine

- Total testosterone
- Dehydroepiandrosterone
- Androstenedione
- Sex hormone–binding globulin
- Free androgen index

Related to coagulation

- Fibrinogen
- Factor VII
- Antithrombin III
- Factor VIII
- Protein C
- Thrombin time
- Anticoagulant functional protein C
- Total protein S
- Activated protein C resistance

Table 1. Cycle evaluation parameters.

Parameter	Normal	Abnormal
Frequency	• ≥24 and ≤38 days	• Absent (no bleeding): amenorrhea • Infrequent (>38 days)
Duration	• ≤8 days	• Prolonged (>8 days)
Regularity	• Regular (shortest to longest cycle variation: ≤7 to 9 days[a])	• Irregular (shortest to longest cycle variation: ≥10 days)
Flow volume (participant determined)	• Participant considers normal	• Participant considers light • Participant considers heavy

Breakthrough bleeding (bleeding or spotting between the cyclically regular onset of menses)	• None	• Random
		• Cyclical (predictable):
		  • Early cycle
		  • Mid cycle
		  • Late cycle

Unscheduled bleeding on progestin±estrogen gonadal steroids (contraceptive pills, rings, patches, intrauterine contraceptive devices, or injections)	• None (for a participant on gonadal steroid medication) • Not applicable for participants not on gonadal steroid medication	• Present

[a]Normal variation depends on age; these data are calculated excluding short and long outliers.

Data Management

Investigators collect the information in a validated electronic data system managed by a contract research organization (Advice Pharma Group Srl). The contract research organization is responsible for checking the completeness of the data, monitoring the quality of the data, identifying any extreme values (outliers), and storing the information securely according to legal requirements. Access to the data is strictly limited to authorized personnel only, and individual patient information is deidentified prior to analysis.

End Points

The primary objective of the study is to investigate menstrual cycle control by evaluating breakthrough bleeding (ie, bleeding or spotting between the cyclically regular onset of menses) during the use of the monophasic NGM/EE 0.25/0.035 mg COC. This is measured by calculating the intermenstrual bleeding or spotting occurrence rate at the sixth cycle and comparing this with the rate at baseline.

Secondary outcomes include the change from baseline at visits 2 and 3 in other parameters of cycle control (frequency, duration, regularity, participant-determined flow volume, and unscheduled bleeding), GAGS score, POMS, FSFI, and dysmenorrhea severity based on the VAS rating. Adherence and contraceptive failure rate over the 6-month study period are also secondary outcomes, as are changes from baseline in the metabolic, hormonal, or coagulation parameters in the subgroup of participants from Genoa. Adherence is being evaluated as a percentage of tablets taken, based on the medication returned by participants at each visit. Contraception failure is defined as the proportion of women who become pregnant during the 6-month study period. The reasons for any contraception failure will be identified and listed (eg, discontinuation or poor adherence).

Safety Outcomes

AEs, including any serious adverse events (SAEs), are the key safety outcome. An AE can be any unfavorable and unintended sign (including an abnormal laboratory finding), symptom, or disease temporally associated with the use of NGM/EE 0.25/0.035 mg, whether considered related or not. This may include exacerbation of existing conditions, suspected drug-drug interactions, or clinically significant abnormal laboratory findings, although an abnormal laboratory finding may not be considered as an AE if there is no change compared to baseline values. Abnormal laboratory values or test results represent an AE only if they induce clinical signs or symptoms, are clinically significant, or require therapy. An SAE is any AE that results in death, is life-threatening, requires inpatient hospitalization or prolongation of an existing hospital stay, results in persistent or significant disability or incapacity, or results in a congenital anomaly or birth defect. Other medical events that may jeopardize the participant or may require a medical or surgical intervention to prevent an SAE are also considered to be serious.

Investigators will record any AEs or SAEs in a case report form, with a description of the event, date of occurrence, an assessment of its severity and potential relationship to NGM/EE 0.25/0.035 mg, and the outcome (including date of resolution). If there is at least a reasonable possibility that NGM/EE 0.25/0.035 mg is the cause of the AE (ie, that causality cannot be ruled out), the AE will be considered as an adverse drug reaction. The severity of the AE will be rated as mild (transient and generally not interfering with usual activities), moderate (sufficiently discomforting to interfere with usual activities), or severe (inability to perform usual activities). AEs of special interest in this study are hypertension, arterial thromboembolism,

myocardial infarction, stroke, transient ischemic attacks, venous thrombosis and pulmonary embolism, liver and breast tumors, cancer of the cervix, and disturbances in liver function (such as increased hepatic enzyme levels).

Statistical Analysis

Based on the previous large-scale study with NGM/EE 0.25/0.035 mg, the rate of breakthrough bleeding is expected to decrease from 4.5% before use to 3% after 6 cycles, and the rate of intermenstrual spotting to decrease from 9% to 4% [17]. Therefore, a sample size of 175 participants would have 80% power to detect a treatment effect on breakthrough bleeding at a 1-sided α level of 5%. To account for a potential dropout rate of 30%, we plan to screen 240 women for eligibility and enroll 228 participants, an average of 38 participants at each of the 6 centers.

Two datasets have been defined for analysis: the per-protocol set, which includes all participants with full treatment adherence and no major protocol deviations, and the intention-to-treat set, which includes all enrolled participants who received at least 1 dose of NGM/EE 0.25/0.035 mg. The primary outcome will be evaluated only in the per-protocol population to avoid any effects of noncompliance on the interpretation of this outcome. However, secondary efficacy outcomes and safety will be assessed in the intention-to-treat population using robust statistical methods against missing data, like linear mixed models.

Continuous variables will be described using the mean and standard deviation if they are normally distributed or using the median and interquartile range if nonnormally distributed. The distribution of these variables will be assessed using the 2-tailed Student *t* test for paired data or the Wilcoxon signed rank test. Categorical variables will be described using frequencies and percentages and compared using the chi-square test or Fisher exact test [25]. There will be no imputation for missing data, and data from unscheduled visits will not be included in the analysis. No adjustment for multiplicity will be made to adjust for a type I error in secondary end points. A *P* value of .05 is considered to be statistically significant.

All statistical analyses will be performed using the R statistical software (version 3.5 or later; R Foundation for Statistical Computing). The final analysis will be completed after all participants have completed the study, any queries have been resolved, and the database has been locked.

Results

Study enrollment began in July 2023 and is expected to be complete by December 2025. The last participant's last visit is anticipated to be in June 2026, and data analysis will be complete by October 2026.

Discussion

Overview

We anticipate that our study will confirm previous research [17,18], showing that monophasic COC with NGM/EE 0.25/0.035 mg reduces breakthrough bleeding in healthy women. However, our study will also investigate other effects of this COC on menstrual characteristics (regularity, flow volume, and dysmenorrhea). Moreover, the study will assess the impact of NGM/EE 0.25/0.035 mg on the other factors women want from their oral contraceptives in terms of pregnancy prevention, safety, and tolerability [14].

The absolute risk of VTE is 6.29 per 10,000 woman-years in women taking COCs, which while being twice the rate in women not taking COCs is still low [26]. Although the risk is low, it is still present; therefore, physicians should be vigilant to the potential for this AE among their patients taking COCs. The risk of VTE appears to be lower with NGM than with many other types of progestin [12,13], so we do not anticipate the development of VTE among women participating in this study, which is probably too small and of too short a duration to estimate the incidence of VTE associated with NGM/EE 0.25/0.035 mg. Nevertheless, thromboembolism of any type is an AE of special interest in the study, and any occurrence will be thoroughly investigated and reported.

Our study includes an evaluation of the effects of NGM/EE 0.25/0.035 mg on acne using the GAGS. It is expected that acne will improve during the use of monophasic NGM/EE 0.25/0.035 mg since the exacerbation of acne is usually related to the androgenic potency of the COC [27].

Comparison to Prior Work

The previous large-scale study conducted in Germany among 59,701 women evaluated 342,348 menstrual cycles and showed a reduction in breakthrough bleeding from 4.5% at baseline to 3% during cycle 6 of the COC and in intermenstrual spotting from 9% to 4% during cycle 6 [16]. In the Italian study by Affinito et al [18], in which 92 women received monophasic NGM/EE, the incidence of breakthrough bleeding decreased from 3.3% to 0% at cycle 6, and the rate of spotting from 14.3% to 3.7%. Our study will include at least twice the number of women as in the earlier Italian study and therefore a more robust assessment of the effects of NGM/EE on these menstrual characteristics.

The large German study highlighted the extremely high contraceptive efficacy of NGM/EE, showing a use-efficacy Pearl index of 0.25 (95% CI 0.19-0.31) pregnancies per 100 woman-years [17], and no pregnancies were reported in the earlier Italian study [18]. There was a low incidence of AEs and a high rate of compliance in both these analyses [17,18]. Our study will provide updated information on the contraceptive efficacy, adherence rate, and safety or tolerability profile of NGM/EE 0.25/0.035 mg. The substudy is investigating the effect of NGM/EE 0.25/0.035 mg on lipid and metabolic parameters, expected to be negligible based on previous research [17,18].

