Abstract

Background: To improve the performance of health care institutions, reduce overmedication, and minimize the waste of medical resources, China is committed to implementing a clinical pathway management model. This study aims to standardize nursing practices, foster clinical thinking in nurses, and promote patient recovery.

Objective: The purpose of this study is to evaluate the clinical effects of a traditional Chinese medicine (TCM) nursing program based on nursing pathways for patients with type 2 diabetes mellitus (T2DM).

Methods: This study uses a prospective, randomized, single-blind, parallel-controlled design. Based on sample size calculations, the study will include 594 patients with diabetes, with 2 groups of 297 patients: an observation group will receive a TCM nursing program based on clinical pathways, while a control group will receive routine care. Both groups will be evaluated before and after the intervention using assessment indicators. The primary outcome is the quality of life score, measured by a diabetes-specific quality of life questionnaire. Secondary outcomes include hospital stay duration, medical expenses, health knowledge, blood glucose control, symptom scores, and patient satisfaction.

Results: This study was funded in August 2021 and has received approval from the Ethics Committee of Guang'anmen Hospital, China Academy of Chinese Medical Sciences (2022-022-KY-01). The trial is ongoing, with the first patient enrolled in September 2022. The study is expected to conclude in April 2025. To date, 380 patients have been recruited, with 202 randomized into the study, though no statistical analysis of the data has yet been conducted. A single-blind method is used; nurses are aware of group assignments and intervention plans, while patients remain blinded. Final results are planned for release in the first quarter of 2025.

Conclusions: This study seeks to integrate existing national standardized nursing protocols with clinical pathways to implement more efficient and higher-quality nursing practices. The goal is to standardize nursing procedures, enhance patients' quality of life, and improve self-care and medication adherence after discharge.

KEYWORDS

type 2 diabetes; traditional Chinese medicine; TCM nursing program; clinical pathway; application research; diabetes; diabetes mellitus; research protocol; nursing; nursing program; nursing care; chronic disease; disease monitoring; prevalence; China; adult; patient recovery; psychological care; health education; quality of life; blood glucose; self-care; medication; control group; patient satisfaction

Introduction

According to the Guideline for the Prevention and Treatment of Type 2 Diabetes Mellitus in China (2020 Edition) [1], the prevalence of diabetes in China has surged from 0.67% in 1980 to 11.2% in 2015-2017 [2,3]. Diabetes management in China faces significant challenges, particularly in rural areas where awareness, treatment, and control rates remain low. Large-scale epidemiological surveys conducted in 2010 and 2013 reported diabetes awareness rates of 30.1% and 36.5%, treatment rates of 25.8% and 32.2%, and control rates of 39.7% and 49.2%, respectively [3-5].

Most existing studies have focused on evaluating clinical nursing pathways or nursing programs. For instance, a study by Li [6] analyzed the effectiveness of clinical nursing pathways in type 2 diabetes mellitus (T2DM) care, demonstrating that a research group using clinical nursing pathways achieved better control of fasting blood glucose and postprandial 2-hour glucose levels compared to a control group (P<.05). The research group also had significantly fewer instances of improper hypoglycemia treatment, insulin injection errors, dietary mistakes, inadequate exercise, and nonadherence to medical advice (P<.05). Additionally, compared to the control group, the research group had shorter hospital stays, lower hospitalization costs, and higher overall nursing satisfaction (P<.05), indicating that the application of clinical nursing pathways can effectively control blood glucose levels, improve nursing quality, and enhance patient satisfaction.

Similarly, a study by Ren et al [7] showed that implementing traditional Chinese medicine (TCM) nursing programs in general hospitals resulted in higher quality-of-life scores for patients in an observation group 1 month after discharge compared to a control group. At discharge, the observation group had a significantly higher nursing satisfaction rate (93%) than the control group (77%; P<.05). This suggests that the TCM nursing program model can improve both quality of life and nursing satisfaction. These studies demonstrate that clinical nursing pathways or TCM nursing programs can effectively control blood glucose levels and reduce medical costs while enhancing patients' quality of life. However, no studies to date have explored the combined clinical application of these two nursing methods, which is the focus of our study.

The evolution of national standards and their integration with nursing practices have increasingly shifted the focus toward nursing pathways aligned with these standards. This development combines nationally standardized nursing protocols with nursing pathways to create a coherent, interconnected, and progressive nursing model. Pathway-based TCM nursing interventions built on TCM clinical pathways standardize the care of single diseases, promote systematic intervention processes, highlight the efficacy and unique features of TCM, and make nursing operations more standardized. This enables nurses to provide planned and anticipatory care based on structured procedures. A preliminary retrospective analysis of clinical data from 4196 patients with diabetes revealed that integrating traditional Chinese nursing techniques with clinical treatments effectively alleviated patients' discomfort. Nurses found this approach more practical and valuable in standardizing care, reducing variability, lowering costs, and improving care quality for patients with T2DM [8,9]. Nevertheless, no research has yet examined the simultaneous clinical application of these two nursing methods, which is the aim of our study.

Thus, we conducted a prospective, randomized, single-blind, parallel-controlled trial to further investigate the impact on patient outcomes of integrating nationally standardized nursing protocols with TCM nursing programs based on clinical pathways. These outcomes include hospitalization indicators (eg, length of stay and medical costs), self-management (health knowledge), clinical efficacy (blood glucose control, clinical symptoms, and quality of life), and patient satisfaction. We expect that the findings of this study will provide robust evidence for delivering personalized care, standardizing procedures, improving patients' quality of life, and enhancing self-care and medication adherence after discharge.

Methods

Study Design

The intervention protocol for this study is titled "TCM Nursing Protocol for Type 2 Diabetes Based on Care Pathway." The study uses a prospective, randomized, single-blind, parallel-controlled clinical design and aims to assess and demonstrate differences, supported by high-quality evidence, in outcomes between an intervention group and a control group that received standard care. The research team comprises nurses from the Department of Endocrinology at Guang'anmen Hospital, China Academy of Chinese Medical Sciences. The study participants are patients with T2DM admitted to our department between September 2022 and December 2024. The study is registered with the International Traditional Medicine Clinical Trial Registry (ITMCTR2022000048). Inclusion, exclusion, and elimination criteria are shown in Textbox 1.

Textbox 1. Inclusion, exclusion, and elimination criteria.

Inclusion criteria

- The primary diagnosis must align with *International Classification of Diseases, Tenth Revision* codes for type 2 diabetes mellitus, specifically in the range of E11.2 to E11.9.
- Admission criteria must be met for inpatient treatment, as determined by the clinical physician.
- In cases where patients have concurrent diagnoses of other diseases, if these conditions do not require special treatment during the hospital stay and do not hinder the implementation of the clinical nursing pathway for the primary diagnosis, the patient can be included in that nursing pathway.
- Informed consent must be obtained from the patient and documented, indicating their understanding and agreement with the proposed care plan.

Exclusion criteria

- Patients who meet the diagnostic criteria for type 2 diabetes mellitus but are unable to comply with the treatment regimen.
- Patients with cognitive impairments or cognitive dysfunction.
- Patients with concurrent diagnoses of other diseases that require treatment during the hospitalization period.

Elimination criteria

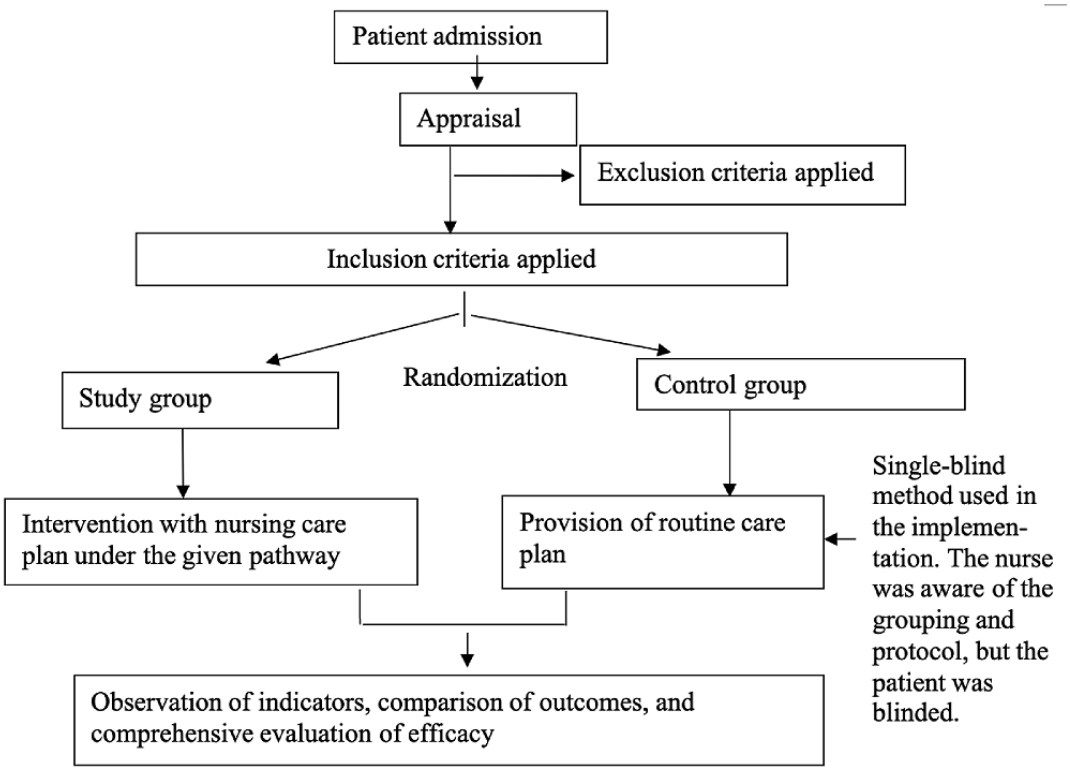
- Patients whose condition worsens, resulting in a hospitalization duration exceeding 14 days and increased hospitalization costs.
- Patients with concomitant systemic diseases that require special treatment, leading to a hospitalization duration exceeding 14 days and increased costs.
- Patients with serious complications that arise during the course of treatment and necessitate discontinuation of the nursing pathway.
- Patient and family preferences and wishes that affect the implementation of this nursing pathway.

Interventions

Intervention Plan

Upon admission, nurses provide admission education and assign eligible patients to the study group or the control group based on the time of admission (Figure 1). The intervention plans for both groups are outlined in a pathway form and include 3 components: executing medical orders, nursing tasks, and health education, along with TCM-specific treatments (Multimedia Appendix 1). For the control group, nurses subjectively implement the nursing plan according to the pathway form. The study group strictly follows the TCM nursing pathway for T2DM.

Figure 1. Study design and flow.



Implementation of the TCM Nursing Pathway for T2DM

Upon admission, nurses provide admission education and assess the patient's condition using an evaluation form for the TCM nursing pathway for T2DM. This assessment determines whether the patient qualifies for inclusion in the study. Eligible patients receive the TCM nursing pathway for T2DM. For patients included in the study, nurses ensure that physicians perform a thorough examination upon admission. The TCM nursing pathway form for T2DM is distributed, and patients are informed about their treatment and the nursing plan during hospitalization. This ensures patients understand the medical and nursing measures to be implemented.

During hospitalization, the responsible nurse uses the evaluation form of the TCM nursing pathway for T2DM to develop an appropriate care plan. This plan may include TCM techniques, syndrome differentiation–based dietary therapy, exercise and health practices, herbal prescriptions, and emotional regulation. The study group strictly adheres to the schedule outlined in the TCM nursing pathway for T2DM. Nurses coordinate with relevant departments promptly to complete necessary examinations. The control group receives routine care.

If there are any changes in the patient's condition, the responsible nurse promptly analyzes and addresses the changes, adjusting the sequence of items in the TCM nursing pathway as necessary. The head nurse checks the implementation of the TCM nursing pathway for T2DM and the routine care plan daily. The head nurse ensures compliance with the nursing pathway protocol and evaluates the quality of care promptly. Relevant data are collected and evaluated at the time of the patient's discharge.

Sample Size Calculation

A literature-based approach was used to compare the preset effect, with α=.05 and β=.10, against the known efficacy of general nursing from previous studies. Based on methods found in the literature [10] and conclusions from earlier research, the historical effective rate (very satisfied + satisfied) was determined to be approximately 74.5% [9]. The effective rate for this pathway nursing program is projected to be 85%. Using *Z* values from standard tables ($Z1 - \alpha / 2 = 1.96$; $Z1 - \beta = 1.28$), the sample size for each group was estimated as follows:

$N1 = N2 = (Z1 - \alpha / 2 + Z1 - \beta)\ 2\ [P1(1 - P1) + P2(1 - P2)] / \delta 2 = (1.96 + 1.28)\ 2\ [0.745 \times (1 - 0.745) + 0.85 \times (1 - 0.85)] / (0.85 - 0.745)\ 2 = 296$. Thus, 242,272 indicated 297 cases, and the sample size of this study was 297 × 2 = 594 cases.

Randomization Method

The randomization method used in this study involves selecting an appropriate block size and assigning participants into 2 groups (the study group and the control group) in a 1:1 ratio. Using the *PROC PLAN* procedure statement in SAS (version 9.2; SAS Institute) and specifying a seed number, a randomized allocation was generated for 594 participants. This process produced a complete randomization table, listing the treatment assignments corresponding to sequential serial numbers from 001 to 594.

Blinding Method

This is a single-blind study, and patients with diabetes are unaware of their group assignment.

Outcomes

Researchers use standardized questionnaires to collect baseline data. The primary efficacy indicator is a quality of life scale (the Diabetes-Specific Quality of Life Scale) [11]. Secondary efficacy indicators include the length of hospital stay, medical costs, blood glucose control, patient symptom scores, patient satisfaction, and the level of health knowledge acquired at admission. Data are collected 1 day before discharge and at 4 weeks, 12 weeks, and 24 weeks after discharge.

Harm

Apart from the risk of data violations, there is no anticipated harm to the study participants. The investigator will be identified by experimenter number to reduce the risk. Although greater adherence to treatment is expected in the intervention group, no systematic differences in diabetes management are expected.

Ethical Considerations

The ethical principles guiding this study include the Measures for Ethical Review of Biomedical Research Involving Humans, Good Clinical Practice for Drug Trials, Regulations on Clinical Trials of Medical Devices, Ethical Review Guidance for Drug Clinical Trials, Clinical Ethical Review Management Guidelines for Traditional Chinese Medicine Hospitals, the Declaration of Helsinki, and the International Ethical Guidelines for Biomedical Research Involving Human Subjects.

The trial has been approved by the Ethics Committee of Guang'anmen Hospital, China Academy of Chinese Medical Sciences (2022-022-KY-01). Prior to the implementation of the study, informed consent must be obtained from patients. Participation in this study is entirely voluntary. Patients may choose not to participate or withdraw from the study at any time without providing a reason, and participation requires signing an informed consent form.

All patient data collected during the trial will remain confidential. Medical records will be identified using research ID numbers instead of names. Identifiable information will not be disclosed to anyone outside the research team unless the patient provides explicit permission.

In accordance with relevant national regulations, in the event of research-related injuries, the study institution, Guang'anmen Hospital of the China Academy of Chinese Medical Sciences, will bear the corresponding medical costs and provide appropriate financial compensation.

For any questions regarding participant rights in this study, individuals can contact the Ethics Committee of Guang'anmen Hospital, China Academy of Chinese Medical Sciences.

The study form will be kept by the data collector in a folder in the study office. Study data will be processed without participants being recognizable. Only the researcher responsible for the analysis can access the final data set; after the trial study is published, we will provide research references and the scientific basis for relevant clinical practice, formulate the

implementation specifications of the nursing program under the chosen pathway, and promote the research results in the industry.

Statistical Analysis

We will use SPSS (version 26.0; IBM Corp) to perform the statistical analysis. Descriptive statistics for quantitative variables will include at least the mean and SD or the median and IQR. Descriptive statistics for qualitative variables will include at least the frequency and percentage for each category. Comparisons between the 2 groups will be conducted using an independent-sample *t* test (for normally distributed data with equal variances) or the nonparametric rank-sum test. For unordered categorical data, comparisons between the 2 groups will be made using the χ^2 test or Fisher exact test, while ordinal categorical data will be analyzed using nonparametric tests. All statistical tests will be 2-sided, with a $P<.05$ considered statistically significant.

Results

This trial received funding in August 2021 and is currently ongoing. The first patient was enrolled in September 2022, and the study is expected to conclude in December 2024. The trial uses a single-blind design where nurses are aware of group assignments and intervention details, but the patients remain blinded. Final results are planned for publication in the first quarter of 2025.

To date, 380 patients have been recruited, with 172 excluded, resulting in 202 randomized participants (101 in the study group and 101 in the control group). Details on the screening process are provided as a Consolidated Standards of Reporting Trials (CONSORT) flowchart in Multimedia Appendix 2.

This study primarily aims to compare health knowledge, comprehension, and scores between the 2 groups, with the goal of optimizing an innovative model for the TCM nursing pathway for T2DM. The findings are expected to enhance the standardization and precision of clinical nursing practices. The pathway will be validated clinically, combining theory with practice through prospective research to provide high-level clinical evidence. This will contribute to the development of a high-quality TCM nursing pathway, expand the global influence of TCM, and support national economic growth and public health.

Discussion

Overview

Data show a significant increase in China in the incidence of diabetes over 30 years, leading to a high prevalence of acute and chronic complications. Simultaneously, deficiencies in patient awareness, understanding, treatment rates, and control rates have become evident in diabetes care. This underscores the urgent need to explore and improve diabetes care methods.

In recent years, China's economic growth has created opportunities for more targeted and standardized care, providing promising prospects for development. Under the framework of National Standards + Nursing Pathways, TCM-based nursing models have become prominent in diabetes clinical care. However, despite positive outcomes with existing standards, a comprehensive clinical pathway management model has yet to be established, resulting in inconsistencies and nonstandardized practices.

Thus, it is crucial to conduct in-depth research to integrate these methods and improve the effectiveness of nursing practices. Exploring and developing nursing plans that combine clinical pathways with TCM principles is essential. High-quality prospective clinical research is needed to meet patients' increasing demand for improved health care quality and to refine standardized nursing protocols.

Since the Ministry of Health launched the clinical pathway pilot project in 2009, the effectiveness of clinical pathway management in improving health care quality and controlling medical costs has become increasingly evident. Against the backdrop of advocating "high quality, high efficiency, and low cost," studying the application of clinical nursing pathways in China's health care quality management is of significant importance. This emphasizes the need for further development and research into the implementation of a TCM nursing model for T2DM based on National Standards + Nursing Pathways.

Principal Findings

This study focuses on comparing health knowledge and scores in the 2 groups, aiming to optimize an innovative model for the TCM nursing pathway for T2DM. This approach should help enhance the standardization and precision of clinical nursing practices. Its application in the clinic will combine theory with practice, providing high-level clinical evidence through prospective research. The goal is to establish a high-quality TCM nursing pathway that will expand the international influence of TCM and support economic and public health development.

Strengths and Limitations

Building on prospective findings from previous studies, this study will use a prospective design to enhance the level and reliability of evidence. The study's significance also lies in providing a foundation for high-quality clinical evaluation that will enable selecting targeted and distinctive TCM clinical nursing pathways. The aim is to improve the clinical application and quality of standard nursing procedures within nursing projects based on a T2DM nursing pathway.

However, this study uses a single-center design and does not include additional hospitals, which is a limitation. Nevertheless, the focus is on optimizing the TCM nursing pathway at this center and obtaining high-quality evidence of its effectiveness to facilitate broader future applications and clinical use.

Future Directions

The TCM nursing pathway explored in this study has a solid foundation, demonstrating its potential for effective care. We anticipate that as the study progresses, high-quality evidence will confirm its efficacy. Subsequently, this TCM nursing pathway will be promoted in more hospitals, benefiting a larger population of patients with diabetes.

Conclusions

This study aims to integrate existing national standardized nursing protocols with clinical nursing pathways to implement more efficient and higher-quality clinical nursing practices. It seeks to standardize nursing procedures, improve patients' quality of life, and promote self-care and medication adherence after discharge.

Abstract

Background: Glaucoma is the leading cause of irreversible blindness worldwide, causing continuous and progressively worsening damage to visual function, which leads to vision loss. Optic nerve protection is an important treatment for glaucoma with controlled intraocular pressure (GPCI), but to date, there is no universally accepted effective optic nerve protection agent. Acupuncture can protect the optic nerve by increasing blood flow to the eye. However, fear of pain or the limitations of treatment place and time lead to poor patient compliance. Press-needle therapy is a characteristic of traditional Chinese medicine (TCM) external treatment methods; its safety is high, the effect is fast and lasting, it is easy to conduct, and it has high patient compliance.

Objective: The objective of the trial is to evaluate the safety and clinical efficacy of press-needle therapy and investigate whether it can improve visual function by regulating eye blood circulation in patients with GPCI.

Methods: In total, 192 participants aged 18-75 years with GPCI from the Mianyang Central Hospital, the Mianyang Hospital of Traditional Chinese Medicine, and the Mianyang Wanjiang Eye Hospital will participate in this study. Participants will be allocated to 2 treatment groups (experimental and control groups) in a ratio of 1:1 and will undergo press-needle therapy and sham press-needle therapy, respectively, for the same 4-week period. Primary outcomes will include the best-corrected visual acuity (BCVA), optical coherence tomography angiography (OCTA), color Doppler flow imaging (CDFI), and visual field assessment results. Secondary outcomes will include the intraocular pressure (IOP) and traditional Chinese medicine (TCM) clinical symptom scales. The primary outcomes and safety assessments will be measured at baseline and 4 weeks thereafter, while the secondary outcomes will be measured at baseline and 1, 2, 3, and 4 weeks thereafter.

Results: Recruitment and data collection began in February 2023. The final outcomes are expected in September 2025. As of October 2024, the project had recruited 220 eligible participants, of whom 192 (87.3%) will complete the study, exceeding initial projections for the study time frame. The remainder of the participants will provide the ability to explore cross-level interactions

that could not be statistically powered at the outset. The strengths of the project include rigorous data collection, good retention rates, and high compliance rates.

Conclusions: This study will provide data on the effects of press-needle therapy on visual function and ocular circulation in patients with GPCI, and these results will help demonstrate whether acupuncture can improve patients' visual function by regulating ocular circulation, thus providing a clinical and theoretical basis for the wider application of acupuncture therapy in GPCI.

Introduction

Glaucoma is a leading cause of irreversible blindness worldwide [1]. Progressive degeneration of retinal ganglion cells (RGCs) and the optic nerve is the basic pathological characteristic of glaucoma [2]. Optic nerve protection is the focus of glaucoma treatment based on intraocular pressure (IOP) control. Neuroprotective targets include glutamate-induced neurotoxicity, nitric oxidase synthetase, neurotropins, calcium channel receptors, free radicals, vascular insufficiency, and the rho-kinase pathway [3]. Nevertheless, at present, there is no satisfactory neuroprotective agent for glaucoma.

Ocular blood flow disorder is a potential cause of visual field deterioration in patients with glaucoma [4]. Therefore, therapeutic options to protect the optic nerve in glaucoma by improving ocular blood flow have attracted increasing attention [3]. Acupuncture therapy has been used to treat glaucoma for thousands of years and has demonstrated favorable safety and convenience [5]. Acupuncture can modify glaucoma blood flow parameters to protect the optic nerve, such as increasing the flow of blood in the eye [6] and reducing anomalies of blood flow in the central artery of the retina [7]. Acupuncture treatments relay electrical signals via the dorsal root ganglion (DRG) and spinal cord, finally regulating ocular blood flow [8].

However, the fear of acupuncture pain or the limitations of the treatment place and time lead to poor patient compliance. Press-needle acupuncture is one kind of acupuncture that has a longer treatment duration and simpler operation with less pain [9]. The theoretical basis of press-needle therapy is the combination of acupuncture theory and skin meridian and acupoint theory. *Suwen: Treatise on the Dermis* states that "all twelve meridians are also part of the skin" and that "the skin is closely related to the veins. The skin is also part of the pulse." The dermis is connected with the 12 meridians by qi and blood. Through the 12 meridians, the 12 dermises are in close contact with the 5 viscera, 6 internal organs, and the eye orifices, forming a coordinated and unified organic whole. Press-needle therapy has been widely used to treat glaucoma with controlled intraocular pressure (GPCI), but useful empirical research is insufficient for its popularization and application. The disadvantages of less rigorous designs, small sample sizes, and low quality have led to many traditional Chinese medicine (TCM) studies being insufficient to convince people of its value. Hence, a randomized, sham-controlled trial will be conducted to assess the potential of press-needle therapy in improving visual function and eye blood circulation in patients with GPCI.

Methods

Research Objectives

The main objectives of this study are twofold: (1) to observe the clinical efficacy of press-needle therapy in patients with GPCI and provide feasible and affordable press-needle treatment for them and (2) to investigate whether press-needle therapy improves the visual function of patients with GPCI by regulating eye blood circulation.

Trial Design and Setting

This multicenter, sham-controlled, blinded, randomized trial of press-needle therapy (Seilini Ltd) for GPCI will be executed in the Mianyang Central Hospital (Sichuan, China), the Mianyang Hospital of Traditional Chinese Medicine (Sichuan, China), and the Mianyang Wanjiang Eye Hospital (Sichuan, China). The study time schedule is presented in Table S1 in Multimedia Appendix 1.

Ethical Considerations

The trial protocol was approved by the Science and Technology Department of Sichuan Province (approval no: 2021YJ0443), the National Natural Science Foundation of China for the Youth (approval no: 82305324), Mianyang Central Hospital Incubation Subjects (approval no: 2020FH07), and the Medical Ethics Committee of the Mianyang Central Hospital (approval no: S2021046 (02)). It has been registered with an identifier (ChiCTR2300067862) with ClinicalTrials. The study will be strictly conducted according to the principles of the Declaration of Helsinki, as well as Good Clinical Practice (GCP) guidelines. The trial will be performed in accordance with the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) checklist [10]. Signed informed consent will be obtained from all patients or their legal guardians by specific researchers prior to beginning the trial. If there are changes to the eligibility criteria, outcomes, or analyses, a new version of the protocol will be submitted to the Medical Ethics Committee of the Mianyang Central Hospital for approval.

Participants and Recruitment Strategy

In total, 192 patients with GPCI recruited from the Mianyang Central Hospital, (Sichuan, China), the Mianyang Hospital of Traditional Chinese Medicine (Sichuan, China), and the Mianyang Wanjiang Eye Hospital (Sichuan, China) will participate in this study. All patients will be screened by specialists and acupuncturists according to the diagnostic criteria in the *European Glaucoma Society Terminology and Guidelines for Glaucoma* [11]. The TCM syndrome of kidney deficiency and blood stasis will be diagnosed based on guidelines delineated in the *Clinical Research Guideline of New Investigational Drugs in Traditional Chinese Medicine* [12].

Inclusion and Exclusion Criteria

Participants who meet the following inclusion criteria will be eligible for the study:

- Diagnosed with primary open-angle glaucoma (POAG) [13]: open anterior chamber angle, pathologically high intraocular pressure (HIOP), with a peak IOP exceeding 21 mmHg (1 mmHg=0.133 kPa) within a 24-hour period, indicative of glaucomatous neuropathy (retinal nerve fiber layer defect [RNFLD] or optic disc changes) or visual field loss or both. Other causes resulting in HIOP were excluded for this diagnosis. Note that only 1 eye from each patient will be selected for examination.
- Having a visual field defect that can be assessed through standard automated perimetry with a reliability factor of less than 15%, as well as an IOP below 18 mmHg, at least 3 months after undergoing antiglaucoma surgery.
- Exhibiting a Chinese syndrome pattern associated with kidney deficiency and blood stasis.
- Refraining from the use of any other optic nerve protective agents, except for methylcobalamin, for a minimum of 2 months.
- Having a spherical refractive error ranging between +3.00 and –6.00 diopters, a fundus clearly visible without the need for pupil dilation, and a BCVA equal to or greater than 0.3.
- Within the age bracket of 18-75 years.
- In a conscious state and capable of cooperating with the examination and treatment process.
- Displaying a willingness to actively participate in the study and provide informed consent.

Participants who have any of the following conditions will not be eligible to participate:

- Poorly controlled IOP (≤7 mmHg or >18 mmHg), accompanied by a thin filtering cystic bleb or bleb leakage.
- Glaucoma that is not open-angle glaucoma.
- A Chinese syndrome pattern that does not meet the criteria of kidney deficiency and blood stasis.
- Other conditions, such as macular degeneration, cataract, proliferative diabetic retinopathy, retinal vascular occlusion, or any other diseases that may cause visual field loss.
- Pregnancy or lactation.
- Abnormal primary liver or kidney function or serious systemic conditions, such as heart disease, primary hypertension, diabetes mellitus, or peptic ulcer disease.
- A history of allergic reactions to the ingredients of press-needle therapy or mecobalamin tablets.

TCM Syndrome Differentiation

The TCM syndrome of kidney deficiency and blood stasis will be based on guidelines delineated in the *Clinical Research Guideline of New Investigational Drugs in Traditional Chinese Medicine* [12]: primary signs and symptoms include blurry visual acuity, narrow visual field, and eye distension, while secondary signs and symptoms include dry eye, limp aching lumbus, and knees.

The conditions for a diagnosis of kidney deficiency and blood stasis are the presence of at least 2 or more primary signs/symptoms and at least 2 or more secondary signs/symptoms. The necessary condition is a dark-purple tongue and a thready deep, stringy, or unsmooth pulse. The investigators must receive training in standard operating procedures (SOPs) for examining TCM symptoms. They will then conduct a symptom assessment survey using the TCM Symptom Score Scale (Figure 1) for each participant.

Figure 1. TCM Symptom Score Scale. TCM: traditional Chinese medicine.

Blurry visual acuity	□ 0: None □ 2: Mild blurred visual acuity □ 4: Unable to read □ 6: Difficult to see anything
Narrow visual field	□ 0: None □ 2: As if something obscures visual acuity □ 4: Inconvenient to walk □ 6: Difficult to walk
Eye distension	□ 0: None □ 2: Mild eye distension □ 4: Endurable eye distension □ 6: Intolerable eye distension
Dry eye	□ 0: None □ 2: Mild dry eye □ 4: Obvious dry eye, as if there is a foreign body in it □ 6: Intolerable dry eye, frequent blinking
Limp aching lumbus and knees	□ 0: None □ 2: Early morning aching lumbus, which can be alleviated by beating; mild limp knees □ 4: Continuous aching lumbus, which is aggravated when working knees are too limp to carry a heavy weight □ 6: Severe aching lumbus, which is not relieved by rest; knees are too limp to desire to walk
Dark-purple tongue	□ 0: None □ 2: Exist
Thready deep, stringy, or unsmooth pulse	□ 0: None □ 2: Exist

Recruitment Procedure

Potential participants with GPCI were recruited from the Mianyang Central Hospital (Sichuan, China), the Mianyang Hospital of Traditional Chinese Medicine (Sichuan, China), and the Mianyang Wanjiang Eye Hospital (Sichuan, China). We used the internet, hospital announcements, and posters to provide a hotline calling for potential volunteers. If patients were interested in our study, researchers informed them in detail of the purpose and content of the research and the benefits and risks of participating.

After screening, participants meeting the inclusion criteria will be enrolled. Frequent follow-up phone calls are an important aspect of adherence monitoring. Every participant will have the right to withdraw from the trial at any time. Furthermore, it will be obligatory for all subjects to sign an informed consent document prior to commencement of the trial.

Randomization and Allocation

Baseline evaluation will be conducted for eligible subjects. All eligible patients will be stratified according to early, moderate, and advanced stages of glaucoma [14]. Patients with early glaucoma exhibit early glaucomatous visual field impairment, as characterized by a mean deviation (MD) of >–6 dB. Conversely, patients with moderate glaucoma present a moderate glaucomatous visual field loss, defined as MD≤–6 to ≥–12 dB. Patients with advanced glaucoma experience advanced glaucomatous visual field loss, defined as MD<–12 dB. SAS software will be used to automatically generate a set of random numbers ranging from 001 to 192. These numbers will be further classified into 3 ranges based on the disease stage. The early stage will incorporate random numbers from 001 to 064, the moderate stage will encompass numbers from 065 to 128, and the advanced stage will comprise numbers from 129 to 192. Following stratification, the participants will be assigned randomly to either an experimental group or a control group in a 1:1 ratio. Random numbers will be inserted into identical envelopes of equal dimensions, which will then be sealed to ensure concealment of group allocation and minimize the risk of selection bias. The random sequence allocation will be preserved and withheld from the investigators, statisticians, and outcome assessors to avoid detection bias.

Blinding

The researcher assistants, outcome assessors, statisticians, and subjects will be blinded to the group assignment. All participants will undergo press-needle therapy while lying on a bed in a tranquil clinic setting. For the control group, a nonpenetrating sham apparatus, similar in appearance to acupuncture needles, will be used to achieve blinding. Moreover, every participant will be asked about their experience subsequent to the acupuncture session to evaluate the efficacy of blinding. Unblinding of researchers is permitted only in exceptional circumstances, such as when there is a strong need to know about the actual treatment in order to manage the subject appropriately.

Interventions

Experimental Group

Acupoints will be selected based on acupuncture combined with clinical experience [15]: main acupuncture points (BL2 Cuanzhu, TE23 Sizhukong, EX-HN5 Taiyang, and ST2 Sibai) and matching points (PC6 Neiguan, SP10 Xuehai, BL17 Geshu, BL18 Ganshu, BL23 Shenshu, SP6 Sanyinjiao, and K13 Taixi) (Figure 1). These points can exert a concerted effect to nourish the liver and kidneys, promote blood circulation, and dredge collaterals. Press-needle treatment will be performed by acupuncturists with more than 3 years of clinical experience. The acupuncturist will disinfect the skin around the acupoints (on the same side of the affected eye) with povidone iodine when the subject lies down on the treatment bed in a supine position. Disposable sterile press needles (0.2 mm in diameter and 0.6 mm in length; Seirin Corporation) will then be inserted into the right acupoints (Figure 1). The needles will be pressed so that they can adhere and be tied, the peelable paper will be removed, and the adhesive tape will be pressed down to ensure a secure fit. The needles will be left in place for 2 days, and participants will be asked to press the needles themselves 3-4 times/day, every 4 hours, for 1 minute each time to achieve deqi sensations, including soreness, numbness, heaviness, fullness, and aching.

Control Group

Sham press needles are the same as press needles but lack the needle element [9]. The procedures and manipulations carried out in the control group will be indistinguishable from those implemented in the experimental group. Subjects will be treated individually in a secluded room to prevent any disruptions from family members or other individuals.

Criteria for Discontinuing or Modifying Allocated Interventions

Participants will have the freedom to withdraw from the clinical study and opt for alternative treatments (eg, citicoline sodium tablets) if they believe their condition will not improve. Reasons for discontinuing treatment may include, but are not limited to, the following: (1) the pregnancy, (2) severe side effects or complications, (3) taking other medications during the study, (4) failure to comply with the study protocol, and (5) request for withdrawal for other reasons.

Outcome Measures

Primary Outcome Measures

The primary outcomes will enable us to evaluate improvements in visual function, retinal blood circulation, and retrobulbar blood vessel circulation due to press-needle therapy. The outcomes will be as follows:

- The mean change in the BCVA will be measured at baseline and 4 weeks thereafter.
- The mean change in the values of the pattern standard deviation (PSD), mean defect, and square root of loss variance (sLV) will be determined using an Octopus 900 perimeter at baseline and 4 weeks thereafter.
- The whole-image vessel density (wiVD), radial peripapillary capillary vessel density (RPCVD), superficial macula vascular density (smVD), parafoveal vessel density (paraVD), perifoveal vessel density (periVD), macular ganglion cell complex (mGCC), and peripapillary retinal nerve fiber layer (pRNFL) will be determined using optical coherence tomography angiography (OCTA) at baseline and 4 weeks thereafter.
- The ophthalmic artery (OA), central retinal artery (CRA), short posterior ciliary artery (SPCA), peak systolic velocity (PSV), end diastolic velocity (EDV), and resistance index (RI) will be determined using CDFI at baseline and 4 weeks thereafter.

Secondary Outcome Measures

The following secondary outcomes will help us determine whether press-needle therapy improves TCM clinical symptoms and changes in the IOP:

- The mean change in the IOP in the study eye will be determined uisng a TX-20P full autotonometer at baseline and at 1, 2, 3, and 4 weeks thereafter.
- Changes in TCM symptoms will be assessed by the investigators trained in SOPs according to the TCM Symptom Score Scale (Table S1 in Multimedia Appendix 1) at baseline and at 1, 2, 3, and 4 weeks thereafter.

Safety Evaluation and Adverse Events

Safety assessments using 3 routine tests (blood, urine, and stool), electrocardiography, liver function tests (alanine aminotransferase [ALT], aspartate aminotransferase [AST], alkaline phosphatase [ALP], gamma-glutamyl transferase [GGT], and serum total bilirubin [TBIL]) and kidney function tests (blood urea nitrogen [BUN], serum creatinine [SCr], uric acid [UA], and β 2-microglobulin) will be measured at baseline and 4 weeks thereafter.

A research assistant will monitor and record data regarding adverse events (AEs) associated with interventions, which may include infection, hematoma, severe pain, needle breakage, bleeding, heart palpitations, fainting, and headaches, in case report forms (CRFs). Severe AEs will be managed by emergency medicine physicians or acupuncturists. Additionally, any significant AEs will be reported to the Ethics Committee of the Mianyang Central Hospital.

Data Collection and Quality Control

Thorough recording of all data will be performed on CRFs subsequent to in-person visits or telephonic communications with participants. The same examiner will assume responsibility for conducting the examination of every patient during each assessment. Baseline measurements, demographics, medical history, and prior medications will only be gathered during the initial visit. Primary outcomes, secondary outcomes, and safety indicators will be gathered at baseline and 4 weeks thereafter. Following adequate training and successful completion of a test, 2 data entry clerks will thoroughly review the CRFs and subsequently enter the collected data independently. Participants' personal information will be kept confidential the same way as their medical histories in the hospitals before,

during, and after the trial. The absence of a data monitoring committee in this study is justified by the anticipated low incidence of AEs and the limited participant numbers at each center. The Epidata 3.1 statistical application will be used for data entry. Subsequently, the collected data will be transferred to IBM SPSS 22.0 statistical software for the purpose of analysis.

Sample Size Calculation

The sample size calculation was based on previous studies. The basis of optic nerve protection effectiveness is 70% [16,17]. We hypothesized an 80% effective rate of the basis of optic nerve protection + press needles for GPCI in a larger sample size. According to the sample size of the estimation formula [18], α=.05 and β=0.10 in a 2-sided test, P_1=.67 and P_2=.87, 2-sided $u_{\alpha/2}=u_{0.05/2}=1.96$, and 1-tailed $u_{\beta}=u_{0.1}=1.282$. We substituted these values into the following formula:

This resulted in $n^1=n^2=79.02$, that is, approximately 80 cases each in the experimental and the control group, or 160 cases in both groups. To account for a 20% dropout rate, the calculation 160 + (160 × 20%) = 192 suggested that 192 patients be recruited.

Quality Control

To guarantee the quality of the proposed experiment, a unified and standardized training program will be conducted for the researchers in each role prior to commencement of the study. Subsequently, the researchers will be subjected to a proficiency assessment, and only those deemed competent will be permitted to participate in the study. Furthermore, to enhance participant compliance, regular health education activities will be conducted, humane care will be enhanced, and a long-term follow-up plan will be developed. Finally, in accordance with the requirements set forth in the Specifications for Quality Control and Quality Assurance of Clinical Research in Chinese Medicine [19], a 4-level quality monitoring system will be established to monitor the clinically collected data on a regular monthly basis, thereby ensuring the authenticity and reliability of the study results.

Statistical Analysis

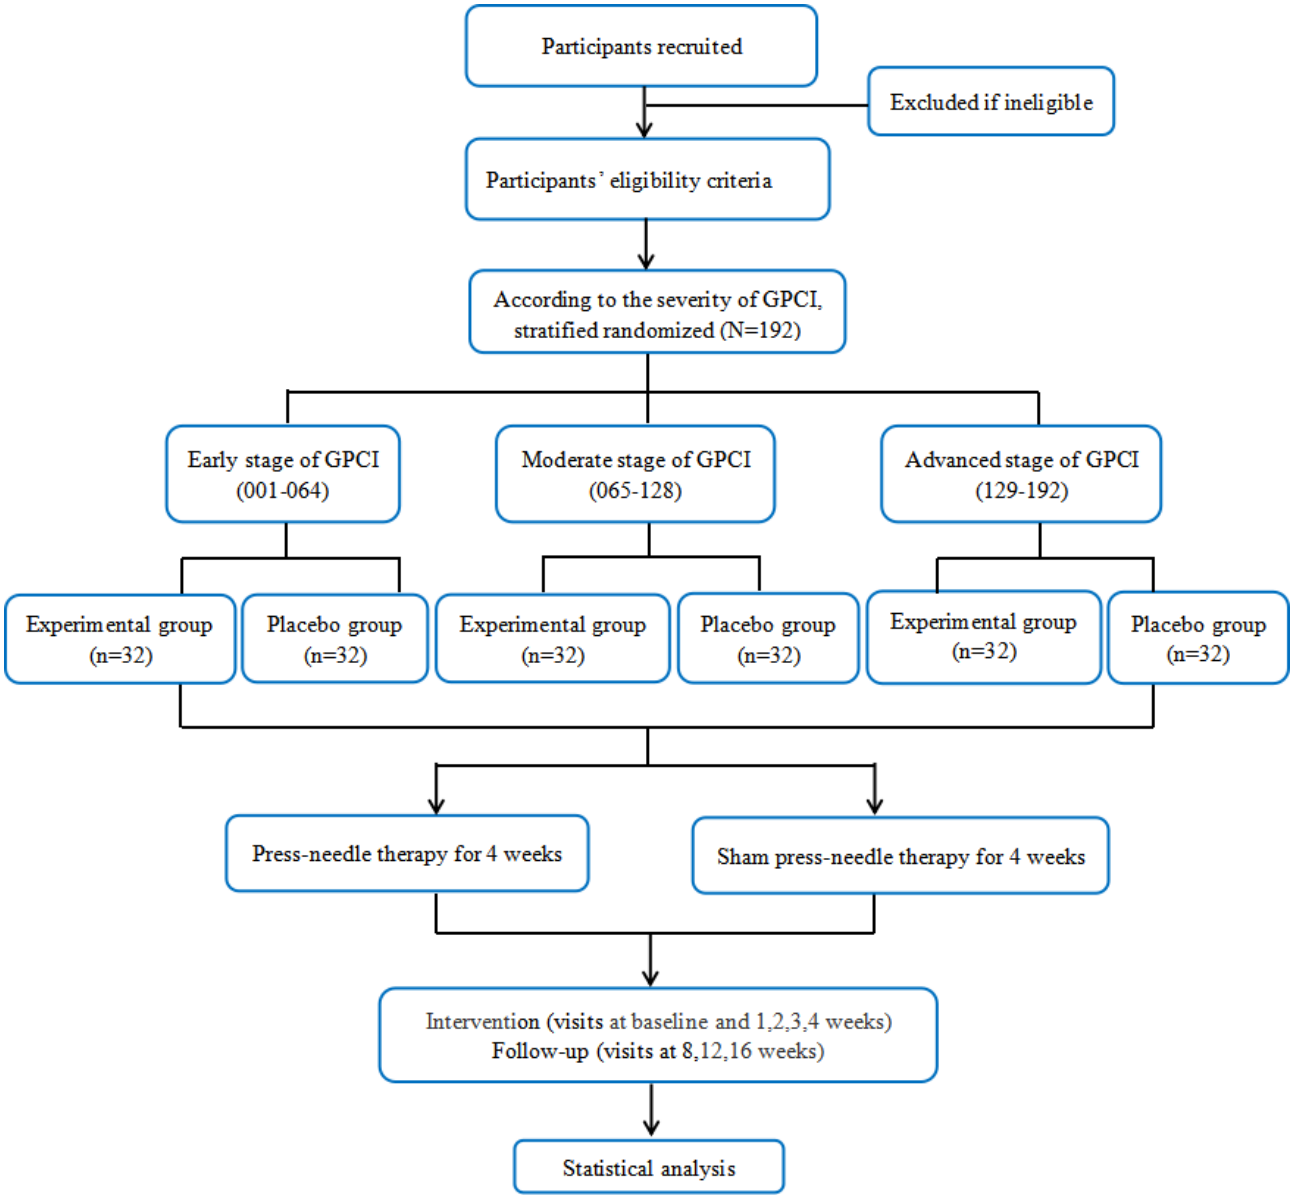
Statistical analysis will be conducted independently by statisticians. The data will be presented as means (SDs). IBM SPSS 22.0 statistical software will be used. All statistical tests will be 2-sided tests, and the limit for statistical significance will be set at P<.05. The chi-square test will be performed for categorical variables, the independent Student *t* test will be used for measurement data, and the rank-sum test will be used for grade data. To evaluate the covariate balance, baseline characteristics will be summarized and compared between the experimental group and the control group using simple descriptive statistics.