Strengths and Limitations

A key difference between our study and the earlier ones is the incorporation of PROs to gather subjective information about the impact of monophasic NGM/EE on the women who take it, specifically the impact on sexuality, mood, and menstrual pain. The inclusion of PROs in our study predated, but is nevertheless consistent with, international consensus recommendations on

research into contraceptive-induced menstrual changes, which recommend investigating the physical and psychosocial impact of these changes on the lives of the women who take them, including their sexual well-being and anxiety or stress [19].

Sexual side effects are a leading reason for women to discontinue or switch contraceptives [28], so it is important to ask women about the effect of COCs on their sexual function. The reported impact of COCs on sexual function is highly variable and encompasses negative, positive, and no effects [29,30]. Female sexuality is complex, and the association between hormone levels and sexuality is nonlinear and multidimensional since a number of different hormones regulate sexual response [29]. Data suggest that the androgenicity of the progestin and the dosage of EE in COCs have a negligible impact on sexual function [31]. Based on the available literature, we do not anticipate a significant effect of NGM/EE 0.25/0.035 mg on sexual function, but to our knowledge, this is one of the first studies to investigate the effects of this COC on sexuality using a validated instrument, the FSFI.

We are also investigating any changes in mood after 6 cycles of NGM/EE 0.25/0.035 mg using the POMS. This instrument has been used previously to investigate changes in mood during oral contraceptive use [32,33], but to our knowledge, this is the first study to use POMS to evaluate mood in women taking NGM-containing COCs.

Finally, our study includes an assessment of the severity of pain associated with menstruation in accordance with international consensus recommendations [19]. Previous studies have evaluated the incidence of pain in women taking monophasic NGM/EE but not the severity of pain [17,18]. This is an important distinction because pain is a continuum rather than a binary outcome. Data indicate that at least 90% of women experience some kind of discomfort during menstruation [34], although their experiences vary across time [35]. Dysmenorrhea is often underreported for many reasons, including that symptoms are considered normal or that women find the symptoms tolerable [36]. Therefore, pain was likely underreported in clinical trials because participants may only report pain that is new, worse, or acute [34]. Using a tool like VAS will provide nuanced information about both the incidence and severity of menstrual pain in women taking NGM/EE 0.25/0.035 mg. Limitations of our study are the absence of a control group and the relatively short duration of follow-up.

Conclusions

This study into the effects of monophasic NGM/EE 0.25/0.035 mg on menstrual characteristics in healthy Italian women will provide up-to-date data on these effects, since there has been no similar study for more than 30 years, and includes the assessment of NGM/EE 0.25/0.035 mg on PROs, in line with recent international consensus recommendations.

Abstract

Background: Childhood cancer survivors (CCS) are at risk of pulmonary dysfunction due to cancer treatments, but evidence on prevalence and risk factors remains limited. Most previous studies had small sample sizes or retrospective study designs, little information about treatments, or a lack of standardization of pulmonary function tests (PFTs) or limited their investigation to certain PFTs. Since spirometry mainly assesses the large airways but cancer therapy also affects peripheral airways, additional functional tests are needed. The nitrogen multiple breath washout test (N_2MBW) is sensitive to peripheral airway damage in other patient populations, but its benefit in CCS is unknown. Therefore, comprehensive and standardized evaluation of pulmonary function after cancer treatment in childhood, using different PFTs that include N_2MBW, is needed to address these knowledge gaps and provide insights into possible early stages of pulmonary dysfunction.

Objective: In the Swiss Childhood Cancer Survivor Study (SCCSS) FollowUp–Pulmo, we will comprehensively assess lung function in children and adolescents after treatment for cancer to identify risk factors for pulmonary dysfunction, assess the ability of N_2MBW to detect pulmonary dysfunction compared to other PFTs, and investigate the association of functional outcomes from PFTs with self-reported respiratory symptoms.

Methods: SCCSS FollowUp–Pulmo is a prospective multicenter longitudinal cohort study embedded in routine clinical care that enrolls CCS aged 6-20 years for whom at least 1 year has passed since a childhood cancer diagnosis, who have completed

treatment, and who attend regular pediatric oncological follow-up care. Inclusion criteria comprise any of the following: systemic anticancer treatment (chemotherapy, immunotherapy, or targeted agents), thoracic surgery, thoracic radiotherapy, or hematopoietic stem cell transplantation (HSCT). CCS undergo a standardized pulmonary assessment, including spirometry, body plethysmography, diffusing capacity of the lung for carbon monoxide (DLCO), and N_2MBW, and complete a questionnaire on respiratory symptoms and lifestyle. Data from previous and subsequent routine care PFTs will be included in this study.

Results: Recruitment started in June 2022 at the University Children's Hospital Bern, Switzerland. Subsequently, patient recruitment expanded to the University Children's Hospitals in Basel and Geneva, Switzerland. By October 2024, we had invited 220 patients, of which 201 have already participated in this study, resulting in a response rate of 91%. Their median age at the time of the study was 14 years (IQR 10-17), and the median time since diagnosis was 7 years (IQR 4-10). The study will continuously enroll new CCS.

Conclusions: This study will contribute to a comprehensive understanding of pulmonary function in CCS and assess related risk factors, as well as the utility of N_2MBW compared to other PFTs. The results will assist in the development of more targeted screening and risk-stratified follow-up care.

Introduction

Survival Rates and Long-Term Complications

Advances in childhood cancer treatment and supportive care have resulted in survival rates that now exceed 80% in high-income countries [1]. Yet, even as cancer treatments are curative in targeting cancer cells, they can harm healthy tissue and potentially cause late complications, such as second neoplasms and chronic diseases [2,3]. The cumulative incidence of such late effects among childhood cancer survivors (CCS) thus predisposes them to increased morbidity and premature mortality [4]. Among late effects, pulmonary complications are the third-leading cause of excess mortality after second neoplasms and cardiovascular diseases [5].

Pulmotoxic Treatments

Several cancer treatment modalities can be pulmotoxic. These include the chemotherapeutic agents busulfan, bleomycin, carmustine, and lomustine; thoracic radiotherapy; thoracic surgery; and hematopoietic stem cell transplantation (HSCT) [6,7]. The underlying mechanisms of pulmonary toxicity involve alveolar, vascular, and parenchymal damage resulting from chemotherapy and radiotherapy, which may progress to lung fibrosis [6-8]. HSCT-related lung damage can result from intensive conditioning regimens, infections, or graft-versus-host disease (GvHD), while surgery of the chest or lungs may reduce lung volumes and impair chest wall compliance [7,9]. However, recently published recommendations for surveillance of pulmonary function among CCS from the International Late Effects of Childhood Cancer Guideline Harmonization Group (IGHG) could not consistently confirm the pulmonary toxicity of all these treatments, particularly certain chemotherapeutics, due to limited and low-quality evidence [10]. Other chemotherapeutics, such as methotrexate and cyclophosphamide, have also been suspected of causing lung damage [8,11], but findings across studies remain inconsistent [12,13]. Considering that these treatments may harm developing lungs and potentially lead to progressive pulmonary damage [14], it is important to study their effects on lung function.

Prevalence and Detection of Pulmonary Dysfunction

Pulmonary dysfunction in CCS exposed to pulmotoxic treatments has been reported in varying proportions of CCS (44%-77%), depending on study populations and criteria used to define obstructive, restrictive, and diffusion impairments [12,13,15,16]. The lung has a large functional reserve, and early disease may often remain asymptomatic, particularly when it affects the lung periphery [17]. Most studies have used conventional pulmonary function tests (PFTs), such as spirometry, body plethysmography, and diffusing capacity of the lung for carbon monoxide (DLCO), to assess lung function in CCS. However, spirometry and body plethysmography lack the sensitivity to detect changes in small airways [18], which may be damaged first [6]. The nitrogen multiple breath washout test (N_2MBW), which measures ventilation inhomogeneity of the ventilated lung, detecting small airway disease, has been increasingly used in other patient populations, including those treated with allogeneic HSCT [19-21]. In a small prospective study of adult CCS, N_2MBW identified more cases of pulmonary dysfunction than spirometry, even among those who had not been exposed to previously defined pulmotoxic treatments [22]. Though larger prospective studies with standardized assessments are still needed, these findings suggest that N_2MBW could be a valuable complementary test in screening CCS for early pulmonary damage.

Current Knowledge Gaps

The recently published IGHG recommendations not only summarized existing evidence but also highlighted large knowledge gaps and methodological weaknesses in previous research [10]. These gaps emphasize the need for prospective, longitudinal studies with larger sample sizes and a broader range of treatment exposures to characterize the onset and progression

of treatment-related pulmonary dysfunction. The long-term effects of newer chemotherapeutic and immunotherapeutic agents on lung function are understudied [23]. Evidence on how treatment-related complications, comorbidities, and genetic variants influence lung damage risk is limited as well. Similarly, standardization is lacking in PFTs and in the use of appropriate age- and sex-specific reference values. For example, results should be reported as z-scores rather than just proportions of patients with reduced lung function. Additionally, few studies have assessed diagnostic tests specific to the location and type of potential dysfunction, such as N_2MBW for peripheral inhomogeneity in ventilation. More data are also needed on the association between PFT outcomes and clinical symptoms. To address these gaps, we designed the Swiss Childhood Cancer Survivor Study (SCCSS) FollowUp–Pulmo.

Study Objectives

The primary objective of SCCSS FollowUp–Pulmo is to longitudinally investigate lung function in children and adolescents after cancer treatment using a comprehensive set of PFTs that also assess small-airway disease. Second, the study will investigate possible effects of treatment-related risk factors (systemic anticancer agents, thoracic radiotherapy, thoracic surgery, and HSCT), treatment-related complications (pulmonary infections, GvHD), and existing comorbidities (eg, pulmonary or cardiac disease) on lung function. Third, the study will examine the ability of N_2MBW to detect pulmonary dysfunction in comparison with other PFTs. Fourth, it will investigate the association between lung function and self-reported respiratory symptoms.

Methods

Study Design and Inclusion Criteria

SCCSS FollowUp–Pulmo is a multicenter prospective longitudinal cohort study integrated into the routine clinical care of several children's hospitals in Switzerland. The study is an interdisciplinary collaboration between the pediatric hematology/oncology and pediatric pulmonology departments of respective centers, the Institute of Social and Preventive Medicine (ISPM) at the University of Bern, and the Swiss Childhood Cancer Registry (ChCR). The ChCR is a nationwide, population-based cancer registry that includes Swiss residents diagnosed up to the age of 20 years with leukemia, lymphoma, central nervous system (CNS) tumors, malignant solid tumors, or Langerhans cell histiocytosis, classified according to the *International Classification of Childhood Cancer, Third Edition* (ICCC-3) [24]. Although the ChCR captures over 95% of children diagnosed in Switzerland [25], SCCSS FollowUp–Pulmo will also include a few patients treated and followed up in Swiss clinics who may not be registered in the ChCR due either to registration delays or residency outside of Switzerland.

All CCS aged 6-20 years for whom 1 year or more has elapsed since cancer diagnosis, who have completed treatment, and who are in regular pediatric hemato-oncological follow-up care are eligible for SCCSS FollowUp–Pulmo. The following treatment modalities possibly affecting lung function are included in SCCSS FollowUp–Pulmo: any systemic anticancer treatment (chemotherapy, immunotherapy, or targeted therapy) [26]; thoracic surgery involving the chest or lungs (excluding central line placement) [27]; radiation of the lungs, the chest (axilla, mantle, mediastinal), or scattered radiation from other radiation fields, including the whole abdomen or any upper abdominal field, spinal doses of 30 Gray or higher, and total body irradiation [27]; and HSCT [28]. Excluded are CCS who were treated only with surgery or radiation outside the thorax due to their low risk for pulmonary dysfunction [29] and patients with relapse or in palliative care at the time of recruitment.

Ethical Considerations

Ethical approval was granted by the Ethics Committee of the Canton of Bern, Switzerland (KEK-BE: 2019-00739), and the study is registered on ClinicalTrials.gov (NCT04732273). All participants provide a signed informed consent form. If any patient declines to participate, their data are not collected. Data are entered into the Research Electronic Data Capture (REDCap) database version 14.0.10 (Vanderbilt University), which complies with legal requirements for data security and data protection.

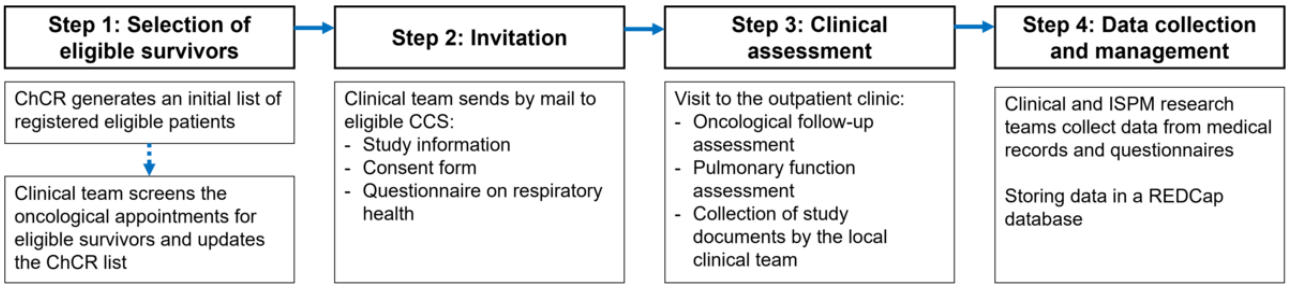
Study Procedures

The study is coordinated by the ISPM research team, which is responsible for overall study management, monitoring recruitment progress, and handling administrative and financial aspects. Clinical teams at each participating center include pediatric oncologists, pulmonologists, data managers, and study nurses.

Step 1: Selection of Eligible CCS

Eligible CCS are identified in 2 ways: (1) the ChCR provides an initial list of eligible patients to participating hospitals, and (2) a member of the clinical team regularly screens upcoming follow-up appointments, cross-referencing with the ChCR and identifying any additional eligible patients (Figure 1). This process ensures the inclusion of all eligible patients. The treating physician organizes pulmonary function assessments for the upcoming oncological follow-up appointment. Detailed recruitment procedures are developed at each center to consider clinical workflows.

Figure 1. Flowchart of SCCSS FollowUp–Pulmo procedures. CCS: childhood cancer survivors; ChCR: Swiss Childhood Cancer Registry; ISPM: Institute of Social and Preventive Medicine; REDCap: Research Electronic Data Capture.



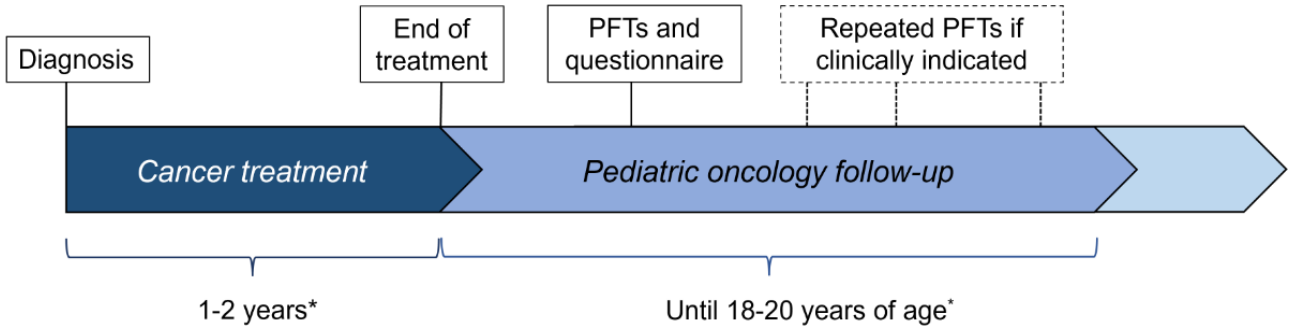
Step 2: Invitation

The clinical team sends the study information, consent form, and a questionnaire on respiratory health to eligible survivors prior to their next oncological follow-up appointment that will include PFTs. CCS who consent to participate send the documents back or bring them to the consultation.

Step 3: Clinical Assessment

At the oncological follow-up assessment, patients first meet their pediatric oncologist, who obtains a history, performs a physical examination, and refers them to pediatric pulmonology for PFTs. Since the PFTs are scheduled within the follow-up care, they are conducted irrespective of study consent. Patients with pathological results will undergo repeated PFTs, as clinically indicated (Figure 2). The clinical team collects the signed consent form and questionnaire. If patients do not complete the consent form and questionnaire prior to or during the clinical visit, they can still return the documents later. If a patient declines to participate, no data are collected for study purposes.

Figure 2. Timeline of pulmonary function assessments during SCCSS FollowUp–Pulmo. *The duration of cancer treatment varies based on the specific cancer diagnosis and the corresponding treatment protocol, while the age at which a patient transitions out of pediatric oncology follow-up may vary individually, depending on the cancer treatment protocol and the practices of the respective center. PFT: pulmonary function test; SCCSS: Swiss Childhood Cancer Survivor Study.



Step 4: Data Collection and Management

The clinical team at the respective study centers and the research team at the ISPM extract the data of each consenting participant from medical records, PFTs, and questionnaires. All data are stored in the REDCap database. In the database, each patient has a unique REDCap ID.