Due to the expected low number of missing data, we will deal with missing data by transferring the last data item to the final dataset. This participant's data will be invalidated in the full analysis set (FAS), and this case will not be included in the per protocol set (PPS). Finally, the statistical significance of the FAS and PPS will be analyzed. A consistent statistical significance will indicate a significant difference.

Results

The study flowchart is shown in Figure 2. The figure also presents an outline of the case distribution across each center, as well as comprehensive outline of precise measurements and designated data collection time points. Recruitment was conducted from February 2023 to March 2024. The first participant was enrolled in February 2023. As of October 2024, the project had recruited 220 eligible participants. At the time of submission, there were 192 (87.3%) participants, who will complete the study. The recruitment process is expected to continue until September 2025. The data will be further processed and analyzed in October 2025.

Figure 2. Flowchart of the clinical trial on patients with GPCI. GPCI: glaucoma with controlled intraocular pressure.



Discussion

Overview

Acupuncture is a major treatment in TCM, and studies have shown that acupuncture can protect the optic nerve in patients with glaucoma [20]. The press needle is a new kind of acupuncture device that can create a more lasting stimulus and simpler operation, while resulting in less pain, with the therapeutic effect of cumulative treatment characteristics. At present, press-needle therapy is widely used in various clinical diseases and has achieved satisfactory therapeutic effects [9,21]. Acupuncture is effective in protecting visual function in glaucoma [22]. Press-needle embedding can improve the deteriorating vision and shrinking visual field of patients with optic nerve atrophy and increase clinical efficacy [23]. Abnormal blood flow is an important factor in optic nerve damage in glaucoma [24], and acupuncture can modify the blood flow parameters in glaucoma [7]. Clinically, we have widely used press-needle therapy for glaucoma visual function protection and achieved good clinical efficacy, and we have further found that press-needle therapy can improve ocular circulation in patients with glaucoma. However, the quality of evidence supporting the use of press-needle therapy for GPCI is limited due to methodological limitations. Therefore, it is necessary to explore the effect of press-needle therapy on visual function and eye blood circulation in patients with GPCI. The double-blind method reduces the differential assessment of outcome events and improves subject adherence. Previous studies have shown that press needles and sham press needles (lacking the needle element) enable effective double-blind settings for acupuncture clinical studies [25]. Therefore, sham press needles were chosen as the control intervention for this study.

Due to the unique nature of glaucoma, patients experience progressive optic nerve damage as the disease progresses. To avoid violating medical ethics and reduce the rate of patient detachment, methylcobalamin has been chosen as the basic optic neuroprotective drug for the experimental and control groups in this study. In addition, to observe the effect of

press-needle therapy on GPCI of different disease severities, participants will be classified as early, moderate, and advanced based on their visual field defects.

This study is designed as a double-blind, placebo-controlled trial. To guarantee the quality of the study, its design and execution will be strictly performed with proper quality control. A training session for each center will be held to explain the detailed study protocol, the diagnosis of the TCM syndrome pattern, and the SOPs. The same investigator will be responsible for the examination of each patient at different times. All indicators will be assessed by independent assessors. The principal investigators, statisticians, and outcome assessors will be blinded to the treatment assignments until the database is locked.

Innovations and Limitations

This is the inaugural clinical trial protocol devised by our team to investigate the potential mechanisms of acupuncture for patients diagnosed with GPCI. We have selected eye blood circulation as the entry point for this study. The trial will be conducted in accordance with rigorous methodology. For example, patients with GPCI will be randomly assigned to 2 groups. For the control group, a nonpenetrating sham apparatus, similar in appearance to acupuncture needles, will be used to achieve blinding. Furthermore, each participant will be requested to provide feedback on their experience following the acupuncture session, with a view to evaluating the efficacy of the blinding process. The data will be subjected to statistical analysis in a blinded trial, with the intervener, efficacy assessor, and statistician all acting independently. However, it is not possible to eliminate gender bias in the randomization process. Consequently, to guarantee the reliability of the data, it is necessary to expand the sample size further.

Conclusion

In conclusion, the purpose of this research is to verify that press-needle therapy can effectively improve visual function and eye blood circulation in patients with GPCI. The outcome of this study will provide evidence-based data for the use of press-needle therapy to treat GPCI accompanied by liver-kidney deficiency, blood stasis, and fluid retention syndrome, thereby providing a new avenue for the treatment of GPCI.

Acknowledgments

We are grateful to all the researchers who participated in this trial. Upon completion of the study, the findings will be disseminated to relevant stakeholders, including health care professionals, the general public, and pertinent organizations, through the publication of academic papers and presentations at academic conferences.

This trial is supported by the Science and Technology Department of Sichuan Province (approval no: 2021YJ0443), the National Natural Science Foundation of China for the Youth (approval no. 82305324), and Mianyang Central Hospital Incubation Subjects (approval no: 2020FH07). The results of the research will be presented in the form of publication or conference reports. All the study funders have no role to play in the study design, data collection and management, or manuscript writing and publication.

Authors' Contributions

HJL designed the trial and drafted the manuscript. HJL, CW, and ST are the principal investigators at each hospital. XY (Xuemeng Yu) is responsible for assisting with patient recruitment. XY (Xing Yan) will perform press-needle treatment for patients with glaucoma with controlled intraocular pressure (GPCI). YD and MY will conduct the quality control of this trial. MX, FL, and RZ will be responsible for data collection. MS is responsible for the revision of this manuscript. All the authors have read and approved the final version of this manuscript. Patients and the public were not involved in the design, conduct, reporting, or dissemination plans of our research.

Conflicts of Interest

None declared.

Abstract

Background: Available evidence on the conservative treatment of knee osteoarthritis still leaves questions about the efficacy of platelet-rich plasma (PRP) and whether stromal vascular fraction (SVF) offers a superior therapeutic tool.

Objective: This study aims to assess the clinical efficacy of SVF as adjuvant therapy to PRP on functionality and tissue regeneration for knee osteoarthritis.

Methods: In a multicenter, randomized, triple-blind, controlled trial, 108 individuals with knee osteoarthritis will be block-randomized in a 1:1 ratio. Patients will receive an initial single PRP or PRP + SVF injection followed by PRP doses at 1 month and 2 months. The primary endpoint is functional improvement measured with the Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) at the 6-month follow-up. Secondary endpoints, collected at the 1-month, 2-month, 3-month, 6-month, and 12-month follow-ups, will include the pain visual analogue scale during maximal physical activity, WOMAC score, length of time to return to work and sports in days, magnetic resonance imaging (MRI)–based Whole-Organ Magnetic Resonance Imaging Score (WORMS), Magnetic Resonance Observation of Cartilage Repair Tissue (MOCART) score, MRI Area Measurement and Depth and Underlying Structures (AMADEUS) score at 6 months and at 12 months, adverse events, and serious adverse events.

Results: Participant recruitment and data collection are expected to begin in July 2025 and finish in July 2027. Final end points will be gathered in August 2027, and the results are expected to be published in late 2027.

Conclusions: The study results will provide insight into the clinical efficacy of SVF as adjuvant therapy to PRP on functionality and tissue regeneration in patients with knee osteoarthritis.

KEYWORDS

stromal vascular fraction; platelet-rich plasma; osteoarthritis; adjuvant therapy; tissue regeneration; clinical efficacy

Introduction

Osteoarthritis, the most common joint disease [1], has a high social and individual impact, and the development of therapeutic options is a public health priority. Its multifactorial etiology is still a source of active research [2,3]. The most common conservative treatments for osteoarthritis include painkillers, active physical therapies, orthotics, corticosteroid infiltrations, hyaluronic acid, and platelet-rich plasma (PRP) [1,4].

PRP may be beneficial in osteoarthritis by interfering with catabolic and inflammatory events and by subsequently promoting anabolic responses. Activation of PRP releases biologically active components, including platelet-derived growth factor, transforming growth factor-β, type I insulin-like growth factor, and vascular endothelial growth factor. These proteins are responsible for a range of critical tissue healing roles, such as chondrocyte and mesenchymal stem cell (MSC) proliferation, bone and vessel remodeling, inflammatory modulation, and collagen synthesis [5].

Several clinical trials have found improvement in clinical outcomes for osteoarthritis [6,7], presumably associated with the chondroprotective effect of PRP. Nevertheless, despite the numerous studies on the subject, the evidence is inconsistent, there is a lack of uniform improvement in functional outcomes, and an in vivo effect on human cartilage regeneration has not yet been demonstrated [8,9].

Stem cell therapy has arisen as a new therapeutic option for knee osteoarthritis. Preclinical models have elucidated how injected adipose-derived mesenchymal stem cells (AD-MSCs) coordinate the cartilage regeneration process [10-12] through paracrine mechanisms [13], producing cytokines and trophic bioactive factors that stimulate cellular proliferation and reduce inflammation, fibrosis, oxidative stress, and chondrocyte senescence [1].

AD-MSCs seem to have a better hypoxic tolerance, fewer immunologic and inflammatory responses [14], better chondrogenic induction and gene expression [15], and less variable and more reliable clinical result [14] than bone marrow–derived mesenchymal stem cells (B-MSC).

Stromal vascular fraction (SVF), a product from processed adipose tissue, contains MSCs, endothelial precursor cells, T regulatory cells, macrophages, smooth muscle cells, pericytes, and preadipocytes. SVF extraction and injection techniques have recently been used as an alternative to harvest AD-MSCs due to their logistical simplicity and feasibility in clinical practice. The superiority or inferiority of SVF compared with AD-MSC has not yet been established.

Randomized trials indicate that intra-articular SVF injections can provide clinical benefits in knee osteoarthritis [16], with some studies noting cartilage quality improvements [16-19]. Despite their potential, SVF treatments are invasive, costly, and supported by a limited number of studies, many of which lack the homogeneity needed for clinical guideline endorsement, even though research in this area is steadily increasing and yielding promising results. Although PRP is often recommended in sports medicine for knee osteoarthritis, it is unclear whether combining it with SVF offers greater benefits for patients unresponsive to conservative treatment. This randomized controlled trial (RCT) will be the first to provide comparative data on the efficacy of SVF as an adjunct to PRP, addressing a critical gap in osteoarthritis treatment research.

The objectives of this study are to assess the clinical efficacy of SVF as adjuvant therapy to PRP on (1) functionality for knee osteoarthritis and (2) tissue regeneration for knee osteoarthritis.

Methods

Study Design

This multicenter, parallel-group, triple-blind study will enroll 108 patients who will be randomly assigned in a 1:1 ratio to either the intervention (SVF+PRP injection at baseline) or control group (PRP-only injection at baseline) using stratified randomization. The study will use a superiority framework.

The follow-up will last 12 months, with endpoints at 1 month, 2 months, 3 months, 6 months, and 12 months.

Study Setting

In this multicenter study, we aim to recruit all patients between July 2025 and August 2027 in the Sports Medicine Division of La Providence Hospital and in the Rehabilitation division, Hôpital Fribourgeois, both in Switzerland. The lead center is the Sports Medicine Division of La Providence Hospital where author AS is the sponsor-investigator. All the interventions will be performed in the lead center.

Eligibility Criteria

Patients will be recruited if they have knee osteoarthritis with persistent symptoms despite appropriate first-line treatment (ie, active physical therapies, sport and daily activity adaptations, orthotics use, medication) and for whom a surgical procedure is not indicated nor recommended.

The following main inclusion criteria will be used: (1) age older than 16 years; (2) symptomatic knee osteoarthritis confirmed by magnetic resonance imaging (MRI); (3) absence of free or displaced meniscal or cartilage fragments on the MRI of the affected knee; and (4) failure of first-line conservative management, including medical or infiltrative treatment, orthotics use, active rehabilitation plan, and adaptation of sports and work habits, in the last 3 months.

The following main exclusion criteria will be used: (1) patients familiar with the lipoaspiration process; (2) significant disease of the contralateral member with a disability, as evaluated with a Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) score >80%; (3) co-existence of microcrystalline disease (ie, gout, pseudogout); (4) active inflammatory rheumatic disorders; (5) a need for regular anti-inflammatory treatment (either nonsteroidal

anti-inflammatory drugs [NSAIDs] or corticosteroids) or anticoagulants; (6) patients with decompensated renal failure, hepatic dysfunction, or severe pulmonary or cardiovascular disease; (7) patients with an immunocompromised status; and (8) women who are pregnant or intend to become pregnant during the study.

If bilateral disease is present and both sides require either the experimental or control intervention, only the most symptomatic side will be studied.

Informed consent will be obtained by the local site investigator. Other physicians in associated structures (ie, orthopedists, general practitioners, physiotherapists) are informed of the study and will be asked to refer patients to the referent sports medicine departments.

Interventions

In both study groups, the intervention will be performed in the operating room under aseptic conditions and following the Arthrex protocols to prepare the autologous conditioned plasma [20], which is our PRP, and autologous conditioned adipose [21], which is our SVF, as described in the following paragraphs.

The patient is placed with a surgical drape hiding the interventional zone from the patient's sight. The blinded investigator performs a 1.5 mm incision under local anesthesia on each abdomen side in order to introduce the microcannula used to extract the SVF. Tumescent solution is prepared by mixing 500 mL NACL with 30 cc 2% lidocaine + adrenaline 1:200000 and 3 cc 8.4% sodium bicarbonate, then 60 mL of this preparation are injected into each side and left in place. An interval of 20 minutes is allowed, which is necessary to let the tumescent solution act on the abdominal adipose tissue. At this point, the blinded investigator leaves the room. In the experimental arm, the unblinded investigator uses a double syringe system to extract 30 mL adipose tissue from the abdominal incisions. This is then centrifugated at 2500 rpm for 4 minutes. The oil and water are discarded. The lipoaspirate is then filtered using two 20 mL syringes and a 1.4-mm diameter transfer hub. One last centrifugation is performed at 2500 rpm for 4 minutes obtaining 2 mL to 6 mL SVF and the remaining oil. This last mixture is then discarded. In the control arm, the unblinded investigator performs a sham adipose tissue extraction by introducing the extraction cannula and moving it for 2 minutes on each side. In both study arms, the venipuncture is then performed, and 15 mL blood are extracted for the PRP preparation using the Arthrex double syringe system [20]. The blood is then centrifuged at 1500 rpm for 5 minutes, resulting in 4 mL to 7 mL of PRP. No anticoagulant, calcium chloride, nor other PRP activator is added. Following the aseptic technique, the unblinded investigator prepares the SVF-PRP mixture or PRP alone in an opaque 10-mL syringe. In parallel, the patient is prepared for the ultrasound-guided injection procedure. With an 18-gauge needle, the SVF-PRP mixture or PRP alone is then injected by the blinded investigator.

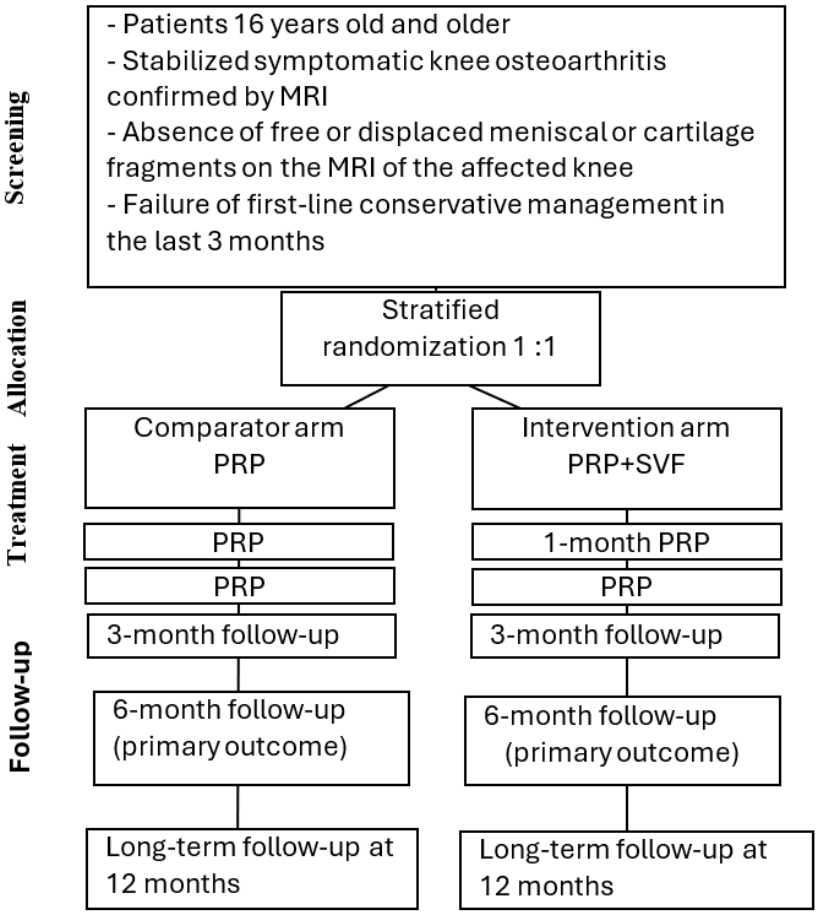
Postintervention care includes (1) partial weight-bearing for 1 month; (2) active strengthening of the muscles without overloading the knee using, if possible, the blood-flow restriction technique and gentle nonweight-bearing muscle activation, including core stability exercises; (3) mobility; and (4) modification of daily activities, work, and sports habits.

A total of 5 follow-up visits are planned for the study, during which principal and secondary outcomes will be gathered by a blinded investigator. At the 1-month and 2-month follow-up visits, patients in both study arms will receive 2 additional ultrasound-guided PRP injections performed by the blinded investigator and following the same Arthrex autologous conditioned plasma technique. The same postintervention care will be provided after these 2 PRP injections. Figure 1 shows the study flow chart.

Anticoagulants (eg, aspirin) and anti-inflammatory drugs (eg, ibuprofen, naproxen, meloxicam) should not be used 2 weeks before and 2 weeks after each injection as it can potentially interrupt the therapeutic acute inflammatory response and cytokine production.

Active physical therapies regimens, orthotics use, sports, and daily activities are adapted to the patient, on a day-by-day basis, during the postintervention care.

Figure 1. Study flow chart. MRI: magnetic resonance imaging. PRP: platelet-rich plasma.



Outcome Measurements and Assessments

The primary outcome is functional improvement measured with the 0%-100% normalized WOMAC at the 6-month follow-up, where 0% indicates complete absence of symptoms and 100% indicates maximal possible symptom severity. A clinically relevant functional improvement is a difference of 9.1 points out of 100 points.

The secondary outcomes will be clinical and radiological parameters gathered at the 1-month, 2-month, 3-month, 6-month, and 12-month follow-ups. These include a 10-point pain visual analogue scale (VAS) during maximal physical activity performed by the patient according to manageable pain and clinical recommendations, the 0%-100% normalized WOMAC [2], length of time to return to work and sports in days, adverse events (AEs), and serious adverse events (SAEs). Pain will be assessed as an AE of interest, during the intervention and 48 hours following the intervention.

The improvement in cartilage quality will be assessed at the 6-month and 12-month follow-ups (previous MRI should not be dated more than 3 months before the intervention) using 3 key MRI-based scoring systems: Area Measurement and Depth and Underlying Structures (AMADEUS) [13], Whole-Organ Magnetic Resonance Imaging Score (WORMS) [22], and Magnetic Resonance Observation of Cartilage Repair Tissue (MOCART) [23].

We initially planned to statistically assess these outcomes at 6 months and 12 months. However, assessment of these parameters at other time points might be subject to exploratory analysis.

The participant timeline is presented in Table 1. The following information will be collected at baseline: age, gender, height, weight, BMI, smoking status, comorbidities, baseline Kellgren–Lawrence grade, current and previous treatments, and posttraumatic etiology. The set of clinical and radiological scores include the VAS, WOMAC, return to work and sports in days, AMADEUS, WORMS, and MOCART.

[a]Screening and baseline visits can be performed on the same day if the patient has been given reasonable time to make a consented decision about participation in the study.

[b]—: not applicable.

[c]MRI: magnetic resonance imaging.

[d]Stromal vascular fraction+platelet-rich plasma (PRP) or PRP-only injection depending on the group.

[e]PRP: platelet-rich plasma.

[f]AEs: adverse events.

[g]SAEs: serious adverse events.

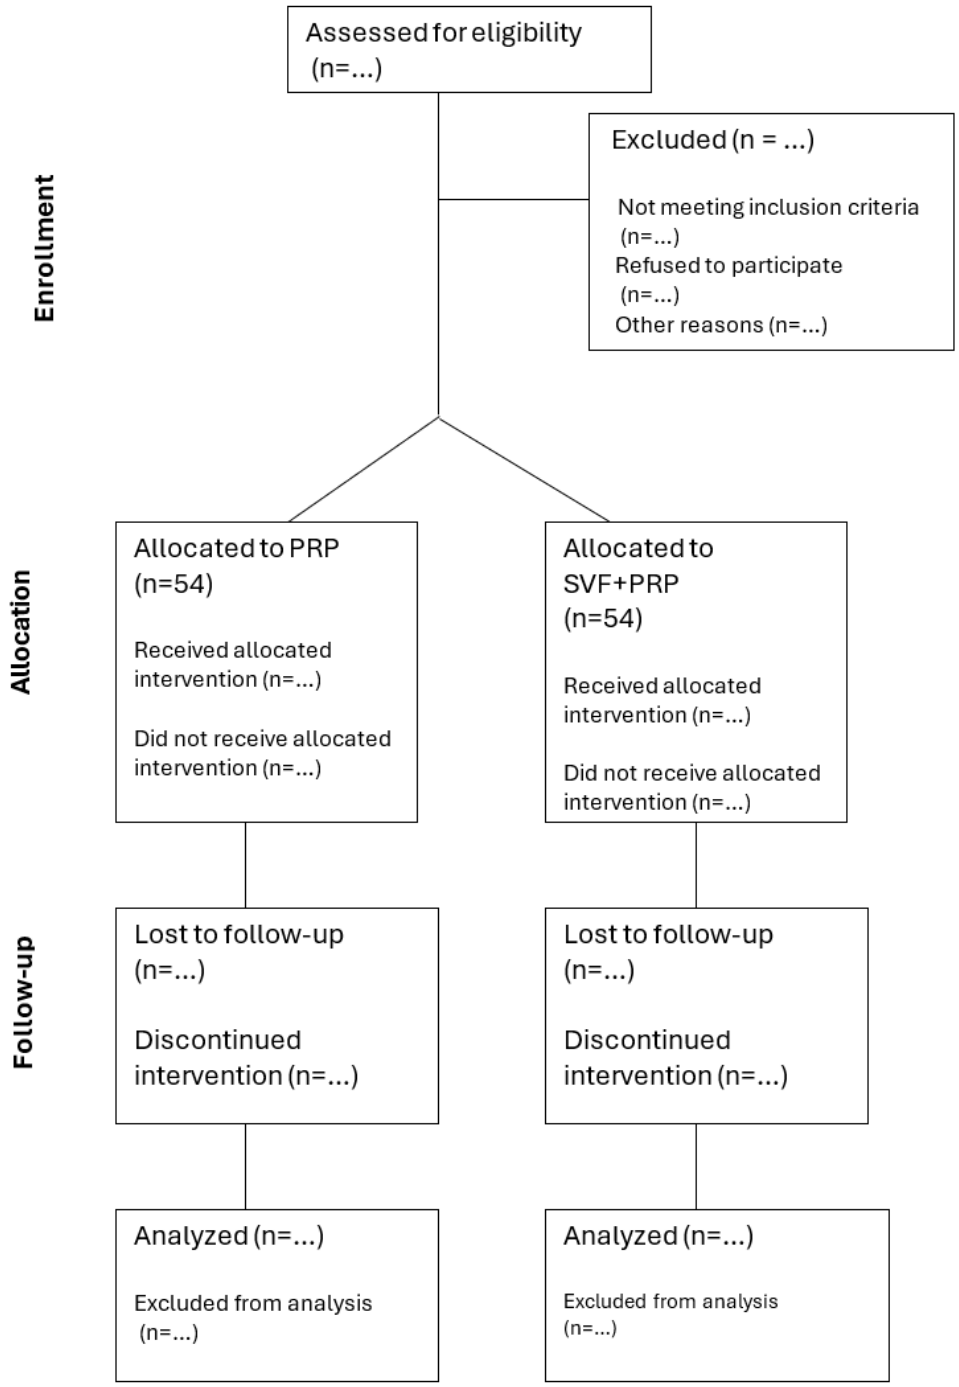
Sample Size

The sample size for this study was calculated using PS software (Vanderbilt University) [24]. We aimed to detect a clinically meaningful difference of 9.1% in the absolute change in the WOMAC function score between the experimental and control groups. The calculation assumed an SD of 13.9%, based on findings from the study conducted by Tubach et al [25].

In their study, Tubach et al [25] evaluated changes in the WOMAC function score in patients with knee osteoarthritis treated with NSAIDs over a 4-week period. They reported an average baseline WOMAC function score of 42.8 (SD 16.1) and an absolute improvement of –11.6 (SD 13.9). These values were used to estimate the variability in absolute changes for our calculation.

With these parameters, a sample size of 108 patients (54 per group) was determined to provide 90% power to detect the specified difference at a 5% significance level using a 2-tailed test. This calculation ensures that our study is adequately powered to detect a meaningful treatment effect based on absolute improvements in functional outcomes. The study will collaborate with health care providers in both study centers to achieve the target sample size. Additionally, potential participants will be contacted through patient registries and referrals. All recruitment efforts will comply with ethical guidelines and prioritize informed consent. Figure 2 shows the CONSORT (Consolidated Standards of Reporting Trials) diagram [26].

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) diagram showing the flow of participants through each stage of the randomized trial. PRP: platelet-rich plasma; SVF: stromal vascular fraction.



Randomization and Blinding

Study participants will be randomized at a 1:1 ratio to either the intervention arm or the active comparator arm using a randomization table and blocked randomization with blocks of 4 patients. Participants will be assigned to specific strata based on age (older or younger than 40 years) and the presence of cartilage defects (partial, full, or full with bone deformation).

The unblinded investigator responsible for the study interventions will perform the randomization shortly before administering the interventions. This study is triple-blinded: (1) Participants will be unaware of their group assignment throughout the intervention and study duration, (2) the investigator performing the intraarticular injection and the outcome assessor will remain blinded, and (3) the statistician will also be blinded. The investigator responsible for preparing the PRP+SVF or PRP-only preparation will be unblinded and will not participate in outcome assessments.

All patients will undergo a venipuncture, either a lipoaspirate or a sham lipoaspirate, followed by an ultrasonographically guided PRP or PRP+SVF injection. It is anticipated that unblinding will not be required to ensure patient safety, as no known adverse effects of the SVF (such as local pain, tenderness, hematoma on donor site, or infection) require

unblinding for clinical management. However, if unblinding becomes necessary due to unexpected circumstances, the unblinded investigator will disclose the allocated intervention for the affected patients.

Data Collection and Management

All data collected in this study will be recorded in standardized electronic case report forms (CRFs; see Multimedia Appendices 1-4). We plan to use Hermes software. Hermes is a tool developed by sponsor-investigator AS, used for a patient registry, and validated by the local ethics committee board (authorization # CERVD AO_2020-00006). Only data with logical numeric variables within the correct ranges or predefined categorical variables can be entered into the electronic CRFs. Data entry for variables of interest is mandatory.

CRFs will be kept current to reflect participant status at each phase during the course of the study. Study-related data will be collected in a coded manner (participants will not be identified in the CRF by name or initials). Identification of patients must be guaranteed at the study site. Patients' identifications will be recorded in a sequential list stored in the local investigator's secured server. At the end of the study, when the database has been checked for completeness and validated by the sponsor-investigator, it will be locked and used for statistical analyses. All "study essential documents" (eg, informed consent form, CRFs) will be archived for at least 10 years after completion of the clinical trial.

Data sharing is not applicable to this article, as, to date, no data sets have been generated nor analyzed.

Statistical Analysis

The WOMAC score will be normalized to a 0%-100% scale, where 0% indicates no symptoms and 100% represents the highest severity of symptoms. This normalization involves converting the raw scores into percentages, facilitating the interpretation and comparison of results across participants and study groups. The absolute difference at 6 months will serve as the primary outcome and will be compared using either the paired Student *t* test or the Wilcoxon signed-rank test, depending on the distribution of the variable, with intention-to-treat analysis. The absolute differences in secondary outcomes (changes from baseline to other time points) between the treatment and control groups will be evaluated with the appropriate statistical test (categorical variables: chi-square or Fisher exact tests; continuous variables: Student *t* or Wilcoxon rank tests). All analyses will include both intention-to-treat and per-protocol analyses. Effect estimates, 95% CIs, and descriptive *P* values will be reported whenever possible, along with corresponding graphs.

A post hoc analysis will attempt to identify variables of interest using the appropriate global linear model.

Since the intervention is considered low risk, no interim analysis is planned. In case of missing primary outcome data, patients will be withdrawn from the analysis. Patients missing secondary outcome data will remain in the study but be excluded from those specific analyses.

Oversight and Monitoring

For quality control of the study conduct and data retrieval, all study sites will have regular monitoring activities performed by appropriately trained and qualified monitors, who are outsourced by the sponsor-investigator. Monitoring activities will consist of on-site monitoring as well as remote and centralized monitoring.

The objectives of a monitoring visit are to (1) verify the informed consent form process for each monitored participant, (2) verify the prompt and accurate recording of all monitored data points and prompt reporting of all safety events, (3) compare collected data with participants' source documents, and (4) ensure investigators comply with the protocol.

The monitors may also inspect the clinical site regulatory files to ensure that regulatory requirements and applicable guidelines (International Council for Harmonisation [ICH] Good Clinical Practice [10]) are being followed.

SAEs will be defined as any untoward medical occurrence that results in death, is life-threatening, requires inpatient hospitalization or prolongation of existing hospitalization, results in persistent or significant disability or incapacity, or in a congenital anomaly or birth defect. SAEs should be followed until resolution or stabilization. Assessment of causality will be based on the criteria listed in the ICH E2A guidelines [10], and severity will be graded based on the Common Terminology Criteria for Adverse Events Version 5 [27]. All SAEs will be reported immediately and within a maximum of 24 hours to the sponsor-investigator of the study. The sponsor-investigator will re-evaluate the SAE and return the form to the co-investigator. SAEs resulting in death will be reported via the sponsor-investigator to the Swiss Business Administration System for Ethics Committees and to the other ethics committees involved in the trial within 7 days.

Regular audits are not planned. For the purpose of on-site inspection or audit, the competent authorities or ethics committee may require access to all source documents and other study-related records. The sponsor-investigator and local investigators must ensure the availability of these documents at any time.

Ethical Considerations

Ethics Review Approvals

To comply with local regulations in Switzerland regarding clinical trials involving human subjects, this study design is classified as risk category C [28-30].

Therefore, both Swissmedic (the Swiss authority responsible for the authorization and supervision of therapeutic products) and the local ethics committee must review and approve the research protocol. Since both applications require a significant investment, a grant request will be submitted prior to applying to these two institutions. The principal investigator will obtain approval from the competent authority (Swissmedic) before the start of the study. Once the protocol is approved, no changes will be made without prior approval from the ethics committee, except when necessary to eliminate immediate hazards to participants.

Informed Consent

The recruiting investigator will explain the study's nature, purpose, procedures, duration, risks, benefits, and discomforts. Participation will be voluntary, and participants can withdraw at any time without affecting their medical care. Each participant will receive an information sheet and consent form to make an informed decision, with time to consult others and ask questions. Consent will be obtained before any procedures, and the signed form will be kept as part of the records. Participants will be informed that authorized individuals may examine their medical records. The informed consent is available in Multimedia Appendix 5.

Privacy and Confidentiality

The investigator upholds the participant's right to privacy and complies with privacy laws, ensuring anonymity in scientific presentations and publications. Medical information from the study is confidential, and third-party disclosure is prohibited. Participant confidentiality will be maintained using identification code numbers. Authorized representatives, such as those from Swissmedic or the ethics committee, may access relevant medical records for data verification.

Compensation Details

There is no compensation provided for participants in this human subjects research.

Identifiable Features

Identifiable features of research participants in any image or supplementary material will not be visible.

Results

This version of the study protocol presented in this article is ready to be presented to the Switzerland regulatory authorities. A request for funding was submitted to the Swiss Medical Foundation in December 2024, and the study was registered in the portal for clinical trials in Switzerland (number pending).

Enrollment to the study is expected to begin in July 2025 and finish in July 2027. Final end points will be gathered in August 2027, and the results are expected to be published in late 2027. The findings will be shared through conference presentations targeting rehabilitation and sports medicine specialists. The Swiss Medical Network and Switzerland's Physical Medicine and Rehabilitation Network will be engaged through presentations at their yearly research events to help implement findings in clinical settings.

Given the open-access nature of the target journal, all results will be publicly available. To gather feedback, we will use postpublication surveys, interactive webinars, and follow-up interviews with patients and practitioners to discuss the applicability and impact of SVF therapy in practice.

Discussion

This study design intends to assess the potential benefits of SVF injection, an easy-to-use, simple, and noninvasive cellular therapy, on the most frequent joint disease. With this high-quality RCT, SVF will be compared with one of the most commonly used noninvasive therapies in the field of sports medicine, PRP.

Based on available clinical trials, we hypothesize that SVF treatment in addition to PRP may lead to significant clinical and radiological improvement in patients with knee osteoarthritis. The WOMAC and VAS scores are among the most commonly used clinical outcomes in RCTs and meta-analyses for knee osteoarthritis research. For radiological assessment, 3 MRI-based scoring systems—AMADEUS, MOCART, and WORMS—are frequently cited in RCTs. Including these scores as primary and secondary outcomes will facilitate future meta-analyses and allow direct comparison of our trial’s results with those of previous studies

Compared with PRP, cellular therapy with SVF requires more physician training, takes more time, and ultimately incurs higher costs. In other words, it demands greater resources. From the authors’ perspective, patients and caregivers should only invest in these additional resources if clear benefits are demonstrated, which this study aims to establish.

Different techniques have been used to inject or implant cellular therapy with MSCs to the required site, but consensus about the best approach does not exist. However, biologically, some elements support the use of AD-MSCs for nonbone tissue. AD-MSCs would theoretically be more resilient than B-MSCs to the hypoxic articular cavity because they are less dependent on mitochondrial respiration for energy production. From an immunological perspective, AD-MSCs should be preferable to B-MSCs since B-MSCs could induce a higher immunological response due to their higher cell-surface human leukocyte antigen class I expression. AD-MSC highly expresses interleukin-33, which promotes regulatory T cell phenotype proliferation, which would theoretically mean a beneficial effect on anti-inflammatory responses [14].

Han et al [11] compared AD-MSC with B-MSC for knee osteoarthritis and found a superior therapeutic effect of AD-MSC compared with B-MSC on VAS and WOMAC scores. Zhou et al [31] performed a meta-analysis comparing AD-MSC and B-MSC therapies, and they found no statistical differences in clinical scores between the two therapies but did find a higher variability in B-MSC results, suggesting AD-MSCs might be a more reliable therapeutic option. Ude et al [32] found better chondrogenic inductions and gene expressions with AD-MSCs than with B-MSCs.

The therapeutic potential of MSCs is of great interest due to their possible long-term chondroprotective and even chondroregenerative effects. A meta-analysis by Lee et al [19] demonstrated significant improvements in imaging outcomes measured using the WORMS and MOCART scores. WORMS scores improved significantly with SVF therapy compared with controls at both 6 months and 12 months posttreatment (6 months: mean difference [MD]=–18.29, 95% CI – 21.75 to –14.84; 12 months: MD=–26.78, 95% CI –29.95 to –23.61). Similarly, MOCART scores showed notable improvements with AD-MSC therapy at 6 months (MD=24.7, 95% CI 5.92 to 43.48) and 24 months (MD=25.8, 95% CI 5.52 to 46.08), while SVF therapy resulted in significant gains at 6 months, 12 months,

and 24 months (6 months: MD=30.11, 95% CI 26.08 to 34.13; 12 months: MD=36.82, 95% CI 23.95 to 49.68; 24 months: MD=10.60, 95% CI 1.37 to 19.83).

The comparative superiority of SVF over AD-MSCs, or vice versa, remains uncertain, as no RCT has yet directly addressed this question. An observational study [33] suggested the superiority of AD-MSCs, but further evidence is needed.

The meta-analysis by Lee et al [19] showed some differences between both therapies on clinical outcomes. A significant improvement in the VAS score was found at 6 months and 12 months with AD-MSCs (6 months: MD=–1.62, 95% CI –2.46 to –0.79; 12 months: MD=–1.97, 95% CI –3.22 to –0.72), whereas SVF showed significant results only at 12 months (6 months: MD=–2.32, 95% CI –5.15 to 0.52; 12 months: MD=–2.13, 95% CI –3.06 to –1.21). In contrast, functionality measured with WOMAC scores improved significantly 6 months after SVF treatment (MD=–6.12, 95% CI –10.71 to 1.52), while AD-MSC therapy yielded significant improvements only after 12 months (6 months: MD=–1.96, 95% CI –5.36 to 1.45). At 12 months and 24 months, both SVF and AD-MSC therapies produced significant improvements in the WOMAC score (12 months SVF: MD=–9.09, 95% CI –12.67 to –5.51; 12 months AD-MSC: MD=–9.19, 95% CI –12.48 to –5.90; 24 months SVF: MD=–10.71, 95% CI –18.49 to –2.93; 24 months AD-MSC: MD=–6.88, 95% CI –10.24 to –3.52).

The first main strength of our study design is the large sample size. Second, our study population is well-designed and reproducible, with standardized diagnostic criteria and failure of a first-line standardized rehabilitation plan. Third, the multicenter design allows for better reproducibility of patient selection and management, even if interventions are performed at the main study center by a single investigator. This is, however, a study strength, as it will avoid bias related to the intervention techniques.

A sham lipoaspiration procedure with the patient awake is performed to maintain blinding in the control group. Despite all precautions taken to uphold allocation concealment, breaches may occur if the patient diligently questions the procedure. For ethical reasons, if at 6 months, the progression is unsatisfactory, the intervention's nature may be disclosed if deemed clinically relevant, allowing the patient to benefit from SVF infiltration. Consequently, the study may be limited, as the initial 12-month secondary outcomes will not be considered in the final analysis. Finally, the patient selection, clinical follow-up, and rehabilitation plan might differ across the various recruitment centers (multicenter design).

The minimal clinically important difference was chosen as the limit to detect a clinically relevant difference for sample size calculation. From the authors' point of view, even in the case of statistically significant positive effects of the treatment, the generalization of the procedure should be balanced by a complementary cost-effectiveness analysis. Indeed, in case of mild benefits, other procedures such as strengthening, biomechanics adaptation, medication, annual PRP infiltrations, shockwave therapies, or even slight daily activity adaptations might be options of choice. One should be aware that cellular therapies should not be presented to patients as a "magic potion" or "youth elixir." Especially, the authors warn about the recognized risk of financial benefits based on overemphasized clinical promises.

This study will contribute data to establish the clinical relevance of SVF treatment for the most relevant disease of the musculoskeletal system.

Acknowledgments

A request for funding has been presented to the Swiss Medical Foundation.

Abstract

Background: Obstructive sleep apnea (OSA) is a common sleep disorder, and in pregnancy, it is associated with an increased risk of complications, including gestational diabetes mellitus and preeclampsia. Supine sleep may worsen OSA, and in pregnancy, it is associated with an increased risk of stillbirth due to effects on fetomaternal blood flow. Continuous positive airway pressure (CPAP) therapy is considered the gold-standard treatment for moderate to severe OSA, although compliance is frequently poor; positional therapy (PT) is generally less effective than CPAP in nonpregnant patients but may be better tolerated and more accessible during pregnancy. There is limited data on whether widespread, early screening for sleep disorders in pregnant women with symptoms of sleep-disordered breathing or at high risk of metabolic complications and subsequent early intervention with CPAP or PT attenuates fetomaternal risks.

Objective: This study aims to determine the feasibility of conducting a randomized controlled trial to assess improved fetomaternal outcomes in a high-risk pregnant population with OSA, using CPAP or PT, initiated by the 16th week of gestation.

Methods: This study is a randomized, controlled, open-label feasibility study in which pregnant women with an apnea-hypopnea index (AHI) or respiratory disturbance index (RDI) ≥5 are treated with CPAP (auto-titrating and fixed pressure) or positional therapy from early gestation (by 16 weeks) until delivery. The primary outcome is the feasibility of the study protocol and the development of gestational diabetes mellitus by the 28-week gestation period. Secondary outcomes include the development of hypertensive disorders of pregnancy (HDP), maternal weight gain, uterine artery blood flow, glycemic control during pregnancy (in participants who develop gestational diabetes), changes in maternal circulating biomarkers, and neonatal birthweight

complications. Polysomnography at 28- to 32-week gestation period, postpartum polysomnography, therapy compliance, and patient acceptability are also assessed.

Results: The trial commenced on September 30, 2019. The trial is ongoing as of August 6, 2024.

Conclusions: The trial intends to contribute to the growing evidence base to support the need for the identification and treatment of OSA occurring during pregnancy and to assess the feasibility of the study protocol. This will be the first trial to compare the early initiation of CPAP (auto-titrating and fixed pressure) and positional therapy in pregnant women from early gestation, providing alternative therapies for the treatment of OSA in this important population.

Introduction

During pregnancy, physiological changes, including upper airway edema and hormone-related upper airway pressure changes, predispose women to sleep-disordered breathing (SDB) [1]. The prevalence of obstructive sleep apnea (OSA) in pregnancy increases from 3.6% in early pregnancy to 8.3% in midpregnancy and is associated with an independent risk of gestational diabetes mellitus (GDM), preeclampsia, and hypertensive disorders of pregnancy (HDP) [2]. In addition, emerging evidence suggests that the presence of SDB before pregnancy may place women at an increased risk of developing GDM [3]. Supine sleeping in late pregnancy is associated with an increased risk of stillbirth [4], and supine sleep avoidance is recommended from the 28-week gestation period [5].

Treatment options for OSA in non-pregnant adults include continuous positive airway pressure (CPAP), weight loss, positional therapy, mandibular advancement splints, surgery (both upper airway and bariatric), and pharmacological therapies, though not all are suitable for use in pregnant populations. CPAP and positional therapies reduce the occurrence of OSA by reducing the occlusion of the upper airway through pneumatic splinting [6] and repositioning the sleeping persons to reduce collapsibility of the airway [7,8], respectively. Within nonpregnant populations, longer duration CPAP compliance (more than 7 hours) was associated with a reduction in hemoglobin A_{1c} by 1% when CPAP was used for more than 85% of the rapid eye movement stage of sleep during the night [9]. Improvements in blood pressure control have been demonstrated in nonpregnant patients with OSA [10,11], and a small benefit in 24-hour diastolic blood pressure in patients using fixed pressure CPAP compared with auto-titrating CPAP has been reported [12].

In pregnancy, CPAP is recommended as the first line of treatment for OSA [13,14], although alternatives to CPAP may be beneficial but require clinical trials to investigate their utility [14]. In pregnant populations, many studies investigating CPAP treatment have used small sample sizes [15] or initiated therapy in later gestation periods. An early study of 12 pregnant women with OSA at risk of preeclampsia demonstrated no improvement in clinical maternal outcomes [16]; likewise, CPAP failed to demonstrate improvements in glucose levels in obese pregnant women with 2 weeks of CPAP use between 24- and 34-week gestation periods, although compliant use of CPAP in this study demonstrated an improvement in insulin secretion and sensitivity [17]. There are, however, some benefits reported in the literature; a single night of CPAP in a study of 10 pregnant women with preeclampsia and coexisting obesity demonstrated improvements in fetal movements [18], and an improvement in blood pressure control both during sleep and wake was reported in a small study of 7 women, resulting in down titration of antihypertensive medication [19].

Compliant use of CPAP remains a challenge, and in some patients, it may be dependent on clinical support mechanisms, with pre- and postacclimatization phase support improving therapy compliance [20]. Gender-based differences in CPAP compliance have been demonstrated in a large study of nearly 800,000 CPAP users, where women aged 18-30 had the lowest CPAP compliance (51.3%) and were most likely to cease therapy [21]. Barriers to compliant CPAP therapy in pregnant women with OSA are relatively unknown though targeted supports, which have demonstrated improvements in maternal medication compliance, may be beneficial [22]. A recent randomized controlled trial assessed blood pressure outcomes in 340 high-risk pregnant women recruited predominantly during the first trimester, allocated to CPAP or no treatment (control). Despite a mean CPAP compliance of 2.5 hours nightly, and an overall compliance (≥ 4 hours nightly) of 32.7% of participants randomized to CPAP, this reported reductions in diastolic blood pressure and preeclampsia rates [23]. This study additionally presents data on CPAP side effects, and despite rhinitis, mask difficulties, and pressure intolerance reported, there was no significant difference in the reporting of these symptoms between compliant and noncompliant participants, indicating the possibility that these side effects are not barriers to treatment in this special population.

CPAP devices are available in fixed and auto-titrating options and in nonpregnant OSA patients, patient preference has demonstrated mixed results [24,25], although data are lacking in pregnant populations. Furthermore, evidence of the efficacy

of auto-titrating devices through gestation advancement is limited, and despite the availability of auto-titrating devices that attempt to target flow-limited breathing using reduced air pressure in premenopausal women [26], their utility in pregnancy is unknown.