Exposures and Outcomes of Interest

Pulmonary Function Tests

CCS undergo a set of PFTs, including spirometry, body plethysmography, DLCO, and N_2MBW, according to the American Thoracic Society/European Respiratory Society (ATS/ERS) recommendations [30,31]. PFTs are conducted in pediatric lung function laboratories by trained technicians. Standard operating procedures for PFTs are harmonized among centers to ensure comparability, with quality control performed by lung function technicians. Because N_2MBW is not yet widely used in clinical settings, centralized quality control is additionally performed to ensure that only high-quality tests and the latest algorithms are included. Specialized software developed by experts at the University Hospital in Bern detects evidence of leaks, insufficient waiting time between tests, early termination of tests, synchronization issues, and abnormal breathing patterns or volumes in accordance with consensus guidelines [32,33]. Experienced pulmonologists interpret and review the results of PFTs.

Since asthma and allergic conditions are common differential diagnoses in young patients, including CCS, most clinics also measure fractional exhaled nitric oxide (FeNO) in those with obstructive patterns on spirometry or asthma-like symptoms [34]. High FeNO levels suggest an asthmatic or allergic etiology, while low levels may indicate noninflammatory causes related to cancer treatment effects.

Table 1 shows the main outcome measures from PFTs, their interpretation, anatomical correlates, and studies for reference values used for respective PFTs. SCCSS FollowUp–Pulmo also collects all prestudy PFT data from patients who previously underwent these assessments and subsequent PFTs conducted as part of ongoing clinical care.

Table 1. PFTs[a] performed in CCS[b], their interpretation, and anatomical correlates.

Test	Main outcomes	Meaning of abnormal results	Anatomical correlates	Reference values
Spirometry	FVC[c], FEV_1[d], FEV_1/FVC, $FEF_{25\%-75\%}$[e]	Airway obstruction, reduced dynamic lung volume	Fibrotic destruction of lung tissue and large airways, reduced lung compliance	Quanjer et al [35]
Body plethysmography	FRC[f], SR_{eff}[g], SR_{tot}[h], RV[i], TLC[j], VC[k]	Reduced static lung volume, hyperinflation	Fibrotic destruction of lung tissue and large airways, reduced lung compliance	Hall et al [36]
DLCO[l]	DLCO	Reduced alveolar-capillary gas transfer, reflected by diffusion deficits	Alveolar-capillary membrane damage	Stanojevic et al [37,38]
N_2MBW[m]	LCI[n], S_{ACIN}[o], S_{COND}[p]	Increased ventilation inhomogeneity of airways with reduced global, alveolar, and conducting ventilation	Fibrotic damage of small airways	Ramsey et al [39]
FeNO[q]	FeNO	Eosinophilic airway inflammation as a key component of allergic asthma	Allergic inflammation as an alternative cause of pulmonary obstruction	Jacinto et al [34]

[a]PFT: pulmonary function test.

[b]CCS: childhood cancer survivors.

[c]FVC, forced vital capacity.

[d]FEV_1, forced expiratory volume in 1 second.

[e]$FEF_{25\%-75\%}$, forced expiratory flow at 25%-75% of the FVC.

[f]FRC, functional residual capacity.

[g]SR_{eff}: specific effective resistance.

[h]SR_{tot}: specific total resistance.

[i]RV: residual volume.

[j]TLC: total lung capacity.

[k]VC: vital capacity.

[l]DLCO: diffusion capacity of the lung for carbon monoxide.

[m]N_2MBW: nitrogen multiple breath washout test.

[n]LCI: lung clearance index.

[o]S_{COND}: conductive ventilation inhomogeneity index.

[p]S_{ACIN}: acinar ventilation inhomogeneity index.

[q]FeNO: fractional exhaled nitric oxide (measured in CCS with symptoms suggestive of asthma, eg, wheeze, dyspnea, cough, or signs of obstruction in spirometry).

Medical and Questionnaire Data

Information obtained from medical records includes anthropometric measures, respiratory disease history, physical evaluation, PFTs, cancer diagnosis and treatment, and additional data from the medical history, including comorbidities and significant treatment-related complications (GvHD, pulmonary infections) (Table 2). CCS complete a detailed questionnaire on respiratory health that includes sections on respiratory symptoms, infectious diseases, exercise-induced problems, allergic and pulmonary diseases, family history of respiratory conditions, lifestyle and environmental factors, and sociodemographic information.

Table 2. Description of medical and questionnaire data collected as part of SCCSS[a] FollowUp–Pulmo.

Data source and data items	Description
Medical records	
Personal information and anthropometric measures	• Date of birth • Sex • Height • Weight • BMI
Respiratory history and physical evaluation	• Recent history of airway infections • Lung auscultation • Thoracic inspection • Signs of dyspnea • Oxygen saturation
PFTs[b,c]	• Spirometry • Body plethysmography • DLCO[d] • N_2MBW[e] • FeNO[f]
Cancer diagnosis	• Date of diagnosis • Type of cancer and location • Metastases • Relapse • Second malignant neoplasm
Cancer treatment	• Treatment protocol and arm • Start and end dates • Cumulative doses of all individual chemotherapy drugs, targeted agents, and immunotherapies • Radiotherapy (cumulative dose, location, duration) • Surgery (location, type) • HSCT[g] (autologous or allogeneic, donor type and source, conditioning regimens, complications)
Additional data from medical history	• GvHD[h] (acute or chronic, affected organs, grade, treatment) • Significant pulmonary infections during or after cancer treatment (diagnosis, causing pathogen, duration of hospitalization) • Comorbidities
Questionnaire	
Respiratory symptoms	• Cough (type, duration, with or without a cold) • Wheeze (frequency, duration, triggers) • Dyspnea(frequency, duration, triggers)
Infectious diseases[i]	• Otitis • Sinusitis • Pneumonia
Exercise-induced problems	• Frequency • Types • Triggering situations
Allergic diseases	• Allergic rhinitis • Hay fever • Atopic dermatitis
Pulmonary diseases[j]	• Asthma • Bronchitis • Lung fibrosis • Emphysema

Data source and data items	Description
Lifestyle and environment	• Physical activity (compulsory school sport, recreational sport) • Active and passive smoking (amount and type of tobacco products)
Sociodemographic data and family history	• Citizenship • Parental education and profession • Family history of asthma, chronic bronchitis, hay fever, and atopic dermatitis

[a]SCCSS: Swiss Childhood Cancer Survivor Study.

[b]PFT: pulmonary function test.

[c]For each pulmonary function test, the date, test quality, and multiple outcomes (as listed in Table 1) are recorded.

[d]DLCO: diffusing capacity of the lungs for carbon monoxide.

[e]N_2MBW: nitrogen multiple breath washout test.

[f]FeNO: fractional exhaled nitric oxide.

[g]HSCT: hematopoietic stem cell transplantation.

[h]GvHD: graft-versus-host disease.

[i]Data includes the recurrence and treatment of each disease.

[j]Data includes the treatment of each disease.

Sample Size Calculation

To determine the sample size needed for our study, we based calculations on the study by Schindera et al [22], who assessed lung function in long-term CCS using spirometry and N_2MBW. This single-center study was conducted on Swiss CCS and applied the same inclusion criteria for treatment exposures, making it a suitable reference. The main outcome from N_2MBW was the lung clearance index (LCI). The mean LCI z-score was 1.37 (SD 2.69). We calculated the number of participants necessary to achieve a statistical significance level of 0.05 and a power of 0.80, while accounting for a 15% dropout rate. This calculation indicated that a minimum of 146 participants would be required to detect a similar deviation in LCI with sufficient statistical power. We plan to include a larger sample size to increase precision, improve our ability to detect smaller deviations, and ensure adequate power to analyze other lung function outcomes and investigate specific subgroups of patients defined by tumor type and treatments received.

Statistical Analysis

To compare PFT outcomes with normal values, we will calculate z-scores and percent-predicted values using external Global Lung Initiative (GLI) reference data [35-37,39]. We will define pulmonary dysfunction as z-scores below –1.64 or above +1.64 for respective PFT indices since these thresholds represent deviations from the reference population mean and indicate abnormalities in pulmonary function. To characterize pulmonary function among CCS, we will analyze z-scores for predefined outcomes and assess differences based on characteristics such as treatment exposure, age at treatment, and time since cancer diagnosis. We will assess group differences using appropriate statistical tests based on the type of variable, such as the *t*-test or the Mann-Whitney test for continuous variables and the χ^2 test or the Fisher exact test for categorical variables. For analyses of associations between outcomes and covariates, we will apply regression models adjusted for potential confounders. For longitudinal data, we will use mixed effects models to account for repeated measures over time. We will use Stata (Stata Corp LLC) and R (Foundation for Statistical Computing) for statistical analyses.

Results

Recruitment started in June 2022 at the University Children's Hospital in Bern, in March 2023 at the University Children's Hospital in Basel, and in March 2024 at the University Children's Hospital in Geneva. The number of new participants per month varies across the centers, depends on clinical capacity, and is steadily growing (Figure 3). As of October 2024, a total of 220 patients had been invited to participate in the study. Of those, 201 patients consented to and underwent PFTs, resulting in a response rate of 91%. Bern registered 125 (62%) participants, Basel 70 (35%), and Geneva 6 (3%). The time required to perform all PFTs and complete the questionnaire was 45-60 minutes per participant.