Positional therapy is less effective at reducing apnea-hypopnea index (AHI) and nocturnal oxygen desaturation [7,27] but is effective at reducing supine sleep time [7], which is associated with the worsening of OSA [8]. Positional therapy (PT) in pregnancy is hypothesized to impact outcomes by two potentially independent pathways: first, by addressing SDB, which is typically worse in the supine position, and second, by minimizing compression of the vena cava by the gravid uterus, which may reduce fatal blood flow. A feasibility study using a back-worn positional therapy band for a single night in healthy pregnant women at 32- to 38-week gestation periods showed improvement in maternal oxygenation and reduced fetal heart rate decelerations compared with the controlled night [28].

Given placentation completes around 16-week gestation period, the timing of OSA treatment intervention may be particularly important, as data demonstrates significant benefits of time-specific interventions in pregnancy, for example, aspirin is generally beneficial in preventing preeclampsia if commenced before 16-week gestation period [29]. We thus outline a protocol to determine the feasibility of a parallel group, individually randomized, controlled, open-label trial comparing CPAP or PT to usual care (control). Commencement of therapy by the 16th week of gestation has been chosen to reduce exposure to intermittent hypoxia on the developing placental function during early pregnancy and to establish early compliance to treatment. The use of fixed pressure CPAP after auto-titration of pressure in this trial was determined by factors including access to trial equipment, cost, and absence of evidence of the superiority of auto-titrating over fixed pressure CPAP in pregnancy. This trial aims to determine the feasibility of conducting a larger trial and to obtain preliminary recruitment and efficacy data that may be used to design and power a larger trial. This study may be of interest to others conducting sleep therapy intervention studies in pregnant women.

Clinical Trial Objectives

This study aimed to determine whether CPAP or PT initiated by the 16th week of gestation in pregnant women with a respiratory disturbance index (RDI) or AHI ≥5 results in improved clinical outcomes, particularly in relation to the development of gestational diabetes.

Trial Feasibility Objectives

This study aims to assess the feasibility and acceptability of trial interventions and schedule of visits and determine limitations of trial design, including patient and hospital staff participation.

Methods

All trial primary and secondary outcomes are described in the Australian New Zealand Clinical Trials Registry Trial Registry.

Ethics Approval and Consent to Participate

Overview

Participant recruitment commenced on September 10, 2019. The final patient was recruited in December 2022 and is expected to complete participation in June 2024. The participants affected by product recalls in this trial will be followed up annually for 5 years, if agreeable as per the protocol. Data from participants who choose to withdraw from study participation will be included in the final analysis unless requested by the participant. The trial was registered on November 6, 2019 (ACTRN12619001530112), 7 weeks after the first participant was recruited for the study. The study protocol was not amended during this time.

Human Subject Ethics Review Approvals or Exemptions

The South Western Sydney Local Health District Human Research and Ethics Committee (SWSLHD HREC) approved this study (June 12, 2019, project identifier 2019/ETH00283). The current protocol version 3.1 was approved on November 11, 2022.

Informed Consent

The participants with scheduled antenatal bookings at Liverpool and Campbelltown hospitals will be invited to undertake a screening eligibility preconsent questionnaire, which is presented in Multimedia Appendix 1 by research study staff to determine participation eligibility as described in the eligibility criteria above. Women will be sequentially approached.

Following the screening, study staff will invite eligible participants to provide written informed consent. Multimedia Appendix 2 presents the postconsent baseline information questionnaire, which will be collected at the next trial consent.

The participants will undertake attended polysomnography to determine eligibility in the RCT. Additionally, the participants will be invited to undertake Apnealink Air and Somte at both the baseline and 28- to 32-week gestation periods, in addition to the attended polysomnography as part of a substudy assessing agreement in AHI or RDI scores in the early to mid-gestation period. Sleep studies will be undertaken within a 7-day window, where practicable. Completion of Apnealink and Somte are not required for RCT participation but will be used to determine the validity of these tests for future use in this population. Eligibility for participation in RCT will be determined by polysomnography outcome.

Women who undergo polysomnography by 14-week gestation period and demonstrate OSA as evidenced by an RDI or AHI ≥5 on polysomnography will be invited to participate in the RCT provided exclusion criteria are not met as described above. A second written informed consent will be collected by study staff, and the participants will be randomized to CPAP, PT, or control as described in the randomization section below.

Validation of home sleep testing in this population will be undertaken via a separate substudy. After validation of the home testing method, further recruitment and screening measurements will continue with screening questionnaires and home Apnealink Air only.

Privacy and Confidentiality

Unattended polysomnography, Apnealink Air, and biomarker data will be deidentified, as described in the relevant methods sections below. Patient data are deidentified for the purpose of randomization, as described below.

Participant consent forms, printed results, and other identifying information on hard copy will be stored in a locked cabinet in a security-access area of the Respiratory and Sleep Medicine Research Department at Liverpool or Campbelltown Hospitals. Where possible, study data will be stored separately to participant identifiers. A master list of study ID numbers and participant identifiers will be stored electronically in a password-protected file within a designated electronic folder on the Respiratory Research drive on the secure Liverpool Hospital server. A separate password-protected folder will be designated for any electronic records with results and identifying information.

Compensation

If the participants suffer any harm, they will be compensated as per health authority regulations.

Trial Design

Pregnancy-associated obstructive sleep apnea (POSA) is a 2-center randomized controlled feasibility trial. The participants will be recruited following participation in an observational study by our group that assesses diagnostic validation of Apnealink air and Somte devices and long-term fetomaternal outcomes. The participants will also be approached at antenatal visits or called by telephone to assess eligibility. Recruitment at both study sites will be concurrent, and the participants who meet the eligibility criteria based on AHI or RDI results in the observational study will be approached for participation in the RCT.

The RCT will use a parallel group, individually randomized, open-label design with two interventions and one control group (1:1:1), with minimization allocation among the 3 arms stratified for BMI, previous history of preeclampsia, or gestational diabetes mellitus. A total of 48 participants (16 in each arm) will be recruited. Study visits will occur monthly after randomization until 32-week gestation period and fortnightly thereafter until delivery, as is local routine clinical practice for antenatal visits. Data collection will include demographic, clinical and physical details, sleep questionnaire responses, sleep study data, maternal pathology, fetal scans, birth details, maternal and fetal clinical outcomes, sleep therapy compliance, and therapy acceptance questionnaires.

We used the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) checklist when writing our protocol [30], which can be found in Multimedia Appendix 3.

Trial Setting

POSA will be conducted at Liverpool Hospital (LPH) and Campbelltown Hospital (CTN) public hospitals within the South Western Sydney Local Health District in metropolitan Sydney, New South Wales, Australia. LPH is a tertiary referral center offering comprehensive antenatal services, delivering approximately 4000 women annually, and includes a level 6 neonatal intensive care unit for neonates from a 24-week gestation period in the district and a comprehensive sleep and respiratory service, including a 5-bed sleep laboratory, ambulatory testing, and a comprehensive outpatient service, including clinics for CPAP therapy. CTN delivers approximately 4200 women annually, with a level 4 nursery that cares for neonates from a 32-week gestation period and a general respiratory and sleep clinic, without the capacity to undertake polysomnography. POSA participants recruited from CTN will be referred to LPH for laboratory polysomnography.

Eligibility Criteria

Eligible participants are defined as women aged 18 years of age and older; in early pregnancy (up to 14-week gestation period); at increased risk of metabolic complications defined as one or more of (1) BMI greater than or equal to 35 kg/m^2, (2) previous GDM, (3) previous personal history of preeclampsia (or in mother or sister), (4) underlying renal disease, (5) maternal type 2 diabetes (pregestational), and (6) symptoms of SDB including snoring, witnessed apnea, mild excessive daytime sleepiness (EDS; which does not meet the criteria for severe EDS defined by Epworth Sleepiness Scale (ESS>15), or a fall asleep accident, or near-miss accident in the previous 12 months), or tiredness; and obstructive sleep apnea diagnosed by polysomnography defined as RDI or AHI ≥ 5.

The participants will be excluded if they have (1) a previous diagnosis of OSA on active treatment, (2) confirmed GDM or preeclampsia, (3) maternal type 1 diabetes, (4) multifetal gestation, (5) known fetal chromosomal abnormality, (6) inability to provide informed consent, and (7) severe EDS based on clinical assessment (eg, including a fall asleep motor vehicle accident or near miss, transient sleepiness while driving or at lights or needing to pull over due to sleepiness while driving, or transient sleepiness in any other dangerous situation, ie, cooking, carrying a baby) or ESS of greater than 15.

Interventions

All groups will have antenatal care as usual without restriction during the trial. The participants will be randomized to CPAP, PT, or control, and the participants randomized to intervention (CPAP or PT) will undertake therapy device education at the randomization visit and commence therapy on the day of randomization or as soon as is practicable. The participants will also be encouraged to use their therapy device for all sleep periods (including naps) from randomization until delivery. CPAP and PT devices will be returned following delivery or withdrawal or discontinuation from the study. The CPAP masks used by the study participants may be retained at the end of the study.

All participants will undertake polysomnography at the 28- to 32-week gestation period. CPAP or PT intervention participants will complete polysomnography at a 28- to 32-week gestation period with the device in situ to confirm treatment efficacy. CPAP will be titrated, if required, as described above. In addition, participants will be invited to complete Somte and Apnealink at 28- to 32-week gestation period, as part of the device validation substudies.

CPAP Intervention

The participants in the CPAP intervention group will use a close-fitting facial mask worn overnight during sleep to ensure that the collapsible upper airway is kept patent with a column of air and they will commence on auto-titrating pressure 6-20 cm H_2O (Philips Dreamstation Auto with heated humidification) per clinical practice at the study site. The participants will also be offered a range of CPAP masks to trial with an option to take home multiple masks or sizes if needed. CPAP participants will be educated in device use and troubleshooting by an experienced sleep therapist before commencing therapy. The trial sleep therapist will telephone CPAP group participants on day 3 to gain access to CPAP efficacy data via remote monitoring software (Care Orchestrator, Philips). Pressure will be changed to the 90th percentile pressure in fixed pressure mode, provided compliance data show average usage of CPAP across a period of more than 4 hours (All Days≥4 hours), and treatment efficacy is achieved as determined by residual AHI≤5. The participants with poor compliance or efficacy will be given additional acclimatization time on CPAP, up to 7 days (or as clinically necessary), and changed to the 90th percentile when clinically appropriate. CPAP data will be downloaded via Secure Digital card (SD) data card and reviewed at each study visit and at the return of the device as per the study schedule and interrogated for CPAP compliance, efficacy, and mask leak.

CPAP pressure will be adjusted empirically at scheduled study visits to maintain treatment efficacy (AHI≤5). Polysomnography will be conducted at 28 weeks on the current CPAP pressure. Titration of CPAP pressure will be undertaken if criteria for pressure increase is met per AASM (American Academy of Sleep Medicine) manual titration guidelines, that is, up to 1 increase by 1 cm H_2O per 5-minute period for any of the following: 2 of obstructive apneas, 3 of hypopneas, 5 of the respiratory event–related arousals, or 3 minutes of loud or unambiguous snoring [31]. CPAP pressure changes will be reported in published study findings at the conclusion of the trial.

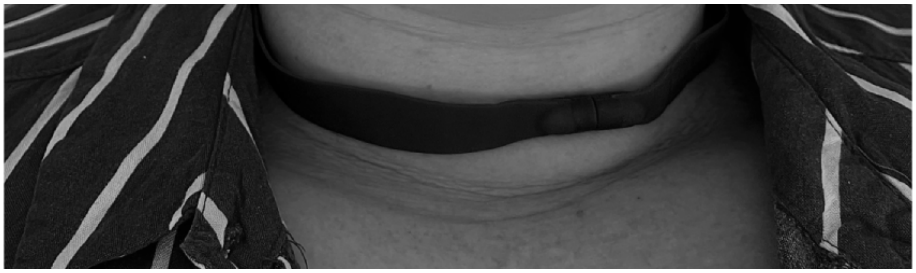
Compliance and efficacy of treatment feedback will be provided to study participants at each visit to encourage compliance. Additional phone or video support will be available, at participants' request, for participants who encounter difficulty with CPAP compliance. To ensure equal therapy support for CPAP and PT treatment arms, remote monitoring of CPAP compliance will not be conducted beyond the acclimatization period. CPAP devices used in this trial have been replaced by the manufacturer in accordance with the Therapeutics Goods Administration device repair or replacement program following product defect correction order RC-2021-RN-01373-1.

Positional Therapy Intervention

The participants in the PT intervention group will use a noninvasive vibratory device (Night Shift Device: Advanced Brain Monitoring, Inc) that is worn around the neck and promotes sleep in the nonsupine position (Figure 1 [source: Frances Clements, Liverpool Hospital, November 10, 2022]). The device provides a vibratory alert to the wearer when the supine position is detected and is secured at the anterior neck with a magnetic closure (Figure 2 [source: Frances Clements, Liverpool Hospital November 10, 2022]).

Figure 1. Nightshift positional therapy device posterior view.

Figure 2. Nightshift positional therapy anterior view.



The participants randomized to PT will be provided education by an experienced sleep therapist before commencing therapy. The device will be fitted by measuring the neck circumference and adjusted to ensure that the device does not slide down the neck. The device will be set with a 15-minute feedback delay, with vibration feedback mode on and the device location at the posterior neck. Downloads of therapy data will be obtained by an experienced sleep therapist at each study visit, where possible, as per the protocol schedule, and at the return of the device, compliance and efficacy data will be interrogated. Recording time, position, patient alert frequency, and snore data will be recorded. Feedback will be provided to study participants at each visit. Additional phone or video support will be available for participants with therapy as requested.

Control Group

Control group participants with significant SDB at polysomnography at the 28- to 32-week gestation period and symptoms of severe EDS (ESS>15) will be identified, withdrawn from the study, and managed according to standard clinical practice under the direction of a sleep physician.

Participant Timeline

The participants will be reviewed monthly until the 32-week gestation period and then fortnightly until delivery, coinciding with scheduled antenatal visits where possible. The trial flow chart is depicted in Multimedia Appendix 4. The flowchart describes the participant's progression through the trial protocol and depicts the timing of the interventions.

Sample Size

There are limited data on this topic, particularly on the estimated risk reduction in event rates. We intend to pilot the RCT with an initial 48 patients. This data will be used to refine the protocol and optimize logistics and will be used to inform a larger RCT.

Randomization, Allocation, Concealment, and Blinding

The participants will be individually randomized via a telephone call to the National Health and Medical Research Council's Clinical Trials Centre at Sydney University, who are independent of the trial, by the study coordinator. Randomization will be based on a minimization method with stratification for previous preeclampsia, personal history of gestational diabetes, and BMI≥35, to either CPAP, PT, or control groups. A maximum imbalance value of 1 between any of the 3 arms will be used in determining whether a forced allocation (ie, to achieve minimization of difference of stratification factor totals) or random allocation is used in a specific subject randomization. Treatment allocation will be unblinded for both study staff and participants.

Data Collection, Management, and Analysis

The complete schedule of study visits, procedures and data collection points is presented in Multimedia Appendix 5, which depicts the trial participant study visits and intervention schedule.

Data Management

Data from Apnealink screening tests, CPAP, and PT will be stored in a deidentified format. Polysomnography data will be stored on the secure hospital network. The system is secured via the Information Management and Technology Division's corporate backup software. Research Electronic Data Capture (REDCap; Vanderbilt University) database [32] will be used for data collection and management. Questionnaires will be completed electronically by participants via an email link where possible or by paper questionnaire where needed. In the event of participant discontinuation from the RCT, long-term fetomaternal outcomes of interest will be collected, where agreed to by participants during consent, in writing.

Data Collection Methods

Blood and Urine Collection

With consent, blood will be collected at 12-16, 16-20, 28 gestation weeks, and 6-12 months post partum by study staff or using hospital pathology collection services in EDTA tubes. The blood will be centrifuged (3000 rpm, 10 min), and plasma will be aliquoted (250 µL). The buffy coat will be collected and stored in approximately 250 µL RNA. Later, all specimens will be snap frozen in liquid nitrogen and stored at –80C at the Ingham Institute of Medical Research (Liverpool, New South Wales, Australia). Biomarkers (sFlt-1 [soluble fms-like tyrosine kinase 1], PlGF [placental growth factor], IL-6 [interleukin-6], TNFα [tumor necrosis factor alpha], and HIF1α [hypoxia-inducible factor 1-alpha]) will be assayed at the conclusion of the study blinded to outcomes.

Urinalysis will be conducted at each study visit using SIEMENS Multistix 10SG Test strips. A score of negative, trace, 30 mg/dL (++), 100 mg/dL (++), 300 mg/dL (++), or >2000 mg/dL (+++) will be recorded. If greater than 1+ protein is detected, a random spot urine sample will be sent to hospital pathology services for measurement of urinary protein adjusted for creatinine excretion.

Fetal Monitoring

Fetal ultrasound will be undertaken at the study site fetomaternal units (FMUs). Uterine artery blood flow (pulsatility index measurements) will be recorded at the randomization visit (12-16-week gestation period), 2-6 weeks later (average 4 weeks

to 16-20-week gestation period), and at 36-week gestation period. Morphology scan (16 weeks) (may be combined with uterine artery blood flow) and growth scan (36 weeks) will be performed. Fetomaternal scans performed at study sites will be performed using ViewPoint 6 (General Electric Healthcare) by experienced sonographers supervised by physician consultants within the FMU.

Questionnaires

ESS [33] and STOP-BANG (snoring, tiredness, observed apnea, high BP [STOP] and snoring, tiredness, observed apnea, high BP-BMI, age, neck circumference, and gender) [34] questionnaires will be used in baseline screening and scored according to standing scoring recommendations (sum of 8 item-scores [ESS] and score 0-8 [STOP BANG]). Functional outcomes of sleep will be assessed using the Functional Outcomes of Sleep Questionnaire (FOSQ-10) [35], which has been validated in pregnancy and scored according to FOSQ-10 marking guidelines [36]. Questionnaires assessing sleep study acceptability, sleep study preference, and therapy acceptability will be undertaken and are presented in Multimedia Appendices 6-13. Questionnaires will be emailed to participants using REDCap or completed in paper hardcopy where the patient is unable to complete electronically. The acceptability questionnaires used in this trial were evaluated on hospital staff unaffiliated with the trial. Feedback was implemented, and questionnaires were redesigned before SWSLHD HREC approval and implementation.

Sleep Study Data Collection

The participants will undergo attended polysomnography (with therapy device in situ for CPAP and PT arms) using Grael v2 (Acquisition System, Compumedics), unattended polysomnography using SOMTE v2 (Acquisition system, Compumedics) and Apnealink Air (Resmed) at 28- to 32-week gestation period at LPH. Laboratory-based polysomnography will be repeated 6-12 months post partum.

Attended and unattended polysomnography will be scored using Profusion PSG 4 auto analysis software (Compumedics) by a single experienced sleep scientist using the 2020 AASM Manual for the scoring of sleep and associated events (Version 2.6 guidelines). Apnealink Air will be automatically scored using Airview (Resmed; AASM 2012, Automatic Scoring) and manually scored by a single experienced sleep scientist using 2020 AASM guidelines (events Version 2.6). All sleep study sets will be reported by the same sleep physician for consistency. Unattended polysomnography and Apnealink Air studies will be scored and reported blindly by sleep scientists and reporting sleep physicians.

Apnealink Air data collection includes airflow (pressure transducer), respiratory effort (abdomen) and oximetry (SpO_2), snoring, and pulse. The participants will complete a self-setup in the home, will be provided with an instruction sheet, and will also manually start study recording as close to anticipated sleep onset as possible and manually stop recording at sleep offset.

Unattended polysomnography data collection included electroencephalography (F3 and F4, M1 and M2), electrooculography (E1 and E2), electromyography (EMG chin [submentalis]), electrocardiogram (modified lead II), airflow (pressure transducer), snoring, airflow (thermistor), respiratory effort (abdomen and thoracic), anterior tibialis EMG (left and right leg), oximeter (SpO_2), and position sensor. The participants will complete a self-setup at home. A comprehensive instruction booklet will be provided, and the participant will be encouraged to watch an instructional video [37]. The participants will have access to phone or video support from experienced sleep staff. Study recording will commence as close to the anticipated sleep onset as possible and manually stop recording at sleep offset.

Attended polysomnography collection includes those in unattended polysomnography as described above, with the addition of electroencephalography (C1 and C2 and O1 and O2), EMG Chin (Chin 1 and Chin 2 and Chin 3), EMG diaphragm, snore (microphone), sound level (dB meter), and digital video (audio and visual). Competent sleep technicians will conduct participant setup.

Outcome Assessment

An oral glucose tolerance test will be undertaken for the assessment of gestational diabetes at 28 weeks (in addition to earlier testing if clinically requested). Collection of fasting blood will be followed by administration of 75 g oral glucose load, with 1 and 2 hours of blood collection. Interpretation will follow the Australasian Diabetes in Pregnancy Society (ADIPS) 2020 guidelines [38].

Blood pressure (BP) will be recorded at each study visit. Diagnosis of HDP will be defined as per the Society of Obstetric Medicine of Australia and New Zealand (SOMANZ) guidelines [39].

Anthropometric measurements (height, weight, and BMI) will be recorded during the randomization visit, and weight will be checked at subsequent study visits by study staff using hospital clinic scales.

Postpartum Follow-Up

RCT participants will be followed up in the clinic at 6-12 months post partum. At this time point, women will be offered repeat polysomnography, an oral glucose tolerance test (if they developed diabetes and have not already undertaken this in the postpartum period), biomarker blood, and urine collection.

Statistical Methods

This trial is a feasibility trial, and as such, no power calculations for the RCT were derived. We prespecified to assess the diagnostic accuracy of the home sleep tests as well as the screening questionnaires following the STARD (Standards for Reporting of Diagnostic Accuracy) guidelines. The accuracy will be assessed at various cutoff points using a receiver operating characteristic curve. The area under the receiver operating characteristic curve and positive and negative predictive values in the patient population will be derived. The first recruitment target will be 50 participants, which provides at least 80% power (α=.05) to detect a C-statistic of 0.7 when the allocation ratio is 1 (ie, 50% prevalence) and 0.75 when the allocation ratio is 2 (ie, 20% prevalence). We will be comparing Apnealink Air and SOMTE unattended PSG to attended PSG. Further exploratory analysis will be undertaken to assess

whether any factors at booking, including the results of the sleep questionnaire, biomarkers, clinical factors, and history in combination with findings of unattended PSG, Apnealink, or attended PSG, are predictive of poor outcomes (either maternal or fetal, as discussed above). A composite of the combined adverse maternal outcomes and combined adverse fetal outcomes will also be assessed as an outcome. Data will be displayed as mean (SD), 95% CIs, and median (IQR) as appropriate based on data distribution. An intention-to-treat analysis will be undertaken for the primary outcome as well as the secondary outcomes. A per-protocol analysis (for primary and secondary outcomes) will also be undertaken, and both data will be presented. A *P* value of <.05 will be considered statistically significant. Where multiple analyses are undertaken, adjustments will be made for multiple comparisons. Longitudinal analysis of repeated measures will be undertaken where measurements are undertaken several times. Where differences at baseline exist between the groups, adjustments will be made statistically. Where less than 10% of any data point is missing, data will be imputed. We have preplanned an exploratory analysis of flow characteristics of all sleep tests to investigate sub-criterion flow changes related to long-term fetomaternal outcomes.

Patient and Public Involvement

The participants were not involved in the design of this study protocol. Participant feedback will be obtained via a series of questionnaires as described above. Members of the public (hospital staff) participated in providing feedback on acceptability questionnaires as described above, and feedback was implemented in the development of the questionnaires.

Data Monitoring

No data monitoring committee has been appointed.

Risk Assessment and Termination of Study

An interim analysis will be performed halfway through enrollment by the safety committee. If there is a convincing signal that either CPAP or PT therapy is associated with adverse outcomes, the study will be terminated immediately, and the SWSLHD HREC will be notified. Significant safety issues and patient complaints will be reported immediately via email to SWSLHD HREC.

Safety Considerations

A safety committee will be established to monitor the safety of participants and to review any potential adverse outcomes. The safety committee will review the outcomes after each of the 4 subjects for the first 16 subjects or if any severe adverse events occur.

Posttrial Care

The participants affected by product recalls in this trial will be followed up annually for 5 years if agreeable as per the protocol.

Results

The trial commenced on September 30, 2019. The trial is ongoing as of August 6, 2024.

Discussion

Principal Findings

Despite the growing interest in the potential for improved fetomaternal outcomes in pregnant women with OSA occurring during pregnancy through the use of CPAP, few large RCTs have been undertaken. In addition, no RCT has compared CPAP and positional therapy for the treatment of OSA occurring during pregnancy. This RCT feasibility study will assess the feasibility of conducting a large RCT to initiate CPAP or positional therapy in pregnant women by the 16th week of gestation.

To date, the largest RCT to investigate the treatment of OSA in pregnant women studied 310 pregnant women with OSA from the first trimester. The primary outcome of the study was BP control during pregnancy and the secondary outcome was the incidence of preeclampsia. The overall CPAP compliance was 2.5 (SD 2.5) hours per night and median use was 1.7 (IQR 0.2-4.5) hours per night, and the authors concluded CPAP therapy reduced the incidence of preeclampsia and demonstrated a reduction in DBP throughout the pregnancy, in high-risk pregnant women with mild to moderate OSA [23]. A recent systematic review assessed the use of CPAP therapy for the prevention of hypertensive-related adverse outcomes in pregnant women with OSA. The authors report risk reduction of gestational hypertension and preeclampsia in the CPAP groups (relative risk [RR] 0.65, 95% CI 0.47-0.89; *P*=.008) and preeclampsia (RR 0.70, 95% CI 0.50-0.98; *P*=.04), which were not correlated with age or BMI. The authors concluded that while the results suggest CPAP therapy as a potential mediator to adverse gestational hypertensive outcomes in pregnant women with OSA, the association remains inconclusive [40].

This feasibility RCT will assist in the understanding of the maternal and health care system challenges in undertaking a CPAP intervention during pregnancy. The therapies in this study will commence by the 16th week of gestation and will be overseen by an experienced sleep therapist to improve CPAP and PT compliance. This is important as many clinical trials involving CPAP are limited by poor compliance of the participants. We will encourage compliance to interventions through an initial education session at randomization by the trial sleep therapist and at each study visit. At these visits, the participants will be provided feedback regarding their therapy compliance and efficacy, and through a series of questionnaires, we will assess barriers to therapy. We anticipate an improvement in fetomaternal outcomes such as improved blood pressure control, reduced incidence of GDM, and preeclampsia in the interventional groups with good adherence to therapy. The learnings from undertaking this work will be important for consideration when expanding to a larger trial. The results of the study will be published in peer-reviewed journals and presented at national and international conferences.

Limitations

Limitations to the trial will be poor acceptability of the trial protocol by the participants and the potential for pregnancy complications to participants in the trial, given the risk of adverse events occurring during pregnancy, particularly in high-risk populations with comorbidities such as obesity and a

history of hypertension and diabetes [41]. Additional limitations to the trial will be the potential for poor CPAP and PT compliance of the participants randomized to these interventions. The use of an experienced sleep therapist in the trial to educate the participants and provide ongoing therapy support during the trial is anticipated to minimize poor therapy compliance but may limit the generalizability of findings.

Conclusions

If this trial protocol demonstrates good overall feasibility, a larger multicenter RCT will be conducted. The results of this feasibility trial will inform a redesign of the protocol for the larger RCT, if required. The use of positional therapy in this trial may provide evidence of the utility of OSA treatment options other than CPAP in pregnant women with OSA. Furthermore, it is anticipated that the follow-up schedule in this trial may inform other study designs involving pregnant women with OSA, ultimately leading to changes to clinical policy in the care of pregnant women.

Data Availability

Data generated during this trial will be available following the completion and publication of the trial from the first and last authors upon reasonable request and approval by the local ethics committee.

Abstract

Background: Occupational cancer and acute cardiac events are the leading causes of death among firefighters. Increased exposure to toxicants on the fire ground, such as polycyclic aromatic hydrocarbons, benzene, and per- and poly-fluoroalkyl substances (PFAS), has been linked to certain cancers, cardiovascular disease, accelerated epigenetic aging, and other adverse health effects. PFAS are a major concern because they are persistent, can bioaccumulate, and are present in several firefighting tools. Compared to the general population, firefighters have elevated serum levels of some types of PFAS. A randomized clinical trial in Australian firefighters found that routine blood and plasma donation for 1 year led to decreased serum PFAS levels, although health outcomes were not directly measured in that study.

Objective: In collaboration with fire service leadership in Arizona, the Firefighter Collaborative Research Project (FCRP) was established to evaluate the effectiveness of 3 interventions in a randomized controlled trial design to reduce serum PFAS levels, reduce cancer and cardiovascular risk, and improve overall health and wellness in US firefighters.

Methods: This study aimed to recruit and enroll up to 1500 active firefighters between August 2023 and October 2024. Between August 2023 and October 2024, active firefighters were recruited and randomized into a study arm based on their eligibility, including serum PFOS levels, for the specific arms. The trial arms include (1) blood and plasma donation, (2) zone 2 physical activity, and (3) intermittent fasting. FCRP outcomes include serum PFAS reduction (arm 1), epigenetic age acceleration (all arms), cardiovascular conditioning (arm 2) and cognitive outcomes (all arms), mental health (all arms), and overall disease risk (all arms). Each study arm includes an intervention and a control group. At enrollment and end of the study, participants provide blood and urine samples and complete a comprehensive questionnaire on their occupational and health history, exposures, and lifestyle behaviors. At the end of the study, participants also participated in a cognitive evaluation. Depending on the study arm,

participants may additionally complete a cardiopulmonary exercise test at baseline and follow-up, a mid-study survey, and a mid-study blood and urine collection.

Results: Participant activities and data collection will conclude by December 2025.

Conclusions: The FCRP is a randomized controlled trial that aims to test the effectiveness of fire service–selected interventions in reducing serum PFAS levels. Study results will contribute to potential interventions that could be used to reduce serum PFAS levels in firefighters.

Introduction

Occupational cancer and acute cardiac events are the leading causes of death among firefighters [1,2]. The firefighting occupation is classified by the International Agency for Research on Cancer as a group 1 carcinogen due to the direct and indirect exposures to hazards on the job [3]. Firefighters have a significantly higher risk of cancer and cancer mortality when compared to the general population, including skin melanoma, other skin cancers, and prostate cancer, with higher mortality for rectal, testicular, brain and nervous system cancers, and non-Hodgkin lymphoma [4,5]. Increased exposure to toxicants on the fire ground, such as polycyclic aromatic hydrocarbons, benzene, and per- and poly-fluoroalkyl substances (PFAS), have been linked to certain cancers, cardiovascular disease, accelerated epigenetic aging, and other adverse health effects [4,6,7].

PFAS are primary toxicants of concern due to their persistence, ability to bioaccumulate, and associated adverse health effects [8]. Firefighters have additional exposure to these chemicals beyond the general population, with significant sources of PFAS exposure on the fire ground including fluorinated class B aqueous film-forming foam and smoke from burning household materials [6]. A study involving 4 municipal US fire departments located in different states and regions of the country found that firefighters had higher levels of several PFAS chemicals in their blood than the general population [9].

In the human body, PFAS accumulates primarily in the liver, kidneys, and blood. Long-chain PFAS, such as perfluoro octane sulfonate (PFOS) and perfluorooctanoic acid (PFOA), have reported half-lives of several years (3.1-7.4 and 2.1-8.5, respectively) [8]. These chemicals bind strongly to albumin, the most abundant protein in plasma [8,10]. Therefore, these chemicals may be removed from the body through blood or plasma donation. An Australian study among firefighters previously demonstrated the effectiveness of blood or plasma donation to lower serum PFAS levels over 12 months, although no health effects were investigated. Findings from the study revealed that plasma donation was more effective than blood donation at reducing the mean serum level of PFOS at 12 months, while serum PFOS did not significantly change in the control group [11]. Plasma donation reduced PFOS levels by approximately 24% (–2.9 ng/mL, 95% CI –3.6 to –2.3 ng/mL), while blood donation reduced PFOS levels by approximately 11% (–1.1 ng/mL, 95% CI –1.5 to –0.7 ng/mL) [11]. Based on the findings from that study and concern for PFAS exposure, Arizona firefighters requested research to replicate the study and additionally investigate health outcomes such as cardiovascular health and epigenetic age acceleration.

Lifestyle and environmental exposures are associated with DNA methylation patterns, a type of epigenetic alteration. DNA methylation affects gene expression by adding a methyl group to 5’—C—phosphate—G—3’ dinucleotides. These DNA methylation patterns can be analyzed to determine epigenetic age or “biological age” through epigenetic clocks. Previous research has found that accelerated epigenetic age can be a risk factor for cancer, cardiovascular and neurological diseases, as well as death from all causes combined [12]. In addition to the physical health impacts, accelerated epigenetic age has been linked to negative mental health impacts [13]. Studies on firefighters have found differential DNA methylation patterns, or accelerated epigenetic age, potentially as a result of fire ground exposure and increased serum PFAS levels [7,14].

Lifestyle interventions, such as physical activity and dietary restriction or intermittent fasting, may be associated with slowed epigenetic aging [12,15,16]. Findings from the Comprehensive Assessment of the Long-term Effects of Reducing Intake of Energy trial revealed that caloric restriction slowed epigenetic aging [17]. Similar findings have been observed in mice [18]. A recent randomized controlled trial tested the effectiveness of a fasting-mimicking diet (low calorie, low protein, plant-based diet) in improving biological age. After 3 cycles, a cycle being a consecutive 5-day period in a month, biological age was reduced by a median of 2.5 years [19].

Zone 2 physical activity, or continuous, moderate aerobic physical activity corresponding to the near lactate threshold (4 mM blood lactate), shows greater benefits than other types of aerobic physical activity for improving cardiovascular risk factors [20,21]. Common examples of this type of activity include brisk walks, light jogs, and cycling for a continuous interval of time. Occupational health clinicians working with the firefighter community also anecdotally noted that zone 2 physical activity confers the greatest benefits for cardiovascular fitness, although this claim has not been formally tested. Both

types of lifestyle interventions, intermittent fasting, and zone 2 physical activity, have received interest from the firefighter community.

The Firefighter Collaborative Research Project (FCRP) aims to assess the effectiveness of fire service–selected interventions for improving firefighter health. The target population for recruitment is participants enrolled in the Fire Fighter Cancer Cohort Study (FFCCS), a national framework study that collects information on firefighter exposures and works to improve the health of the fire service [22]. Through this randomized controlled trial, we seek to engage our existing cohort of firefighters to evaluate 3 firefighter-identified lifestyle interventions: blood or plasma donation, zone 2 physical activity, and intermittent fasting. The primary outcomes of the study include epigenetic age acceleration, serum PFAS reduction (blood or plasma arm only), and cardiovascular risk reduction (zone 2 arm only). Based on the previously mentioned associations with accelerated epigenetic age and therefore aging and aging-related diseases, secondary outcomes of this study include mental health, sleep quality, and cognitive functioning [12,13].

Methods

Overall Study Design

The FCRP is a community-engaged, randomized controlled trial with the goal of screening 1500 firefighters. The study enrollment period is planned for August 2023-October 2024. Based on eligibility criteria, participants are randomly assigned to regularly donate blood or plasma for 1 year, engage in zone 2 physical activity for 4 months, intermittent fast for 4 months, or serve as a control for the duration of the respective study arm.

We have chosen a community-based approach working with fire service leaders in participating states that are willing to educate firefighters on the importance of the study and encourage participation. Departments designate a liaison who completes training for institutional review board (IRB) approval to distribute study information, coordinate events, and serve as an additional point of contact between researchers and participants. The study team also hosts online informational sessions upon request and actively maintains a study website. Individuals interested in participating in the study are directed to complete a screening survey and to schedule an appointment for an in-person event near them. Both surveys may be accessed through informational materials dispersed by liaisons. Events are hosted regionally, and locations are prioritized based on interest numbers and resources for study activities.

Initially, the state of Arizona was designated as the only state for enrollment for all 3 study arms (blood and plasma donation, intermittent fasting, and zone 2). However, upon interest from other US fire departments, the blood and plasma donation arm of the trial has been expanded to Idaho, California, Washington, Oregon, and Massachusetts. The intermittent fasting and zone 2 arms of the trial will not include non-Arizona fire departments. Given that there are a limited number of volunteer departments with who we have established contacts within these areas, enrollment is focused on career departments. Firefighters of all demographic backgrounds were encouraged to enroll.

Participants

Eligibility Criteria

Individuals interested in participating in the study are directed to complete an online screening survey to assess eligibility. Overall study eligibility criteria include active firefighters enrolled in the FFCCS, with full criteria described in Textbox 1. If participants are not already enrolled in the FFCCS at recruitment, they are given the opportunity to enroll. Individuals currently doing study arm activities at the time of screening are deemed ineligible for participation in the respective study arm. Subjects with conditions that may affect their ability to complete study activities (eg, they do not meet national standard criteria for blood or plasma donation, or have an injury preventing physical activity) are also deemed ineligible for participation in the respective study arm. Individuals who are deemed ineligible for all study arms are thereby ineligible for participation in the overall study. Specific inclusion criteria are detailed in Textbox 1.

Textbox 1. Inclusion and exclusion criteria for the Firefighter Collaborative Research Study (FCRP).

Inclusion Criteria

- Active firefighter (including emergency medical responder and all firefighter subgroups) with either a volunteer or career status
- Individual plans to remain in active service with their current agency for the next 2 years (not planning to retire or resign)
- 18 years of age and older
- Fluently speak and write in English
- All genders, races, and ethnicities
- Enrolled in the Fire Fighter Cancer Cohort Study before enrolling in the FCRP
- Complete a signed and dated informed consent document that indicates the participant has been informed of all aspects of the study before enrollment.
- Agree to avoid participating in FCRP intervention activities outside of their assigned intervention group for the duration of the study.
- Able to comply with scheduled visits, laboratory tests, and other study procedures
- BMI ≥17.5 kg/m^2 and weighing more than 115 pounds

Exclusion Criteria

- Overall
  - Not able to fluently speak or write in English
  - Younger than 18 years
  - Currently a tobacco smoker or vaping (eg, >2 cigarettes or cigars, or incidents of vaping in the past month)
  - Those with planned travel or extended leave (eg, >6 weeks) that would prevent their ability to participate in other interventions
  - Those who are pregnant or become pregnant during study, breastfeeding, or have given birth within the past year
  - Those with a history or diagnosis of any significant metabolic, hematologic, pulmonary, cardiovascular, gastrointestinal, neurological, immune, hepatic, renal, urological disorders, severe injury, or cancer that, in the opinion of the investigator, would potentially put the candidate at risk.
- Blood or plasma
  - Those with any medical contraindication (medical condition or medication) to blood donation, according to Red Cross Guidelines
  - Those who donated blood or plasma in the past 3 months
  - Those knowing they have a condition indicative of levels of hemoglobin, hematocrit, red blood cells, or iron below the lower limit of normal levels
- Zone 2
  - Currently participating in zone 2 physical activity
  - Currently participating in more than 120 minutes per week of aerobic, and cardiovascular training (eg, jogging, cycling, walking, swimming, high-intensity interval training) at >60% of their max heart rate.
- Intermittent fasting
  - Those with a history or diagnosis of diabetes, hypoglycemia thyroid disease, or an eating disorder
  - Those who recently participated in intermittent fasting or Time Restricted Eating
  - Those who recently used antidiabetic medication such as Semaglutide (sold as Ozempic, Wegovy, and Rybelsus) or Tirzepatide (sold as Mounjaro) for the treatment of type 2 diabetes or weight loss will also be excluded from this group.
  - Use of drugs that might affect intermittent fasting or eating behaviors

Interventions

Randomization groups are created at regular monthly intervals and clustered by recruitment region. Participants who have consented to participate in the study are randomized into 1 of the 4 study arms as either an intervention or control, accounting for their eligibility determined during the screening process and baseline serum PFOS concentrations. Upon enrollment into their specific group, participants are provided with instructional materials for assigned activities, activity timelines, and frequently asked questions.

Participants randomized in the blood donation or plasma donation arm include all participants with serum PFOS ≥5

ng/mL, following the previous Australian study [11], while also meeting additional study criteria outlined in Textbox 1. We also included a smaller intervention group of participants with PFOS <5 ng/mL in the plasma arm, to evaluate whether improvements in epigenetic age are independent of baseline PFOS. Participants in the blood intervention arm are expected to donate whole blood every 12 weeks for 12 months, while those in the plasma intervention are expected to donate plasma every 6 weeks for 12 months. Participants are provided with a list of donation centers in their region and acceptable types of donations (eg, whole blood donation is acceptable, but not "Power Red" or platelets). Participants go to donation centers on their own. Controls are asked to refrain from donating plasma or blood throughout the trial period.

Participants randomized into the zone 2 physical activity arm complete a Cardiopulmonary Exercise Test (CPET) before starting their intervention. The CPET uses a mouthpiece and external sensors to measure the heart rate and other cardiovascular health indicators of the individual while they engage in mild exercise on a stationary bicycle. The initial CPET provides a baseline evaluation of cardiovascular fitness, as well as the zone 2 heart rate zone used for the intervention. The calculated range from this exam is provided to participants in their results and they are asked to self-report these results to the study team. The zone 2 heart rate range was based on current American College of Sports Medicine guidelines and corresponded to a lower limit of 40% and an upper limit of 60% of achieved peak VO2 to indicate the anaerobic threshold [23]. Functionally, engaging in zone 2 translates to moderate physical activity, with examples of zone 2 physical activity including hiking up a hill, a light jog, or a moderate cycling session. Participants in the intervention are asked to complete a minimum of 45 minutes of physical activity in their zone 2 range for at least 4 days a week, tracked by a study-provided heart rate monitor watch. Controls are permitted to continue their regular physical activity regimen but are asked to not intentionally engage in zone 2 activity. All participants randomized to the zone 2 physical activity arm are provided with a wrist-worn accelerometer (Garmin Forerunner 45) to passively record their physical activity and sleep data. They are reminded to always wear the device except when it is charging and receive regular compliance checkups from study staff. Participants are also reminded to open the application on their phones at least once a week to allow data to be uploaded to their Garmin account. This data is synced with Fitabase to allow the study team to monitor adherence. Participants in the zone 2 physical activity arm are monitored for compliance through Fitabase and can manually report exercises if they do not wear their wrist-worn heart tracker [24]. At the end of the 4-month period, participants complete a final CPET exam and share their results with the study team to evaluate changes over time.

Participants randomized into the intermittent fasting arm are asked to fast for 14 to 16 hours per day, for at least 4 days a week for the 4-month period. Participants select their own time windows to accommodate firefighter shift schedules. During fasting windows, participants are allowed to consume medications and zero-calorie beverages (eg, black coffee, sparkling water, unsweetened tea). They are not asked to alter their diet in any other manner. Controls are asked to not engage in intermittent fasting throughout the trial period and continue their current dietary regimen. Additional details are provided in Textbox 2.

Textbox 2. Description of study interventions within the firefighter collaborative research project.

Arm 1: Blood or plasma donation

- Blood or plasma donation
  - Participants with perfluorooctane sulfonate >5 ng/mL were prioritized for this arm
  - Blood: 12-month commitment to donating blood every 12 weeks. Each blood donation will take approximately an hour to an hour and 15 minutes each time.
  - Plasma: 12-month commitment to donating plasma every 6 weeks. Each plasma donation will take approximately an hour and 30 minutes to 2 hours each time.
  - Additional surveys administered will involve a time commitment between 30 to 45 minutes.
- Blood or plasma control group
  - 12-month commitment into the control group
  - Additional surveys administered will involve a time commitment between 30 to 45 minutes.

Arm 2: Zone 2 physical activity

- Zone 2 physical activity intervention
  - 4-month commitment to completing a minimum of 45 minutes of physical activity in zone 2 for a minimum of 4 days per week.
  - Cardiopulmonary Exercise Test (CPET) testing before beginning and after completing the zone 2 arm for 4 months.
  - 4-month commitment to wear a wrist-worn heart and health tracker at all times unless it is charging.
  - Additional surveys administered will involve a time commitment between 30 to 45 minutes.
- Zone 2 control group
  - 4-month commitment to wear a wrist-worn heart and health tracker at all times unless it is charging
  - CPET testing before beginning and after completing the participation in zone 2 control group arm for 4 months.
  - Additional surveys administered will involve a time commitment between 30 to 45 minutes.

Arm 3: Intermittent fasting

- Intermittent fasting intervention
  - 4-month commitment. The participant will limit intake of food and calorie-containing beverages to an 8-10 hour window a day and fast for the remaining 14-16 hours on 4 days per week.
  - Additional surveys administered will involve a time commitment between 30 to 45 minutes.
- Intermittent fasting control group
  - 4 month-commitment into the control group
  - Additional surveys administered will involve a time commitment between 30 to 45 minutes.

Data Management

Research activities primarily occur through electronic communications such as email, text, and internet-based surveys, telephone contacts, or postal or express mail. Surveys are self-administered by participants on a computer or smartphone. Should participants be unable or unwilling to access them online, they may be administered by study staff by telephone. Participant information given to study staff via phone or email conversation is entered and stored in the REDCap database [25].

The database for this study is maintained through REDCap, which securely keeps participant identifiers and contact information according to the University of Arizona's standard operating procedures. These procedures operate with respect to cybersecurity, privacy, patient confidentiality, and compliance with applicable patient privacy regulations. All study-related documents and specimens contain a unique identifier for each participant, with any study-related documents with personal identifiers stored in a locked cabinet in lockable offices on campus. Laboratory results are entered directly into the REDCap study database from the study reference laboratory.

Twilio is a cloud-based communications platform that allows for automated text messaging chains to be sent to study participants. It is used to send study survey links to their phones that will take them directly to secure REDCap surveys.

At enrollment and their end-of-study visit, all participants provide biological specimens (blood and urine), and a survey is administered to collect information on occupational history

and exposures, relevant medical history, sleep quality, physical activity information, a food frequency questionnaire, the Center for Epidemiological Studies Depression scale (short form), and environmental exposures (Table 1, and described further in the Outcomes section). Throughout their enrollment period, all participants also receive regular study adherence questionnaires (described below). At end-of-study only, all participants additionally take a cognitive assessment (MindCrowd, described below). Participants assigned to the zone 2 physical activity arm complete a CPET before the beginning of the 4-month intervention and again after the conclusion of the intervention. Once participants in the zone 2 physical activity arm report the results of their first CPET, they are sent a wrist-worn accelerometer (Garmin Forerunner 45) that they are instructed to wear throughout the 4-month period and to return upon completion.

Zone 2 wears their accelerometer every day for the duration of the trial.

Table 1. Participant data collection time points for participants enrolled in the firefighter collaborative research project.

	Baseline	Mid-intervention	End of study[a]
Blood	All	BP[b]	All
Urine	All	BP	All
Questionnaires[c]	All	BP	All
Adherence[d]	N/A[e]	All[f]	N/A
Cardiopulmonary Exercise Test	Z2[g]	N/A	Z2
MindCrowd cognitive assessment (verbal cognition, processing speed)	N/A	N/A	All
Accelerometer	Z2	Z2	Z2
Epigenetics (Infinium MethylationEPIC v2.0 BeadChip)	All	N/A	All
VO2max, resting heart rate, HRV[h], HR[i] recovery	Z2	Z2	Z2
Sleep quality (accelerometer): deep, REM[j], light	Z2	Z2	Z2
Sleep quality (National Health Interview Survey Questionnaire): hours, rested, interruptions	All	N/A	All
Depression (CES-D[k] Short form)	All	N/A	All
Firefighter gear and occupational exposures	All	N/A	All
Dietary quality	All	N/A	All
Self-reported weight	All	All	All

[a]End of the study is approximately 4 months after randomization for zone 2 and intermittent fasting and approximately one year for blood or plasma.

[b]BP: blood/plasma arm.

[c]Questionnaires include diet, depression or mood, physical activity, occupational characteristics, and lifestyle.

[d]Intervention adherence questionnaires are evaluated weekly for IF and Z2, and monthly for blood or plasma.

[e]N/A: not applicable.

[f]All: all arms.

[g]Z2: Zone 2 physical activity.

[h]HRV: heart rate variability.

[i]HR: heart rate.

[j]REM: rapid eye movement.

[k]CES-D: Center for Epidemiologic Studies Depression Scale.

Biological Specimens

All participants provide up to 50 mL of blood via venipuncture at baseline as part of the study screening process and at the completion of assigned study arm activities. Participants in the blood and plasma arm complete an additional collection at mid-study, between 4 and 8 months. Each venipuncture is performed by qualified study staff, phlebotomists, nurses, or paramedic-EMTs at organized study events hosted at participating fire stations or facilities. Upon collection, blood specimens are stored locally in coolers with ice packs for transportation to the University of Arizona, where they are processed within 24 hours, with aliquots stored at –80 °C before testing. Baseline blood specimens for all participants are analyzed for PFAS as the final step in the study screening process and for markers of epigenetic age, such as DNA methylation patterns. At the end of assigned activities, only participants in the blood and plasma arm will have their blood specimens analyzed for PFAS. All blood specimens collected at the end of assigned activities for all study arms will be analyzed for markers of epigenetic age.

Participants are asked to self-collect approximately 80 mL of urine at baseline as part of the study screening process and at

the completion of assigned study arm activities per FFCCS protocol and to be stored for future analyses. Participants in the blood and plasma arms complete an additional collection at mid-study, between 4 and 8 months. Collections take place at organized study events hosted at participating fire stations or facilities. Upon collection, urine specimens are locally stored on dry ice for transportation to the University of Arizona, where specific gravity is measured using the Atago Refractometer (Model PAL-10S, Cat# 4410, Fisher Scientific). The sample is aliquoted and prepared for long-term storage at –80 °C for potential future analyses associated with these interventions.

Adherence to Study Activities and Retention

To determine activity adherence, participants are contacted at regular intervals determined by their intervention via email or secure SMS test messages using Twilio. Each survey asks if the participant has completed their required study activities. Participants randomized to an intervention are asked detailed questions about completing their activities, and participants randomized to control are asked if they engaged in the intervention activities since the last study survey. During the check-in surveys, participants are able to report any adverse events. They will then be contacted by study coordinators, and the events will be reported to the IRB for review to determine any necessary actions to take.

Study coordinators call and email noncompliant participants each week to improve adherence. Participants are contacted if they are due to start study activities but have not completed their baseline survey, have at least 1 week past due for a blood or plasma donation, have not completed a weekly survey for zone 2 physical activity or intermittent fasting in 2 weeks, or have not scheduled an appointment for a follow-up biological collection. Participants may also be contacted if they do not sync their wrist-worn accelerometer (Garmin Forerunner 45) with their mobile application, or if they do not share the results of their CPET with the study team. If the participant does not respond and continues to fall behind on study activities, then the IRB-approved liaison for their department is contacted to engage with the participant and ensure they complete their activities.

Laboratory Methods

Per- and Poly-Fluoroalkyl Substances Concentrations

Serum samples are tested for PFAS by the New Jersey Department of Health Centers for Disease Control method #6304.09 as a reference using Chronos online SPE – uHPLC by Spark Holland coupled with a Sciex 7500 MS/MS. A total of 20 analytes are tested, including perfluorobutanesulfonic acid, perfluorodecanoic acid, perfluoroheptanesulfonic acid, perfluoroheptanoic acid, perfluorohexanesulfonic acid, perfluorohexanoic acid, perfluorononanoic acid, perfluorooctanesulfonamide, perfluoroundecanoic acid, PFOA (perfluorooctanoic acid), PFOS, branched and linear isomers of PFOA and PFOS, 9-Chlorohexadecafluoro-3-oxanonane-1-sulfonic acid, 4,8-Dioxa-3H-perfluorononanoic acid, 2-(N-Ethyl-perfluorooctane sulfonamido) acetic acid, 2-(N-Methyl-perfluorooctane sulfonamido acetic acid), and Hexafluoropropylene oxide dimer acid. Note that total PFOA and total PFOS are calculated as the sum of the branched and linear isomers [26].

DNA Methylation Analysis

DNA methylation analysis of serum samples is conducted at the University of Arizona Genetics Core. After sample accessioning and preparation, genomic DNA is extracted using a Qiagen DNeasy Blood and Tissue Kit (REF: 69581) or similar following the manufacturer's recommendations for whole blood. The extracted DNA is then quantified using promega quantiflor fluorometric dsDNA assay (PN: E2671) and dsDNA quantities are detected using a SynergyHT plate reader (Agilent or Biotek). Samples are then normalized or diluted robotically with HPLC water to the range of 200-500ng in a total volume of 45uL. Following normalization, a bisulfite conversion using the Zymo EZ-96 DNA Methylation Kit (PN: D5004) is performed with the specified thermocycler conditions (95 °C for 30 sec, 50 °C for 60 min for 16 cycles, and Hold" at 4 °C) with 15uL as the final elution volume.

The bisulfite-converted DNA is then input into the illumina infinium methylation EPIC Kit (PM 20087706-8) following the manufacturer's recommendations. Whole genome amplification is then performed on the bisulfite-converted DNA. The amplified DNA is then fragmented and precipitated before being resuspended and hybridized onto the bead chip (v2.0) during an overnight incubation. Unhybridized DNA is washed off before the bead chip undergoes single base extension and staining. Before scanning, the bead chip undergoes a final round of washing and coating to prepare the chip for imaging. Once prepped for imaging, the bead chip is then scanned on an Illumina NextSeq 550 following the manufacturer's recommendations.

Outcomes

The primary outcomes of the study include epigenetic age acceleration, serum PFAS reduction, and cardiovascular risk reduction, with secondary outcomes including mental health, sleep quality, and cognitive functioning. Intervention-specific outcomes include PFAS concentrations (plasma or blood arm), and cardiovascular fitness (zone 2 arm). Urine and blood samples are stored at –80 °C for future biomarker-based outcomes. In total, 20 PFAS types are measured for all participants at baseline and again at end-of-study for participants in the blood and plasma study arm. Participants are provided with a report back of their PFAS concentrations at baseline and again at follow-up if measured. Epigenetic age acceleration will be calculated for baseline and end-of-study samples for all participants using several different clock-based methods, including the Horvath clock, GrimAge, Hannum, SkinBlood, PhenoAge, and Dunedin PACE [26-28]. Epigenetic age acceleration will be calculated using residuals after regressing each clock on chronological age [29,30]. Participants who complete activities required by the study protocol will have their epigenetic age acceleration reported back to them.

Cognitive functioning is measured with the MindCrowd web-based platform created by TGen. MindCrowd measures verbal memory performance using paired associates learning, and processing speed via simple visual reaction time. Both tests

are strongly predictive of age and functional ability across the lifespan, and MindCrowd has been validated in hundreds of thousands of participants across the world [31-33]. To minimize the time burden on enrollment and possible learning effects, MindCrowd is only assessed at follow-up.

Cardiovascular fitness is evaluated with baseline and end-of-study CPETs, and additionally on an ongoing basis with wrist-worn accelerometers. The CPETs produce validated measures of resting VO2 (maximal aerobic capacity), peak VO2, VO2 reserve, and heart rate. The accelerometers from the wrist-worn watch also generate an estimate for peak VO2, and we will assess the progression of this over time as a function of intervention status.

Depression and mood are evaluated at baseline and follow-up using the revised version of the Center for Epidemiologic Studies Depression Scale. Diet quality is measured from a food frequency questionnaire at baseline and follow-up. Sleep quality is measured via the wrist-worn accelerometers for those in the zone 2 arm, and through a modified version of the Centers for Disease Control's National Health Interview Survey's Sleep Surveillance questionnaire for all participants. The National Health Interview Survey sleep survey is slightly modified to account for firefighter's shift work.

Statistical Considerations

Power Analysis

We conducted a power analysis based on the outcomes of changes in PFAS concentrations, as well as changes in epigenetic ages. Following the initial Australian study, to see a change in concentration of 20% PFOS from before and after, we calculated an N of approximately 100 participants per group or 300 total for the blood, plasma, or control groups. However, to observe a change of one year of epigenetic age acceleration, with a standard deviation of 3, we required an N of 141 per group. To account for missingness, we are targeting an N of 150 per group.

Therefore, the targeted sample size for PFOS ≥5 ng/mL is 150 plasma test participants, 150 blood test participants, and 150 shared controls for blood or plasma; and for PFOS <5 ng/mL we are targeting 75 intervention participants; for zone 2 is 150 controls and 150 test participants; for intermittent fasting, sample size is 150 controls and 150 test participants. Thus, the total number of participants that complete the study is targeted at 1120. Randomization of the intervention groups is conducted using R v4.2.0 [34].

Data Analysis

All models will evaluate intent to treat effects, as well as the average treatment effect of the treatment. We will first evaluate characteristics by treatment group to ensure randomization is effective.

To estimate the effect of blood and plasma donation on the reduction of PFAS concentration, mixed effects models with random effects by department or region will be fit to compare changes in PFAS concentration before and after the study among intervention groups. We will report mean differences in the change from baseline to end-of-study measurements by group and adjust for residual confounders. We will also evaluate whether the volume of plasma and blood donated is a significant predictor of PFAS change, and account for adherence in these models. The results of these models will evaluate if there is a statistically significant difference in the change of PFAS concentration from baseline to follow-up, in cases compared to controls, and if there is a dose-response relationship between volume donated and PFAS concentration change.

Linear mixed-effect models will also be used to examine differences between groups in epigenetic age acceleration, cardiovascular fitness, cognitive functioning (measured only at follow-up), mental health, sleep quality, and other measured outcomes. Similar models will be used for zone 2 physical activity and intermittent fasting interventions. Missing data will be assessed and if substantial missing data is identified (greater than 10%), a sensitivity analysis will be conducted using multiple imputations by chained equations.

Ethical Considerations

This study was reviewed and approved by the University of Arizona IRB (STUDY00002462). All participants complete informed consent electronically through the REDCap database system and all collected identifiable data is stored within the database (Multimedia Appendix 1). The research staff verifies that participants fully understand all risks and the necessary study activities that are required of them. Once participants agree to be active participants in the study, the study staff sign the informed consent. All participants receive the results of their PFAS concentrations, measured from the baseline blood collection during the screening process. No monetary compensation is provided to any participant in the study. At the end of study activities, only participants in the blood and plasma donation arm will receive a second set of PFAS results, measured from the blood collection at the end of the study. In addition, following the completion of all study activities, all participants receive the results of their epigenetic clocks.

Any participant information provided in this manuscript is de-identified. Any identifiable information is stored within the REDCap database, which securely keeps participant identifiers and contact information according to the University of Arizona's standard operation procedures. These procedures operate with respect to cybersecurity, privacy, patient confidentiality, and compliance with applicable patient privacy regulations. All study-related documents and specimens contain a unique identifier for each participant, with any study-related documents with personal identifiers stored in a locked cabinet in lockable offices on campus.

Results

This study was funded by the Arizona Board of Regents. Enrollment began in August 2023 and concluded in November 2024. As of January 2025, a total of 916 participants were enrolled in the study and 1893 participants were screened. The conclusion of the blood and plasma interventions is set for December 2025, contingent upon funding. Data analysis will begin once sufficient data has been collected.

Discussion

Overview

All study interventions were selected based on interest from a community-engaged participatory framework with the fire service. Testing the effectiveness of blood and plasma donation in reducing serum PFAS levels in firefighters is a high priority among firefighters, given that this population has been found to have higher serum levels of these chemicals compared to the general population [6,9]. Evaluating all interventions as potential ways to improve epigenetic age acceleration and reduce disease risk is a priority in improving the health of the fire service. A primary strategy for promoting participant adherence to study activities is by reporting the results of their serum PFAS concentrations and epigenetic clock measurements back to them. Newsletters and website updates are also to provide study updates and promote participant engagement.

Strengths

One strength of the study includes measuring the baseline serum PFAS concentrations of approximately 2000 firefighters, leading to a better understanding of the impact of occupational activity history on PFAS. In addition, given that all interventions were requested by fire service leaders, there is more interest and determination to complete study activities. This study will also contribute to research into epigenetic age acceleration and potential interventions to improve it.

Limitations

Our study has some limitations; first, there are significant barriers to plasma donation, including time commitment and distance, which can impede participant adherence. The Australian study being replicated identified an adherence rate of 93.7% to their interventions [11]. All the intervention arms require a time commitment; therefore, compliance is a concern [35]. Finally, not meeting enrollment targets will reduce our study's power to evaluate relationships between the intervention and PFAS levels and epigenetic age acceleration.

Conclusions

The design, enrollment, and research activities of this randomized controlled trial provide an opportunity to observe PFAS interventions in real time and assess their feasibility and benefit.

Acknowledgments

Members of the University of Arizona study team assist with screening and enrollment events, participant contacts, daily operations, and laboratory processing. The University of Arizona team includes Hailey Freeman, Elizabeth Valdivia, Nina Wittmer, Samantha Castro, Danielle Stea, Erin Woods, Joe Mirabito, Elisabeth Hoornaert, Jessica Hlomatchi, Nagateja Yeddulla, Jordan Baker, Dylan Rogers, Alissa Coleman, Mia Huerta, Kylie Lew, and Natalya Mayhew. The Arizona State University team assists with screening and enrollment events in Phoenix and surrounding areas. The Arizona State University team includes Brendan Thomas, Kinta Schott, Avaani Bhalla, Theresa Jorgensen, Alexandra Levendi, Debra Baldauff, Margarita Stirk, Theresa Crain, Hanna Lybbert, Olivia Tilley, and Kyle Reid. Jackie Goodrich of the University of Michigan provided expertise in epigenetics and analyses. A special thanks to our fire service liaisons who assist in recruitment and coordination of events. Our fire service liaisons include Jason Miller, Kane Nixon, Jake Rhoades, McKenzie Hess, Rayne Gray, Dan Jarrett, Jeff McMenemy, Bryon Mabery, Ed Pahl, Orion Godfrey, Brad Pitassi, Jay Evans, Rob Brewster, Stephen Gunn, Blas Minor, Val Gale, David Switzer, Jodi Spargo, Joe Fioresi, Scott Figgins, Clint Steeves, Eric Valliere, Shauna O'Dell, Colt Weddell, Dave Endres, Kevin Montgomery, Kyle Carman, Mark Manor, Rick Olson, Scott Freitag, Adrianne O'Brien, Greg McLaughlin, Chris Sanchez, Elliot Riggs, Jeremy North, Joe Kosiorowski, Robert Corbell, Holger Durre, Jason Heartisan, Dennis Gasrow, Steve Legros, Craig Artrip, Jason Schnase, Rob Mathis, Karyn Barr, Jay Lee, David Hunt, Michael Warmuth, Mark Niemeyer, Heather Fleek, Kirk Carpenter, Derek Biering, Jeff Hughes, Jonathan Hernandez, Doug Menard, Kyle Taylor, Pat McKenna, Paul Lombard, Conor Flaherty, Nick Querzoli, Aaron Guggenheim. The certified testing locations for participant Cardiopulmonary Exercise Tests are 1582 (Rick Hutton) and HeartFit for Duty (Kepra Jack).

Funding for this study was provided by the Arizona Board of Regents to the University of Arizona and Arizona State University (contact information for sponsor: Ken.polasko@azregents.edu) and by NIEHS P30 ES006694.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to participant confidentially, and final datasets are accessible by approved study staff.

Authors' Contributions

JLB, MF, SCB, and KL handled the concept and design. RC and CP managed the drafting of the manuscript. All authors contributed to the critical revision of the manuscript for important intellectual content. JLB, MF, and FW managed funding. KJK, JH, CP, and OH performed data management. MindCrowd Implementation was handled by MH, MF, and CP. JJG and KJ managed Firefighter Research Liaisons. Granting final approval of the version for publication was managed by all authors.

Conflicts of Interest

FW received grants from external partners that were not related to this project, including Arizona Parks and Trails, Pac-12 Health and Wellbeing Initiative, the Collegiate and Professional Sports Dietetic Organization, FrieslandCampina, Standard Process Inc, Kraft Heinz Company, Unilever Corporation, and FEMA. The other authors have no conflicts of interest to report.

Abstract

Background: Research has shown that engaging in a range of healthy lifestyles or behavioral factors can help reduce the risk of developing dementia. Improved knowledge of modifiable risk factors for dementia may help engage people to reduce their risk, with beneficial impacts on individual and public health. Moreover, many guidelines emphasize the importance of providing education and web-based resources for dementia prevention. Internet-based interventions may be effective, but few have been studied rigorously or widely disseminated. We created DementiaRisk, an award-winning, web- and email-based education platform for the public focused on modifiable risk factors, featuring multimedia e-learning and email "microlearning" content, to help raise awareness and improve knowledge of actions to reduce dementia risk.

Objective: This protocol describes a randomized controlled trial to (1) evaluate whether exposure to DementiaRisk changes knowledge of dementia risk factors, intention to engage in risk reduction activities, and health behaviors related to dementia risk reduction and to (2) explore qualitative aspects including participants' engagement and satisfaction with the intervention and barriers and facilitators to use.

Methods: Using a sequential explanatory mixed methods design, this study conducts a quantitative analysis followed by a qualitative inquiry to evaluate outcomes and feasibility. In total, 485 participants will be recruited on the web and randomly assigned to 2 groups: one accessing DementiaRisk and the other receiving alternative e-learning on mild cognitive impairment. Assessments will be delivered on the web at baseline (T1), at 4 weeks (T2), and at 2 months after the intervention (T3). Knowledge will be assessed using items from the Dementia Knowledge Assessment Scale, intentions to engage in risk reduction activities will be assessed using items in line with current evidence, and health behaviors related to dementia risk reduction will be assessed using items from the Godin-Shephard Leisure Time Physical Activity Questionnaire along with additional questions related to a range of health status domains. Outcomes and feasibility will be assessed using the Information Assessment Method for patients and consumers. A linear mixed effects model will be used to examine the relationship between each outcome score by group and time point.

Results: This study was approved by the Hamilton Integrated Research Ethics Board on August 24, 2022 (project ID 14886) and received funding in February 2023. Recruitment took place from March 28, 2023, to April 28, 2023, with the final participants completing the intervention by August 18, 2023. Analyses and interpretation of data are ongoing.

Conclusions: DementiaRisk is a readily scalable, technology-enhanced solution for dementia prevention education. It has been designed using evidence-based principles of multimedia learning. It has the potential to scale and spread widely using the open internet, so it may be able to reach a wider audience than traditional in-person educational interventions.

Introduction

Background

Developing a better understanding of how dementia can be prevented and sharing information about how Canadian people can reduce their risk of developing dementia or delay its onset are critical to keeping Canadian people healthy and improving their quality of life. The Landmark Study, which developed evidence-based data modeling to demonstrate the impacts of improving risk reduction efforts to delay onset across the population, suggests that a delay of 1 year could result in nearly 500,000 fewer cases of dementia by 2050 [1]. Additionally, if dementia prevention efforts can delay the onset of dementia by 10 years, then over 4 million new cases of dementia could be avoided by 2050 [1]. Web-based learning about the promotion of brain health is a readily scalable, technology-enhanced solution for dementia risk prevention education. Web-based learning has the potential to reach a wider number of audiences with modifiable risk factors for dementia than traditional face-to-face interventions.

While there have been studies of web-based health information on intentions and behavior change, most of those studies have looked at text-based health information rather than internet-based interventions that have incorporated best practices in instructional design for e-learning. Most of the web-based content about modifying dementia risk factors currently is text based, such as static web pages or pamphlets or booklets. Of the few multimedia e-learning courses available, some require a substantial commitment (eg, weeks long), are synchronous (ie, require real-time participation), are associated with a commercial entity or product for sale, or have a cost associated with them. During the design of our intervention, we could not find any instructionally designed, evidence-based, multimedia e-learning content about dementia risk reduction available in Canada in both languages (English and French). Moreover, very few educational interventions related to dementia risk reduction have been rigorously studied using methods such as randomized controlled trials (RCTs).

While multidomain interventions have been shown to be effective [2], our study will complement those types of more intense, in-person components with a view to expanding awareness of modifiable risk factors to the general population. In addition, while text-based information about risk factors is widely available, DementiaRisk [3]—our instructionally designed, multimedia intervention—is designed to share this knowledge broadly in a way that can improve the understanding of Canadian people. Many interventions about dementia are designed specifically for older adults. However, the development of dementia can begin as early as 20 years before symptom onset or diagnosis [4], so we will be targeting the intervention to all Canadian people of 18 years and older of age to reduce the risk of dementia as early as possible.

A recent EKOS dementia public opinion survey highlighted that there are still many important gaps in the knowledge of Canadian people about dementia risk factors, with only 37% of respondents knowing the link to chronic conditions that affect brain health, such as hypertension, heart disease, and diabetes [5]. Moreover, just over one-tenth believe that hearing loss can increase the risk of developing dementia; and many believe that exposure to toxic chemicals is a risk factor, despite lack of evidence [5].

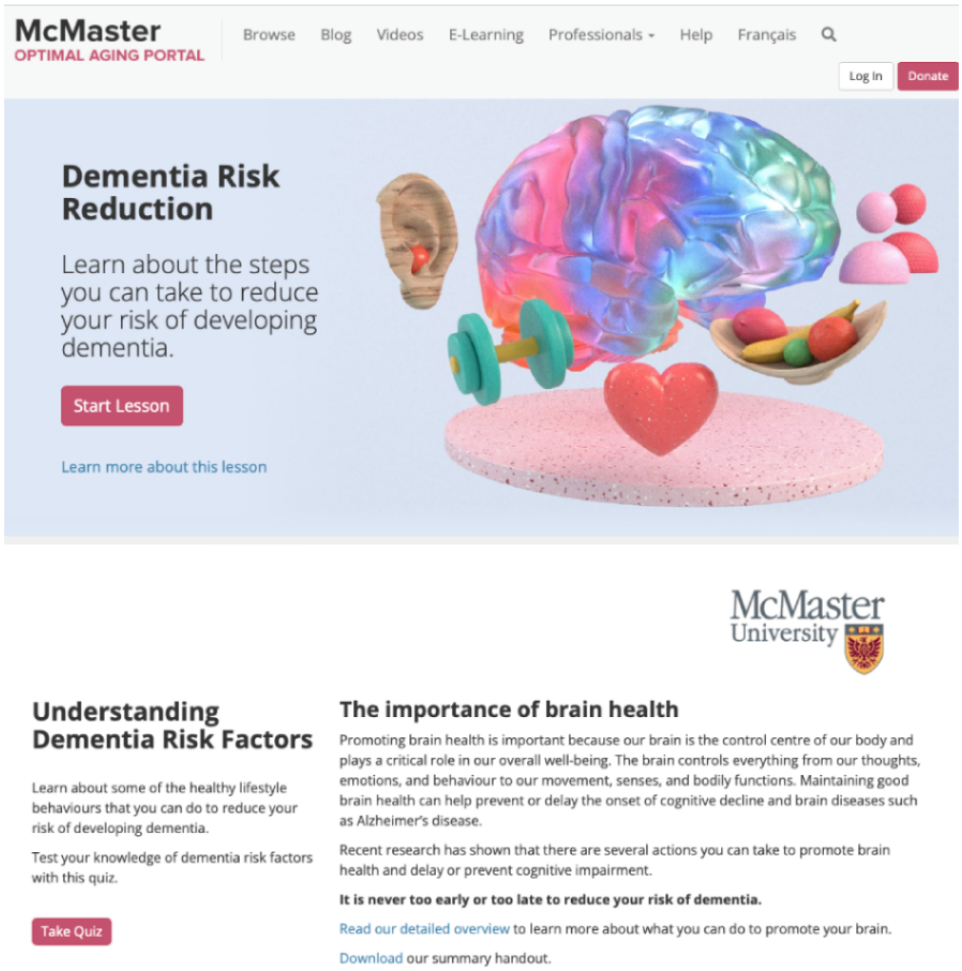
e-Learning Instructional Design

DementiaRisk (Figure 1), when compared to other web-based content, is unique because it uses best practices in multimedia e-learning instructional design, is open-access, and includes asynchronous e-learning with email-based microlearning. To our knowledge, it is also the only asynchronous multimedia e-learning dementia education program with French translation available. Key components of the instructional design include the use of the principles of multimedia learning and audio narration; personalization, including the use of a web-based "coach" or embodied instructional agent; segmenting the content into manageable topics to reduce cognitive load; authentic scenarios and worked examples; review questions; and learner control over navigation [6]. An iterative, participatory instructional design and development methodology—the successive approximation method [7]—was used, with extensive involvement and review from a range of experts in dementia care, including care partners.

In this study protocol, we describe a sequential explanatory mixed methods design RCT comparing the efficacy of DementiaRisk, a high-quality, web- and email-based dementia risk reduction education platform that includes asynchronous multimedia e-learning and email-based "microlearning" content, to our alternative web-based learning program on mild cognitive impairment. This study will be an important contribution to the literature on improving knowledge of dementia risk factors through web-based interventions. These innovations are an important complement to traditional approaches to dementia and brain health education, a key component of quality dementia

care and public health policy. This is the first research study of the effectiveness of DementiaRisk.

Figure 1. DementiaRisk home page.



Research Aim

The overall aim of this study is to explore if and how our dementia risk reduction e-learning influences participants' knowledge, intentions, and health behaviors related to dementia risk factors.

Specific Objectives

The specific objectives of this study are (1) to evaluate whether exposure to the e-learning intervention changes knowledge of dementia risk factors, intention to engage in risk reduction activities, and health behaviors related to dementia risk reduction and (2) to explore qualitative aspects such as participants' engagement and satisfaction with the intervention, as well as barriers and facilitators to use, through surveys.

Research Questions

This study aims to answer the following research questions: (1) Does DementiaRisk increase knowledge of dementia risk factors? (2) Does DementiaRisk increase intentions to engage in risk reduction activities? (3) Does DementiaRisk increase health behaviors related to dementia risk reduction? and (4) Are participants engaged and satisfied with DementiaRisk?

Methods

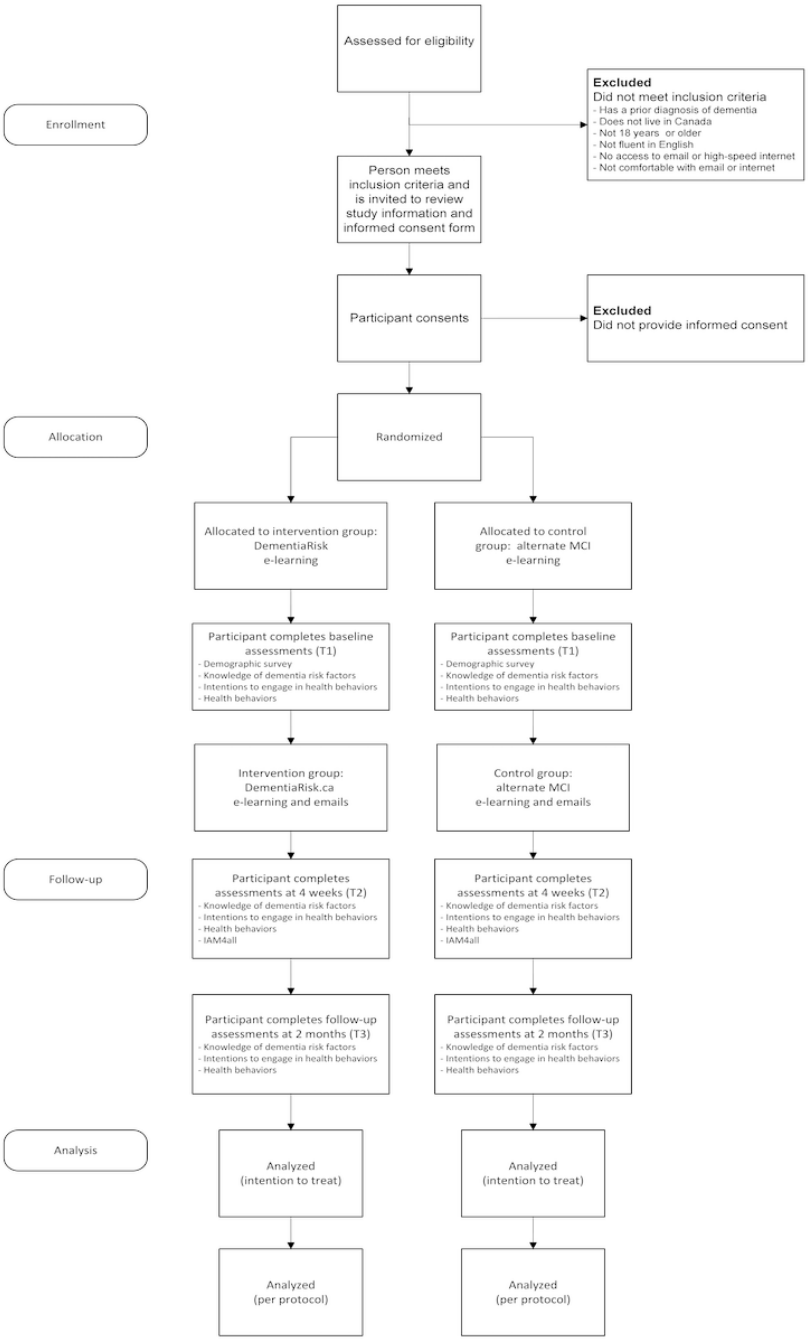
Study Design

A sequential, explanatory, mixed methods design RCT will be conducted to test the effectiveness of DementiaRisk on increasing knowledge, intentions, and behavior change related to modifiable risk factors of dementia. Participants will receive assessments at the following time points: baseline (T1), at 4 weeks (T2), and at 2 months after the intervention (T3; Figure 2). This specific research design offers a valuable approach because it strategically combines the strengths of both quantitative and qualitative research methods.

The underlying philosophy guiding this mixed methods approach is pragmatism, which emphasizes the practical application of research to address real-world problems [8]. This philosophical approach encourages the use of both quantitative and qualitative methods, allowing for more flexibility from other methodological constraints. This flexibility is particularly advantageous in mixed methods research, as it allows us to adapt our approach to capture unexpected findings that may emerge during the study [9]. By incorporating both quantitative and qualitative data, we can gain a more comprehensive and nuanced understanding of the relationship between

DementiaRisk and impacts on knowledge, intentions, and behavior change.

Figure 2. Participant flow through the study. MCI: mild cognitive impairment. For a higher-resolution version of this figure, see Multimedia Appendix 1.



Participants, Setting, and Procedure

Overview

Participants will be recruited using AskingCanadians, a paid panel service that can find representative Canadian participants, including those at increased risk of dementia. AskingCanadians was established in 2005 as a web-based data collection firm, which now allows for access to over 1 million Canadian consumers. The panel will send a copy of our recruitment email to their network where interested participants will be redirected to a survey to identify their eligibility. We will ensure a representative sample of diverse participants with key nonmodifiable and modifiable risk factors for dementia, including a greater percentage of women, some participants with lower level of education, and other risk factors such as hearing impairment, hypertension, smoking, alcohol consumption, and others.

Inclusion and Exclusion Criteria

Participants are eligible to participate, if they meet the following self-reported inclusion criteria: (1) they do not have a prior diagnosis of dementia, (2) they reside in Canada, (3) they are 18 years and older of age, (4) they have a good command of the English language, (5) they have access to email and high-speed internet, (6) they are comfortable using email and

internet, and (7) they have the ability to grant web-based informed consent. Participants are not eligible to participate if (1) they have a prior diagnosis of dementia, (2) they do not reside in Canada, (3) they are not 18 years and older of age, (4) they do not have a good command of the English language, (5) they do not have access to email and high-speed internet, (6) they are not comfortable using email and internet, and (7) they do not have the ability to grant web-based informed consent. Eligibility screening, informed consent, and surveys will be conducted entirely on the web.

Randomization and Allocation Concealment

Participants will be randomized and directed to their assigned group after submitting web-based informed consent using the Division of e-Learning Innovation's research platform. Participants will be randomized using a permuted block stratified randomization, using education and age as the stratification variables. Our stratified block randomization approach will be based on the following components: (1) level of education: we will stratify participants based on educational background or highest level of education completed: "high school or equivalent," "some college or university," and "college or university graduate or graduate degree" and (2) age: we will stratify participants based on ages: "younger than 45 years," "45-65 years," and "older than 65 years."

To ensure a balance between the intervention and the control groups, we will use stratified block randomization with variable block sizes of 4, 6, and 8 (randomly arranged) in a ratio of 1:1. To the best of our ability, efforts will be made to blind participants to their allocation group and study hypotheses. We will ensure that promotional advertisements do not contain logos or direct website links. The informed consent form will not contain the exact outcome measures or the title of the intervention. Allocation concealment will be aided by referring to the intervention as "e-learning related to cognitive impairment and dementia prevention" without biasing participants to study hypotheses or study design.

Sample Size Calculation

Using a conservative estimate of a small effect size (0.16, from a meta-analysis of internet health behavior change interventions), with a power of 0.80 and α of .05, we require a total of 388 participants in the study [10,11]. To allow for a 25% dropout rate, we aim to recruit 485 individuals [10,11]. These recruitment numbers and strategies have been used successfully in similar knowledge translation intervention studies and are a feasible target, given the use of the paid panel [12].

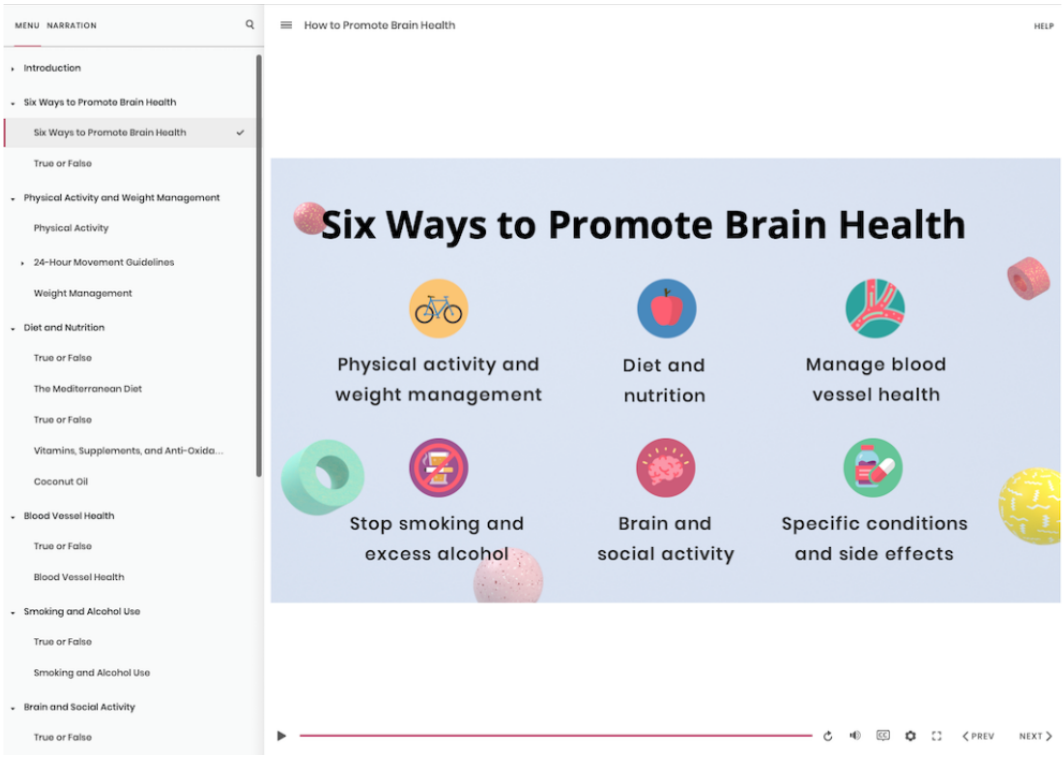
Intervention

Overview

Participants in the intervention group will be provided e-learning about dementia risk reduction and promoting brain health (Figure 3), consisting of the following components: (1) one 35-minute multimedia e-learning lesson on promoting brain health and preventing dementia and (2) a series of 12 "microlearning" emails (3 emails per week) with small segments of content to reinforce the material from the lesson. Participant progress is saved, so they can return to the lesson to complete it at another time. Participants will have 4 weeks to complete the intervention.

The lesson will be delivered through the Division of e-Learning Innovation's learning management system to record participants' access, progress, and completion of the lessons. This allows us to measure the "dose" of educational exposure to the intervention and to provide automated timed reminders to encourage participants to complete the lesson.

Figure 3. DementiaRisk intervention group e-learning lesson.



Microlearning Emails

In addition to the lessons, participants will also receive 3 microlearning emails per week with a small amount of content that reinforces the information from the lessons. This spaced repetition has been shown to benefit knowledge transfer [6]. Content for the emails will be taken directly from the promoting brain health e-learning lesson.

Control Condition

Participants randomized to the control group will be provided e-learning about mild cognitive impairment, consisting of the following components: (1) one 20-minute multimedia e-learning lesson on mild cognitive impairment and (2) a series of 12 "microlearning" emails (3 emails per week) with small segments of content to reinforce material from the lesson.

Outcomes

Overview

Primary and secondary outcomes will be assessed at baseline (T1), at 4 weeks (T2), and at 2 months after the intervention (T3). Qualitative data will be collected at 4 weeks (T2; Multimedia Appendix 2). Participants will access web-based surveys through the password-protected research platform hosted by the Division of e-Learning Innovation. Participants will be required to complete all components of the intervention. Surveys will not be submitted unless the participant completes all questions. Participants will not be able to change their answers after submitting and will not be able to submit multiple attempts.

Primary Outcome

The primary outcome measure of this study is knowledge change related to dementia risk factors. Knowledge of dementia risk factors will be assessed using a custom 15-item multiple-choice assessment aligned with the content of the intervention as well as the risks and health promotion subdomain of the Dementia Knowledge Assessment Scale [13]. Response options are "false," "probably false," "probably true," "true," and "I don't know." The total maximum score for this assessment is 30 (maximum 2 points per question), with higher scores indicating higher levels of knowledge related to dementia risk factors. Individual scoring is as follows: (1) 2 points for answering "true" to a true question, (2) 2 points for answering "false" to a false question, (3) 1 point for answering "probably true" to a true question, (4) 1 point for answering "probably false" to a false question, (5) 0 points for answering "probably false" or "false" to a true question, (6) 0 points for answering "probably true" or "true" to a false question, (7) 0 points for answering "I don't know."

Secondary Outcomes

Secondary outcome measures include (1) intentions to engage in health behaviors in line with evidence will be assessed using a 10-item Likert scale–based survey and a composite score and (2) health behaviors related to behavior change for modifying dementia risk factors will be assessed using the Godin-Shephard Leisure Time Physical Activity Questionnaire along with additional questions related to a range of health status and behavior domains including diet, smoking, alcohol consumption, social activity, traumatic brain injury, blood pressure, depression, air pollution, diabetes, sleep habits, cognitive activity, and hearing to determine a composite score. Where possible, these questions were selected from validated tools (Multimedia Appendix 2). Additional data will be collected on engagement with the web-based intervention throughout the study, including (1) e-learning analytics: progress or completion, login activity, and time on the lesson and (2) email campaign analytics: open rate and click-through rate.

Qualitative Data

Qualitative data will be collected through structured survey questions and open-ended questions. The effectiveness and impact of the intervention will be assessed using the Information Assessment Method for patients and consumers, a validated questionnaire that assesses outcomes of web-based consumer health information [14]. End-of-intervention and poststudy surveys will include open-ended questions to assess participant satisfaction with the intervention, changes in attitudes, beliefs, and behaviors during the study, and feedback on proposed future dissemination methods.

Data Analyses

Overview

All outcome assessors and data analysts will be blinded to participant allocation. The CONSORT (Consolidated Standards of Reporting Trials) extension for randomized pilot and feasibility trials and CONSORT-EHEALTH [15-17] will guide reporting of the study. The 12-item TIDieR (Template for Intervention Description and Replication) checklist was used for the intervention description [18]. Qualitative reporting will adhere to the COREQ (Consolidated Criteria for Reporting Qualitative Studies) [19].

Quantitative Data

All data will be entered into RStudio (version 2022.02.3; Posit PBC) [20-22]. A linear mixed effects model will be used to examine the relationship between total knowledge score and group by time point. The same model will be used to look at health behavior scores and total intention scores. We will look at outcome scores from all 3 time points (baseline [T1], at 4 weeks [T2], and at 2 months after the intervention [T3]). The stratification variables, age and level of education, will be included in all models. Additionally, we will examine possible effect modifiers of age, sex, and education on the relationship between groups and outcomes as well as time point and outcomes. For knowledge scores specifically, we will look at a family history of dementia or having been a care partner of a person living with dementia as a possible effect modifier of the relationship between group and knowledge score and time point and knowledge score. These models will be run for both intention-to-treat and per-protocol participant data.

Qualitative Data

All data will be entered into NVivo (version 14; Lumivero) [23]. Data will undergo a conventional, inductive, content analysis approach [24,25]. Data will be systematically examined by a single analyst; codes and themes will be generated based on the content without relying on preconceived theories. To maintain accuracy and credibility, weekly meetings will be held by the analyst and the research team to discuss developing themes, confirm the coding process, and ensure consistency and depth in the representation of the data.

Ethical Considerations

This study gained Hamilton Integrated Research Ethics Board approval on August 24, 2022 (project ID 14886). Participants were required to provide informed consent and were informed of the length of time of the e-learning, surveys, and email campaign as well as informed about details surrounding data collection, storage, and investigator identities. Participants' identities and confidentiality were maintained throughout the research study. All participant data were deidentified, and all findings will be nonidentifiable. There is no known risk or harm to participating in this study of publicizing its results or findings. Participants were provided with AskingCanadians points that can be redeemed for various gift cards as compensation for participation in the study.

Results

The study received funding in February 2023. Recruitment took place from March 28, 2023, to April 28, 2023, with the final participants completing the intervention by August 18, 2023. Analyses and interpretation of data are ongoing. The analysis is expected to be completed by summer 2024, and the results will be published by winter 2024.