More than half of the 201 participants (n=119, 59%) were male, the median age at the time of the study was 14 years (IQR 10-17), and the median time since diagnosis was 7 years (IQR 4-10), as shown in Tables 3 and 4. The most common diagnoses were leukemia (n=105, 52%), lymphoma (n=22, 11%), and neuroblastoma (n=18, 9%). All but 2 (1%) participants had been treated with chemotherapy, 25 (13%) had received thoracic radiotherapy, and 15 (8%) had undergone thoracic surgery. In total, 20 (10%) participants had undergone HSCT, with 11 (6%) having been treated with autologous and 9 (4%) with allogeneic HSCT.

Discussion

Summary

This prospective, multicenter cohort study of lung function in children and adolescents after cancer treatment investigates risk factors, compares the detection of pulmonary dysfunction using N_2MBW and conventional PFTs, and examines the association of functional outcomes from PFTs with respiratory symptoms.

Comparison With Previous Research

Previous studies of pulmonary dysfunction after treatment for childhood cancer have mostly been retrospective, based on chart reviews [14,40-42]. This has entailed methodological weaknesses, particularly a risk of selection bias because CCS for whom PFT results were obtained might overrepresent symptomatic CCS or those treated more intensively. We identified several prospective studies on pediatric CCS, but like the retrospective ones, they mostly recruited specific groups of patients treated with previously defined pulmotoxic treatments, such as HSCT [42-44] or thoracic radiation [14,45], or specific tumor types like leukemia [46] or lymphoma [47,48]. Data on the pulmotoxic effects of individual agents, such as busulfan [49], melphalan [50], cyclophosphamide [46,50], and methotrexate [51], remain limited. By including CCS exposed to systemic therapies, including any chemotherapy, targeted agents, or immunotherapy, our study will provide a better understanding of treatment-related pulmonary dysfunction in a broadly representative population of CCS. Continuous recruitment will allow us to collect data on the pulmonary effects of newer treatments used in contemporary protocols, whose impacts remain largely unknown [52]. Detailed information from medical records will allow the investigation of effects of comorbidities and treatment-related complications on PFT outcomes.

Previous studies have rarely included sensitive tests, such as N_2MBW, that can detect early changes in the lung periphery. Most have used spirometry, body plethysmography, and DLCO [12,14,15,49]. A study investigating 57 pediatric CCS with a median follow-up time of 6.2 years from end of treatment did not find differences in ventilation inhomogeneity measured using N_2MBW compared to healthy controls [53]. In contrast, several studies on patients after allogeneic HSCT have reported the LCI to be a sensitive measure for early pulmonary complications [20,21,54]. This study will obtain N_2MBW data for CCS exposed to a wide range of treatment modalities and investigate whether N_2MBW is more sensitive than other PFTs in detecting early pulmonary dysfunction.

Another drawback of many existing studies is that they report PFT data using binary cut-offs and describe results as either normal or abnormal [12,15,49]. This reduces statistical power and introduces interpretations based on predefined threshold values. Reporting PFT results as raw data and z-scores based on internationally agreed-upon, age-adjusted reference values will allow better comparison and pooling across studies. Limited data exist on how lung function correlates with clinical symptoms [10]. Questionnaire data collected in this study will help investigate symptoms and other patient-reported outcomes, as well as their correlation with PFT results.

Collaboration With Other Ongoing Studies

The SWISS-Pearl Study (ClinicalTrials.gov ID: NCT05427136), currently conducted in multiple centers in Switzerland, investigates lung function in patients with pediatric cancer. The study includes spirometry, body plethysmography, N_2MBW, magnetic resonance imaging of the lungs, and questionnaires at different points during cancer treatment. We plan to combine that study with ours to create a comprehensive database, enabling us to analyze lung function trajectories in patients and survivors of pediatric cancer.

The GECCOS (Genetic Risks for Childhood Cancer Complications Switzerland) study is a nationwide cohort study collecting germline genetic data from patients and survivors of childhood cancer in Switzerland [55]. In consenting patients, we will link clinical and PFT data with the genetic data from GECCOS, allowing us to investigate the effects of genetic predisposition on pulmonary toxicity. This will assist the development of personalized treatment strategies and risk-adapted long-term care for survivors.

Study Limitations

A current limitation of this study is the limited number of participants and the heterogeneity of the study population, which can limit the statistical power for conducting subgroup analyses. For instance, exploring rare tumors or assessing specific effects of individual chemotherapeutic agents may at present be challenging. However, we plan to expand the study to more centers and pool data with international collaborations. Another limitation is the lack of systematic baseline PFT assessments before cancer treatment, making it difficult to distinguish treatment-related pulmonary dysfunction from preexisting conditions. Future studies should include pretreatment PFTs to better track changes in z-scores over time and improve the assessment of therapy-related effects. Finally, there is a small risk of selection bias because CCS with a longer time since the end of treatment, who do not experience respiratory symptoms or were not exposed to pulmotoxic treatments, may be less likely to participate in the study, potentially leading to underrepresentation of healthy CCS. Yet, because the study is embedded in regular follow-up care and supported by oncologists, with initial results showing a high participation rate, exceeding 90%, this bias should be minimal.

Conclusion

This multicenter cohort study prospectively investigates pulmonary dysfunction in young CCS. By assessing lung function as an intermediate outcome, rather than established disease or mortality, this study will provide a resource for evaluating pulmonary dysfunction at an earlier stage in the disease trajectory, particularly within the early years posttreatment. The initial response shows that integrating standardized pulmonary evaluations into routine follow-up care in Switzerland is feasible and widely accepted by both survivors and health care providers. The findings of this study will provide new insights to inform the development of guidelines and recommendations for pulmonary follow-up care.

Acknowledgments

We would like to acknowledge all childhood cancer survivors for their participation in the study. We thank the clinical teams from participating centers and the quality control team at the University Hospital in Bern. We thank the study team of the Childhood Cancer Research Group, Institute of Social and Preventive Medicine, University of Bern, and the team of the Swiss Childhood Cancer Registry. We also appreciate the editorial assistance provided by Christopher Ritter.

This work was supported by the Swiss Cancer Research and Swiss Cancer League (grant nos: KFS-5027-02-2020, KFS-5302-02-2021, KLS/KFS-4825-01-2019), Childhood Cancer Switzerland, Kinderkrebshilfe Schweiz, Stiftung für krebskranke Kinder-Regio Basiliensis, the CANSEARCH Foundation, and the Association Jurassienne d'Aide aux Familles d'Enfants atteints de Cancer (AJAFEC).

Data Availability

Researchers interested in collaborative work can contact the corresponding author (CK) to discuss planned projects.

Authors' Contributions

All authors contributed to the study's conception and design. MŽ, CS, GS, and CK wrote the initial draft of the manuscript, and all authors provided feedback on earlier versions. All authors have read and approved the final manuscript.

Conflicts of Interest

PL reports relationships with Vertex, OM Pharma, Vifor, Polyphor, Santhera, Allecra, and Sanofi Aventis. These include grants, consulting fees, payments for lectures, advisory board memberships, and travel reimbursement. None of these relationships are associated with this study.

Abstract

Background: ChAdOx-1s, CoronaVac, BBIBP-CorV, mRNA-1273, and BNT162b2 are the five common COVID-19 vaccines used in Jakarta. Randomized controlled trials have provided robust evidence of the safety and efficacy profile of these vaccines, but their real-world vaccine effectiveness against symptomatic COVID-19 and deaths in communities with social inequalities and health care constraints remains unclear.

Objective: This study aims to evaluate the real-world effectiveness of these COVID-19 vaccines during the waves associated with the Delta and Omicron variants by analyzing existing electronic health care sources.

Methods: A population-based study with a test-negative case-control design will be used to evaluate COVID-19 vaccine effectiveness in Jakarta, focusing on the Delta and Omicron waves. It includes adults 18 years and older who underwent reverse transcription polymerase chain reaction testing for symptomatic COVID-19, classifying them as cases or controls based on their test results. The analysis will consider multiple COVID-19 vaccines introduced during these periods, with participants categorized by vaccination status. Several potential confounders will be assessed, including demographic factors and comorbidities. Data will be linked from various health datasets, and statistical analyses will be performed to determine vaccine effectiveness and potential waning immunity over time. After data linkage, patients' identities will be encrypted.

Results: The research, funded from 2022 to 2024, involved proposal preparation and ethical review in 2023 and enrollment from early 2024 to July 2024, resulting in about 4 million linked data points. Data analysis is ongoing, with initial results expected for publication in early 2025.

Conclusions: This study will be the first to evaluate the effectiveness of different types of COVID-19 vaccines (inactivated, viral-vector, and mRNA) used in Jakarta during the pandemic, providing valuable scientific evidence to inform future vaccination strategies in the country.