Discussion

Expected Findings

Many Canadian people are not aware of the potential impact of modifiable risk factors with respect to the development of dementia. DementiaRisk represents an important and innovative contribution to consumer health education in the area of promoting brain health and dementia prevention. Specifically, this study aims to explore the impact of DementiaRisk for reducing modifiable risk factors of dementia, specifically through changes in knowledge of dementia risk factors, intention to engage in risk reduction activities, and health behaviors related to dementia risk reduction. Such improvements could contribute to a reduction in the risk of developing dementia, among other benefits [26]. A range of positive effects has been shown for web-based interventions for various target audiences (ie, health care providers and family or friend care partners) on a wide range of outcomes (eg, knowledge, attitudes, burden, stress, and others) [27-34].

Previously, we have shown that e-learning is effective for health professions' learning, and we have also outlined some of the more effective instructional design elements with respect to web-based learning [35,36]. Well-designed e-learning that uses best practices in multimedia such as the use of instructional graphics, audio narration, and personalization has been shown to be more effective than e-learning that does not conform to best-evidence instructional design [6,37]. Interventions delivered through the web have the potential to augment traditional face-to-face or paper-based approaches (so-called "blended delivery"); and web-based interventions may allow for greater access to a multitude of users [34,38], facilitating scale and spread [14,39]. DementiaRisk is based on evidence-based studies of dementia risk factors, including addressing several factors at the same time [2]. In addition to a positive impact on participants in the intervention, we anticipate long-term impacts on the Canadian public as well as a benefit for intervention agents (eg, primary care providers and public health units), given the ease of adoption, "trialability," scale, and spread of DementiaRisk.

Potential Challenges

We anticipate several limitations in this study. First, we anticipate that due to the nature of self-directed web-based interventions, we may encounter higher dropout rates. To mitigate this, we have opted to use AskingCanadians, a paid panel recruitment service that will allow for ensured efficiency of recruitment, potentially higher retention rates, and the ability to attract a diverse and representative sample of Canadian people. Second, many of the instruments for measuring primary and secondary outcomes were custom-created. Although many of the specific survey questions were pulled from validated tools, there is still the possibility that their novelty may influence result validity, which will require cautious interpretation and the use of qualitative data to enrich findings. Third, although the control group will receive e-learning that is related to mild cognitive impairment, and not dementia risk factors, there is the possibility for some contamination or confounding, with some overlap in content domains and the potential for positive outcomes related to the control group content.

Conclusions

Canada's dementia strategy highlights the need to bring awareness to dementia prevention nationally to promote healthy behavior change, in particular, to build the evidence base to inform and promote the adoption of effective risk reduction interventions as well as expand awareness. As the population of older adults living with dementia grows, the demand for high-quality information on dementia prevention is growing as well. Developing a better understanding of how dementia can be prevented and sharing information about how Canadian people can reduce their risk of developing dementia or delay its onset are critical to keeping Canadian people healthy and improving their quality of life. DementiaRisk is a readily scalable, technology-enhanced solution for dementia prevention education. It has the potential to reach a wider number of audiences with modifiable risk factors for dementia than traditional face-to-face interventions.

Acknowledgments

This work was supported by the team at the Division of e-Learning Innovation at McMaster University. Funding was provided by the Public Health Agency of Canada Dementia Strategic Fund. AJL receives support through the John R. Evans Chair in Health Sciences Educational Research and Instructional Development, Faculty of Health Sciences, McMaster University. The authors would like to thank Drs Parminder Raina, Vladimir Khanassov, Wei Wang, Tarek Rajji, and Sid Feldman for their time and participation in this project.

Data Availability

The datasets generated and analyzed during this study can be made available from the corresponding author upon reasonable request.

Authors' Contributions

AJL and SA drafted the original study protocol. AJL, SC, and RW led the intervention. SA drafted the protocol manuscript. All authors have reviewed the manuscript and approved the final version.

Conflicts of Interest

AJL, RS, and McMaster University are co-owners of DementiaRisk.

Abstract

Background: Black adults in the United States experience disproportionately high rates of tobacco- and obesity-related diseases, driven in part by disparities in smoking cessation and physical activity. Smartphone-based interventions with financial incentives offer a scalable solution to address these health disparities.

Objective: This study aims to assess the feasibility and preliminary efficacy of a mobile health intervention that provides financial incentives for smoking cessation and physical activity among Black adults.

Methods: A total of 60 Black adults who smoke (≥5 cigarettes/d) and are insufficiently physically active (engaging in <150 min of weekly moderate-intensity physical activity) will be randomly assigned to either HealthyCells intervention (incentives for smoking abstinence only) or HealthyCells+ intervention (incentives for both smoking abstinence and daily step counts). Participants will use study-provided smartphones, smartwatches, and carbon monoxide monitors for 9 weeks (1 wk prequit date through 8 wk postquit date). Feasibility will be evaluated based on recruitment rates, retention, and engagement. The primary outcomes include carbon monoxide–verified, 7-day smoking abstinence at 8 weeks postquit date and changes in average daily step count. Feasibility benchmarks include a recruitment rate of ≥5 participants per month, a retention rate of ≥75%, and a smoking abstinence rate of ≥20% at 8 weeks postquit date. Expected increases in physical activity include a net gain of 500 to 1500 steps per day compared to baseline.

Results: Recruitment is expected to begin in February 2025 and conclude by September 2025, with data analysis completed by October 2025.

Conclusions: This study will evaluate the feasibility of a culturally tailored mobile health intervention combining financial incentives for smoking cessation and physical activity promotion. Findings will inform the design of larger-scale trials to address health disparities through scalable, technology-based approaches.

Introduction

Background

In the United States, tobacco- and obesity-related diseases are among the top 10 leading causes of death in the Black and African American (henceforth Black) population, and these diseases are more common and deadlier among Black adults compared with the overall US population [1-3]. For example, while smoking prevalence is similar among Black and White adults, Black adults are less likely to quit smoking than other racial and ethnic groups [4-6], and rates of lung cancer incidence and mortality are higher among Black male individuals than White male individuals [3]. Likewise, the Black population has high rates of obesity in the United States [7]. Physical inactivity (ie, no physical activity outside of work during the past month), a leading cause of obesity [8,9], is higher among Black adults compared with most other racial groups [8,9]. High rates of smoking (14.2%) [10] and insufficient physical activity (30%) [11] among Black adults are important modifiable health risk factors for cancer and chronic illness [12]. Interventions that simultaneously address these behaviors may promote holistic lifestyle changes, provide significant health benefits, and increase health equity within the Black population [13,14].

Multiple health behavior change (MHBC) interventions are defined as those that promote 2 or more health behaviors and thus have a more comprehensive focus on lifestyle health promotion [15,16]. Smoking and low physical activity are strong candidates for these interventions because people who smoke generally report less physical activity than those who do not smoke [17], and individuals may benefit from replacing smoking with physical activity during a quit attempt [18]. Importantly, engaging in physical activity may increase self-efficacy for quitting and alleviate cigarette cravings during withdrawal [19-22]. Physical activity also improves mood and reduces stress, which are common triggers for smoking relapse [23]. However, numerous studies have shown mixed results regarding the physical activity's effectiveness for smoking cessation [24], in part because adherence to physical activity varies significantly across individuals [23,25,26], with stronger adherence among adults with existing physical activity habits and strong social support, and the type of activity (eg, low-intensity activity vs high-intensity activity) [27].

Low-intensity activities, such as walking, may be more practical and palatable for people trying to quit smoking while still offering benefits for smoking cessation, such as reduced cravings and stress relief [13,19,28]. Low-intensity activities may also promote greater adherence to physical activity because they are accessible, comfortable, and less likely to cause fatigue or injury than high-intensity workouts [29]. Furthermore, low-intensity activities can be included in daily routines, such as walking to a bus stop or church [30]. The inclusivity and ease of low-intensity physical activity may encourage long-term engagement and consistency. Thus, combining low-intensity physical activity with other cessation strategies may synergistically increase the likelihood of smoking cessation and have a greater impact on overall health.

Contingency management (CM) is a simple, powerful, and widely used behavioral strategy where tangible rewards are offered for meeting a prespecified behavior change goal [31-33]. CM is efficacious for improving smoking cessation and physical activity [34-38], but common concerns about CM are intervention costs and maintenance of long-term behavior change once incentives cease [39]. Yet, recent research on smoking and physical activity has shown that CM interventions are cost-effective, and even small financial incentives can lead to long-term changes in smoking and physical activity after incentives are withdrawn [34-38]. Thus, an MHBC intervention that incentivizes behavior change could help Black adults initiate and sustain smoking cessation and adequate physical activity in conjunction with other recommended tobacco treatment components (ie, counseling and pharmacotherapy) [40].

Despite the rapid growth of mobile health (mHealth) technologies, such as smartphone apps, that offer new opportunities to reach and treat at-risk populations, Black adults remain underrepresented in mHealth research [41]. As of 2024, 84% of the Black population owned a smartphone [42]; therefore, app-based interventions have the potential to increase the reach and use of effective treatments for smoking and physical activity within this population. Furthermore, apps combined with sensors and wearables can be powerful tools for self-regulation [42], which is a core component of behavior change [43], and can provide frequent feedback and engagement opportunities. Initial evidence suggests that app-based interventions may be a useful supplement to more intensive behavioral or pharmacological treatments and may even show comparable outcomes to traditional face-to-face interventions in some cases [44-47]. Furthermore, smartphone apps can be used to characterize the behaviors, needs, and outcomes of traditionally understudied and underserved groups.

Research indicates that interventions incorporating culturally relevant content resonate with Black adults, enhancing their motivation and commitment to behavior change [48-53]. Such content has increasingly been incorporated into mHealth interventions targeting smoking cessation and physical activity among Black adults [54-57]. Drawing from publicly available resources such as *Pathways to Freedom*—a short documentary highlighting the historical and cultural ties between the Black community and tobacco use and incorporating health education and culturally relevant messages to motivate Black adults to quit smoking [48,49]—mHealth apps can provide educational content on the historical and social influences of smoking within the Black community. mHealth apps can also provide motivational messages and stress-management techniques grounded in culturally relevant themes, such as prayer and seeking support from family and friends. Furthermore, app-based interventions can deliver education about the purpose and benefits of nicotine replacement therapy (NRT) and debunk myths and misconceptions about NRT that are present in this population [58-60]. Apps can also make it easier for Black adults to create activity goals that reflect their current life circumstances and environment [61,62], and these goals can be adjusted dynamically based on daily performance and feedback, ensuring that goals remain challenging yet attainable. This content can be presented alongside success stories from notable

and relatable Black figures to provide additional motivational support [63-65]. Altogether, when delivered with evidence-based treatment for smoking cessation and physical activity, culturally relevant content may reinforce the quit journey and help address common challenges that Black adults face when quitting smoking and engaging in physical activity.

Objectives

The purpose of this project is to explore the feasibility of an app-based MHBC intervention (HealthyCells) for Black adults who smoke and are insufficiently physically active. In addition to evidence-based tobacco cessation treatment [66], HealthyCells will incentivize daily smoking abstinence, while an enhanced version of the intervention, HealthyCells+, will also include incentives for meeting physical activity goals [36,67]. The inclusion of 2 active study conditions allows for a direct comparison to evaluate the added benefit of financial incentives for physical activity. The central hypothesis is that participants in the HealthyCells+ group will demonstrate greater increases in daily physical activity (measured via step counts) and improved smoking abstinence rates compared to those receiving smoking cessation incentives alone (HealthyCells). HealthyCells will also include an interactive educational e-book experience inspired by the documentary *Pathways to Freedom* [48,49], designed to guide individuals during their quit attempt and provide opportunities to set personalized activity goals, which can be dynamically adjusted daily to reflect current readiness. The primary aim will be to demonstrate intervention feasibility, including recruitment, retention, and adherence metrics, along with rates of carbon monoxide (CO)–verified smoking abstinence and prequit and postquit changes in physical activity.

Methods

Overview

Black adults who smoke and are insufficiently physically active (ie, not meeting physical activity guidelines) [68] will be randomly assigned to 1 of the 2 versions of an MHBC intervention that targets smoking cessation and insufficient physical activity: (1) HealthyCells (incentives for smoking abstinence only) or (2) HealthyCells+ (incentives for both smoking abstinence and physical activity). Both groups will receive a comprehensive tobacco treatment intervention, including 8 weeks of NRT, an initial counseling session to create a quit plan, and 5 weekly counseling sessions (6 sessions in total). Likewise, all participants will receive a study-provided smartphone and intervention app, a Samsung smartwatch to measure daily steps, and a Bedfont iCOquit Smokerlyzer to verify smoking status. Participants will be asked to use their assigned app and equipment for 9 weeks (1 wk prequit date through the eighth wk postquit date).

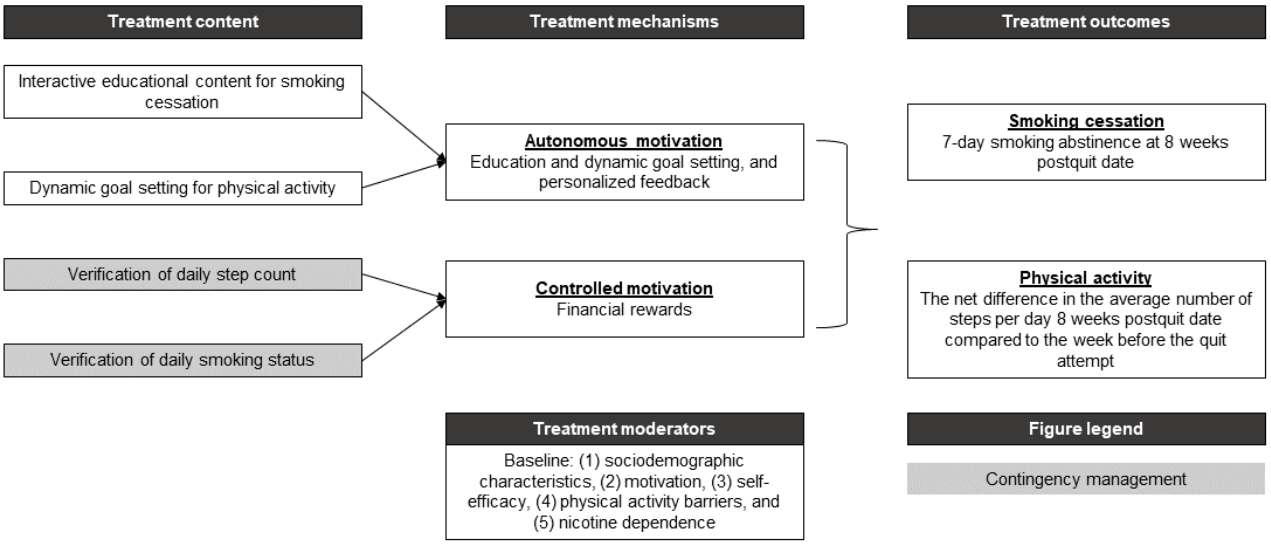
Ethical Considerations

This study was approved by the institutional review board of the University of Oklahoma Health Sciences Center (protocol #14094), and the study was registered at ClinicalTrials.gov (NCT05188287). All procedures involving human participants will adhere to the Declaration of Helsinki and relevant institutional guidelines. Written informed consent will be obtained digitally from all participants before enrollment, and they will be informed of their right to withdraw from the study at any time without penalty. To ensure privacy and confidentiality, participant data will be deidentified and stored on a secure, password-protected server. All breath sample photos and step count uploads will be encrypted, with access restricted to authorized research personnel. Following a structured and transparent payment schedule, participants will receive compensation based on their engagement with study activities, including breath sample submissions, step count verifications, surveys, and interviews (refer to the Study Compensation section). To protect participant privacy, all devices used for data collection, including Samsung smartphones and smartwatches, will be reset to factory settings after study participation has ended for each participant. Any adverse events or deviations from the protocol will be promptly reported to the institutional review board in compliance with ethical oversight requirements.

Theoretical Framework

As shown in Figure 1, this intervention will be guided by self-determination theory principles [69-72]. Self-determination theory posits that two forms of motivation are involved in behavior change: (1) autonomous motivation and (2) controlled motivation [72]. Autonomous motivation consists of engaging in behavior out of curiosity, interest, a sense of challenge, or for its inherent enjoyment. Conversely, controlled motivation involves engaging in a behavior because of external rewards or punishment avoidance [72]. Autonomous motivation is associated with sustained behavior change, whereas controlled motivation is related to temporary change [73]. CM interventions provide financial rewards for immediate behavior change, primarily targeting controlled motivation [74].

Figure 1. The theoretical framework of HealthyCells app, a multiple health behavior change intervention for smoking cessation and physical activity.



Incentives can be paired with resources and activities that cultivate autonomous motivation to sustain long-term behavior change [75]. The research team created an interactive educational e-book experience inspired by *Pathways to Freedom* [48,49] intervention that focuses on several key topics highlighted in Textbox 1, such as the harms of smoking, tobacco marketing, NRT education, and stress management, and includes narratives from several prominent Black individuals who have struggled with smoking, such as the former US President Barack Obama [76]. The research team also developed a personalized activity goal algorithm based on findings from mHealth physical activity interventions [54,77] and qualitative interviews with Black adults [61,78].

Textbox 1. Overview of topics covered in the HealthyCells, Healthy Habit e-book.

Chapters and interactive educational content

- Chapter 1: discusses health and economic harms caused by smoking and the benefits after quitting
- Chapter 2: covers the hidden history of Black adults and the tobacco industry
- Chapter 3: describes how habits are created and why smoking is one of the deadliest habits to break
- Chapter 4: provides an overview of how nicotine reinforces the smoking habit
- Chapter 5: reviews the purpose and benefits of nicotine replacement therapy

Inclusion and Exclusion Criteria

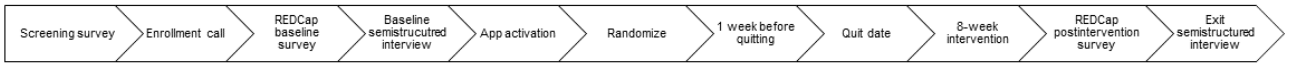
Inclusion criteria for the participants will be as follows: (1) resident of Oklahoma (verified via driver's license or ID); (2) aged ≥18 years; (3) self-identify as *Black* or *African American*, either alone or in combination with other races or Hispanic ethnicity; (4) smoke ≥5 cigarettes or cigarette equivalents per day (ie, cigars and cigarillos); (5) currently (per self-report) engage in <150 minutes of moderate-intensity aerobic physical activity or <75 minutes of vigorous-intensity aerobic physical activity per week [68]; (6) willing to use NRT, a smartwatch, or the study app and able to attend smoking cessation counseling; (7) willing to quit smoking within the next 3 weeks; and (8) exhaled CO level of >6 ppm at app activation.

Exclusion criteria for the participants will be as follows: (1) unwilling to complete the screening survey, (2) unable to understand or speak English, (3) not a US citizen or permanent resident (due to university taxation policies), (4) unwilling to provide social security number, US residency status, or university employee status (to adhere to university reporting requirements), (5) unwilling to abstain from smoking marijuana or cannabis during their quit attempt, (6) unwilling to provide a picture of a tobacco product (to provide initial evidence of current smoking), (7) medical condition (per self-report) that is a potential contraindication for NRT use (eg, uncontrolled hypertension, heart disease, or recent heart attack), or (8) has had a severe allergic reaction or side effect from the use of NRT.

Recruitment

Participants will be remotely recruited and enrolled. No in-person visits are required (Figure 2). Eligible individuals will be identified through the Tobacco Treatment Research Program [79], which offers free tobacco cessation support to adult Oklahomans and assists with study recruitment [38,80-82]. Prospective participants will also be contacted by SMS text messages, email, and phone, and recruitment flyers will be posted in community locations (eg, barbershops and churches) and on social media through a geotargeted campaign focused on Black adults who smoke. Those interested can access a brief web-based eligibility screener via a QR code or direct link.

Figure 2. Participant flow. REDCap: Research Electronic Data Capture.



Study Enrollment

Study staff will contact via phone adults who meet preliminary eligibility to confirm eligibility and discuss study participation. To prevent fraudulent enrollments [83,84], participants will be asked to provide a photo of their driver's license or ID (or other proof of address) and an image of a personal tobacco product to provide initial evidence of smoking status. Eligible and willing participants will be informed about the study and asked to acknowledge their consent with a digital signature. Following enrollment, participants will complete a baseline survey via REDCap (Research Electronic Data Capture; Vanderbilt University) [85] (refer to Multimedia Appendix 1 for a complete list of study measures), and their first semistructured phone interview will be scheduled to discuss their openness to using smartphone apps and to identify potential barriers to mHealth research participation (Table 1). After the interview, participants will receive a welcome packet with study instructions, copies of informed consent, and other signed study documentation, a reloadable Greenphire ClinCard [86], intervention equipment (smartphone, smartwatch, and Bedfont iCOquit Smokerlyzer), and NRT by mail.

Table 1. Overview of qualitative domains covered in each interview.

Domain	Baseline interview	Exit interview
Participation in mHealth[a] research	✓	
Understanding smartphone use and habits	✓	
History of using health apps and Bluetooth-enabled devices	✓	
History of using apps that promote smoking cessation and physical activity	✓	
Understanding preferences for smartphone apps that promote health behavior change within the Black population	✓	✓
History of quitting smoking and the methods used to quit smoking before study participation		✓
Problems with study equipment and smartphone app		✓
Overall impressions of app features		✓
Experiences using smartwatch during study participation		✓
Experiences using NRT[b] during study participation		✓

[a]mHealth: mobile health.

[b]NRT: nicotine replacement therapy.

Upon confirming receipt of the study phone and materials, participants will complete an activation assessment in the study app, independently or with study staff. This will assess their ability to use app features, including viewing images, hearing sounds, reading text, and using the Bedfont iCOquit Smokerlyzer. Participants with an expired breath CO <6 ppm or who cannot use the Bedfont iCOquit Smokerlyzer will be withdrawn before randomization and asked to return the study phone and smartwatch. Participants can keep the NRT and Bedfont iCOquit Smokerlyzer to support their quit attempt and will be transferred to the Tobacco Treatment Research Program for cessation services. Participants who pass the activation assessment will be randomly assigned to the HealthyCells or HealthyCells+ intervention.

Study Randomization

Participants will be stratified according to self-reported sedentary time at baseline (high: >8 h/d, medium: 4-8 h/d, and low: <4 h/d) assessed via the International Physical Activity Questionnaire [87]. Participants (n=60) will be randomized 1:1 in REDCap [85], and research staff will text each new participant a unique code (HealthyCells: 0101 and HealthyCells+: 0202) to access assigned app content.

Standard Care

All participants will receive standard intensive tobacco treatment [66], beginning with a phone counseling session 1 week before the scheduled quit date and continuing weekly through the fourth week after the quit date. Counseling sessions will cover topics, including creating a quit plan, the health impact of tobacco, stress management, adopting lifestyle changes, developing coping strategies, and relapse prevention. In addition, participants will receive 8 weeks of combination NRT (nicotine patches+gum or lozenges) based on package-recommended dosing tailored to baseline smoking and nicotine dependence levels [88]. The first 4-week supply will be mailed, and participants can request the remaining supply through the study app as needed.

MHBC Intervention: App Development and Pilot Testing

Overview

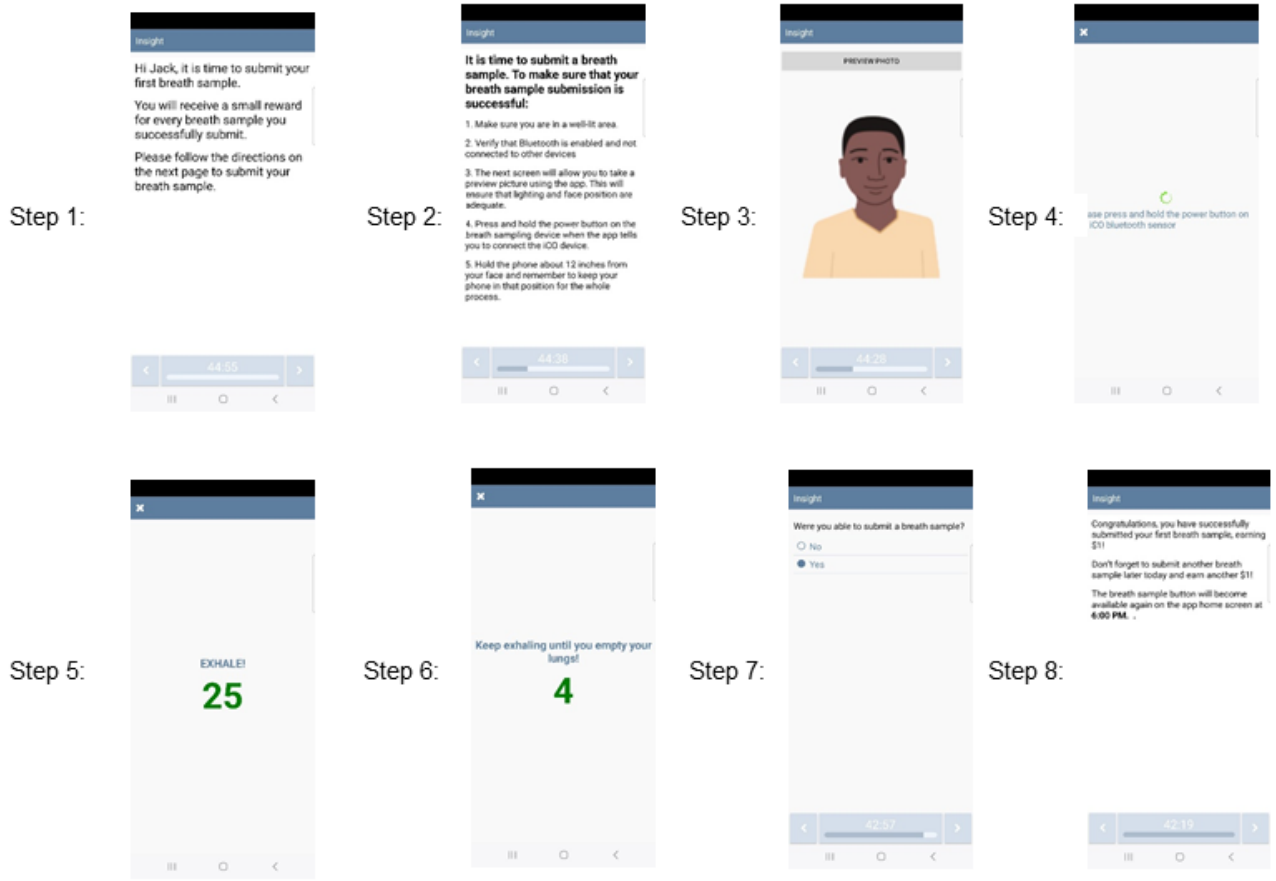
The HealthyCells app was developed using the Insight mHealth Platform [47]. All app content, including breath sample submissions, step count tracking, and interactive educational material, was presented to the African American Cancer Research Community Advisory Board at the Stephenson Cancer Center in November 2024 to solicit community feedback. This meeting was digitally recorded, and the study team reviewed transcripts to identify strengths, weaknesses, and gaps where the app content could be refined. Additional systematic usability testing will be conducted in this feasibility trial to evaluate app engagement, functionality, and acceptability among participants. Findings from this study will inform further refinements to the app in preparation for future large-scale trials to maximize its effectiveness and user experience.

MHBC Intervention: HealthyCells

In addition to all components of standard care described earlier, HealthyCells participants will be able to earn daily financial incentives for CO-verified smoking abstinence each day. Smoking status and identity will be assessed remotely via (1) self-reported daily smoking status, (2) CO breath sample submissions (ie, via the Bedfont iCOquit Smokerlyzer), and (3) Microsoft Azure facial recognition software; each of these assessment types has been successfully integrated into the Insight mHealth Platform [89,90]. Participants will be asked to upload a photo of themselves during the app activation phase, which will be stored as the reference photo for future identity verification. Participants will be instructed to keep their appearance consistent with the baseline photo during breath sample submissions (eg, removing or staying consistent with glasses, hats, and ponytails). During breath sample submissions, 2 photographs will be taken randomly during the exhalation phase to verify identity. Photographs will be encrypted and stored on the study server for later viewing by study staff as needed. A facial recognition mismatch will pause the delivery of incentives and will be flagged for internal review by study staff. Staff will click “thumbs up” or “thumbs down” for an identity match or mismatch, and incentives will be earned on schedule or unearned with incentive levels reset to the starting level.

To earn incentives for smoking abstinence, participants will be instructed to submit 2 breath samples each day (Figure 3). These participant-initiated assessments will appear on the home menu screen, with the first assessment appearing at the beginning of each day (based on participants’ self-reported waking hours) and the second assessment appearing 8 hours after the initial evaluation is completed. Participants will earn US $1 for each breath sample submission regardless of current smoking status. The incentive schedule used in this study is an adaptation of a low-cost incentive schedule the investigators have used in their previous and ongoing work with adults who are socioeconomically disadvantaged [38,89-91]. Participants who demonstrate abstinence (ie, self-reported abstinence that day, CO ≤6 ppm, and identity verification) on both breath sample submissions on their scheduled quit date will receive US $20 to reinforce the initiation of the quit attempt strongly. After that, abstinent participants will be rewarded US $4 per day, increasing by US $0.50 per week until US $5.50 per day is reached during the fourth week postquit date. Participants who are nonabstinent (or who do not provide a sample) will not earn an incentive that day, though they may begin earning incentives for abstinence again the next day. However, the amount will reset to the starting level of US $4 per abstinent day. Participants will earn US $7 per abstinent day during the eighth week postquit date. To gain the maximum incentives for smoking cessation (US $325), participants must report daily smoking abstinence and submit 2 breath samples each day (CO ≤6 ppm) with identity verification during all eligible assessment weeks (ie, wk 1-4 and the eighth wk postquit date).

Figure 3. An example of a breath sample submission to verify smoking status.



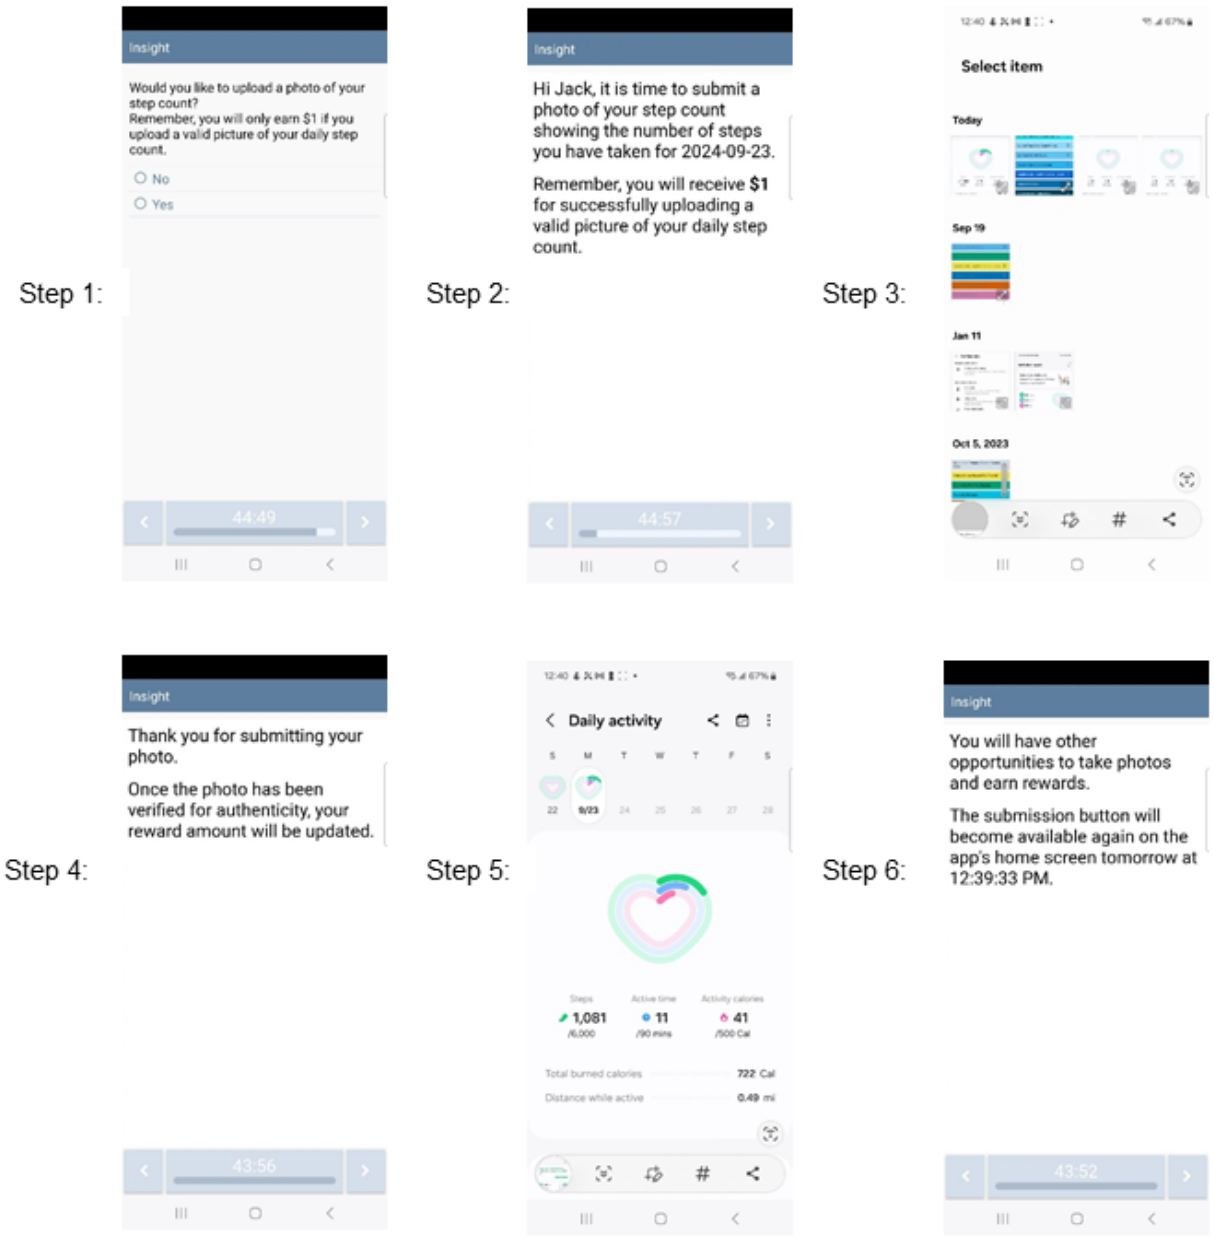
HealthyCells intervention participants will receive a Samsung smartwatch to track their activity and a daily SMS text message about the benefits of increasing physical activity via the app (refer to the Daily Smoking Cessation Progress Report section). They will also have access to content and features that provide strategies for engaging in physical activity to aid their quit attempts (refer to the Set and Review Activity Goals section). However, HealthyCells intervention participants will not receive incentives to increase their physical activity.

MHBC Intervention: HealthyCells+

In addition to the small financial incentives earned for biochemically verified abstinence, HealthyCells+ intervention participants will earn small incentives for increasing physical activity (ie, daily step count) during their quit attempt. Starting on their scheduled quit date, participants will be rewarded US $0.50 per 1000 steps for every step >4000 daily steps, and they will receive a US $2.50 bonus if they walk at least 6000 steps a day. These criteria were set based on research showing Black adults walk about 4000 steps per day on average [92]. Providing incentives above this threshold will ensure the incentive protocol will not reinforce a sedentary lifestyle, and a bonus for meeting the 6000-step per day goal will reinforce higher levels of daily physical activity and greater positive health benefits [92-100]. Participants will not be incentivized beyond 10,000 steps per day, consistent with previous research showing limited additional health benefits [93,95-100]. Therefore, the maximum amount participants can earn per day for daily steps will be US $5.50 (ie, US $3.00 for 10,000 steps +US $2.50 for step goal bonus), an amount that parallels the amount participants can earn at the fourth week postquit date for daily smoking abstinence.

Participants will self-report their daily step count via an assessment on the app home menu at the end of each day (based on self-reported typical time to bed). This assessment will also ask participants to upload a picture of their step count (captured by the smartwatch; Figure 4). To promote compliance, participants will receive US $1 for each successful photo upload (up to 7 submissions/US $7/wk). Participants will not earn incentives for their self-reported step count total if an image is not uploaded. Consistent with the incentive schedule for smoking cessation, participants will earn these incentives for increasing physical activity starting on the scheduled quit date up to 4 weeks postquit date. Incentives may also be earned during the final 7 days of the intervention period (eighth wk postquit date). To gain the maximum incentives for increasing physical activity (US $255.5), participants must submit all step count photos and take 10,000 steps daily during all eligible assessment weeks (ie, wk 1-4 and the eighth wk postquit date).

Figure 4. An example of a valid photo upload of activity data to verify daily step count.



App Features

Overview

Several app features will be available to help participants earn incentives for abstinence and increase physical activity (Table 2 and Figure 5). Multimedia Appendix 2 provides a complete list of features and a detailed description. A summary of each feature is presented in Table 2.

Figure 5. Home screens for HealthyCells (left) and HealthyCells+ (right) apps. NRT: nicotine replacement therapy.

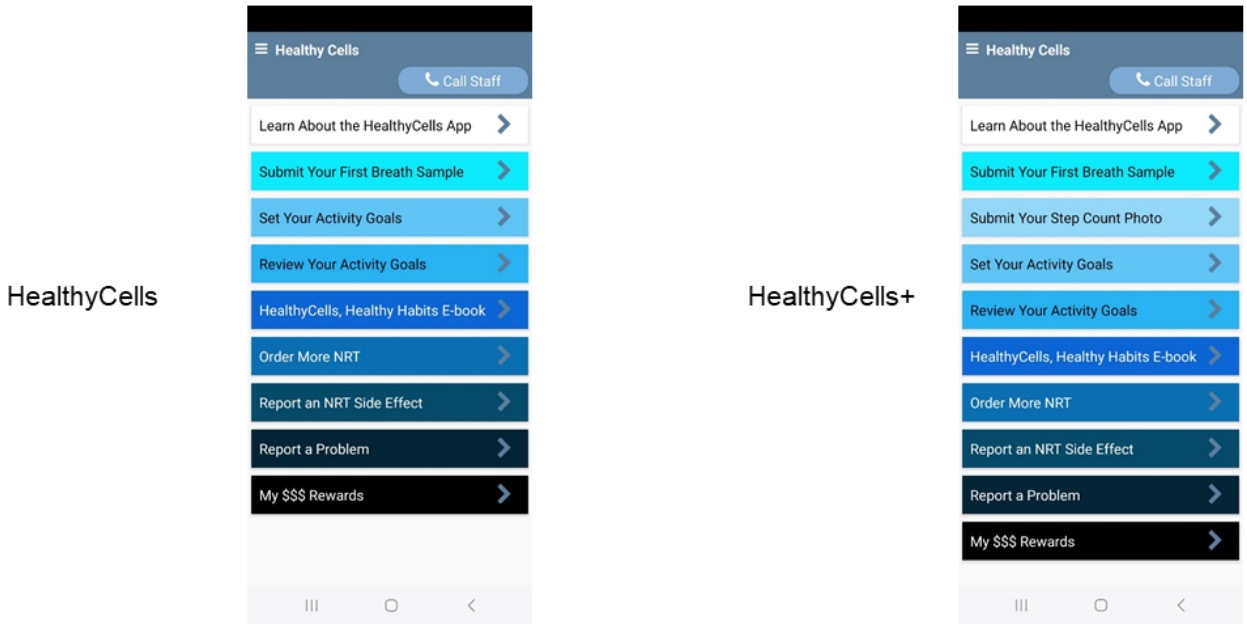


Table 2. Overview of app features.

App features	HealthyCells	HealthyCells+
App Instructions: provide participants with an app overview and study instructions	✓	✓
HealthyCells, Health Habits e-Book: interactive information about smoking and smoking cessation	✓	✓
Breath Sample Submission: submit breath samples using an Bedfont iCOquit Smokerlyzer to verify smoking status and facial recognition software to verify participant identity	✓	✓
Set Activity Goals: set daily steps, active time, and caloric goals	✓	✓
Review Activity Goals: review activity goals and receive feedback to adjust goals for the next day	✓	✓
Submit Step Count Photo: upload an image of activity data for independent verification of step count goals		✓
Report an NRT[a] Side Effect: report side effects from NRT and receive assistance from study staff	✓	✓
Order More NRT: request more NRT during a quit attempt	✓	✓
Track My Rewards: displays the amount of compensation received for completed study assessments	✓	✓
Report a Problem: report a problem with study equipment or assessments	✓	✓

[a]NRT: nicotine replacement therapy.

Learn About the HealthyCells+ App

This feature will be accessible on the home screen at any time during the intervention and will provide an overview of the study apps and instructions for accessing them on their phone.

HealthyCells, Healthy Habits E-Book

Participants can access a short e-book to help them prepare for their upcoming quit attempt. Textbox 1 gives an overview of the topics covered in each chapter. On days 3 to 7 of the prequit week, participants will be informed 1 hour before self-reported typical bedtime about the availability of e-chapters. The entire e-book will be accessible on the home screen at any time after the participant's scheduled quit date.

Set and Review Activity Goals

This feature will be accessible on the home screen at the beginning of each day, allowing participants to set activity goals. If a participant inputs a step goal below the recommended amount needed to receive health benefits or incentives, the app will notify them that they have selected an amount below the recommended threshold. Participants can adjust their goals

before confirming. Once the participant has set their step goal, this feature will be removed from the home menu screen until the next day.

A total of 8 hours after setting their goal, an option to review their progress will appear on the app home screen. Participants self-report their current step count as indicated on their smartwatch, and the app will automatically calculate whether the participant has met their step goal set earlier in the day. The app will ask participants to rate how challenging it was to meet their current step goal, and their feedback will be used to adjust their step goal for the next day. We created a simple algorithm to set new goals based on the participant's response dynamically: if they rate their current step goal as "not challenging," the next day's step goal will increase by 10%; if "just right," it will increase by 5%; and if "very challenging," it will decrease by 10%. For example, if a participant's goal was 6000 steps and they found it "not challenging," their new suggested goal would be 6600 steps. Once they review their activity progress, this feature will be unavailable on the home menu until the following day.

Report an NRT Side Effect

This feature will be accessible on the home screen at any time, and participants can select from a list of side effects associated with NRT that they experienced during the intervention. Only serious reported side effects will be sent to the study staff and research team via an encrypted email.

Order NRT

This feature will be accessible on the home screen at any time, and participants can order up to 4 weeks of additional NRT, which will be sent directly to the participant's current mailing address.

Track My Rewards

Any time during the intervention, participants can track their rewards for submitting breath samples and activity photos (refer to the Study Compensation section) from the app home screen.

Report a Problem

From the app home screen, at any time during the intervention, participants can report any issues they have encountered during study participation via an encrypted email sent directly to the research team.

Return Study Materials

This menu option will appear on the app home screen after the participant has submitted their final breath sample and uploaded the final photo of their smartwatch activity data to verify their step count. Participants can access instructions about returning their study equipment via study-provided shipping materials.

Daily Smoking Cessation Progress Report

Each day during the intervention, participants will receive a notification from their study app 30 minutes after their self-reported wake time to complete a "Daily Smoking Cessation Progress Report." The app will alert participants visually and audibly for 30 seconds, with a 15-minute snooze option available up to 5 times; after the fifth snooze, the assessment will be marked as missed. The assessment provides feedback on whether smoking status assessments were completed during the previous day, and participants will be asked to self-report confidence in using the Bedfont iCOquit Smokerlyzer and facial recognition. Participants will receive a reminder to use nicotine patches and gum or lozenges daily (or as needed). Participants will also be reminded to wear their smartwatch and set daily activity goals. In addition, participants will be asked to respond to 5 questions assessing sleep quality, mood, stress, energy, and focus.

Study Compensation

Participants will earn up to US $650 in the HealthyCells condition and up to US $905.5 in the HealthyCells+ condition by earning incentives and completing various study activities (Table 3). Upon completing the enrollment call (ie, the participant is fully eligible and agrees to join the study), participants will receive US $25. Completing the baseline survey (US $50) and interview (US $50) within 72 hours will qualify them for a US $25 bonus, totaling US $125. During the intervention, participants will earn US $1 per breath sample submitted twice daily, with additional bonuses if both samples indicate smoking abstinence (CO <6 ppm), for a possible total of US $325. HealthyCells+ intervention participants will earn US $1 daily for submitting step count photos, with bonuses for exceeding 4000 steps (up to 10,000 total steps) and meeting a 6000-step goal, potentially totaling US $255.5. Completing the postintervention survey at the end of the intervention will offer US $50 and an additional US $50 for participating in the exit interview. If these 2 activities are completed within 72 hours, participants will earn a US $25 bonus, totaling US $125. Participants who return study materials will receive US $25, with an additional US $25 bonus if returned within 7 business days, totaling US $50.

Payments will be delivered via a reloadable GreenPhire ClinCard [86] once per week, with the first payout occurring after the baseline interview and the final payment after study materials are returned. This structured payment system encourages consistent engagement and ensures the timely return of valuable study materials by tying the final payment to their return. Participants can also track their earnings in real time through the app (refer to the Track My Rewards section), which adds transparency to the process.

Table 3. Compensation amount and payment schedule for completed study activities.