KEYWORDS

COVID-19; protocol; vaccine; vaccine effectiveness; Delta; Omicron

Introduction

Background

Since its emergence in December 2019, SARS-CoV-2, which is the virus that causes COVID-19, has been continuously spreading worldwide [1]. As of November 12, 2021, this pandemic has caused more than 250 million cases and more than 5 million deaths over the previous 2 years [2]. Vaccination programs are one of the most successful public health interventions that primarily aim to develop herd immunity and protection against pathogens. To date, the World Health Organization has approved 8 COVID-19 vaccines that are efficacious in preventing infection, reducing the level of severity and the number of deaths due to SARS-CoV-2 infection [3]. However, most data were generated from clinical trial studies that were different from a real-world setting due to their well-controlled nature [4]. Furthermore, real-world vaccine effectiveness (VE) studies were mostly conducted in high-income nations, and few studies came from low- and middle-income countries, even though these countries might have unique social and economic characteristics that not only affect vaccination acceptance but also disease outcomes [5]. A previous study has reported the association of living in an impoverished neighborhood with an increased risk for mortality even after COVID-19 vaccination [6]. Therefore, studies investigating how these COVID-19 vaccines might perform in real-world settings where social inequalities exist are still essential for informing policies and strategies to improve disease outcomes in future pandemics, especially in societies with health care system constraints [7]. This study aims to evaluate COVID-19 VE against symptomatic and fatal SARS-CoV-2 infection during the Delta and Omicron waves in Jakarta, where income inequality and socioeconomic segregation have become a common phenomenon [8].

Study Objectives

The primary objective is to study real-world VE against symptomatic COVID-19 (mild, moderate, and severe).

The following secondary objectives were also explored:

- Real-world VE against mortality 30 days after the first positive COVID-19 result
- Real-world VE based on vaccination status at the time of the reverse transcription polymerase chain reaction (RT-PCR) test
- Real-world VE based on the time since receipt of the last vaccine dosage

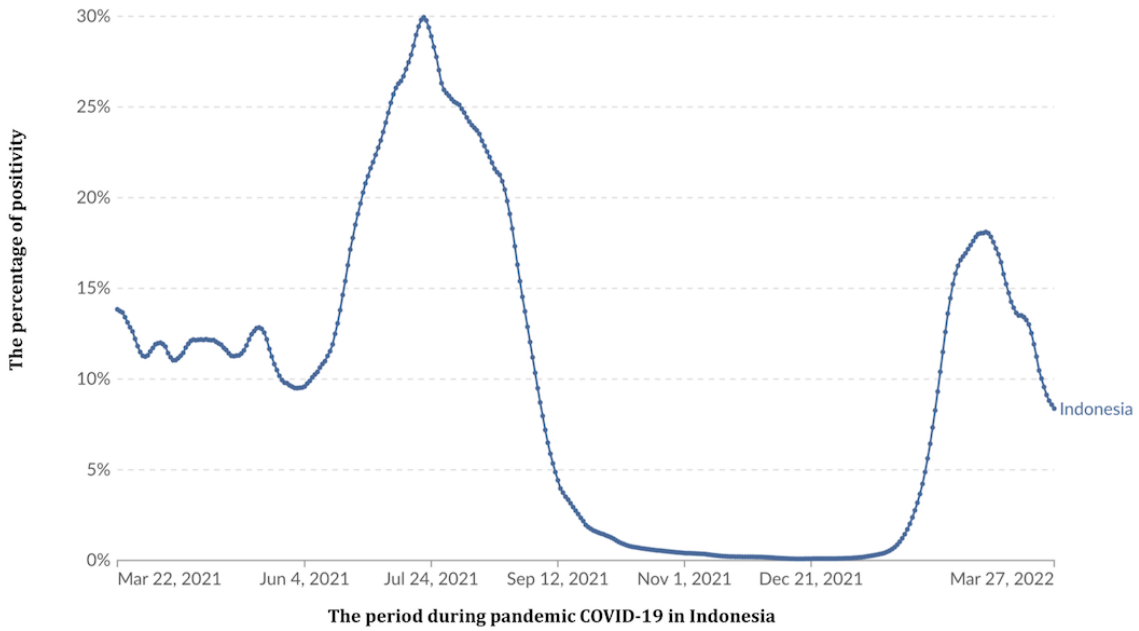
Methods

Study Design and Setting

This population-based study adopts a test-negative case-control design to analyze COVID-19 VE against symptomatic and fatal SARS-CoV-2 infection from available health care datasets in the Special Capital Region of Jakarta, one of the provinces with the highest population density (15,900 people per km^2 in 2020) and case rate per population relative to other regions in Indonesia [9]. Despite its robust development and economic growth, the contrast between rich and poor neighborhoods was highly prevalent in many parts of Jakarta's districts [8,10].

This study will estimate VE against COVID-19 during the period of interest, which were the COVID-19 waves associated with the Delta and Omicron variants, from June 1 to August 31, 2021, and January 1 to April 2, 2022, respectively. Within each of these periods, a cycle of sustained upward and downward trends of the test positivity rate was observed [11-15] (Figure 1). Furthermore, the Delta and Omicron variants were estimated to be responsible for around 90% of SARS-CoV-2 infections in Jakarta during these two periods [14,16].

Figure 1. Trend of the national COVID-19 positivity rate in Indonesia from 2021 to 2022. This modified image is cited from Our World in Data.



During the Delta and Omicron periods, several brands of COVID-19 vaccines were introduced in Jakarta for vaccine rollout, such as AstraZeneca, SinoVac-CoronaVac Biofarma, Covovax-Novovax, Indovax, Johnson & Johnson, Moderna, Sinopharm BBIBP, and Pfizer (Table S1 in Multimedia Appendix 1) [17]. Among these COVID-19 vaccines, Coronavac-Sinovac was the earliest COVID-19 vaccine to be introduced in January 2021 and used for mass vaccinations of doses 1 and 2, followed by AstraZeneca, Sinopharm, Pfizer, and Moderna in August 2021 [18,19]. Booster vaccinations 6 months after the 2-dose primary vaccination with Moderna and Pfizer vaccines were initially introduced to health care workers in July 2021, followed by the approval of the AstraZeneca vaccine as a booster in the national vaccination program in January 2022 [20,21]. To expedite the booster vaccination coverage, the timeline for booster administration was shortened to 3 months after the 2-dose primary vaccination, and additional inactivated COVID-19 vaccines, such as SinoVac and Sinopharm, were included in the national booster program [22]. Different from Pfizer, Moderna, and AstraZeneca, these inactivated COVID-19 vaccines were only approved as boosters for patients who received similar vaccine platform for their primary vaccination regimen [23]. Until the end of the Omicron period, all of the distributed COVID-19 vaccines in Jakarta were developed from the ancestral strain of SARS-CoV-2.

Study Participants

The study will include people 18 years or older who domiciled in Jakarta and underwent an RT-PCR test for SARS-CoV-2 infection due to symptoms of influenza-like illnesses within 10 days of the test date. Although people may have more than one RT-PCR result during the period of interest, this study will only account for the first positive or negative result per person as the index test date for each of the COVID-19 waves. People who had at least one sample with a positive SARS-CoV-2 RT-PCR result during the period of interest will be classified as cases, while people with a negative SARS-CoV-2 RT-PCR without any positive results over the period of interest will be classified as controls.

People with a positive RT-PCR test result within 90 days of the preceding index test date, with inconclusive RT-PCR results, who received different vaccines for dose 1 and dose 2 or a heterologous primary vaccine series, or who had a time interval between dose 1 and dose 2 that was less than the government recommendation (<21 days for Pfizer and Sinopharm, <28 days for CoronaVac and Moderna, and <12 weeks AstraZeneca) will be excluded from the analysis. We will also exclude people with incomplete vaccination records, such as people who declared receiving 2 vaccine doses without being able to verify the previous dose.

Study Variables

The primary outcome in this study is symptomatic SARS-CoV-2 infection, defined as a positive RT-PCR test within 10 days from the onset of influenza-like illness. The secondary outcome in this study is fatal SARS-CoV-2 infection, defined as death within 30 days after a positive RT-PCR test result [24]. Meanwhile, the primary exposure in this study was vaccination status, which can be classified as unvaccinated, dose 1 or partial vaccination, dose 2 or primary vaccination, and booster dose. People without any vaccination entries after data linkage with the PCARE Vaksin dataset at the end of each period of interest will be classified as unvaccinated persons. For vaccinated people, we will only consider the last vaccination data entry that happened before the patients' index RT-PCR test date.

Several covariates should be assessed as potential confounders in the study, such as age in years at the index test date, gender, calendar week of the RT-PCR collection during the period of interest, living in impoverished neighborhoods, presence of any

comorbidities, occupation, and reinfection status. The calendar week of the RT-PCR collection during the period of interest will be presented as a whole number starting from week 1 as the start of the period of interest. Living in an impoverished neighborhood will be presented as a dichotomous variable. People will be classified as living in an impoverished neighborhood if their neighborhood number at the subdistrict level is listed as one of the impoverished neighborhoods in the 2018 Jakarta Governor's regulation concerning improving the quality of settlements in residential areas. Occupation will be presented as categorical variables that consist of health care worker, public or government official, and civilian. Reinfection or people with previous SARS-CoV-2 infections will be presented as a dichotomous variable. People with a previous positive RT-PCR SARS-CoV-2 result that occurred more than 90 days after the current case will be classified as people with a previous SARS-CoV-2 infection [25].