Activity	Compensation (US $)	Bonus condition	Total compensation (US $)	Study condition	
				HealthyCells[a]	HealthyCells+[b]
Study enrollment[c]	25	None	25	✓	✓
Baseline survey	50	Complete both the baseline survey and interview within 72 h (US $25)	Up to 125	✓	✓
Baseline interview	50	Complete both the baseline survey and interview within 72 h (US $25)	Up to 125	✓	✓
Breath sample submission	1 per sample (2 samples/d)	Not smoking when completing breath samples (up to US $20)	Up to 325	✓	✓
Step count photo Submission	1 per photo (1 upload/d)	Per step above 4000 steps (maximum 10,000 steps; US $3); meeting 6000 step goal (US $2.50)	Up to 255.5		✓
Postintervention survey	50	Complete both the postintervention survey and baseline survey within 72 h (US $25)	Up to 125	✓	✓
Exit interview	50	Complete both the postintervention survey and baseline survey within 72 h (US $25)	Up to 125	✓	✓
Return study materials	25	Return study materials within 7 business days (US $25)	Up to 50	✓	✓

[a]The total compensation was up to US $650.

[b]The total compensation was up to US $905.5.

[c]Participants only earn US $25 if they successfully enroll in the study.

Postintervention Assessment and Treatment Outcomes

At the eighth week postquit date, participants will complete a postintervention assessment via REDCap [85], answering questions similar to those in the baseline assessment to track changes in physical and mental health and health behaviors and to assess app impressions (Multimedia Appendix 1). A final semistructured interview will gather feedback on the app and suggestions for improvement (Table 1). The primary outcome for smoking cessation will be CO-verified, 7-day point prevalence smoking abstinence at 8 weeks postquit date, which will be assessed via smartphone-based self-report and a corroborating CO assessment. Expired CO is a valid indicator of smoking and cessation and compares favorably with cotinine and other biochemical measures [101]. Daily abstinence will be examined as a secondary outcome and defined as self-reported abstinence within the day combined with 2 breath CO sample submissions <6 ppm and identity verification. The number of days and consecutive days of CO-verified abstinence will be explored as additional outcomes. The other primary outcome will be the net change in average daily steps during the eighth week postquit date compared with average daily steps the week before the quit attempt (HealthyCells+ group only). Second, we will explore the number of total and consecutive days that ≥6000 steps were achieved as additional outcomes [102]. A valid day of observation for daily steps will be defined as (1) a smartwatch that was worn for at least 10 waking hours with (2) ≥500 steps taken within a day [103].

To ensure accurate, objective measurement of step count, study staff will pair each participant's Samsung smartwatch with a Samsung smartphone and create a unique Samsung Health account before shipping the study materials. The Samsung Health app integrates seamlessly with the smartwatch, allowing continuous step count tracking. These data sync automatically from the watch to the app, enabling real-time data capture. Throughout the intervention, the research team will periodically access each participant's Samsung Health account to securely export step data, which will be saved as a file for analysis. Once participants return the phone and smartwatch, the study team will directly extract step data from the smartwatch to verify and complement the app-synced step data. This dual extraction process enhances data reliability, ensuring comprehensive and objective measurement of participants' physical activity [102]. After this extraction, the phone and smartwatch will be reset to factory settings to prepare them for use with another participant, ensuring privacy and consistency across participants.

Feasibility and Engagement Outcomes

We will assess several metrics to gauge the feasibility of evaluating the intervention in a larger-scale trial. Key metrics include completion rates for surveys and interviews (retention and engagement), instances of lost or damaged phones or

watches (technology use barriers), and participant engagement with app features, such as completing the e-book for smoking cessation and setting and reviewing daily step goals. We will also characterize the frequency of photo uploads of daily step counts, completion of daily smoking status assessments, NRT adherence, completion of counseling sessions, and duration of smartwatch wear. These feasibility metrics will also be explored qualitatively by interviewing participants about their experiences with the intervention (ie, exit interview), such as their engagement with app features, ease of completing assessments, and any challenges encountered with study equipment.

Sample Size Justification

The sample size of 60 participants was chosen based on recommendations for feasibility trials [104,105], which prioritize assessing study processes, recruitment, retention, and intervention engagement rather than detecting statistically significant effects. This sample size is sufficient to evaluate key feasibility metrics, such as recruitment rates (target: ≥5 participants/mo), retention (≥75% completion), and adherence to intervention components, which are critical for planning a fully powered randomized controlled trial. In addition, this sample size allows for preliminary comparisons between the HealthyCells and HealthyCells+ groups to explore trends in CO-verified smoking abstinence and changes in daily step counts.

Analytic Plan

This analytic plan will focus on describing intervention feasibility. Feasibility indicators will include enrollment of all study participants within 12 months (≥5 adults enrolled/mo), retention of at least 75% of the participants at 8 weeks postquit date, achieving 20% smoking abstinence at 8 weeks postquit date (consistent with NRT and behavioral support standards) [104,105], and observing a meaningful 500 to 1500 [106,107] average daily step increase at eighth week postquit date. SAS (version 9.4; SAS Institute) [108] will be used for all statistical analyses, generating descriptive statistics to compare demographics, smoking status, and physical activity levels by treatment group. Group comparisons on participant characteristics and outcomes will use 2-tailed *t* tests for continuous variables and chi-square tests for categorical variables. Given the small sample size and pilot design (N=60), we will report all potential group differences with the α set at $P<.20$, following recommendations for pilot studies [109].

Smoking cessation will be analyzed in two ways: (1) an intention-to-treat analysis with missing data classified as smoking and (2) a completers-only analysis excluding participants with missing data. For physical activity outcomes, specifically the change in average daily step count from the baseline week to the eighth week postquit date, *t* tests will evaluate pre-post differences between groups. Days with <500 steps or <10 hours of watch wear time (indicating nonwear time or recording error) will be excluded. Participants must have at least 4 days of valid step count data to be included in the analyses.

Exploratory analyses will examine the association between physical activity and smoking cessation success using continuous and categorical approaches, with 6000 steps as the threshold for categorical analyses. Logistic regression analysis will evaluate the impact of average daily step count based on all postquit assessment weeks (5 wk in total) on CO-verified 7-day point prevalence abstinence at 8 weeks postquit date. In addition, participants will be categorized based on achieving a daily average of ≥6000 steps, allowing us to evaluate whether higher activity levels (≥6000 steps) are associated with greater cessation success. Finally, we will explore additional metrics, including the number of consecutive abstinent days and the frequency of meeting daily step goals. The analysis will examine these metrics as continuous and categorical variables to assess their association with smoking cessation rates.

Qualitative Analysis Plan

The baseline and exit interviews will be evaluated separately to comprehensively understand participants' experiences and impressions at different stages of the mHealth intervention. Transcripts from both interviews will be analyzed in NVivo (version 12; Lumivero) using an inductive thematic approach [110,111]. A codebook will be developed collaboratively by coding a subset of interviews, with iterative refinements to ensure reliability before the lead author's independent coding of the remaining transcripts. Periodic team reviews will resolve discrepancies.

The baseline interview will assess participants' initial perspectives and familiarity with mHealth tools, which may inform their engagement with the intervention. Key focus areas will include motivation for participating in mHealth research, smartphone use habits, and previous experiences with health apps and Bluetooth-enabled devices. By examining these factors, the analysis will capture participants' baseline comfort levels with digital health tools, previous exposure to apps for smoking cessation and physical activity, and any initial preferences for culturally tailored health behavior interventions within the Black population. Insights from these domains will provide context for interpreting participants' engagement with the intervention and potential barriers that could influence adherence.

The exit interview will assess participants' experiences with the intervention, focusing on perceptions of the cultural tailoring and usability of the intervention components. A central focus will be feedback on the e-book modeled after *Pathways to Freedom* [48], with analysis capturing participants' impressions of its cultural relevance, clarity, and perceived impact on smoking cessation. Participants' feedback on which sections resonated, any challenges encountered, and suggestions for improvement will provide insights into enhancing this culturally tailored component. Further domains in the exit interview will evaluate participants' overall impressions of the app features, experiences with the smartwatch, adherence to NRT, and any technical issues encountered with study equipment. This analysis aims to identify strengths and weaknesses of the intervention from the user perspective, including insights into specific app features that supported or hindered engagement and practical challenges with using the devices.

We will synthesize findings from the baseline and exit interviews to identify overarching themes related to engagement, cultural resonance, and barriers to adherence. This holistic

analysis will reveal how initial expectations and previous experiences influenced participant experiences and how the intervention can be refined to improve acceptability and effectiveness for larger-scale studies. Examining recurring themes across interviews may provide actionable insights for enhancing intervention design, especially regarding cultural tailoring, usability, and support for behavior change.

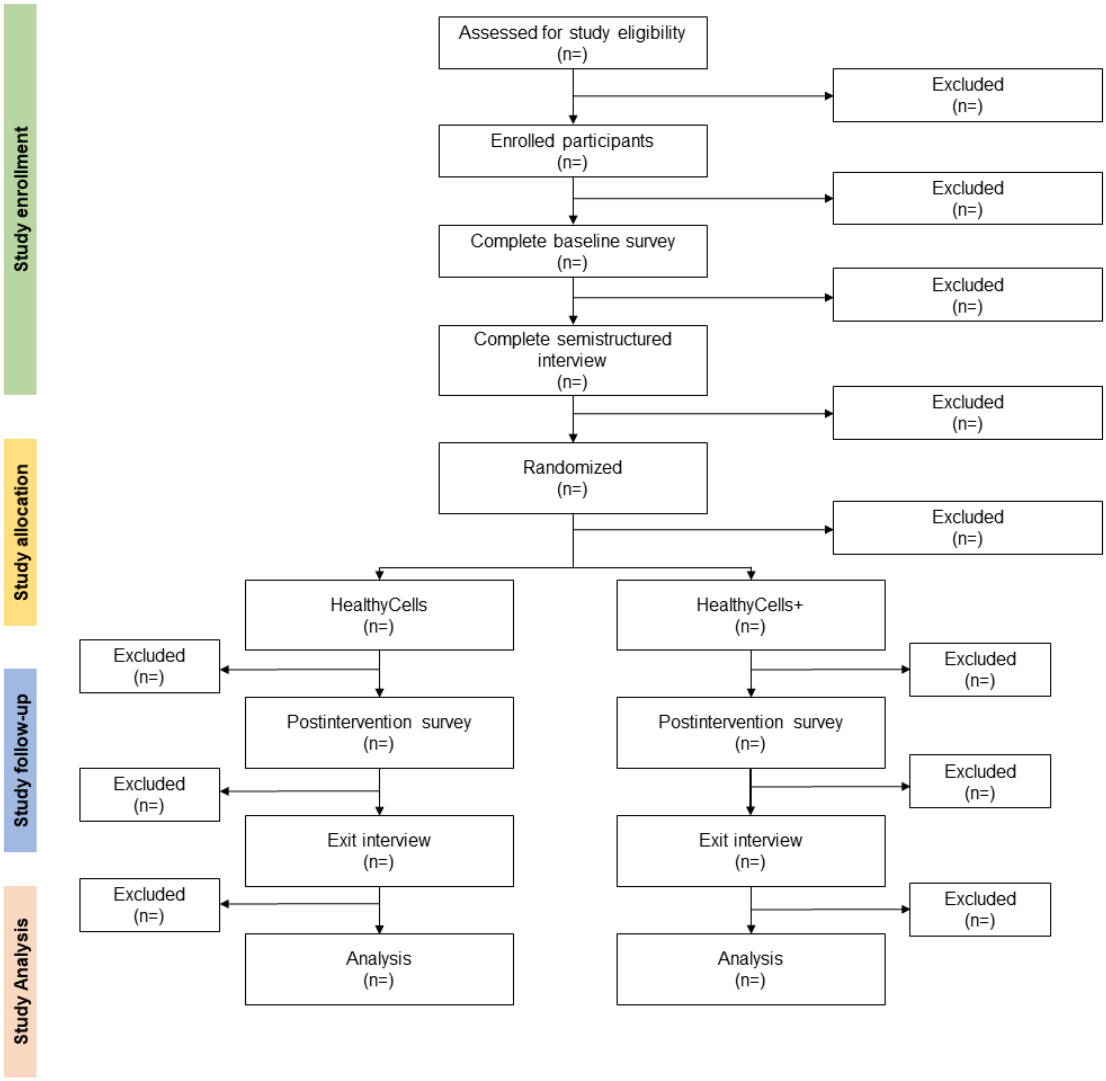
Integration of Study Findings

We will use a mixed methods approach to capture a holistic view of intervention feasibility and participants' experiences [112]. Quantitative data will provide intervention outcomes and milestones, and qualitative findings will uncover insights into participants' expectations, experiences, and perceptions regarding the intervention. Triangulation will occur through a systematic comparison of quantitative metrics with qualitative themes [112,113]. For example, if quantitative results indicate high smoking cessation rates, qualitative data will be examined to identify participant-reported factors that facilitated this success. Conversely, if step count improvements are minimal, qualitative insights may help reveal barriers to physical activity engagement or limitations within the app that could be addressed in future studies. This combined approach will provide information about feasibility and generate participant-driven insights, increasing the likelihood that future interventions will be effective and tailored to meet community needs.

Results

This study was reviewed and funded by the National Institute of Minority Health and Health Disparities (Multimedia Appendix 3). This study was approved by the institutional review board of the University of Oklahoma Health Sciences Center (protocol #14094) on 12/10/2021. Data collection is expected to start in February 2025 and finish in September 2025 (Figure 6 depicts the CONSORT [Consolidated Standards of Reporting Trials] diagram). Primary data are expected to be analyzed by October 2025. The preparation of manuscripts on primary and secondary outcomes is expected to start in late 2025 and early 2026.

Figure 6. Participant recruitment, allocation, intervention adherence, and follow-up in the feasibility randomized controlled trial evaluating the HealthyCells interventions for smoking cessation and physical activity promotion (CONSORT [Consolidated Standards of Reporting Trials] flow diagram).



Discussion

Principal Findings

This study evaluates the feasibility of the HealthyCells intervention, an app-based mHealth approach integrating financial incentives for smoking cessation and physical activity promotion among Black adults. We anticipate that participants in the HealthyCells+ group, who receive incentives for both smoking abstinence and physical activity, will achieve greater increases in daily step counts and higher rates of CO-verified smoking abstinence compared to the HealthyCells group, who are incentivized for smoking abstinence only. Feasibility metrics, including recruitment, retention, and participant adherence, are expected to demonstrate strong engagement and acceptability of the intervention over the 9-week study period.

Comparison to Prior Work

This study builds upon previous MHBC mHealth interventions, such as See Me Smoke-Free [114] and PhoS [115], which showed potential to promote behavior change but were limited by reliance on self-reported outcomes and low adherence rates [46,116,117]. In contrast, HealthyCells incorporates objective measures of behavior (eg, CO breath samples for smoking abstinence and step counts verified by smartwatches), addressing these limitations. In addition, culturally relevant content, such as that inspired by *Pathways to Freedom* [48,49], distinguishes HealthyCells from other interventions by tailoring messages to resonate specifically with Black adults. This study also advances CM research by combining financial incentives for multiple behaviors, a strategy that has shown promise in previous studies [34-38].

Strengths and Limitations

A key strength of this study is its focus on a population disproportionately affected by tobacco- and obesity-related health disparities. By leveraging mHealth technology and CM, this intervention offers a scalable and accessible approach to behavior change. Objective tracking of outcomes ensures data reliability, and the inclusion of culturally tailored content enhances the potential for participant engagement.

However, this study has limitations inherent to feasibility trials. The sample size (n=60) is small and not powered to detect statistically significant differences in outcomes. In addition, the absence of a control group limits conclusions about the intervention's effectiveness. Despite these limitations, this study will provide critical pilot data for a fully powered randomized controlled trial.

Future Directions

Findings from this feasibility study will guide the refinement of the HealthyCells intervention for larger-scale trials. Future research will explore the effects of long-term interventions, the maintenance of behavior change after incentives are withdrawn, and the scalability of interventions to other underserved populations. In addition, further refinements to the app based on participant feedback will aim to enhance usability and engagement. Ultimately, this research has the potential to contribute to health equity by addressing smoking and physical inactivity in high-risk populations using innovative, culturally tailored, and technology-driven strategies.

Acknowledgments

This work was supported by the Oklahoma Tobacco Settlement Endowment Trust (STCST00400_FY25), the OU Health Stephenson Cancer Center through a National Cancer Institute Cancer Center Support Grant (P30CA225520), and the National Institute on Minority Health and Health Disparities (1K01MD015295-01A1). The Mobile Health Shared Resource at the Stephenson Cancer Center provided programming and technological support.

Data Availability

The datasets generated and analyzed during this study will be made publicly available in a suitable data repository following the publication of all primary and secondary analyses. Until that time, the data will be available from the corresponding author on reasonable request.

Authors' Contributions

AA designed the intervention and formulated the research questions and hypotheses. AA prepared the first draft of the manuscript. All authors revised it and approved the final draft.

Conflicts of Interest

MSB is one of the inventors of the Insight mHealth Platform and receives royalties related to the use of this platform by investigators external to the University of Oklahoma Health Sciences Center. All other authors declare no conflicts of interest.

Abstract

Background: Older adults are more likely to have multiple chronic conditions, be prescribed multiple medications, and be more susceptible to adverse drug reactions (ADRs) to their medications. In addition, older adults often use over-the-counter medications and supplements, further complicating their medication regimens. Complex medication regimens are potentially harmful to older adults. Interventions aimed at reducing medication discrepancy in the ambulatory clinic setting, such as reviews of medication lists and the implementation of "brown bag" reconciliation, continue to be challenging, with limited success. Pharmacist-led interventions to improve appropriate medication use in older adults have demonstrated effectiveness in reducing ADRs. Video visits have the potential to provide direct visualization of medications in older adults' homes, thereby reducing medication discrepancy and increasing medication adherence. Pharmacist-led management of older adults' medication regimens may improve appropriate medication use in older adults.

Objective: The objective of this study is to examine the effect of pharmacist-led medication through home televisits compared to usual care on appropriate medication use, medication discrepancies, medication adherence, and ADRs.

Methods: We will conduct a 2-site cluster randomized controlled trial (RCT). The intervention will be a pharmacist-led home televisit including medication reconciliation and assessment of actual medication use. The cluster RCT was iteratively adapted after a pilot test. The primary outcome of medication appropriateness of the intervention will be measured using the STOPP (Screening Tool of Older Persons' Prescriptions) criteria for potentially inappropriate medications (PIMs) at 6 months. Medication lists obtained will be compared against electronic medical records (EMRs) by a clinician to establish discrepancies in medications. The clinician will review medications using the validated Medication Appropriateness Index (MAI).

Results: This project has been peer-reviewed and selected for support by the Veterans Affairs (VA) Health Services Research Service. The pilot phase of the study was completed December 2021 with 20 veterans and was primarily informed by the Steinman model of the prescribing process adapted to include system- and provider-level factors. The last date of enrollment was August 6, 2021. We anticipate the completion of the ongoing trial in spring 2025. The first results are expected to be submitted for publication in 2025.

Conclusions: The cluster RCT will provide evidence on medication management through televisits. If found effective in improving the use of medications, the intervention has the potential to impact older adults with multiple chronic conditions and polypharmacy.

Introduction

Polypharmacy in Older Adults and the Importance of Medication Reconciliation

The US population is aging rapidly; the population aged 65 years and above is projected to be doubled by 2050. The most rapidly growing segment is the population of older adults aged 85 years and above, which will more than triple from 5.9 million in 2012 to 18 million in 2050 [1,2]. Older adults aged 65 years and above often have multiple chronic diseases—more than 60% have 2 or more chronic diseases [3], and 17% have 4 or more chronic diseases [4]. Older adults with multiple chronic comorbidities often require multiple medications for management, particularly with guideline-based management of chronic diseases [5,6]. The use of multiple medications in older adults is common, with almost 20% of older adults aged 65 years and above taking 10 or more medications [7,8]. Multiple-medication use in older adults is associated with a lower adherence rate and increased use of inappropriate medications [9,10]. The use of multiple medications increases the risk for potential drug interactions, leading to undesirable adverse drug reactions (ADRs), which could also contribute to lower medication adherence. In particular, older adults are more susceptible to ADRs due to the changes in their physiology, clearance, and reserves [11], particularly with polypharmacy [9,12] Based on the phycological changes in the older population, knowing the drug regimens with older adults is an important feature in order to provide medication safety and make adjustment to their regimen accordingly to ensure appropriate medication use. The START/STOPP (Screening Tool to Alert to Right Treatment/Screening Tool of Older Persons' Prescriptions) criteria [13-15] and American Geriatrics Society (AGS) Beers criteria [16,17] for potentially inappropriate medications (PIMs) were developed to provide evidence-based guides to signal clinicians about medications that are potentially inappropriate and to enhance medication appropriateness. These medications include those with strong anticholinergic properties, which may disproportionately affect older adults and are linked to adverse outcomes of ADRs, and other medications that are demonstrated to have significant side effects in older adults.

Use of Telemedicine to Improve Medication Use in Older Adults

Telemedicine is a modern visit option enabled by advances in telecommunications technology [18]. The use of telemedicine in older adults has been examined in prior small studies that have demonstrated feasibility, acceptability, and user satisfaction [19-22]. Extending televisits to patients' homes has the potential to impact many aspects of care that rely on patient self-management, such as medication use. Although telephone-based pharmacist interventions have the potential to impact medication use at home [23,24], they still rely on accurate information reported by older adults over the phone without a mechanism for confirmation. The addition of video has the potential to further enhance the visit [25,26] by (1) visual ascertainment of actual medications taken by patients, (2) visual demonstration of the patients' actual use of medications, and (3) education of patients on proper use. Although in-person home-based reconciliation has the potential to improve accurate appraisal of medication use and reconciliation, it is not feasible for wide adoption as it is resource intensive. The study proposed here will examine the impact of home televisits by pharmacists on patients at high risk for ADRs (ie, with polypharmacy and multiple chronic conditions).

Methods

Research Design Overview

This study is designed as a mixed methods hybrid type 1 effectiveness implementation study [27], where we will test the health impact of pharmacy televisits, while also collecting data on the implementation process to facilitate subsequent scale-up efforts [28]. As older adults have higher rates of chronic conditions and polypharmacy, we included veterans aged 65 years and above in this study. The inclusion criterion of 5 or more medications is based on prior literature on polypharmacy and findings of increased risk for drug interactions and ADRs. The enrollment criteria are consistent with and exceed the criteria set in fiscal year 2019 by the Center for Medicare Services for provision of medication therapy management in Medicare Part D [29]. Among patient characteristics, polypharmacy (≥5 medications) and multiple chronic conditions

are considered important risk factors for ADRs and are highly prevalent among frail older adults at risk for ADRs [30].

The intervention for the cluster randomized controlled trial (RCT) was iteratively adapted after a pilot test with 20 veterans [31]. Home televisits, where pharmacists conducted medication reconciliation and management, were refined, after which a formative evaluation [32] was conducted, guided by the Consolidated Framework for Implementation Research (CFIR) [33]. Data were gathered in several ways: (1) enrolled veterans (n=20) were observed by study staff present within the veterans' homes during the clinical pharmacist home televisit, and (2) study staff administered a postencounter questionnaire with the goal of improving the veteran-based technical experience and clinical encounter. The data points were used to adapt and make changes to the intervention for the cluster RCT.

The cluster RCT is registered on ClinicalTrials (NCT04340570). The intervention will be a pharmacist-led home televisit including medication reconciliation and assessment of actual medication use. Pharmacists will review medication appropriateness using evidence-based criteria and provide recommendations for change of medication use to the patients' primary patient-aligned care team (PACT). PACTs provide team-based care and consist of a primary care provider (PCP), a registered nurse, a medical assistant, and, often, either a social worker or a pharmacist. In the control group, participants will receive usual care in which medication reconciliation and review will be conducted in clinics by primary care teams. As a primary outcome, we will examine the effect of the intervention on the number of veterans with PIMs, as determined using evidence-based criteria. As secondary outcomes, we will determine the number of PIMs, medication discrepancy using data from record reviews and interviews, and medication appropriateness using validated instruments at 6 months after the intervention. We will also compare the intervention's effects on the incidence of ADRs using data from record reviews and interviews. To assess the potential for future implementation of the intervention, we will administer postintervention questionnaires to key stakeholders, including veterans and PACT clinicians, to examine implementation barriers to and facilitators of the intervention.

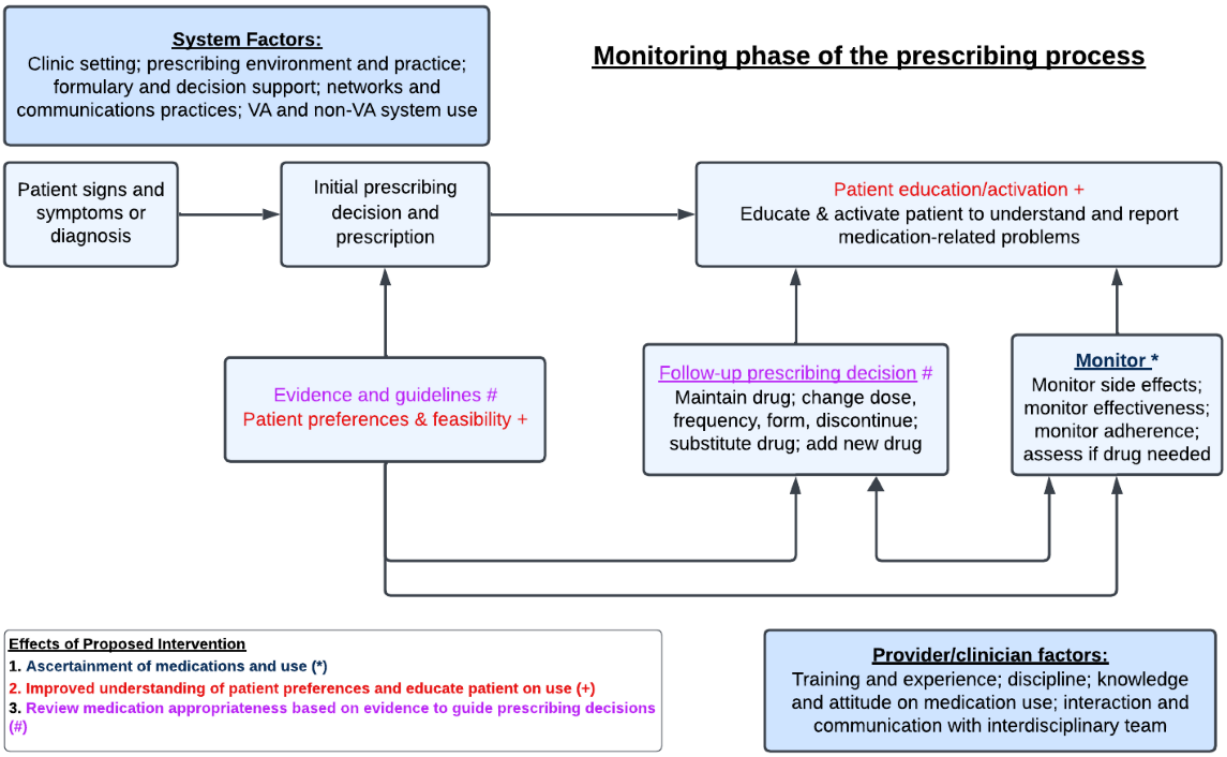
Ethical Considerations

This study was approved by the Veterans Affairs (VA) Central Institutional Review Board (CIRB; IRBNet ID 1612635). To obtain participants' informed consent, a research assistant (RA) will determine whether eligible patients have the capacity to provide informed consent to participate in the study using a screening questionnaire that assesses the 4 elements required for capacity understanding of study procedures, appreciation of what will happen if enrolled, communication of a choice to enroll or not, and demonstration of a rationale for that choice. Recruitment and written informed consent will take place in a location that ensures privacy and convenience for the patient.

Conceptual Framework of Medication Prescribing in Older Adults

Our conceptual framework is informed by the CFIR [34] and Steinman et al [35] on prescribing and prescription monitoring processes. The pilot phase was primarily informed by the Steinman model of the prescribing process adapted to include system- and provider-level factors. The system-level factors include the Veterans Health Administration (VHA) policy on medication management (including non-VA care use), facility-level prescribing environment and practices, and decision support systems. In designing our proposed intervention, we considered the potential effect of home televisits by pharmacists to ascertain the medication regimen and use, identify discrepancies and educate patients on use, and review medication appropriateness, thereby enhancing steps in the monitoring phase of the prescribing process (Figure 1).

Figure 1. Conceptual framework of prescribing and prescription-monitoring process. Modified from Steinman et al [31]. VA: Veterans Affairs.



Cluster Randomized Controlled Trial Patient Recruitment

The inclusion criteria include the following: (1) the veteran must be a PACT patient in a Bronx VA or Bedford VA geriatrics or primary care clinic; (2) be 65 years or older; (3) have 2 or more chronic conditions; and (4) have 5 or more medications listed on the VA medication record continuously in the previous 6 month. Patients fulfilling these criteria will be approached for study enrollment through letters of invitation after approval by human subjects' committees.

Cluster Assignment by PACT

We will randomize patients by PACT to prevent a team from having participants in both treatment and control groups and to reduce contamination. Prior to initiating enrollment, the project coordinator will assign PACTs to intervention and control groups using lists of computer-generated random numbers in a 1:1 ratio, with separate lists for the Bronx VA and the Bedford VA, in order to maintain balance in both groups within each study site. There are 69 primary care and geriatric PACTs in the Bronx VA and 14 in the Bedford VA, and each PACT will keep the group assignment for the duration of the study.

Study Flow

After enrollment, veterans who agree to participate in the study will be interviewed by a trained research coordinator using survey instruments that will include data elements listed in Table 1. Veterans will receive the televisit intervention, or not, based on the PACT team they belong to, as discussed earlier. The detailed procedure for control and intervention groups is described later. To observe what occurs at follow-up appointments with the PACT provider, after the first follow-up appointment postintervention, participants will be asked about whether medication use was discussed during the appointment, whether medication reconciliation was performed and how, and what, if any, medication changes were made. Electronic charts will be reviewed for documentation of medication reconciliation and management during the visit. Primary outcomes will be ascertained at 6 months after study enrollment and are described in Table 1, including the subject survey and chart review. The subject survey for outcome assessment will be conducted by a research coordinator trained to take the subject's medication history, and the chart review will be conducted by a clinician blinded to the study assignment. The subject survey will include confirmation of medications participants are currently taking, including names, dosages, and frequency. Participants will be asked to list medications that they take, including over-the-counter drugs and supplements. A clinician rater blinded to the study assignment will review medication data from the subject survey and chart review to determine medication discrepancies and appropriate use of medications.

Table 1. Data elements and instruments.

Data elements	Source	Instruments or measurements
Outcomes		
Primary: PIM[a] use	Chart review, interview	STOPP[b] criteria, assessment of medication list by blinded clinical reviewer [14]
Secondary: medical discrepancies	Chart review, interview	Medication discrepancies (omissions, duplications, additions)
Medication appropriateness	Chart review, interview	MAI[c] [36]
Patient satisfaction, self-efficacy, and adherence	Interview	CAHPS[d] item pertaining to medication use [37], MUSE[e] [38]
Health-related quality of life	Interview	EQ-5D-5L [39]
ADRs[f]	Chart review, interview	ADRs determination by clinical reviewer
Baseline covariates		
Sociodemographics	Baseline survey, chart review	Gender, age, race, ethnicity, education, income, Medicare, Medicaid
Chronic illness burden	Patient interview, chart review	Modified RAND index [40]
Medication list	Chart review, patient interview	Number and type of medications, source (VA[g], non-VA, over the counter)
Medication use	Interview, chart review	Number and type of medications, method of administration, presence of refill gap (>90 days)
Patient's self-efficacy on medication use	Patient interview	MUSE
Health literacy	Patient interview	Short Test of Functional Health Literacy in Adults (S-TOFHLA) [41]
Cognitive function	Patient interview	MoCA[h] [42]
Physical function	Patient interview	Katz Activities of Daily Living (ADL) index/Lawton Instrumental Activities of Daily Living (IADL) scale [43,44]
History of acute care use (hospitalization, emergency department)	Patient interview, chart review	Days prior to enrollment for most recent hospitalization and emergency department visit, number of episodes in the previous year
Health-related technology use attitude, self-efficacy, and comfort	Patient interview	Self-reported comfort and confidence in using technology [45]

[a]PIM: potentially inappropriate medication.

[b]STOPP: Screening Tool of Older Persons' Prescriptions.

[c]MAI: Medication Appropriateness Index.

[d]CAHPS: Consumer Assessment of Healthcare Providers and Systems.

[e]MUSE: Medication Understanding Use and Self-Efficacy Scale.

[f]ADR: adverse drug reaction.

[g]MoCA: Montreal Cognitive Assessment.

Intervention

Patients assigned to the intervention will have a pharmacist televisit appointment made and coordinated. Participants will be asked whether they have a device at home capable of supporting televisits, including home computers with cameras, tablets, smartphones, and a broadband or 4G connection. Participants who do not have appropriate devices will be provided with VA-issued internet-enabled tablets on which to conduct the visits. On the scheduled day of the visit, the research team will coordinate with the participants over the phone to facilitate the initialization of the televisit by the pharmacist. The content of the televisit is described next, in the *Design of the Televisit Intervention* section, and has been adapted through the pilot phase with direct observation of the televisit at home. Subsequent to the televisit, the pharmacist will document the visit content in the electronic medical record (EMR) to note discrepancies noted during the televisit, a review of medications with START/STOPP criteria, and recommendations based on the criteria-based review for PCP review and concurrence for adjustments of medications. Recommendations will be communicated to the PCP electronically through secure email or an electronic note or over the phone or through a face-to-face discussion if preferred by the PCP. Adjustments in the medication regimen will be noted at 7 days in the EMR after recommendations are made. If recommendations are not

adopted, the pharmacist will communicate with the PCP electronically to request reasons for not adopting recommendations. Participants will then continue follow-up primary care with their PCP.

Design of the Televisit Intervention

We plan to use the VA video connect (VVC) capability introduced in fiscal year 2018 to conduct televisits between clinical pharmacists located at the VA medical centers and participants at home. An appointment will be scheduled with each participant for time to conduct the home televisit. The devices, EX90s or web cameras, used at the clinician side will be located at the Bronx VA or the Bedford VA and at the participants' side will be their choice of computer, tablet, or smartphone with an internet connection and webcam capability or a VA-provided tablet if they do not have a device or home internet capabilities. Because the experience of the televisit may differ with different participant devices, various devices were tested in phase I of the study, and their strengths and pitfalls and modes of connecting were identified.

After establishing a video connection, the pharmacist will conduct home-based medication reconciliation by asking the participants to show and explain the use of each of their medications. The pharmacist will also include a brief medication-focused functional assessment, including asking the participants to read aloud and interpret 1 or more of their prescription bottles and to demonstrate the ability to open the bottles. Before ending the visit, the pharmacist will educate the participants regarding possible side effects or interactions between their medications. The pharmacist will also solicit and answer any questions the participants have about the medications. The pharmacist will note the medications used and compare them against the list of medications on each participant's EMR to note discrepancies and then generate a note in the EMR to notify the primary care team of the review and information obtained. If the pharmacist finds that patients are taking medications differently, they will clarify the correct usage of the medications.

Pharmacist Review of Medications

After the televisit is completed, the pharmacist will conduct a medication review using the START/STOPP criteria to review the indication of each medication (see Table 2). They will also review whether there are medications prescribed beyond the recommended duration of each medication, where the treatment duration is well defined. The pharmacist will use evidence-based guidelines to inform follow-up prescribing decisions (maintaining, adjusting the dose, or stopping the medication); see Figure 1. Medications noted to be inappropriate or those that do not have an indication will be flagged for consideration of deprescribing. Duplication of drug class prescriptions will also be noted. Other disease-specific criteria will be reviewed based on the criteria [13-15]. Recommendations generated from the medication review based on START/STOPP criteria will be communicated to the PCP for consideration of modification of the medication regimen. Final decisions on medication modification will be made by primary care clinicians in consultation with their patients as it usually would be in a clinical setting.

Table 2. Scope of pharmacist-led intervention televisit, laying out the steps, content, and approximate duration of each step.

Step	Content and sample questions	Approximate duration (60-75 minutes total)
Setup	Establish a connection, preparation for the visit.	5-10 minutes
Introduction	Identify individuals in the visit and discuss the purpose of the visit.	5 minutes
Identification of the medication regimen and visualization of medications	• What medicines do you currently take? • How about over-the-counter medicines? How about vitamins and supplements? • Where do you keep your medications? Can you show me?	15 minutes
Description and visualization of how to take medications	• What do you take this medicine for? • When do you take this medicine? • Can you show me how much you take each time?	15-20 minutes
Clarify medication instructions	If medications are taken incorrectly, ask why. Educate and use the teach-back method to confirm understanding.	15 minutes
Questions and closing	Answer the patient's questions, if any. Discuss the next steps of review and communication with the PCP[a].	5-10 minutes

[a]PCP: primary care provider.

Control Arm (Usual Care)

After baseline MoCA and technology comfort assessment, medication reconciliation and management will be conducted by the control primary care teams in the manner they usually do. PACTs are guided by the VHA Directive on Medication reconciliation [46], which includes in-clinic assessment of medication information provided by patients via lists, recall or actual medication reviews, comparing information obtained to the VA EMR to note discrepancies, and educating the patient on updated medications. PACT PCPs may also request assessment of medication regimens by pharmacists embedded in their clinic based on clinical decisions regarding the needs of the individual patient and the availability of such services. The prescription of a new medication may trigger a review by a VA pharmacist guided by EMR-based interaction alerts. We

considered using an active control group with pharmacist review (in-clinic or chart review); however, the intervention with pharmacist-led home televisits informing medication review represents a bundled intervention, and the study will examine the effectiveness of the intervention as an enhancement of care to what currently occurs (usual care). This design involving participant interviews and chart reviews will also allow us to characterize current usual medication management for older adults in PACTs.

Outcomes

Primary Outcome

PIM use, which is the primary outcome, will be assessed by the blinded clinical reviewer based on the medication data obtained from home visit surveys using the STOPP criteria [14]. Proportions of participants with PIMs in the intervention group will be compared with proportions of participants with PIMs in the control group.

Secondary Outcomes

Medication lists obtained through subject surveys will be compared against the EMRs by a clinician to establish discrepancies in medications. Discrepancies will be characterized as "no potential harm," "monitoring or intervention potentially to preclude harm," or "potential harm," similar to prior approaches to assess potential clinical impacts [32]. In addition, the clinical reviewer will assess the medications using the validated Medication Appropriateness Index (MAI) [36]. Each medication will receive a score based on the 10-item tool to determine its appropriateness. Patient satisfaction will be ascertained using an item pertaining to medication use from Consumer Assessment of Healthcare Providers and Systems (CAHPS) version 3.0 [37], a 7-item, 5-point Likert scale on medication management by pharmacists adapted from a validated instrument [33,47]; self-efficacy on medication use will be assessed using the Medication Understanding Use and Self-Efficacy Scale (MUSE) to assess change from before and after the intervention [38]. Health-related quality of life will be assessed using the EQ-5D-5L instrument, a brief validated instrument with good test-retest reliability [39,48].

Implementation Factors

Postintervention questionnaires will be administered to key stakeholders, including veteran participants and PACT clinicians, to assess the potential for future implementation of the intervention. This will allow us to examine implementation barriers and facilitators. An invitation to complete the postintervention questionnaires will be emailed to PACT providers in the intervention arm. To ensure we understand PCP decisions on pharmacist recommendations, we will track PCP adoption of recommendations provided by pharmacist reviews and examine PCP reasons for adoption or nonadoption of recommendations, as well as provider factors that can influence those decisions. Patient and clinician interviews and questionnaires will identify perceived barriers and facilitators on a Likert scale. The knowledge and attitude on prescribing for older adults will also be obtained using validated Likert questions, although the attitude and behavior in clinician communication with pharmacists will be gathered using the Home Medicines Review Inventory (HMRI).

Results

The study flow is summarized in Figure 2. The pilot phase of the study was completed December 2021 with 20 veterans and was primarily informed by the Steinman model of the prescribing process adapted to include system- and provider-level factors. This project has been peer-reviewed and selected for support by the VA Health Services Research Service. The last date of enrollment was August 6, 2021. We anticipate the completion of the ongoing trial in spring 2025. The first results are expected to be submitted for publication in 2025.

Discussion

Summary

The complex medication regimens of many older adults contribute to increased risk for drug interactions, ADRs, and other poor health outcomes. A number of studies have found that the use of PIMs is associated with adverse outcomes, such as falls, acute care use, and other negative outcomes [49,50]. Improving medication prescribing using START/STOPP criteria has been found to reduce adverse effects and improve patient outcomes in a number of studies, although mostly in institution-based settings (acute care hospitalization, nursing homes) [50]. Pharmacist-led interventions have been demonstrated to have beneficial effects [51,52] but often do not reach the majority of those who would most benefit from them. Leveraging the advances of telemedicine, clinicians can provide medication management services to older veterans at home. The televisit intervention with pharmacists in medication management has the potential to bridge the current gaps in older adult care and provide a scalable solution to improve medication use in older adults.

The study's pilot phase refined the procedure for pharmacists to conduct home televisits. It is possible that veterans will consider televisits to home cumbersome or invasive and that VA primary care staff will consider tailoring medications for older adults an additional task burden that competes with other mandated tasks. Our prior experiences of home televisits suggest that they are well accepted, and our hybrid effectiveness implementation study will enable us to identify potential implementation challenges and thus can inform future implementation. To ensure we understand PCP decisions on pharmacist recommendations, we will track PCP adoption of recommendations provided by pharmacist reviews to identify PCP reasons for adoption or nonadoption of recommendations, as well as provider factors that can influence those decisions.

The older adult population has increased the use of technology, allowing the VA to use technological advances for VA televisits, overcoming previous barriers, and we expect future changes in technology will further facilitate use. Our study design will allow us to observe older adults using technology at home to enhance our understanding of the barriers to use, and qualitative interviews with clinicians and patients will further identify factors to guide future implementation. We have elected to use 2 separate sites in the RCT phase in order to enhance our understanding of contextual issues and external validity.

Strengths and Limitations

This study design includes both a pilot phase trial and a hybrid effectiveness implementation trial, which ensures that we would observe and be able to address challenges prior to the RCT, although the results of the hybrid implementation effectiveness trial would allow us to determine its effectiveness, while preparing us to spread the intervention, if effective, in the health system. We aim to limit crossover contamination for providers with cluster randomization. Lastly, the standardized intervention and structured pharmacist protocol will ensure consistency and reliability.

The study design also has a few limitations. One is that the study will be conducted in urban and suburban settings, which may limit generalizability Another limitation is that the pilot phase was conducted during the COVID-19 pandemic, which introduced unique challenges in recruitment due to factors such as travel restrictions and increased risk for participants; however, the study team tackled those challenges and completed the pilot phase of the study despite limitations introduced by COVID-19. This study will contribute toward the literature on pharmacist-led medication management through home televisit procedures, as

well as interventions aimed at improving medication use in older veterans.

Conclusion

This study design will demonstrate how medication management will be beneficial through televisits. The implementation effectiveness trial will show how it can improve the use of medications and interventions related to the potential impact on older adults with multiple chronic conditions and polypharmacy. Clinicians can offer older veterans medication management services at home by using telemedicine's advancements. The use of pharmacists in televisit medication management interventions has the potential to close existing gaps in older adult care and offer a scalable way to enhance older adults' medication use.

Abstract

Background: Caregivers of persons with Alzheimer disease and related dementias (ADRD) neglect their health, including by ignoring stress levels. African American women are vulnerable and susceptible to hypertension. Chronic caregiving stress and hypertension place them at high risk for cardiovascular disease. Addressing stress reactivity or resilience is vital in lessening their caregiving stress, enhancing their quality of life (QOL), and fostering healthy blood pressure (BP) self-care behaviors.

Objective: This pilot study aims to investigate the feasibility and acceptability of implementing the Mindfulness in Motion (MIM) plus the Dietary Approaches to Stop Hypertension (DASH) intervention in this population and to evaluate its effect on ADRD caregivers' stress and QOL. Additionally, it explores the mediation of stress reactivity or resilience between interventions and self-care behaviors.

Methods: A small randomized controlled trial pilot study will recruit 28 African American or Black female caregivers aged 40 years diagnosed with hypertension and on an antihypertensive medication. Participants will be randomly assigned to either the MIM DASH or the Alzheimer's Association caregiver training group (attention control). Trained facilitators will deliver both interventions over 8 weeks through 1-hour, group, internet-based sessions, via video or telephone. After completion, both groups will receive coaching calls over 9 months, beginning with 8 weekly calls followed by 4 monthly calls to encourage use of the educational materials. Primary outcome measures include feasibility (recruitment and retention) and acceptability (attendance). Secondary measures assess caregiver stress (Perceived Stress Scale), QOL, and self-care behaviors (Food Frequency Questionnaire and self-reported physical activity). Data collection occurs at baseline, 3 months, and 9 months. Quantitative data will be analyzed using descriptive statistics, CIs, and mediation models.