To control for unmeasured confounders [26], such as societal preventive measures or the changing dynamic of the viral transmission within the community, this study will match each case with a control using a ratio of 1:2 by matching for age within 10 years of the case's age, gender, and the calendar week of the RT-PCR collection during the period of interest. The matching procedure will be assessed with standardized mean differences, with values less than 0.1 indicating sufficient matching [27,28].

Data Sources

This study will analyze the final datasets derived from the integration of several datasets provided by the Jakarta Provincial Health Office, Ministry of Health, and Social Security Agency on Health after April 2022 (Table 1). Variables such as ID number and date of birth will be used for the dataset linkage (Figure 2). From the New All Records (NAR) and Suspect and Probable (SUSPROB) datasets, symptomatic people with a positive or negative first RT-PCR test result within each of the periods of interest will be identified as cases or controls. Furthermore, people identified as cases will be linked to the entries in the REV POS dataset to extract the outcome of their disease course (Figure 2). People with incomplete data for ID number, date of birth, gender, swab collection date, PCR test result, domicile address, outcome, and date of death (if the case ends in death) will be excluded from further data linkage.

Table 1. List source for merged datasets.

Name	Developer	Description	Variable identified
NAR[a]	Ministry of Health Republic of Indonesia	Record of all RT-PCR[b] SARS-CoV-2 tests carried out by affiliated laboratories	• Name • ID number • Date of birth • Sex (male, female) • Comorbidity • Domicile address • Laboratory name • Reason for testing • Swab collection date • RT-PCR result confirmation date • RT-PCR testing result
SUSPROB[c]	Jakarta Provincial Health Office	Record and follow-ups of all people with influenza-like illness or probable COVID-19	• Name • ID number • Date of birth • Sex (male, female) • Comorbidity • Domicile address • Presence of influenza-like illness (fever, chill, cough, etc) • Date of symptom onset • Travel history • Plan swab testing date • Swab collection date • RT-PCR testing result
REV POS	Jakarta Provincial Health Office	Records and follow-ups on all positive cases in Jakarta	• Name • ID number • Date of birth • Sex (male, female) • Comorbidity • Domicile address • Date of swab collection • Case severity (asymptomatic, mild, moderate, severe) • Outcome (survived or death) • Date of death
PCARE[d] Vaksin	Social Security Agency on Health Indonesia (BPJS Kesehatan)	Record of all administered COVID-19 vaccines and their recipients	• Name • ID number • Date of birth • Sex (male, female) • Domicile address • Occupation or vaccination batch group (health workers, government officials, elderly, children, civilians) • Name of health care facility/vaccination center • Vaccination date • Vaccination ticket number • Vaccination dose • Vaccine name • Vaccine batch/lot number
Variant dataset	Jakarta Provincial Health Office	Sequencing and genotyping results of the randomly picked positive SARS-CoV-2 samples in the Jakarta area	• Sample registry number • Date of sample collection • Name of the sender laboratory • Date of the sample arrival at sequencing lab • Name of the sequencing lab • Date of the sequencing test • Date of result confirmation • Variant of SARS-CoV-2

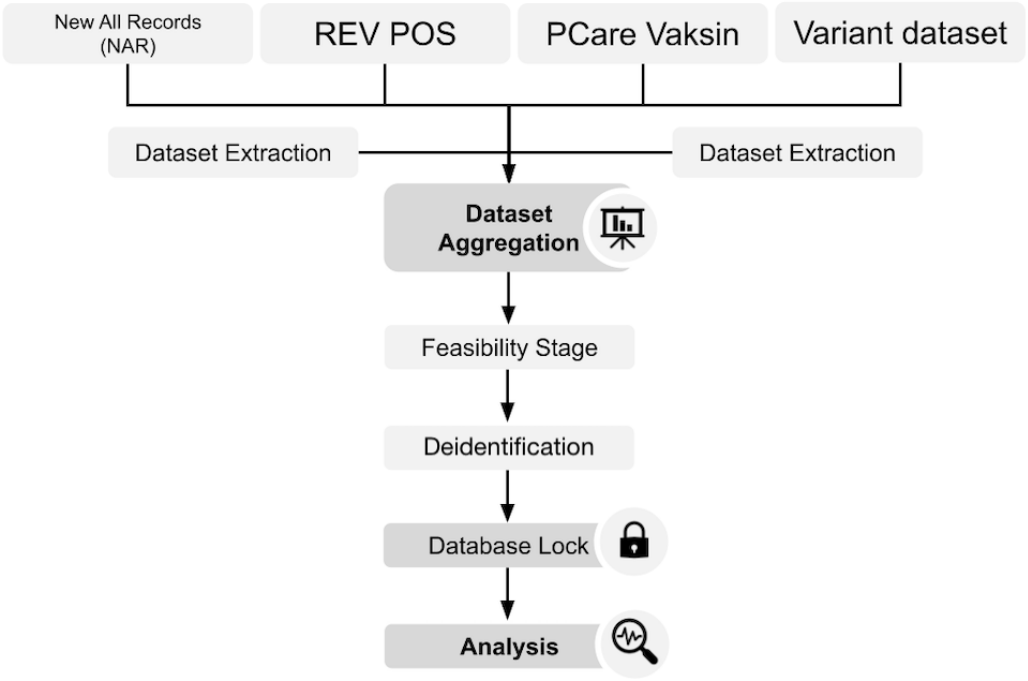
[a]NAR: New All Records.

[b]RT-PCR: reverse transcription polymerase chain reaction.

[c]SUSPROB: Suspect and Probable.

[d]PCARE: Primary Care.

Figure 2. Study workflow. PCare: Primary Care.



People with data linked to the entries within the Primary Care (PCARE) Vaksin dataset will be classified as vaccinated people (Figure 2). To avoid misclassification of foreigners as unvaccinated people, the study will only use entries with national identity card numbers as ID numbers from each of the study datasets. Vaccinated people with incomplete data on vaccination date and vaccine name will be excluded from the final dataset (Table S2 in Multimedia Appendix 1). From the final dataset, a subset of data containing the matched cases and controls will be created (Table S3 in Multimedia Appendix 1).

As genomic testing was not routinely performed in Indonesia, no data linkage will be performed on the variant dataset. In contrast, the variant dataset, which consisted of the genomic test result of the randomly sampled specimen from the population, will be used to confirm the dominant SARS-CoV-2 variant in Jakarta during each period of interest.

Sample Size

The calculation formula for the sample size used in this study will follow the methodology described by O'Neill [29]. Assuming vaccination coverage between 20%-90%, a precision of ±5%, a type 1 error rate of 0.05, and an anticipated VE of 50%-90%, the minimum sample size needed for each specific COVID-19 vaccine brand and dose VE analysis is roughly around 15,000, with 5000 cases and 10,000 controls [24,29] (Table S4 in Multimedia Appendix 1).

We expect to analyze 400,000-900,000 people after the aggregation of all datasets. Therefore, we should have enough data to conduct the VE analyses for each specific COVID-19 brand and regimen in our final dataset. We will compare the proportion of COVID-19 vaccines received by eligible people in our dataset during each period of interest to those reported by the Ministry of Health [17] (Table S1 in Multimedia Appendix 1). Furthermore, we will exclude people who received COVID-19 vaccine brands with vaccination coverage of less than 20%, as these vaccines are usually distributed briefly in the population or only available to specific subgroups within the community. Moreover, we might consider combining different COVID-19 vaccine brands with the same platform into one group to decrease the required sample size, especially for the subgroup VE analysis [24].

Statistical Analysis

We adopted our VE analysis from the Interim Guidance of Evaluation of COVID-19 Vaccine Effectiveness by the World Health Organization, where the final estimate of absolute VE (aVE) will be determined by calculating the adjusted odds ratio (aOR) for vaccination using the formula aVE = (1 – aOR) × 100% [24]. Unconditional multivariable logistic regression will be used to analyze the aOR of having symptomatic and fatal SARS-CoV-2 infection between the unvaccinated and vaccinated participants. We will perform separate analyses for the Delta- and Omicron-dominant periods. Furthermore, within each period, we will also analyze each vaccinated person separately by their vaccine brand or platform and vaccination doses, such as dose 1, dose 2, or booster. For the main aVE analyses, we will include only vaccinated people with the last dose 1 or dose 2 vaccination date within 14-90 days or with the last booster dose within 7-90 days before their index test date and compare them to the unvaccinated people.

One main logistic model will be assembled by forward inclusion, and only covariates with less than 20% missing data will be considered to be included in the model building. Assessment for confounders and effect modifiers will be performed with the Wald test and by observing the change in the primary exposure coefficient SE. Covariates that act as confounders will be included in the model. If effect modification is present, it is essential to report VE and CIs for each subgroup individually.