Results: This study was approved by the institutional review board in April 2022 and funded in May 2022. The first data were collected in January 2023, and the last data were collected in September 2024. The completion of all aims' data analysis is anticipated in spring 2025. The participants' mean age was 62.4 (SD 7.98) years, with a mean baseline systolic BP of 128 (SD 19) mm Hg and diastolic BP of 79 (SD 10) mm Hg. Participants reported that MIM DASH was acceptable (at a mean score of 59.08, SD 7.38, compared to 60.83, SD 5.56 for caregiver training). Regarding feasibility, as reflected in attendance, MIM DASH participants had a mean attendance of 6.3 (SD 2.3) sessions, and the caregiver training group had 4.9 (SD 2.9) sessions.

Conclusions: This study's findings demonstrate the feasibility of conducting an internet-based intervention (MIM DASH) for African American women with hypertension who also care for families living with ADRD. These results will inform the design of a larger randomized controlled trial to evaluate the intervention's efficacy and scalability further.

KEYWORDS

African American women; high blood pressure; stress reactivity and resilience; caregiving; hypertension; stress; Alzheimer disease; dementia; lifestyle and healthy self-care behaviors

Introduction

Background

Family caregivers of individuals with Alzheimer disease and related dementias (ADRD) provided an estimated 18.4 billion hours of unpaid care, valued at nearly US $350 billion [1]. The prevalence of ADRD is higher among African American individuals, leading to a disproportionately more significant share of the family caregiving burden. Approximately one-third of these caregivers of individuals living with dementia acknowledge postponing or neglecting their health due to their caregiving role [1]. Given African American individuals' heightened risk of ADRD, particularly vascular and mixed dementia, this problem disproportionately affects African American family caregivers [1].

Although African American caregivers generally express positive feelings about caregiving and report cultural justification for providing care [2,3], they nonetheless endure the adverse effects of chronic caregiver stress—increased cortisol levels, hypertension [4,5], and consequently, cardiovascular disease [6]. Compounding their risk, African American women face a heightened danger of uncontrolled hypertension and cardiovascular disease [7]. No demographic group is more at risk for the double jeopardy of caregiving stress and hypertension than African American women caring for a family member who has ADRD.

Hypertension is the leading cause of cardiovascular disease among African American women, affecting 56.7% of this group [8]. Numerous studies recommend lifestyle changes such as stress management, reducing sodium intake, increasing the intake of fruits and vegetables, weight management, and engagement in regular physical activity to manage hypertension [9,10]. Researchers have hypothesized that African American individuals face excess chronic stress that makes adopting healthy self-care behaviors difficult [11,12].

One of the underlying mechanisms behind adopting healthy self-care behaviors is stress reactivity or resilience—the body's psychological and physiological response to stress [13]. Understanding these factors can contribute to more effective and sustainable behavior changes such as healthy eating, stress management, and physical activity.

Only a few studies have explored the stress and resilience associated with healthy self-care behaviors among African American caregivers. No research to date has used an interdisciplinary methodology to examine the intricate relationship between stress and resilience in this demographic. This protocol paper describes a mind-body intervention designed to address the complex interplay of stress and hypertension in African American caregivers.

Purpose

This randomized controlled pilot study examines the feasibility and acceptability of Mindfulness in Motion (MIM) combined with Dietary Approaches to Stop Hypertension (DASH) to promote hypertension self-care in African American women who are family caregivers of people living with ARD.

MIM uses gentle yoga stretches and teaches mindful awareness skills, while the DASH program promotes a diet rich in vegetables, fruits, whole grains, and lean proteins [14,15]. These interventions combined provide a comprehensive strategy for stress management and hypertension reduction. The control group will receive the Alzheimer's Association's caregiver training [16-19].

Study Aims

This study aims (1) to determine the feasibility and acceptability of MIM DASH and caregiver training for African American female caregivers with hypertension; (2) to compare the influence of MIM DASH on caregiver stress and quality of life (QOL) with the influence of caregiver training; and (3) to investigate the potential mediation effects of stress reactivity or resilience between each program and self-care behaviors.

Theoretical Models

Of MIM

Developed in 2004, MIM was based upon the ideas of Urie Bronfenbrenner's Socio-Ecological Model, which highlights the multilevel influences on behavior [20]. The Socio-Ecological Model has been extensively researched and is an effective way to structure multilevel interventions to aid in the long-term adoption and sustainability of programming [21]. MIM's combination of dietary education and experiential mind or body practices aligns with the multilevel Socio-Ecological Model of change. MIM was first implemented in 2009 as a small, randomized controlled trial with 48 employees [22]. Guided by the question of "Is MIM effective?" the program was tested in various additional studies with medical center faculty, staff, residents, and patients [23-30]. These trials showed significant stress and burnout reduction results with improved resilience.

Of DASH

The 8-week DASH education uses a critical thinking model of behavior change and culturally appropriate approaches to emphasize eating vegetables, fruits, whole grains, fat-free or low-fat dairy choices, fish, poultry, beans, and nuts and using vegetable oils [31]. Additionally, it limits foods high in saturated fat, sugar-sweetened beverages, and sweets. Critical thinking provides individuals with the tools for reasoning, empowerment, problem-solving, and making sound decisions [16]. The DASH eating plan decreases cardiovascular outcomes, including subclinical injury and systematic inflammation biomarkers, and improves blood pressure (BP), especially among African American individuals [32]. The critical thinking approach allows individuals to analyze information and their behavior to make fully informed decisions in the best interest of African American individuals; it also provides opportunities for reflection.

MIM and DASH

MIM and DASH both address health behaviors but from different perspectives. MIM integrates mindfulness practices, while DASH emphasizes critical thinking and heart-healthy dietary choices. Together, they contribute to holistic well-being and improved health outcomes.

Study Timeline

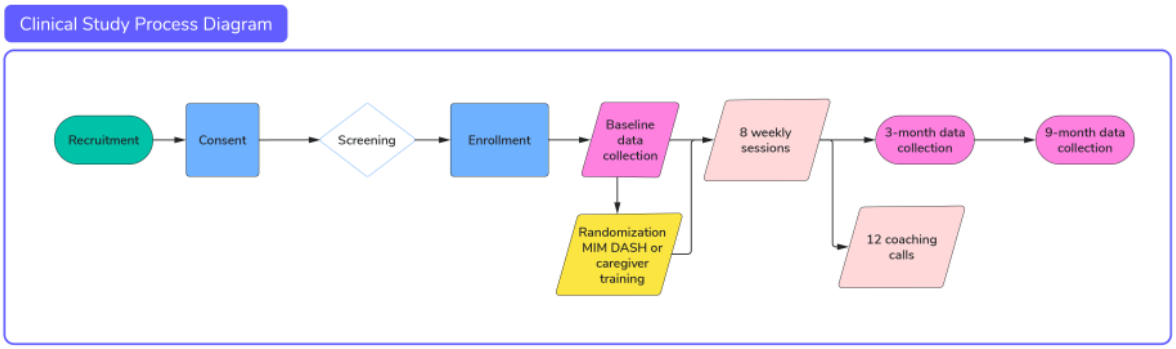
The participants will be tracked for 9 months in the 2-year funded trial. Data will be collected at baseline, at 3 months, and during a 9-month follow-up.

Methods

Design

In this randomized controlled trial, 28 community participants will be enrolled and randomly assigned to MIM DASH (n=14; intervention group) or caregiver training (n=14; attention-control group). This study's team will use REDCap (Research Electronic Data Capture; Vanderbilt University) to deliver informed consent to prospective participants via an online check box. Figure 1 provides a flow chart for this study.

Figure 1. Flow Chart for the Study: The figure visually represents participants' enrolment and randomization into training or intervention programs, followed by their sessions and data collection phases.



Recruitment

Participants will be recruited from clinics, the African American Alzheimer's and Wellness Association, the Central Ohio Alzheimer's Association, local churches, the Research Match registry, and social media. Additionally, study flyers will be displayed in places potential participants are likely to frequent, such as libraries, beauty salons, health provider offices, and senior centers. To maintain confidentiality, the list of all potential participants will be securely kept separate from the documentation and tracking spreadsheet in the REDCap. Basic demographic information and reasons for refusal will be noted for eligible individuals who decline participation. Enrollment and screen failure data will be tracked using the National Institutes on Aging (NIA) Common Data Screening, and enrollment forms will be reported to the NIA once every month (NIA Clinical Research Operations & Management System) [33].

Eligibility

Study participants will be adults aged 40 years and older who self-identify as Black or African American women and as family caregivers to someone living with ADRD. Inclusion criteria include the following: (1) have a diagnosis of hypertension that is treated with an antihypertensive medication; (2) have a score of two or greater on the eight-item Informant Interview to Differentiate Aging and Dementia [34]; (3) provide unpaid care for a person living with ADRD at least 10 hours per week and assist a person living with dementia with at least 1 instrumental activity of daily living (eg, bill paying, medication management, or transportation); (4) speak English; and (5) have access to a telecommunications device such as a desktop computer, laptop, tablet, smartphone, or telephone, to enable participation. Exclusion criteria include the following: (1) expect to move out of the area within nine months; (2) have a diagnosis of resistant hypertension (BP that remains above goal despite concurrent use of a diuretic or water pill and at least two other antihypertensive medications of different classes), or (3) are actively participating in a mindfulness or yoga program.

Randomization

All caregivers who enroll in this study and complete the baseline assessment will be randomly assigned into either the intervention group (MIM DASH) or the attention-control group (caregiver training). The rationale for an attention-control condition is to strengthen this study's design and minimize the chance that differences between the groups could be related to receiving social support from interacting with others [14]. Once one of

this study's staff members has completed the baseline data collection, the statistician will randomly assign this study's participants using a randomization table generated from the statistical software in the REDCap database. Trial participants will be blinded to this study's hypotheses.

MIM DASH (Intervention Group) Delivery

A trained MIM facilitator and a dietitian will deliver the intervention in eight 1.5-hour (~45 minutes for MIM and ~45 minutes for DASH) sessions via Zoom (Zoom Video Communications, Inc) with telephone access. Participants will receive session materials such as PowerPoint (Microsoft Corp) slides to follow along by phone or the Zoom videoconferencing app. Table 1 provides a list of the topics.

Table 1. Weekly topics for MIM[a] DASH[b] (intervention group) and caregiver training (attention-control group).

Week	MIM DASH	Caregiver training
1	• Introduction to MIM • What African American individuals should know about hypertension and its consequences	Healthy brain and body
2	• Mindful sleep • Understanding blood pressure overview	10 warning signs
3	• Vision of self • Clearing up myths about hypertension	Dementia conservations
4	• Mindful eating • Basics of the DASH diet	Effective communication
5	• Balance through movement • Be a DASH detective: sodium is the culprit	Understanding behaviors
6	• Sensation • DASH: throughout your day—breakfast, lunch, and dinner	Safety and driving
7	• Clarity and release • DASH: when eating out	Physician's visits
8	• Staying grounded and moving forward • DASH: diet is only part of the story	Money and legal

[a]MIM: Mindfulness in Motion.

[b]DASH: Dietary Approaches to Stop Hypertension.

Each MIM session will consist of mindfulness-related material—the somatic mind and body connection, relaxation, yoga, meditation, self-awareness, and bodily cues relating to emotional reactivity. Group interaction will center on sharing ideas toward effective practice and practical daily challenges to being mindful. Each class will begin with a prompt for participant contemplation during the session that references a unique weekly theme, which will be reiterated in the session materials. Then, the participants will be led through a body scan, gentle stretching, yoga, progressive relaxation, and mindful eating meditation, ending with formal meditation. Each participant will receive a new weekly link to online video mindfulness practice recordings. The workbook has a diary section to document study activities. The diary is personalized and retained by the participant. Participants will be instructed to perform mindfulness video meditations at least 5 times weekly and record the time in their diary.

The DASH portion focuses on education to increase intakes of vegetables, fruits, and whole grains and decrease intakes of fat, sodium, sugar-sweetened beverages, and sweets. The education includes adapting traditional "soul" food dishes to meet the DASH dietary guidelines. Participants will be provided practical tips on incorporating DASH into their daily lives. They will receive an individual MyPlate (United States Department of Agriculture Center for Nutrition Policy and Promotion) displaying serving sizes and food groups comprising a balanced meal and a home BP monitor. Principal investigator KDW will provide training on using the BP monitor and American Heart Association infographics and video [35,36]. Repetition of key concepts will be embedded throughout the sessions to increase critical thinking and problem-solving [17]. After completion of the 8-week sessions, the MIM DASH participants will receive 8 weekly and then 4 monthly coaching calls to review sessions and support the adoption of self-care behaviors. Our team has successfully delivered the MIM DASH intervention for older African American individuals with hypertension [14].

Caregiver Training (Attention-Control Group)

A study team member trained by the Alzheimer's Association will deliver the caregiver training. Participants in this group will attend eight 1.5-hour group lessons via Zoom for 8 weeks (Table 1). The training uses the Alzheimer's Association caregiver topics listed in Table 1. The Alzheimer's Association

materials are based on the latest scientific evidence of dementia researchers and practitioners in partnership with various community-based, academic, and health care organizations [37].

As with the MIM DASH group, participants will receive educational materials to follow along using Zoom videoconferencing or phone. Participants will have group discussions and role-play using a case study scenario. After completing the 8-week sessions, participants will receive 8 weekly and then 4 monthly social calls to encourage them to maintain their involvement and enhance study retention for subsequent data collection [14].

Fidelity

To maintain the fidelity of the intervention, a detailed protocol manual will be developed for MIM DASH and caregiver training. The MIM facilitators will be enrolled in 8 weekly 1-hour sessions as participants and attend a half-day workshop with return demonstrations. Before leading an MIM session independently, the facilitators will observe an 8-week MIM course and be the designated fidelity checker [38]. During each weekly session, the facilitator will show MIM educational and practice videos created by coinvestigator MDK. For the DASH component, the registered dietitian, also a coinvestigator IKRA, will develop a training plan and materials. Coinvestigator IKRA will deliver the DASH component and train others if needed. The materials for DASH will include a scripted facilitator manual. The principal investigator will also be trained to deliver MIM DASH as a backup facilitator. A study staff member will use a fidelity checklist for MIM DASH to observe the facilitators.

Sample Size and Power Analysis

Our sample size of 28 participants (14 participants per arm) conforms to the recommended sample size rules of 20-30 for pilot studies, as there are diminishing returns for precision, particularly over sizes of 12 per group (“rule of 12s”) [39-41]. Further, a sample of 28 is considered a sufficient pilot sample to determine variance in a main trial powered to 80% to detect an effect of 0.4 [41]. In line with pilot studies, the sample size lacks the power to detect a small-to-medium effect size for aim 3. Therefore, our mediation analysis will not emphasize statistical significance but report point estimates, 95% CIs, and effect sizes.

Measurements

Data collection measures consist of surveys, systolic and diastolic BP, the Pittsburgh Stress Battery, a Food Frequency Questionnaire, and the collection of a hair sample for cortisol analysis. Study staff were trained and observed before independently collecting data. Table 2 provides a data collection timetable, including the constructs, measures, and brief psychometrics provided in validation studies. These data will be collected in the treatment and attention-control groups at baseline, 3 months, and 9 months. Each study visit is estimated to take 2 hours. Maximum flexibility is critical to engage busy caregivers in research. Our team offers several options for data collection. Study visits may be conducted at the participant’s preferred time, day, and location. For example, participants may select the visits at their home, a dedicated research study office, or a private room at a local library. Study visits can take place outside of traditional office hours and workdays. The participant may have this study visit broken up into two 1-hour visits if needed. In these cases, the research staff will prioritize the collection of data that requires an in-person visit (eg, BP and hair collection) and offer to meet again in person or via telephone or Zoom to collect the remaining data.

Table 2. Data collection variables, measures, and psychometrics.

Construct and measures	Psychometrics			
	Baseline	3 mo	9 mo	Reliability and validity

[d]DASH: Dietary Approaches to Stop Hypertension.
[e]BP: blood pressure.
[f]QOL: quality of life.
[g]WHO-5: World Health Organization-5.
[h]PHQ-9: Patient Health Questionnaire-9.
[i]GAD-7: Generalized Anxiety Disorder Assessment.
[j]ADRD: Alzheimer disease and related dementias.

Pre-Enrollment Screening

We will screen potential participants using the Informant Interview to Differentiate Aging and Dementia. The survey is a dementia screening interview that differentiates typical signs of aging from dementia [42]. The instrument contains 8 items to examine memory, orientation, judgment, and function. The instrument demonstrated strong discrimination in a validation study (area under the receiver operating characteristic [ROC] curve=0.834) [42]. A score of 2 or greater indicates that cognitive impairment is likely present.

Biologic

Age in years and a self-reported list of comorbidities will be obtained at baseline.

Measure of Health Literacy

At baseline, we will administer the 6-item Newest Vital Sign (Pfizer Inc) to assess functional health literacy [43]. The data collector will ask the participants to read a food label for a pint of ice cream. Then, participants will be asked questions regarding serving size, calories, carbohydrates, saturated fat, and food allergies. Scores range from 0 to 6, with lower scores indicating lower health literacy. Scores of less than 4 indicate the possibility of the respondent experiencing low literacy. The scale was initially validated in a sample of 492, including English- and Spanish-speaking adults residing in the United States. Our study will use the English version of Newest Vital Sign that has adequate internal consistency (α=.76) and excellent discrimination (area under the ROC curve=0.88) [4].

Self-Care Behaviors

Four measures will be used to assess self-care. First, the stress management practices will be measured using the Measure of Current Status (MOCS) Part A [44]. MOCS is a list of 13 statements, such as “I am able to use muscle relaxation techniques to reduce any tension I experience,” to which participants respond using a Likert scale (0=I cannot do this at all to 4=I can do this extremely well). This scale also has 4 subfactors: relaxation, awareness of tension, having needs met, and coping confidence. Scores will be summed and range from 0 to 52, with higher scores indicating a more significant use of stress management strategies. Reported internal consistency (α) across MOCS Part A was .71, .77, .86, and .89 [44].

Second, the Block Food Frequency Questionnaire will be used as a validated measure with a food and beverage list that includes 127 items, plus supplementary questions to adjust fat, protein, carbohydrate, sugar, and whole grain content. The questionnaire also includes self-reported physical activity [45]. The questionnaire assesses the frequency with which the respondent generally consumes each food or beverage. It has 9 continuous responses ranging from “never” to “every day” for most foods. The Block Food Frequency Questionnaire provides a Healthy Eating Index score for diet quality (range 0-100) [46]. The DASH index will be calculated using the resulting data and a quintile system to score foods related to the DASH diet. All components are equally weighted. Vegetable, fruit (including fruit juice), nuts and legumes, and whole grains intake are scored from 1 (lowest quintile) to 5 (highest quintile). The overall DASH component scores range from 8 to 40.

Third, we will obtain a list of medications from participants. Finally, the Krousel-Wood Medication Adherence scale captures 4 domains of medication adherence behavior. It was developed to identify low adherence to medication refills in older adults [47]. The scale has reported adequate discrimination (area under the ROC curve=0.704). Scores range from 0 to 4, with a score of 1 or greater indicating lower adherence to medication refill behavior.

Stress Reactivity or Resilience

Systolic and diastolic BP is measured 3 times, starting with a 5-minute rest [35]. Stress resilience and reactivity will be assessed using 2 measures. First, the Daily Inventory of Stressful Events was identified from the Science of Behavioral Change research network list of instruments recommended to assess stress reactivity or resilience**.** The instrument is a semistructured interview in which participants report whether specific stressful events had occurred within the past 24 hours. This instrument categorizes scores for each reported stressful event by examining (1) content classification of the stressor, for example, work overload, argument over housework, or traffic problem; (2) who was the focus of the event; (3) threat type experienced (eg, loss, disappointment, or frustration); (4) objective and subjective severity of stressors; and (5) primary appraisals (eg, areas of life that were at risk because of the stressor). Scores range from 0 to 27. This instrument will be distributed and the data will be collected via an automated text link from the Mosio app. Research staff will call participants who prefer not to use Mosio to deliver the inventory daily to gather the data. Second, the Pittsburgh Stress Battery is a test of stress reactivity. It measures BP response during stressful tasks. The tasks include the Stroop color matching test, mirror tracing, and mental mathematics. For example, during the mental math task, participants will be given 3 trials of fundamental arithmetic problems lasting 1 minute per trial. Participants who score 60% or greater will advance to the random-medium level; those who do not will repeat the easy level. Before the third trial, the data collector

will place the BP cuff on the participant's left arm unless contraindicated. At the 30-second mark of the third math trial, the data collector will use an automatic BP machine (clinician grade) to measure systolic BP, diastolic BP, and heart rate. CN is a neuropsychologist who will assist in the interpretation of data. The Pittsburgh Stress Battery was identified as a valid measure of stress reactivity by the Science of Behavior Change Research Network [48].

Stress or QOL

We will use the Perceived Stress Scale, which has 10 items rated on a Likert scale with a reference range of 0-40 regarding stress over the past month, with higher scores indicating higher stress [49]. The scale was validated across 3 samples, 2 made up of college students and 1 from a smoking cessation program. Internal consistency across the 3 samples was 0.84, 0.85, and 0.86. Further, the scale correlated well with measures of stress symptoms (correlations ranged from 0.52 to 0.76), and the measure is appropriate for multiple applications. The Everyday Discrimination Stress in the Healthcare Setting Survey is a 7-item scale adapted for use in a medical setting from the Everyday Discrimination Scale [50]. The survey questions load to a single factor [51]. Using this scale, we will examine the respondents' experiences and frequency of race-based mistreatment while accessing health care. The scale has a reported internal consistency of α=.89 and a test-retest reliability of 0.58. Further, the scale correlates well with the Krieger Experiences of Discrimination (r=0.51), a measure of societal discrimination.

Hair cortisol will be used as a proxy for chronic stress. To collect the hair samples, approximately 25-75 mg of hair (approximate width of shoelace tip when bunched) will be cut from the posterior vertex region of the scalp as close to the scalp as possible. The posterior vertex has the lowest variation in cortisol levels, making it the preferred area for sampling. To prep for assay, the hair sample is cut, washed twice with isopropanol, and dried over 1-3 days. A total of 10-75 mg of hair is placed into a microcentrifuge tube, minced, and then ground in a Retsch 400 Mill. A total of 1.1 mL of high-performance liquid chromatography–grade methanol is added to the ground sample and incubated for 18-24 hours at room temperature with constant agitation. The tubes are centrifuged at 5000 g for 5 minutes at room temperature to pellet the powdered hair. The entire amount (~1 mL) of supernatant is transferred to a clean microcentrifuge tube, and the methanol is removed by evaporation using a stream of air for 6-8 hours at room temperature. The cortisol extract is reconstituted in 100 µL of Salimetric immunoassay cortisol analysis diluent buffer. Samples are assayed in duplicate inter- and intra-assay coefficients of calculated variation. Hair cortisol levels are expressed in hair as picogram per milligram and generally logged due to skewed distributions as needed. Participants will be surveyed on corticosteroid use, as these medications may suppress cortisol levels, and hair care practices, such as frequency of washing, chemical treatments, and hair product use [52]. Hair samples will be collected at baseline and 9 months.

We will use the World Health Organization-5, a short questionnaire consisting of 5 Likert scale statements of well-being over the past 2 weeks [53]. Scores range from 0 to 25, with higher scores indicating greater well-being. The measure is adapted from more extended versions (10 items and 28 items) and is approved for use in diverse populations by the World Health Organization [53].

Depression and Anxiety

The Patient Health Questionnaire (PHQ-9) is a widely used measure of depression symptoms and severity. The questionnaire's 9 items describe conditions that the respondent may be experiencing and how frequently they experience those specific conditions. Each item is scored on a scale of 0-3, with 0=not at all and 3=nearly every day. Items are summed with total ranges of 0-27; scores of 5-9 are mild depression, 10-14 are moderate depression, 15-19 are moderately severe depression, and 20 are severe depression. The measure was initially validated by administering the questionnaire to 6000 patients in 15 clinics [54]. The PHQ-9 demonstrated 88% specificity and 88% sensitivity for a score ≥10. The Generalized Anxiety Disorder Assessment (GAD-7) is based on 7 items scored from 0 to 3. Like the PHQ-9, the GAD-7 asks respondents about the frequency of feelings and behaviors, with 0=not at all and 3=nearly every day. The score is then summed up with totals ranging from 0 to 21, with cutoff scores for mild, moderate, and severe anxiety symptoms being 5, 10, and 15, respectively. The GAD-7 was tested in a sample of 1184 patients and demonstrated strong reliability with both internal consistency (α=.92) and test-retest (0.83) [55].

Memory and Behavior

The Revised Memory and Behavior Problems Checklist assesses the psychological comorbidities of the caregiver and the health status of the person living with ADRD [34]. It consists of 24 items that evaluate activities of daily living and problematic behaviors in people living with ADRD. Factor analysis has 3 distinct subscales related to memory, depression, and disruptive behavior. Scores range from 0 to 96, with higher marks indicating more behavioral problems in the care recipient. Overall, the measure demonstrated good internal consistency (α=.84), with subscale internal consistency ranging from 0.67 to 0.89.

Feasibility and Acceptability

We will track the feasibility of recruitment by counting the number of participants screened per month, the number who are eligible, the number enrolled per month, the average time delay from screening to enrollment, and the completion of data collection [56]. We will track treatment-specific preference ratings (pre- and postintervention) for acceptability. The participants will complete the Acceptability of Participant Preferences 13-item Likert-type survey ranging from 1 (strongly disagree) to 5 (strongly agree). Interventionists will keep detailed intervention session records describing participant responses to the intervention. For the MIM DASH group, we will collect data regarding the usage of self-care equipment (home BP monitor and MyPlate) from follow-up coaching calls. We will use a credibility scale for both groups regarding the expectation of benefits of this study. The Credibility Scale (α=.86) measures attitudes toward the treatment condition and the participants'

expectation of benefit once the treatment has been explained [57,58]. The scale consists of 5 questions rated 0 (not at all confident) to 10 (very confident). Higher scores, up to 45, will indicate greater credibility of the treatment condition. This will also aid in determining participants' willingness to be randomized for future studies.

Data Analysis Plan

To assess data quality, we will check biweekly data for completeness, accuracy, timeliness, and consistency. These checks will be completed by examining frequencies and descriptive statistics, summarizing participant characteristics, and examining variable distributions. Once identified, data anomalies will be fully investigated, and remediation strategies will be considered as appropriate.

We acknowledge potential confounders, such as health literacy and problem behaviors that the care recipient exhibits, that could influence participation in the intervention and outcomes. As this study's sample size is small, we are limited in the number of covariates that can be used in the analysis. Therefore, we will control for the participant's health literacy and the participant's report of problem behaviors of the care recipient.

To address aim 1, determining the feasibility and acceptability of MIM DASH and caregiver training for African American female caregivers with hypertension, we will conduct descriptive data analyses to report findings related to feasibility and acceptability. These analyses will include a summary of participant background characteristics, including age, educational attainment, relationship to the individuals they care for, and baseline health measures. Descriptive analysis will include frequency counts and percentages for categorical variables and mean, median, range, and SD for continuous variables.

Next, we will use descriptive statistics to examine the feasibility and acceptability of the MIM DASH intervention and caregiver training, including (1) the approach-to-enrollment ratio, (2) the proportion of participants that complete all 8 sessions of the assigned intervention arm and attention control arm, (3) frequency of completion of the follow-up calls, and (4) proportion of sessions that the interventionist deviates from the delivery of the intervention protocol. Further, we will report the mean rating of the MIM DASH intervention from participants and the proportion of participants rating the MIM DASH intervention positively (4 or above). We will report point estimates along with 95% CIs to indicate the precision of these estimates. Based on our previous experience enrolling African American participants in studies, feasibility will be defined by (1) enrolling at least 40% of potentially eligible patients and (2) completing at least 75% of the assigned intervention. Acceptability will be determined by an average rating of 4 or higher and at least 80% of participants rating the intervention positively.

To address aim 2, comparing the influence of MIM DASH on caregiver stress and QOL with the influence of caregiver training, we will conduct an intention-to-treat (ITT) analysis. Thus, all outcomes for enrolled participants will be included regardless of the intervention dosage. The Perceived Stress Scale will be used to measure caregiver stress, and the cortisol level extracted from hair will be a proxy measure of chronic stress. The World Health Organization-5 will be used to measure QOL. The data will be collected in person and documented in REDCap at baseline and 3 and 9 months after the intervention. Descriptive statistics, including mean and SD, will be used to summarize each primary and secondary outcome. We will also report mean differences, 95% CIs, and effect sizes for both within- and between-group differences at each visit. The fixed effect of MIM DASH intervention will be examined by mixed-effects models with measurements nested within persons.

To address aim 3, investigating the potential mediation effects of stress reactivity or resilience between each program and self-care behaviors, we will conduct a mediation analysis with self-care as the outcome (y), participation in MIM DASH as the predictor (x), and stress resilience or reactivity as the mediator (m). We hypothesize that heightened stress reactivity will diminish the relationship (between x and y). In contrast, heightened stress resilience will enhance the relationship between MIM DASH (x) and adopting self-care behaviors (y). To quantify these variables, we will use the Daily Inventory of Stressful Events and the Pittsburgh Stress Battery to measure stress reactivity or resilience. Self-care behaviors will be calculated using the Stress Management Practices survey and the DASH eating index by the Block Food Frequency Questionnaire. The data will be collected in person and by online surveys at baseline and 3 and 9 months after the intervention. We will report descriptive statistics for each of the measures. Finally, we will conduct a mediation analysis to examine if stress resilience or reactivity explains a significant amount of the relationship between MIM DASH participation and self-care behavior. The estimated effects of the mediation and 95% CIs will be reported.

Ethical Considerations

This study has received ethical approval from the Ohio State University Behavioral and Social Sciences institutional review board (IRB; approval 2022B0031) and conforms to the World Medical Association's Declaration of Helsinki requirements. All participants were provided written informed consent before their inclusion.

This study will use descriptive data through surveys and objective measures that include computer tasks while measuring BP, heart rate, and hair samples for cortisol level. The research has minimal risk, as the Ohio State University Behavioral and Social Sciences IRB deemed. There may be no direct benefit to the participant. However, their participation may provide data that will provide insight into ways African American women can reduce their BP and improve their overall health. Autonomy and rights will be given to participants, including the right of refusal at any time, without penalty or loss of benefits to which they are otherwise entitled. If a participant is a student or employee at Ohio State, their decision will not affect their grades or employment status.

The consent and study staff will also describe the use of Mosio for 2-way communication via text messaging. The restricted website associated with Mosio will contain the participant's cell phone and study ID numbers, which the designated study

staff member assigns. The participants can choose not to use the Mosio system at any time. Participants will be informed that there are no costs related to participation. They will not incur any additional charges related to text messages to and from Mosio over and above what they normally have.

All participants will receive the BP categories flyer from the American Heart Association and be instructed to consult their provider if they have a systolic BP higher than 180 mm Hg or a diastolic BP higher than 120 mm Hg. The participant will be instructed to seek immediate assistance or contact their provider. The data monitoring plan is in place and consists of a physician, nurse scientist, and a biostatistician who will review data and any unexpected events at least once per year. Participants will receive US $50 after completing each data collection point, including the home BP monitor, for a total of US $150.

Study staff will be carefully trained to protect participant confidentiality. They will work with participants to devise a plan for contacting them by phone, email, text messaging, or some other means determined by the participant and decide if messages may be left. Participants will be assigned a study ID number, and a master log will be created associating participant names and study numbers. The master log will be stored separately from the College of Nursing's secure server. Only the primary investigator and designated study staff will have access to the master log, which will be destroyed at the end of this study. Study staff's access to study data will be determined based on the relevance to their responsibilities. Only aggregate data will be reported for the dissemination of study findings. Duo Mobile authentication and Zscaler cloud security are used to access REDCap and the College of Nursing secure server.

To mitigate the risk that participants violate the privacy and confidentiality of others in their group sessions, we will ask that those participants (and their family or support person) refrain from discussing with other participants outside the group. Likewise, they will be asked not to acknowledge meeting if they encounter each other elsewhere. These steps are not foolproof, and participants will be informed of the associated risks at the time of consent.

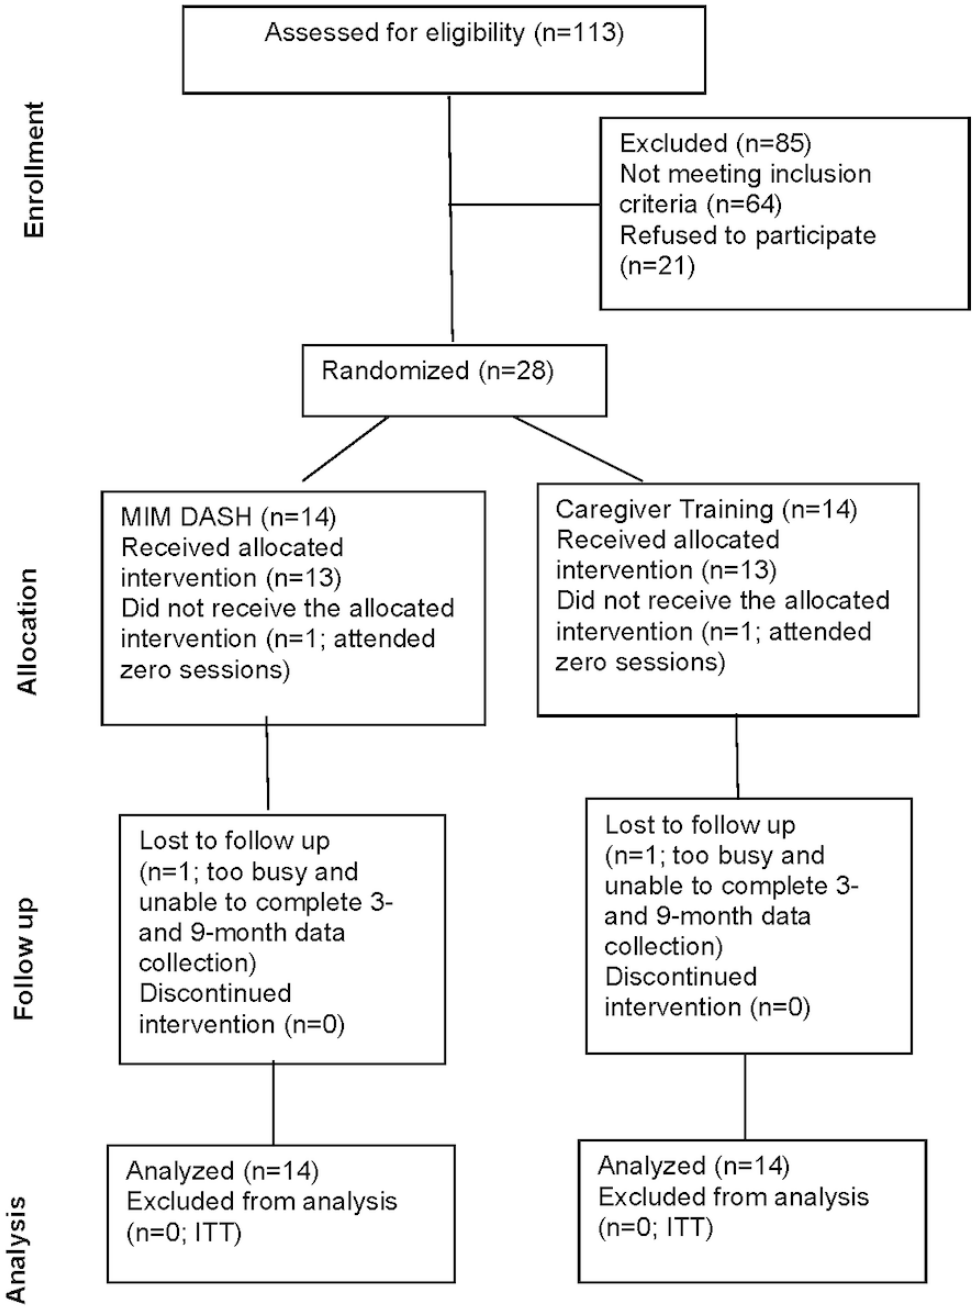
Results

The study was approved by the IRB in April 2022 and funded in May 2022. The first data were collected in January 2023, and the last data were collected in September 2024. Participants were recruited beginning in February 2023. Intervention delivery commenced in April 2023 for the first cohort and November 2023 for the second cohort. Completion of data analysis for all aims is anticipated in spring 2025. A CONSORT (Consolidated Standards of Reporting Trials) flow diagram is presented in Figure 2.

Of the 28 individuals enrolled, 82% (n=23) and 92% (n=26) completed the 3-month and 9-month data collection, respectively. Two participants were lost to follow-up. The mean age of the participants was 62.4 (SD 7.98) years. Eighteen participants were included in the first cohort, and 10 were included in the second cohort.

The participants had a mean systolic BP of 128 (SD 19) mm Hg and diastolic BP of 79 (SD 10) mm Hg. The Newest Vital Sign (health literacy) screen had a mean score of 4.08 (SD 4.5), with a reference range of 0-6 where lower scores indicating lower health literacy. and The Perceived Stress Scale had a score of 12.75 (SD 6.7), with a reference range of 0-30 where higher scores indicating greater stress. Most participants reported that MIM DASH was acceptable (at a mean score of 59.08, SD 7.38, compared to 60.83, SD 5.56 for caregiver training). Regarding feasibility, as reflected in attendance, MIM DASH participants had a mean attendance of 6.3 (SD 2.3) sessions, and the caregiver training group had 4.9 (SD 2.9) sessions.

Figure 2. CONSORT flow diagram illustrating participant progression through the eligibility, allocation, follow-up, and final analysis stages of the clinical trial. CONSORT: Consolidated Standards of Reporting Trials; DASH: Dietary Approaches to Stop Hypertension; ITT: intention-to-treat analysis; MIM: Mindfulness in Motion.



Discussion

Principal Findings

This paper presents a protocol to deliver a culturally responsive mind-body intervention (MIM DASH) specifically designed for African American women who have hypertension and are family caregivers of individuals living with ADRD. We hypothesize that the MIM DASH intervention will be feasible and acceptable, reduce stress, and improve QOL for African American female caregivers. Additionally, we explore behavioral change mechanisms, stress reactivity, and stress resilience that may explain how self-care is adopted or not, which can inform future studies. We hypothesize that lower stress reactivity and higher stress resilience will result in higher adoption of self-care behaviors. Although numerous studies support self-care behaviors (eg, mindfulness practice, healthy eating, and physical activity) to prevent cardiovascular disease—a complication of uncontrolled hypertension [59]—gaps remain in targeting interventions to address the complex interplay of caregiving stress and adoption of healthy self-care for African American female family caregivers of individuals living with ADRD. The findings from this study may contribute to developing and disseminating culturally responsive interventions to improve self-care behaviors and augment the treatment of hypertension and other cardiovascular disease risk factors.

Our principal finding thus far—that MIM DASH is feasible and acceptable—is similar to other studies that have used

mindfulness as an intervention for stress and to promote healthy dietary habits [60-62]. Unlike previous interventions that lack cultural responsiveness or sufficient representation of African American participants, MIM DASH focuses on African American caregivers. This culturally responsive intervention integrates evidence-based approaches such as DASH and mindfulness, offering 8 weekly sessions focusing on healthy eating and stress reduction. The intervention also builds upon prior research but addresses critical gaps in cultural relevance and participant diversity. For example, noncaregiver studies on cardiovascular disease risk reduction, such as those promoting physical activity and healthy eating, often exclude culturally responsive strategies or include remarkably few African American participants, reducing their applicability to African American caregivers [59,60,63]. MIM DASH addresses these limitations by offering a potentially scalable, tailored approach that acknowledges this population's cultural and systemic barriers.

Limitations of This Study

This study will examine the feasibility and acceptability of the MIM DASH intervention in African American female caregivers of individuals living with ADRD. However, this protocol may have some limitations. The small sample size is a notable limitation, which may restrict the generalizability of the findings. Re-evaluation of inclusion criteria, including only those with a diagnosis of hypertension and those on an antihypertensive basis, may be too restrictive, making this study less generalizable. The multiple measures for data collection and the use of the Pittsburgh Stress Battery as measures of stress and resilience may increase the risk of burden and missing data. Although the Pittsburgh Stress Battery provides a standardized means of cardiovascular reactions to acute stress, it is limited in assessing chronic stressors. The limitations of using the Pittsburgh Stress Battery inventory include time to administer the test, challenges of internet connectivity to access the mirror test, and the cost of materials for administering the test. Other measures, such as heart rate variability, would burden participants and data collectors less [48]. Additionally, other theoretical mechanisms of behavior change, such as self-regulation (temporal discounting of immediate small rewards over larger future rewards) and interpersonal and social processes (social interactions), could be used as the facilitators of behavior change. Given that the MIM DASH intervention was delivered in a group setting and includes elements of self-regulation through mindfulness practice, future studies may consider exploring other, less costly mechanisms of behavior change.

Future studies with more extensive and diverse samples will be necessary to validate and scale the intervention. Furthermore, while this study aims to evaluate feasibility and acceptability, long-term outcomes such as sustained behavior change and clinical improvements in hypertension management remain unexplored.

Future Directions

The findings of this study will be disseminated to this study's participants in the form of a brief report or newsletter that will be submitted for approval to the Ohio State University IRB. Additionally, presentations will be given to the local African American community, churches, and Alzheimer's disease support groups. The findings will be disseminated to the scientific community using multiple strategies, such as presentations at the Gerontological Society of America, the Alzheimer's Association International Conference, and nursing and interprofessional peer-reviewed journals. By disseminating our study findings via traditional (researchers) and nontraditional (community), we will contribute to the science of behavior change and ADRD research for African American caregivers with hypertension.

To prepare for scalability, we will evaluate the delivery of the intervention from the facilitators' perspective to determine what worked well and what needs to be refined. We are refining the training materials and facilitator fidelity monitoring for a larger trial. Data from the pilot feasibility study will help to inform the sample size for efficacy testing. To scale up, we will include additional measures of self-care management and behavioral change, such as actigraphy. We will use a framework such as Reach, Effectiveness, Adoption, Implementation, and Maintenance (RE-AIM), which provides a guide for evaluating the reach, effectiveness, adoption, implementation, and maintenance within the objectives of a larger randomized controlled trial [62]. If efficacy is successful, then using such a framework as RE-AIM would position the work for real-world implementation. Funding for the efficacy trial will be sought through grants from the National Institute on Aging or nonprofit organizations such as the American Heart Association, Alzheimer's Association, or Bright Focus.

Conclusion

The burden on African American dementia caregivers is expected to rise alongside the aging US population. Addressing the health of these caregivers is paramount to sustaining effective care for individuals with ADRD. The MIM DASH intervention represents a step toward providing culturally responsive hypertension self-care strategies for African American caregivers. This protocol sets the stage for improved caregiver health and contributes to the growing body of research on tailored interventions that address health disparities in minority populations.

Abstract

Background: The COVID-19 pandemic and the protracted lockdowns have heavily impacted university students' mental health. Digital Escape Games represent a good means to reach students and propose them solutions for their psychological well-being.

Objective: This study aimed to evaluate a cocreated digital Escape Game on students' mental health in the aftermath of the COVID-19 pandemic, called EscapeCovid Game. The evaluation of the effectiveness of this stand-alone intervention concerns mental health outcomes (mental health literacy, appraisal and change of beliefs about mental health, management of emotions, and development of coping strategies) and the appreciation and relevance of the game.

Methods: A randomized controlled trial with pre- and posttest data collection (online questionnaires with validated scales) is conducted among 500 students in Bordeaux, France, to evaluate the EscapeCovid Game cocreated with students, researchers, health professionals, and web developers. A subsample of students is randomly selected for responding to a semistructured interview following a mixed methods design. Recruitment is done through mail invitations from student associations and presentations in university classes. Half of the sample of the trial plays the Escape Game, while the other half receives an email with mental health–related information. Within the game, students discuss their personal experiences. The text is further used for the qualitative analyses. The whole study is carried out online.

Results: The EscapeCovid Game has been developed, tested, and finalized by the end of March 2023. As of November 4, 2024, a total of 191 students have answered the baseline questionnaire (90 intervention vs 101 control). A total of 23 students have played the game and 53 are in the control arm. Among participants, by the end of September 20, 2023, twenty were interviewed (10 intervention and 10 control) reaching sample saturation. According to preliminary results, the EscapeCovid Game has had a positive impact on all defined outcomes, while the email has been effective in increasing knowledge on resources available and on coping strategies and meditation techniques. We expect the trial to be completed by the end of June 2025.

Conclusions: The mixed methods findings of this study are due to demonstrate the effectiveness of the EscapeCovid Game in improving students' mental health outcomes. Preliminary results from the qualitative substudy are promising: in the aftermath of the COVID-19 crisis, this intervention is intended to promote players' mental health through gamification, knowledge transfer, and a learning-by-doing approach.

Introduction

Background

Mental health problems among young people have skyrocketed with the COVID-19 crisis [1]. Repeated lockdowns and curfews between 2020 and 2021 were the causes of a general mental distress well-documented in the literature [2]. These measures had detrimental and long-lasting psychosocial consequences like acute stress and trauma-related disorders, particularly in specific at-risk populations such as students [3].