The linearity between continuous variables and the log odds of having symptomatic SARS-CoV-2 infection will be assessed, and the continuous variables will be modified into categorical variables if necessary. The overall fit of the final multivariate logistic regression model will be assessed with Hosmer and Lemeshow goodness-of-fit test [30], as matching might incur matching-related bias from the cases and controls having similar exposure, thus underestimating the aVE. We will also perform conditional logistic regression as a sensitivity analysis for measuring the aVE estimation against symptomatic SARS-CoV-2 infection or our primary objectives [31,32]. Furthermore, for the analysis of the Omicron period, we will perform an additional analysis of relative VE (rVE) by comparing recipients of one booster dose to recipients of the 2 doses who were eligible to receive the booster dose. The rVE will be calculated using the formula rVE = [(aVE from booster dose – aVE from 2 doses and eligible for booster)/(1 – aVE from 2 doses and eligible for booster)] × 100%. For the rVE analyses, we will include only people whose last booster dose was within 7 to 90 days before their index test date and compare them to people whose last 2-dose vaccination date was ≥90 days before their index test date [24].

This study will also conduct subgroup analyses based on the time between the last vaccination date and test index date to assess for waning of immunity (Table 2). These subgroup analyses will be conducted separately for each wave and vaccine brands or regimens. Similar to the main analysis, each vaccinated subgroup will be compared to unvaccinated people.

Table 2. Subgroup analysis based on time since last vaccination.

Subgroup	Description
1	7-14 days between the last vaccination dose and index test date
2	14-28 days between the last vaccination dose and index test date
3	28-56 days between the last vaccination dose and index test date
4	56-90 days between the last vaccination dose and index test date
5	90-180 days between the last vaccination dose and index test date
6	>180 days between the last vaccination dose and index test date

A 2-sided *P* value derived from the multivariable logistic regression analysis will be used to assess VE. Data linkage and data cleaning will be performed in Google Collaboratory with the Python programming language. Furthermore, the Statsmodel library package will be used for statistical analysis [33].

Ethical Considerations

The research protocol received ethics approval from the Ethical Committee of Persahabatan Hospital Jakarta (40.A.1/KEPK-RSUPP/11/2022). The research conducted in accordance with this protocol will not collect consent from people as it involves the use of secondary data. A consent waiver statement has been issued by the Ethical Committee of Persahabatan Hospital Jakarta (DP.04.03/D.XX.10.4/0001/2024).

Results

This research received funding from 2022 to 2024. The proposal preparation, protocol development, and ethical review processes began in 2023, alongside efforts to gather access to datasets from various stakeholders. Enrollment commenced at the beginning of 2024 and was completed in July 2024 after the data-cleaning process. A total of approximately 4 million data points were available from the linked datasets. Data analysis is currently underway, with the first results expected to be submitted for publication at the start of 2025.

Discussion

The general objective of this research is to estimate the real-world effectiveness of COVID-19 vaccines during the Delta and Omicron waves. Since the study covers two different periods, the results may also reveal changes in VE across these two variant phases. The study follows World Health Organization guidelines for conducting real-world COVID-19 vaccine research and incorporates linkage across multiple research datasets to enhance its validity. The use of the Google Collaboratory online platform for data integration demonstrates adaptability to modern technologies. As of mid-2024, there are over 4 million combined records from RT-PCR test results and vaccination data.

Vaccine effectiveness refers to the average response to the vaccine under real-world conditions, assessed through observational studies, and is generally lower than the efficacy observed in controlled settings [34]. When a vaccine is administered to the general population, various factors such as individuals' medications and overall health status, and vaccine storage and administration conditions, among others, can diminish its effect and increase variability in responses among recipients. This phenomenon is anticipated for all vaccines, underscoring the importance of continuous monitoring for emerging data as vaccination programs progress. The collection, analysis, and communication of these experiences are crucial for gaining authoritative knowledge on effectiveness, including potential rare or delayed side effects. Assessments of COVID-19 VE also contribute to understanding the overall community immunity required to safeguard the population [35].

The study's inclusion of a wide variety of vaccine platform, including mRNA, adenovirus-based, and inactivated vaccines, is one of its main strengths. For low- and middle-income countries, which may depend on several types of vaccine due to availability constraints, this variety enables a more nuanced knowledge of vaccination performance across various methods.

In contrast to many previous studies, this study additionally considers important factors that could affect the chance of vaccination and the risk of contracting or dying from COVID-19 in various communities. The study provides a more complete picture of VE in the real world by taking these factors into account, particularly in different urban environments like Jakarta.

Nevertheless, certain limitations still exist despite the test-negative design study design's attempts to lessen biases. If those who test negative for COVID-19 were exposed but did not exhibit symptoms, misclassification bias may occur, as indicated in Table 3 on potential biases related to test-negative design. Furthermore, since those who choose to get tested might not be representative of the whole community, health care–seeking behavior may introduce additional bias. Collider bias is still a worry and has not yet been completely mitigated, even though sampling has been used to reduce problems like selection bias. This is especially important because the study looks at communities with different socioeconomic and health characteristics, which could affect the results. Addressing collider bias in future research could significantly improve the reliability and validity of the findings, offering a clearer understanding of the true VE in different contexts.

Table 3. Potential biases of COVID-19 vaccine effectiveness studies using test-negative design.

Potential bias	Explanation	Magnitude	Direction on VE[a] estimate	Outcome/subgroups affected	Method to control	Comments
Health care–seeking behavior bias (access to health care)	Individuals who are more likely to get vaccinated tend to seek medical care more frequently, which increases their chances of being identified as cases	Large	Underestimate VE	Nonsevere outcome	Using TND[b]	By using TND, we only include individuals who seek care for similar symptoms or indications thus reducing differences in health care–seeking behavior, but TND can create collider bias
Health care–seeking behavior bias (vaccine status)	Vaccinated individuals less likely to seek testing for COVID-19–like illness due to perception of protection	Small to moderate	Underestimate VE	Nonsevere outcome	Using TND	TND partially controls this bias
Collider bias	This arises when we restrict analysis on a collider variable (eg, testing). TND only analyzes individuals who were tested.	Unknown	Depends on how health care–seeking behavior and infection affects testing	Nonsevere outcome	Limit to severe individuals or older adults	We could not control this bias because the information on the collider variable (testing) is not available.
Misclassification of the exposure	During high levels of transmissibility, infection may occur soon after vaccination. Meanwhile, vaccines need time to confer an acceptable protective immune response.	High	Underestimate VE	All	Limit analysis only after vaccine performance has acceptable time to confer acceptable protection (eg, 14 days after the first or second dose, 7 days after third dose)	This study excludes infection that occurs <14 days after vaccination in the analysis of primary vaccine (first and second dose) and excludes events (eg, infection) that occur <7 days after vaccination in the analysis of booster vaccines. This measure will prevent underestimation of VE in the time when infection occurs during suboptimal immune response after vaccination.
Misclassification of the outcome	False positive and false negative	Small	Underestimate VE	All	Use only highly sensitive test (eg, RT-PCR[c])	This study only includes RT-PCR SARS-CoV-2 results (see eligibility criteria) to control this bias
Spurious waning bias	This refers to an apparent VE reduction over time that does not reflect the decay of immunity over time but rather results from biases or confounding factors in the study design or analysis (eg, different variants, differences in exposure risk).	Small to large	Underestimate VE	All	Perform analysis for specific variant/period. Control difference in viral dynamic transmissibility over time. Perform stratification analysis by time since vaccination.	To prevent bias due to variants, this study conducts two sets of analyses (Delta and Omicron). To prevent bias due to differences in exposure risk over the periods of interest, we conducted matching case and control by calendar week of sample collection. To show VE waning, we perform stratification analysis by time since vaccination.

[a]VE: vaccine effectiveness.

[b]TND: test-negative design.

[c]RT-PCR: reverse transcription polymerase chain reaction.

The response to the COVID-19 pandemic has highlighted new challenges in Indonesia's healthcare system, particularly data fragmentation from numerous health applications and insufficient standardization [36]. Disparities in recording and storing health data in Indonesia also present challenges during the pandemic [37]. Both of these obstacles hinder large-scale health research in the country. To address this, dataset integration is necessary to obtain comprehensive and complete data. Upon completion of our study, it is hoped to demonstrate the capability of health researchers in Indonesia to conduct research using big data, serving as an initiation for the digital transformation of health care.

Acknowledgments

This study will receive an AstraZeneca research funding grant (ESR-21-21574 – D8111L00006.) as an external sponsor, and the sponsor will not be involved in conducting the study.

Data Availability

The data that supports the findings of this study will be available upon request from EB and FA. The data, which contain personal information, are not publicly available due to the strategic health policy of the province of Jakarta.

Authors' Contributions

Conceptualization: EB, FA, FM
Methodology: FA, FAGS, ATR, RAR, HA
Project administration: FM, MIDR, IA
Supervision: EB, FA
Validation: EB