University students were in fact concerned as a vulnerable population. Independently from the presence of a pandemic, suicide is the second leading cause of death among them and, by the age of 25 years, 75% of those who will have a mental health disorder have had their first onset [4,5]. During the COVID-19 crisis, students were exposed to supplementary heavy stressors: isolation, classes exclusively online, and uncertainty about their academic and professional future. Several studies have shown how the COVID-19 pandemic and its lockdowns had negatively affected students' mental health across the world [6,7]. Therefore, it is fundamental to implement mental health promotion and prevention interventions aimed to support students during this crisis. Evaluation of these interventions is a pivotal process in public health research to determine their effectiveness and improve their quality in relation to the targeted population [8].

Among innovative interventions, Escape Games are "live-action team-based games where players discover clues, and solve puzzles [...] in order to accomplish a specific goal, usually escaping from the room, in a limited amount of time" [9]. Escape Games are the digital internet-based online version of Escape rooms. Previous research has proved that Escape Games can increase knowledge on health-related topics using the learning-by-doing technique [10]. Furthermore, gamification is based on a learning by making mistakes approach. Related flow theory states that simple simulation can be perceived as more anxiety-provoking than the purely playful approach which integrates error as a dynamic element.

Compared with other interventions, they are supposed to be more attractive and acceptable for a young audience, especially because of their gamification approach. Gamification relies on immersion through which players feel embedded in the game as several psychosocial determinants (eg, social support, environment) are leveraged. In particular, health-related Escape Games use puzzle solving as a strategy to access health promotion and prevention messages. The step-by-step sequencing and the resolution of the enigmas stimulate the learning loop and over-solicit the cognitive capacity of participants (ie, better awareness of the concerned topic, and better capacity to deconstruct one's beliefs).

Escape Games can contribute not only to increasing knowledge, but also to behavioral change by providing instruments to act in real-life. For instance, by relying on teamwork, participants can develop the notion of mutual support which could be transposed to their communities. Thus, individual and collective behaviors are at stake. The positive outcomes of Escape Games are boosted by their digitalization: through the internet, Escape Games can reach a larger audience with no time or space limit. This should be even more promising in a period where face-to-face contact is very limited. Success of these interventions can also be fostered if they are cocreated with the target population through a design thinking approach (ie, understanding of users' experience and needs, brainstorming sessions with several stakeholders, and testing of the tool). Cocreation is a collaborative approach offering various benefits such as enriched insight into problems and increased feasibility and acceptability [11]. We applied this approach to produce the EscapeCovid Game, a stand-alone intervention to promote mental health and prevent psychological diseases among university students in the era of COVID-19.

The EscapeCovid Game

The EscapeCovid Game is focused on four main outcomes: (1) mental health literacy (knowledge of the concept of mental health, from illnesses to psychological well-being), (2) appraisal and change of beliefs about mental health (destigmatization), (3) management of emotions (their recognition and regulation), and (4) development of coping strategies (building resilience). It addresses specifically anxiety and depression whose symptoms were exacerbated by the COVID-19 crisis including the measures undertaken to limit the spread of the virus (eg, repeated lockdowns and curfews, University closure).

The underpinning theories of the game are the COM-B model of behavior (capability, opportunity, and motivation to change behavior) [12], the Plutchik's wheel of emotions (visualization of emotions to change behavior) [13], and the Transtheoretical model of behavior change (stages of change, processes of change, levels of change, self-efficacy, and decisional balance [14]).

The EscapeCovid Game takes place in Thomas' apartment which he shares with another student, Hana. Thomas is a university student and we follow him during a typical day in lockdown. To move from one room to another, players must solve all the puzzles by clicking on the objects spread out in Thomas' room. At the end of each room scenario, a set of cards is shown, with each card containing a mental health-related message. The cards synthesize the messages transmitted through the puzzles in the room.

The game can be played in groups of 4 players who help each other and discuss using their computer cameras and headphones. All along the game, they are helped by a game guide who explains the rules and answers any questions. The same guide concludes the game session with a final debrief where all participants share their experiences.

The EscapeCovid Game has been cocreated jointly by a team of researchers at the University of Bordeaux and a start-up specialized in the production of both physical and digital Escape Rooms, Tricky, in France. We used the PRODUCES (Problem, Objective, Design, End Users, Cocreators, Evaluation, and Scalability) framework [15] composed of 3 steps. First, we tested the hypothesis that the game was effective in promoting the four mental health-related outcomes. Second, we

accumulated evidence on the good functioning of the game. Third, we leveraged the right behavior change mechanisms.

Within this framework, the game was cocreated in particular by 1 project manager from a public health research center, 1 student intern completing a degree in cognitive engineering, 1 game designer, 1 developer specialized in computer science, 1 medical doctor, and 1 psychology researcher. Supplementary data to improve the game was provided by 45 questionnaires on the appreciation and relevance of the game by student players, and qualitative semistructured interviews with 10 students of the same sample. The cocreation of the game is detailed in an article by Labrosse et al [16].

Objective and Hypotheses

The objective of this study is to evaluate among a population of university students the effectiveness of the EscapeCOVID Game on 4 mental health outcomes: mental health literacy, appraisal and change of beliefs about mental health, management of emotions, and development of coping strategies. The appreciation and relevance of the game are also considered in the overall evaluation of the game. This stand-alone intervention is implemented in the era of the COVID-19 pandemic.

Consequential research hypotheses of the study are (1) compared with a group receiving another classical intervention, after playing the digital Escape Game and having received a debriefing, students remarkably improve their mental health literacy, appraisal, and change of beliefs about mental health, management of emotions, and development of coping strategies; and (2) cocreation enhances appreciation and relevance of the digital Escape Game among university students.

The objective of this study is original since, to the best of our knowledge, no Escape Game on students' mental health outcomes has been developed before following a cocreation approach and evaluated through mixed-methods to prove its effectiveness.

Methods

Evaluation of the EscapeCovid Game

Mixed Methods Research Design

The EscapeCovid Game is evaluated through a mixed-methods approach using exclusively online data from a Randomized Controlled Trial (RCT) including 2 web-based questionnaires, and video interviewing. Within the mixed methods framework, we apply the embedded design [17]. According to this design, the quantitative and the qualitative data are collected simultaneously, but the qualitative data is embedded within the quantitative data. This means that the data from the questionnaires is prominent, but we still need to understand how the qualitative data further explains the effectiveness of the intervention.

As for the cocreation of the Escape Game, all tasks of the evaluation are conducted jointly by the university research team and the private start-up, thus proving the sharing of skills and the management of potential risks and their solutions in a combined effort. In particular, the research team is in charge of the collection and analyses of the data, while the start-up handles logistics including the organization of the game sessions. The postulate of the start-up is that a product can be really evaluated as significantly efficient in the serious game industry mostly or exclusively through the collaboration with a public research laboratory.

The Randomized Controlled Trial

We implement a rigorous RCT design using pre- and postintervention data coming from online self-administered questionnaires. The sample must be of at least 500 students at the University of Bordeaux. We estimated a sample size of 500 participants for the 2 arms: statistical power=.80, Cronbach α=.05, Cohen d=0.5, and 40% attrition with a 2:1 allocation ratio for the intervention group.

At study entry, the 500 students complete the online baseline questionnaire. Among them, 250 students play the EscapeCovid Game while 250 students receive an email with tips and resources for managing their stress during the COVID-19 pandemic. Participants are randomized so that the 2 groups are similar in terms of sex, age, and field of study (stratified balanced randomization). Participants are informed from the beginning of the study that they can be allocated to either the intervention of interest or the comparator. We tell students in the control arm that they are in a waiting list and that they can play the game once the experiment is concluded.

Inclusion is stopped when at least 500 participants have completed at least 3 quarters of each questionnaire, and 250 have played the game until the end. The statistician and the project manager of the EscapeCovid study are in charge of generating the random allocation sequence, enrolling participants, and assign them to one of the 2 arms.

Briefly, the 250 students of the intervention arm (1) complete the online baseline questionnaire, (2) play the EscapeCovid Game at their home within the week after the online baseline questionnaire—a link to the game is given at the end of the questionnaire, and (3) complete the same online questionnaire of the baseline plus some items on the appreciation of the game (satisfaction survey) 2 days after having played the game. After some tests with Tricky staff, the game duration is estimated at about 2 hours, from the online registration with the creation of an account, until the end of the debrief. Instructions to connect and play online are provided in an email sent by the start-up to the student of the intervention arm 2 days before the game session.

The 250 students of the control arm will (1) complete the baseline online questionnaire, (2) receive the same day an email with tips and resources to manage their stress during the COVID-19 pandemic, and (3) complete the same internet-based questionnaire of the baseline 2 days after having received the email with tips and resources.

Students can complete all steps of the evaluation from anywhere using a smartphone or a computer. However, they can play the game exclusively from home, considering the need for a stable internet connection and a performance computer.

Internet-Based Interviews

There are two sources of qualitative data: (1) semistructured interviews after the intervention with students from both arms and (2) open discussion with the game guide at the end of the game session. Concerning the first source of qualitative data, 20 students were randomly selected among the 2 groups (10 for the intervention arm, and 10 for the control arm) to respond to a semistructured interview. For the discussion embedded in the game, the text produced during the debrief is recorded and analyzed so that the developers of the start-up can work on an algorithm for building a chatbot messenger capable of providing tailored advice to gamers, replacing the game guide. Machine learning will be used for this purpose. In terms of simplicity and feasibility, the sample is recruited on the sole criterion of sex, 50% of girls, through sample saturation. The interviews have been conducted remotely by a public health researcher through an internet-based interview tool. Students are recommended to make the interview at home.

Recruitment of Study Population

Inclusion criteria are (1) being a student at the University of Bordeaux, (2) being aged ≥18 years, (3) understanding, speaking, and writing French, and (4) having given the electronic consent to be enrolled in the study. We consider that students have a sufficient level of computer literacy for playing the game as only few basic skills are required: knowing how to navigate the web, keyboarding, and typing. These skills are essential for any student from any field of study and represent a prerequisite for the undergraduate and graduate programs at the University of Bordeaux.

Students are invited through the social media of the study partners (University of Bordeaux and Tricky), posts in the Facebook groups of more than 100 student associations, and mailing lists from the University of Bordeaux. The associations are manually selected from a list provided by the University of Bordeaux to cover the different fields of study. Overall, we plan to reach about 10,000 students which is a substantial number considering potential very low enrollment and retention rates. The invitations by email are sent to a maximum of 500 recipients at a time, so that we can proceed step by step with the inclusion of participants and the organization and schedule of the game sessions. The invitations will be sent until we reach a sample of a minimum number of 500 students.

The recruitment is exclusively web-based. Clicking on the link displayed on social media posts or on the text of the email, students will access an online form to enter the study.

The inclusion of participants to the RCT will be conducted based on a continuous monitoring through statistical analysis. Data on sex are available only for males and females, since information on gender is not reported in the University records. The year of study goes from 1 (first year of university) to >8 (corresponding to a doctoral degree or a diploma in medicine). The fields of study offered by the University of Bordeaux are more than 50,000 and are categorized in Health Studies, Law and Economics, Technical Sciences, and Human and Social Sciences.

Finally, a maximum of 5 reminders will be sent through email to all 500 participants for the completion of the second questionnaire. For the intervention group, an additional maximum of 5 reminders will be sent to schedule a game session and eventually play the game. An additional maximum of 5 reminders will be sent to the students randomly selected to be interviewed. If after the 5 reminders per phase of the study, the student does not reply, we will proceed with the invitation of new students from the contacts we have from the University and attached associations.

The participation to the study is completely voluntary and all students are rewarded with a €20 (US $21.59) gift card.

Data Collection Tools

The pre and postintervention questionnaires are administered through the Sphinx software (Georg Brandl) distributing surveys on all media (web, smartphone, QR code, and SMS). The data are automatically imported in a Microsoft Excel file.

The first questionnaire is composed of 112 items. It includes validated scales measuring mental health literacy (French Mental Health Literacy Scale [MHLS-FR]) [18], beliefs about mental health (Health Belief Model [HBM]) [19], emotions (Plutchik's wheel of emotions) [20], Coping Strategies (Ways of coping questionnaire) [21], Depression (Patient Health Questionnaire-9 [PHQ-9]) [22], Anxiety (Generalized Anxiety Disorder-7 Scale [GAD-7]) [23], Stress (Perceived Stress Scale [PSS4]) [24], and Help-seeking actions (Kessler Psychological Distress Scale in help-seeking youth [K6]) [25]. Sociodemographic information (email address, gender, date of birth, field of study, year of study, and self-perceived health) are also collected to assess the representativeness of the sample (stratifications by sex, age, field of study etc). A question specifically asks the gender giving students the possibility to indicate whether they belong to the LGBT (lesbian, gay, bisexual, and transgender) category (considering the confidentiality of this data). The question of gender as a determinant of mental health will be important to analyze the results considering this confounding variable if the number of individuals is sufficient. The questionnaire is developed by several researchers through different stages of drafts and reviews, following a structured survey construction method in 5 steps [26]. Operational staff members from the team of the coordinator and a group of students pretest the questionnaire for readability, comprehensibility, and face validity. The response modalities are varied: multiple choice, binary responses, Likert scales, and visual analog scales. Mental health indicators and appreciation and relevance results are the main outcomes of the study. All items provided the nonresponse option "not applicable," "I don't know," and "I do not want to answer." Respondents are required to select an option from a predefined list. The questionnaire is not validated if at least one question is not answered. Respondents are not able to review and change their answers, but they can ask the principal investigator for a document with exclusively their answers. Corrections cannot be made manually in the database in order to avoid any further error.

The second questionnaire is the same, but it does not include the sociodemographic items. It contains new items on the appreciation and relevance of either the game or the email

(satisfaction survey). These items are created ad hoc, but are also inspired by existing instruments evaluating digital health interventions (eg, items by Fadda et al [27]). The questionnaires, composed of both validated scales, sociodemographic items, and satisfaction survey questions, have been developed by 1 researcher and 1 project manager in public health. A pool of researchers in psychology and in statistics have reviewed the questionnaire to assess its readability, understanding, and relevance. The questionnaires have been tested on the internet by 10 students of the School of Public Health of the University of Bordeaux. Testers reported some technical errors, that has bugs and repetitions of items, and suggested different wording for making the questionnaires more adapted to a young target population between 18 and 25 years of age. The questionnaires were constructed following the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) [28]. For both questionnaires, outcomes are self-assessed. The questionnaires are available in Multimedia Appendix 1.

Qualitative data from the semistructured interviews are collected through an ad hoc grid including questions on the impact of the game or email on mental health–related knowledge, on the access to mental health care services and the attitudes toward mental illnesses or stigmatization. Participants are particularly asked to evaluate whether the game is adapted to their needs and to discuss the cocreation approach as a means to produce tailored interventions. The main objective of these interviews is to assess the appreciation and the relevance of the game. The interview grids are available in Multimedia Appendix 2.

Questions addressed to the control group allow to capture the utility of the contents of the email (eg, list of mental health care services and a short description of mental health problems) and to compare the contribution of each tool to knowledge about mental health. Qualitative data form the debrief correspond to the free discussion between the players and the game guide. The latter follows a script and makes questions on the specific topics covered by the game: overall recognition and management of the emotions; symptoms of depression, stress and anxiety; relevance of mental health in daily life; and sources available in the case of a mental health problem.

The semistructured interviews were conducted by a public health researcher trained in qualitative data analyses. The project manager analyzed the same dataset using the triangulation approach.

The quality of both quantitative and qualitative data is ensured by keeping documentation accurate, that are clean databases and well-stored texts. Ensuring ethical standards is a further guarantee of the quality of this study.

Data Analyses

Overall Mixed Methods Analyses

First, we will conduct statistical analyses on quantitative data (descriptive statistics, modeling, and exploratory data analysis) processed from the RCT; second, we have analyzed the discourse of qualitative data (thematic analysis based on a predefined interview guide); and third, we will couple the analysis of both types of data. In particular, we will integrate quantitative and qualitative data for the purposes of convergence, contextualization, and expansion to gain a detailed understanding of the evaluation and impact of the game.

Quantitative Data Analyses

For the data from the RCT, we will compare the answers between exposed and nonexposed students (intergroup) and measure the change in their answers within the intervention group before and after playing the game and debriefing (intragroup). Our primary analysis will be based on intention-to-treat at the individual level using linear regression comparing the outcomes of the intervention and the control arm. We will measure our primary outcomes in terms of absolute scores and as a percentage of the total possible score. We will control baseline covariates: (1) gender, (2) age, (3) field of study, (4) year of study, and (5) self-perceived health. We will analyze the data from all participants only if at least 3 quarters of the questions are completed. We consider that some users will not go through all questionnaire pages. Missing values will be imputed by replacing them with the mean or median values of the dataset at large, or some similar summary statistics.

Qualitative Data Analyses

Concerning qualitative data from the semistructured interviews (intervention and control groups), they have been analyzed through content analysis: we have identified patterns across collected texts which are coded according to key elements. These can include, for instance, reported advantages and drawbacks of the game, or players' opinions on the usefulness of the game in general. The semistructured interviews are either video or audio recorded depending on the availability of the participants, during the lunch break or in the late evening after the classes. In-depth analyses were conducted using a reflexive approach so as to appraise and evaluate how subjectivity and context influence the research processes, especially during the interpretation of the data on intimate topics like mental health. Before the association with the quantitative data, the texts will be cross-analyzed to identify similarities and differences between the experience with either the escape game or the email.

Data from the debrief at the end of the game were recorded automatically within the game. The texts were collated in a single document which was used to generate repeated and automated messages. Through artificial intelligence and, more specifically, the machine-assisted topic analysis (MATA), the human conversation will be processed to simulate answers to players' requests. The outcome will correspond to a chatbot, which will a computer program that will be able to animate a discussion and provide tips concerning mental health–related issues.

Ethical Considerations

The study has received the French identifying number (ID-RCB) 2024-A00436-41 from the National Agency for the Safety of Medicines and Health Products. This number is compulsory for registering projects on human subjects in France.

The Ethics and Health Research Center of the University of Bordeaux approved the study (2024-A00436-41). The procedures are in accordance with the Helsinki Declaration of 1975, as revised in 2024.

It is compulsory that students carefully read the consent form and sign it electronically (by clicking on the "I agree button") in order to participate to all steps of the study and share their data collected through questionnaires, interviews, and during the game. The consent form includes all the details of the study: (1) principal investigator, (2) rationale, (3) objectives, (4) methods, (5) length, (6) conditions of the storage data and analyses, and (7) expected impact. Students access directly to the consent form when they click on the link in the social media posts and the study invitation email. Participants are given the chance to opt out.

All confidential information, including participants' contact details or other sensitive data like self-reported mental health status will only be accessible to authorized staff members from the study. Thus, information is quasi-anonymous for the proper running of the study. In fact, the email address is necessary to organize the game sessions, to send the links to the web-based questionnaires and to schedule the internet-based interview. The phone number is also required to resolicit the participants, only once, for the organization of the game session. We guarantee the noncommercial use of the email addresses and the phone numbers.

Overall, participants are informed that they are not blinded.

All data, including the sensitive ones, are imported automatically from the software Sphinx to Excel. The document is protected by a password known only to the principal investigator and the statistician of the research team. The data will be destroyed 2 years after the last article based on this study is published. The collection, storage, and analysis of the data comply with the European General Data Protection Regulation (GDPR).

As already mentioned, students will receive US $21.5 gift cards for their participation to the study. The authors have filled the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) form V1.6.1 (Multimedia Appendix 3).

Results

Key Dates of the Study

The study received funding by the French National Research Agency in January 2022. The production of the EscapeCovid Game ended in March 2023. The cocreation process, the test, and the refinement of the intervention lasted 15 months. For the evaluation of the finalized game, the collection and analyses of qualitative data through semistructured interviews has been completed by September 2023. The end of the evaluation phase through the RCT is scheduled to be completed by the end of June 2025. The results of the mixed methods analyses are expected to be published by the end of December 2025. The timeline of the study is illustrated in Figure 1.

Figure 1. Timeline of the phases of the study.

Study Population

The recruitment started in December 2023.

As of November 4, 2024, a total of 191 students have answered the baseline questionnaire and have been randomly assigned to one of the 2 arms, 90 intervention versus 101 control. A total of 23 students have played the EscapeCovid Game (intervention arm) and 53 are in the control arm. Specifically, 54% (103/191) of the participants at the baseline are students in health care disciplines; 11.5% (22/191) in sciences and technologies; and the remaining participants study other subjects 34.5% (66/191) including psychology, law, and so on.

Concerning qualitative data, 20 students (10 for each arm) have been interviewed on the appreciation, relevance, and acceptability of either the game or the email. Students of the game arm were between 18 and 28 years of age. There were 9 females and 1 male. Their year of study ranged from the first year of their bachelor's degree to the first year of their doctoral

studies. Fields of study included medicine, chemistry, physics, biology, sociology, speech therapy, and political science. Students of the control arm were between 18 years and 28 years old. Their year of study ranged from the second year of their Bachelor's to the third year of their doctoral studies. Fields of study included medicine, physics, nursing and marketing.

Preliminary Quantitative and Qualitative Results

As of November 4, 2024, the sample size of the trial is too small for providing robust data and for reaching significance level.

As far as qualitative data are concerned, we completed all 20 interviews. According to the students from the intervention harm, the game was appealing and fun. The use of gamification to communicate mental health-related messages was appreciated.

> *I like the initiative of doing something more fun, more educational than just distributing information, which is also a way in itself, we agree, but I like the way of trying to learn.* [Student 7–Male]

The game was described as "innovative," "unique," "instructive," and "beneficial" considering its alternative approach to conventional public health interventions, for example, educational materials, and social marketing campaigns.

The notion of stigmatization emerged. Attached outcome was the appraisal and change of beliefs about mental health.

> *I found it very interesting that we raise awareness about mental health because I have the impression that it is something that we talk about more than before but there is still a taboo behind it.* [Student 2–Female]

The game also contributed to increase participants' mental health literacy.

> *It gave me knowledge I didnot have about mental health.* [Student 1–Male]

The impact of the intervention on support recognition and management of emotions was also positive.

> *The way in which the symptoms or rather really what the person thinks to themselves are well represented and so it really allows us to understand what is going on in the person's head and also to know the symptoms and emotions. So it's very interesting, rather than just listening to someone talk about it and having a slide, it's much better.* [Student 9-Female]

The other study outcome (teach positive coping strategies) was also reported:

> *Well, you see that I have to do things that finally make us happy and otherwise, not to work too late, to take a break to eat, to see my friends and that's it and from time to time go out when we need to get some fresh air.* [Student 5-Male]

However, the students also declared that the content of the game should be enriched with the presentation of more coping strategies in order to support the player's psychological well-being. Thus, the impact of the intervention should be directly on the mental health of the players and not only on their knowledge and beliefs.

> *Not particularly, I don't think so, it was more focused on knowing emotions rather than how to manage them.* [Student 1-Male]

In comparison to the game, the informative email was not an immersive experience and was not expected to influence students' cognition, affect, potential, and health behavior. However, it provided useful tips to students from the control arm, including the following: a list of existing sources in case of mental health distress (eg, helplines and free-of-charge consultations with a psychology based at the University of Bordeaux); breathing techniques and meditation; and mental health problems explained with accessible but accurate terminology.

> *It gave me knowledge I didn't have, about the numbers to contact in case of need [...] we can't know them all by heart and I think that having them all written down in an email or in a document, well I think that it can help us because not everyone knows where to refer and where to go in case of need.* [Student 1-Male]

The usefulness of the email consisted in the fact that it could be used as a memorandum and repertoire of the basics of mental health literacy: knowing that mental health includes both positive mental health and the absence of a mental health problem; knowing the signs of the most common mental health problems (depression, anxiety, and stress); recognizing and managing emotions; learning coping strategies; and having a list of the most known services in case of a mental health distress.

As of November 4, 2024, data from the game debriefs is not transcribed and cannot be analyzed.

Discussion

Principal Findings

This paper outlines the protocol for the evaluation of a cocreated Escape Game on students' mental health outcomes contributing to prevent and manage mental health diseases and promoting psychological well-being: mental health literacy, appraisal and change of beliefs about mental health, management of emotions, and development of coping strategies. The evaluation is conducted through mixed methods, combining the quantitative results of a RCT with the qualitative results of semistructured interviews.

Concerning quantitative, as of November 4, 2024, the recruited sample is too small to make inferences on the impact of the game. Actually, recruiting students is the hardest challenge of the trial. All along the study, we have observed that the most successful recruitment strategies are: offering gift cards to students completing the whole study (baseline questionnaire, intervention or control arm, and repeated questionnaire); counting on the support of student associations promoting the study among members; and involving professors who present the study during their classes. We will reinforce these strategies to attract and retain students in the trial.

As for the qualitative data, the recruitment of students was far easier and we rapidly interviewed 20 participants by September 2023. The comparison of the responses across the 2 groups, game versus email, showed that gamification improved the retention of messages, especially in terms of recognition and management of emotions. On the other hand, email was considered useful as a memorandum of mental health–related information. In particular, students appreciated the list of available services that they could keep and save for contacting professionals in case of need.

Based on preliminary results, these 2 distinct tools, the EscapeCovid Game, and the informative email, could prove to be mutually complementary in promoting student mental health. By consolidating the specific advantages of each approach while mitigating their respective limitations, we can aspire to a more holistic and informed approach to strengthening psychological well-being within the student community.

Comparison to Previous Work

Recently, interventional research took an interest in digital games to promote positive well-being and prevent mental health problems. This might be due to the emerging mental health challenges because of the COVID-19 pandemic [29]. A scoping review of 16 articles has identified positive effects of gamified interventions, with beneficial consequences for psychological well-being and depressive symptoms [30]. Three articles focused specifically on university students, but described interventions were gamified mobile or web applications, and did not include Escape Games.

Overall, Escape Games addressed to university students are mostly used as educational tools aimed at guiding learners toward achieving specific learning outcomes through a game-based design [31]. Concerning mental health, the literature reports 1 game addressed to students to improve their knowledge on psychological well-being and mental illnesses, but it is an Escape Room exclusively on site [32].

It is essential to support this population and reinforce their psychological status and resilience since they will be the future workforce. They will especially be in charge of rebuilding the economy of the country after this huge crisis.

Strengths and Limitations

The robust evaluation process of this study will provide evidence of the effectiveness of one of the few digital gamified interventions addressed to students' mental health. This will be among the first promising Escape Games produced jointly by a public university research team and a private start-up. The collaboration between these 2 institutions is an added value guaranteeing that, on the one hand, the intervention is well-designed and functioning, and that, on the other hand, researchers have accurately assessed its performance.

The main strength of the evaluation process in that relies on mixed methods. This approach can balance out the limitations of each method (questionnaires from an RCT and qualitative data from semistructured interviews and game briefing); it can lead to stronger evidence and reliability; and it can provide more details than each individual method. Concerning quantitative data, mixed methods limit straightforward and stereotyped interpretations, and reduce ambiguity and misunderstanding.

On the other hand, the limitations of qualitative data are mitigated by a rigorous quantitative approach: coding of the text in structured interview grids, word-by-word data management, and detailed records of data collection and analysis like in an audit trial [33].

Thus, mixed methods can increase the trustworthiness, transferability, dependability, and confirmability of the thick description of combined quantitative and qualitative data.

This study is primarily limited by the low participation of students and inclusion at the baseline. This might be due to the fact that the game lasts more than 1 hour and requires a good computer operating system, as it is already stated in the interviews. Students' agenda are really busy and their workload is heavy. As suggested, new structured communication strategies would improve the participant recruitment. Furthermore, the inclusion in the study is completely voluntary and, considering that we do not use quota sampling because of feasibility, results may not be generalizable to students in Bordeaux and to French students in particular.

Another barrier is the correct implementation of a complex evaluation through an RCT and mixed methods design with the collection of several data. Researchers involved in the study have renowned experience on this type of methodology and are keen to ensure the smoothness of the evaluation process. As far as technical barriers are concerned, the development of the digital Escape Game has to overcome potential IT challenges. The final product will need to be both high-tech and appealing, mixing solid technology with a modern design and avoiding bugs. IT developers of the start-up of the study have already proven their competencies and skills for that.

Future Directions

If the results of the study show the impact of the intervention on mental health outcomes (mental health literacy, appraisal and change of beliefs about mental health, management of emotions, and development of coping strategies) among students, the game will be commercialized and sold to universities for its deployment on the campuses across France. The evaluation process is meant to guarantee that the game can be diffused with an economically sustainable model defined by the start-up. In particular, this study will help the start-up to define a "gold standard" for selling other similar interventions.

The promising results of the study open the way to crucial questions: how can we secure funding and optimize the economic efficiency of the EscapeCovid Game in order to guarantee its sustainability and make it a mental health promotion tool, accessible to a wide range of students from diverse backgrounds? For instance, using artificial intelligence, it will be possible to make the intervention autonomous with automatized debriefing. This will make the game more sustainable cutting the costs of the salary of the game guide.

Furthermore, who will be the legal owner of the EscapeCovid Game? Intellectual property must be deeply discussed to ensure the shared collaboration of the partners to create the game before

its real commercialization. In order to overcome any potential disagreement, the roles of all parties must be clearly stated in a business partnership agreement.

Thus, the protocol of this study describes how to evaluate with a robust methodology a game on students' mental health as an example for producing further effective interventions on the same topic. Based on evidence, these interventions can be commercialized through an economically sustainable model.

Finally, this protocol presents a study whose objectives are both research (studying several indicators of young people's mental health during the COVID-19 pandemic)- and business-oriented (producing an evidence-based tool for further deployment).

Acknowledgments

The authors acknowledge and thank all students who participated to the study. The authors are also indebted to the student association for helping recruit participants. We especially thank Clément Tisseron and Flavie Coudouin for their valuable contribution to the launch of the study and its first results. Florence Francis Oliviero also assisted the authors with the definition of the best methodology for the study. We thank Antoine Lanusse for the development of the R programming (R Development Core Team) for the statistical analyses to be conducted for the RCT quantitative data. Finally, we particularly acknowledge Lucie Pariente for the coordination of the RCT.

The study was funded by the French National Research Agency (ANR; grant ANR-21-CE36-0011-02). IM was supported by the Digital Public Health Graduate Program within the framework of the PIA3 (Investment for the Future; project reference 17-EURE-0019). Further support was given by the Agence Universitaire de la Francophonie (CO//ectif; DREO-7450).

Data Availability

The text of fully transcribed interviews is available from the corresponding author upon request. Quantitative data from the first participants to the randomized controlled trial are preliminary and cannot be shared until the study is concluded.

Authors' Contributions

DL and IM conducted conceptualization and writing-reviewing. DL handled investigation. CV managed data curation and writing-original draft preparation. MH performed qualitative data curation and writing—final manuscript preparation. IM handled methodology, investigation, writing—reviewing and editing, and supervision.

Conflicts of Interest

DL is the chief executive officer of the start-up Tricky developing the game described in this paper. Results of the study are totally transparent.

Abstract

Background: Maintaining functional health, or the ability to live independently, is a primary goal of individuals as they age, but most older adults develop chronic conditions that threaten this goal. Physical activity is a key aspect of self-care that can improve functional health, and digital interventions offering guidance on appropriate exercise can help. However, older adults with multiple morbidities may be unable to use a laptop or smartphone-based eHealth because poor vision, dexterity, mobility, or other physical challenges make typing or touch navigation difficult. A smart display platform—comprising a smart speaker plus a small visual screen—has the potential to remove these barriers because it is voice-activated.

Objective: The study aims to compare usage patterns of an eHealth intervention for older adults when delivered via a voice-based smart display versus a typing-based laptop, and assess whether the smart display outperforms the laptop in improving functional health and its specific physical and mental aspects.

Methods: A minimum of 356 adults aged 60 years and older with at least 5 chronic health conditions are to be recruited from primary care clinics and community organizations. Participants will be randomized 1:1 to 12 months of access to an evidence-based intervention, ElderTree, delivered on either a smart display or a touchscreen laptop, with a postintervention follow-up at 18 months. The primary outcome is differences between groups on a comprehensive measure of physical and mental functional health. Secondary outcomes are between-group differences in the subscales of functional health (eg, physical function and depression), as well as measures of health distress, loneliness, unscheduled health care, and falls. We will also examine mediators and moderators of the effects of ElderTree on both platforms. Participants will complete surveys at baseline, 6, 12, and 18 months, and ElderTree use data will be collected continuously during the intervention period in system logs. We will use linear mixed-effect models to evaluate outcomes over time, with treatment condition and time point as between-subjects factors. Separate analyses will be conducted for each outcome.

Results: Recruitment began in July 2023 and was completed in May 2024, with 387 participants enrolled. The 12-month intervention period will end in May 2025; data collection will end in November 2025. Findings will be disseminated via peer-reviewed publications.

Conclusions: Voice-activated digital health interventions have theoretical but untested advantages over typing-based technologies for older adults with physical limitations. As the population ages, and as multiple morbidities threaten the functional health of the majority of older adults, innovations in self-management are a matter of public health as well as individual quality of life.

Introduction

Background

A key measure of the physical and mental quality of life, functional health is the ability to perform basic personal care activities as well as more complex skills such as finances, transportation, and housekeeping: in essence, the ability to maintain one's own agency [1]. Maintaining such agency, including living at home rather than in a care facility, is a primary goal of older adults [2]. Yet with age, most older adults develop chronic health conditions that erode their functional health and threaten their independence [3].

In the United States, chronic conditions such as diabetes, hypertension, and arthritis affect almost 95% of adults aged 60 years and older [4]. Among Medicare beneficiaries, about two-thirds have 3 or more chronic conditions and nearly one-fourth have 5 or more [5,6]. Treatment of co-occurring morbidities is complicated and costly given their complexity, prevalence, and ongoing nature [5,7]. For these same reasons, self-management is a vital aspect of patient care. Self-management includes skills and knowledge related to one's health conditions, attention to emotional and cognitive states, and efforts related to lifestyle factors such as nutrition and exercise [8].

In its most recent Healthy People initiative, issued every 10 years since 1980 [9], the US Department of Health and Human Services (DHHS) declared a goal of improving the health and well-being among older adults. The first objective in meeting the goal is: "Increase the proportion of older adults with physical or cognitive health problems who get physical activity" [10]. According to health guidelines established by the Centers for Disease Control and Prevention [11], a consistent regimen of strengthening, balance, and aerobic activity can help older adults "feel, function, and sleep better; stay independent and fit so [they] can complete daily tasks; improve [their] mental health; and decrease pain and improve function". Moreover, these beneficial impacts may be experienced immediately [12].

To accomplish this objective, labeled OA-01 (Older Adults-01), *Healthy People2030* recommendations include the use of digital health interventions that provide instruction and guidance in the form of "web-based interactive content" and "apps with goal-setting, activity tracking, and reminder functions" [13]. The initiative's Community Preventive Services Task Force found that appropriately tailored home-based digital interventions with exercise content improved older adults' balance, strength, and muscular endurance. In addition, people who used such interventions reported spending more time doing physical activity than they would have otherwise [14].

Digital health interventions have typically been delivered via computer websites (which require typing) or smartphone apps (which require touch navigation). Various academic and popular press accounts have suggested that smart speakers and smart displays, which also access the internet but are primarily navigated by voice rather than touch or typing, might be more accessible and appealing for older adults and others struggling with physical limitations [15-19]. Specifically, they have proposed that voice interactivity could alleviate challenges of hand tremors and vision loss and might seem more intuitive and companionable than a traditional app or website [20-22].

On the other hand, researchers have also suggested potential difficulties: age-related reductions in the volume, clarity, and pace of older adults' speech may lead the device to misinterpret their questions and commands, and hearing loss may make it challenging for some older adults to understand the device's responses [23-26]. More broadly, there is some indication that older adults may be less inclined to use technology-based interventions than to engage with traditional, in-person treatment. A 2023 meta-analysis of randomized trials of interventions for older adults' functional mobility found slightly higher dropout rates for older adults assigned to technological interventions (eg, virtual reality exergaming, wearable devices, and telerehabilitation) than those assigned to conventional in-person rehabilitation or no treatment [27].

To summarize, it remains unclear whether voice interactivity versus touch or typing delivery of intervention will be more effective for older adults and help advance the objectives for older adults' health and physical activity outlined in *Healthy People 2030*. This paper reports on the protocol of a large clinical trial comparing the effectiveness of an eHealth intervention delivered on a smart display versus a laptop.

The intervention, ElderTree, is a web-based system that aims to improve the health and quality of life of older adults by offering interactive, informational, and motivational content and services such as health tracking, reminders, and social support. Developed by our Agency for Healthcare Research and Quality Center of Excellence in Active Aging, it was first tested in a randomized controlled trial (RCT) involving a community sample of 390 participants age 65+ years who received a laptop either with or without ElderTree access for 12 months [28]. In that study, participants in the ElderTree group who reported 3 or more primary care visits in the 6 months before baseline showed significantly better results on measures of mental quality of life, social support, and depression compared to control participants. Because primary care use is relatively high among patients who are managing multiple chronic conditions, these results suggest that patients with comorbidities may be most

likely to benefit from a system such as ElderTree. A subsequent RCT testing a version of ElderTree among a clinic-based sample of older patients with at least 3 chronic conditions found socio-emotional health improvements, especially among women [29,30]. In the most recent RCT (ClinicalTrials.gov NCT04798196), ElderTree was adapted for older adults experiencing chronic pain and at least three comorbid conditions, with the primary aim of reducing pain interference. As in the current trial, participants were randomized to receive the intervention via a laptop or a smart display [31]. The outcome paper is currently in preparation.

The current study differs from the chronic pain study, by focusing on functional health among older adults with 5 or more chronic conditions. We recruited adults with an array of conditions known as metabolic syndrome (ie, vascular risk factors including hypertension, hyperglycemia, abdominal obesity, and dyslipidemia), for whom physical activity is of particular therapeutic import [32,33]. We increased the number of chronic conditions required to participate from 3 to 5. Almost a quarter (23%) of Medicare beneficiaries have 5 or more chronic conditions [34] and health risks and costs increase with the number of comorbid conditions [35,36]. As such, it is important to understand whether this sizable, high-risk, high-expenditure group is more likely to use and benefit from a voice-activated intervention for functional health, rather than a laptop version.

Study Objectives

Although voice-activated systems seem to offer an easy, engaging way to use an intervention, it is an open question whether older adults coping with multiple chronic conditions would show more sustained use of a voice-activated platform and whether this would lead to improved health outcomes. To test this hypothesis, we propose a trial comparing the text and typing-based version of ElderTree delivered on a laptop to a voice-based version delivered on a smart display. The goal is to compare usage patterns of the two platforms and assess whether the smart display version outperforms the laptop in improving our primary outcome of functional health and associated secondary outcomes.

Methods

Trial Design

This is a nonblinded, 2-arm, parallel-design randomized trial, with participants allocated 1:1 to receive ElderTree on either a voice-based smart display or a text and touch-based laptop. The intervention period is 12 months, with surveys at baseline, 6, and 12 months, and a follow-up survey at 18 months.

Sample Size and Study Setting

We planned for a minimum of 356 older adult participants to be recruited from both clinic and community settings throughout the state of Wisconsin.

Study Arms

ElderTree Via Laptop

Participants in the ElderTree via Laptop (ET-LT) arm receive a touchscreen laptop computer, access to ElderTree, and Internet service for 12 months, and continue with their usual care. They will also receive US $10 for each completed survey, for a possible maximum of US $40.

ElderTree Via Smart Display

Participants in the ElderTree via Smart Display (ET-SD) arm continue with their usual care and receive a smart display, Internet service, and access to ElderTree for 12 months. The smart display consists of a voice-activated smart speaker and a small visual display that is optionally touch-activated. They will receive US $10 for each completed survey, for a possible maximum of US $40.

Eligibility Criteria

Eligible participants must (1) be age 60 or older, (2) have at least 5 chronic conditions identified by the Centers for Medicare & Medicaid Services as prevalent among older adults [5,37], (3) among which 3 of which must be hypertension, hyperlipidemia, obesity, prediabetes, diabetes, or depression, (4) be willing to share medical record data about health care use (30-day hospital readmissions, emergency room urgent care, primary care, and specialty care visits), (5) allow researchers to share information with the patient's primary care provider, (6) have no current psychotic disorder or form of dementia, (7) no acute medical problem requiring immediate hospitalization, (8) no need of an interpreter, and (9) no physical impairments preventing use of a computer or tablet.

Recruitment

The Clinical and Health Informatics Institute at the University of Wisconsin–Madison (UW–Madison) searched clinic records from the Department of Family Medicine and General Internal Medicine system (UW Health) to identify patients meeting eligibility criteria and has sent eligible patient data (name, address, birth date, age, UW Health clinic location, primary care doctor) to the UW (University of Wisconsin) Office of Clinical Trials (OCT) via REDCap (Research Electronic Data Capture, Vanderbilt University). OCT then sent potential participants an opt-in letter describing the study, a consent form, and a stamped return letter inviting contact from the study team.

We supplemented recruitment from UW Health with additional clinic and community efforts aimed at achieving a diverse patient population. To increase our outreach to both participants of color and underserved patients, we worked with staff at Access Community Health Centers in Madison, who disseminated a recruitment flyer, consent form, and return card or opt-in to potentially eligible patients. In addition, advertisements on local television stations have been deployed in Madison, Milwaukee, Beloit, and other communities within driving distance, with specific outreach to older adults and African Americans. Last, through collaborations with leaders in the Black community, we reached out to churches, community centers, senior living communities, and other organizations, distributed a recruitment flyer and consent form with a return

card or opt-in, placed advertisements in local publications, and conducted community sessions to introduce the study and invite participation.

Finally, we sent a one-time mass email to all current UW–Madison faculty and staff with information regarding the study, asking those interested to reply via email or call for more information. We also encouraged recipients to share the email with others they believed might be interested (eg, a parent or neighbor with multiple chronic conditions).

Regardless of recruitment method, when a return card or opt-in was received or a potential participant called, study staff assessed eligibility over the phone; provided a study overview that included potential benefits and risks, study procedures, and compensation; thoroughly walked through informed consent; conducted a brief exercise screen to allow tailoring of exercise content [38]; and addressed questions. If the individual met eligibility criteria, the baseline survey was mailed; community participants also received the consent form, while clinic participants had already received it with their opt-in letter. Patients were given as much time as needed to decide whether to participate and had the option for a follow-up call after reviewing the materials. The baseline survey takes 20-30 minutes to complete. Measures are the same in both arms to avoid differential dropout. As the trial progresses, we document those who choose not to participate and why, following the CONSORT (Consolidated Standards of Reporting Trials). Patients can opt to stop their participation at any time by contacting the research team.

Randomization

The project manager used a computer-generated allocation sequence to randomize participants on a 1:1 ratio to ET-SD or ET-LT, stratified on gender (male or female), number of chronic conditions (5-7 or 8+), and recruitment site. There are 7 site variables: 3 UW Health clinics, the Access Community Health clinic site, and 3 communities (Madison, Milwaukee, and Beloit). Once an individual verbally consented, a home visit was scheduled to collect the baseline survey, randomize, determine the preferred location of the laptop or smart display, and set up the device. Staff then conducted training on the assigned intervention. If no visit was desired, equipment could be shipped after the completed baseline survey was mailed and received, and technology setup and training could be conducted by phone. The research team is available during usual operating hours for participants to contact them with questions or issues.

Once an assignment has been made, it is of course not possible to blind participants to their condition. Further, in order to set up participants on their assigned system, the researcher conducting the training also could not be blind to the condition after the assignment.

Timeline

Table 1 shows the timeline by year of the study, with year 1 beginning in August 2021 and year 5 ending in July 2026.

Table 1. Timeline of key project activities.

Activity	Timeline
Develop and test ElderTree intervention on the smart display	Year 1, months 2-11
Develop content plan for ElderTree on both platforms	Year 1, months 5-9
Prepare and finalize study and data collection materials	Year 1, months 7-9
Obtain institutional review board approvals	Year 1, month 8
Finalize data quality monitor plan	Year 1, month 9
Train research staff	Year 1, months 9-10
Recruit and randomize patients	Year 1, month 9 to year 3, month 10
Produce and manage ElderTree content for both systems	Year 1, month 9 to year 5, month 4
Collect data	Year 1, month 9 to year 5, month 4
Clean and prepare data	Year 2, month 4 to year 5, month 6
Analyze results	Year 5, months 7-10
Publish	Year 5, months 11-12

Intervention

System Overview

ElderTree is one of a suite of eHealth systems developed by our Center and collectively known as CHESS (Comprehensive Health Enhancement Support System). Like other CHESS systems, ElderTree is built on principles of continuing care and self-management, such as long duration [39], tracking [40], prompts [41], goal setting and action planning [42], problem-solving and self-tailoring [43], and social support [44]. In randomized trials, CHESS systems have significantly improved risky drinking [45]; asthma control [46]; quality of life and cost of care in human immunodeficiency virus patients [47]; quality of life and self-efficacy in breast cancer patients [48-50]; and caregiver burden, symptom distress, and median length of survival in patients with lung cancer [51]. All CHESS systems, including ElderTree, are consistent with self-determination Theory, which asserts that satisfying these 3 basic psychological needs contributes to adaptive functioning: competence (feeling effective or not overwhelmed), social

relatedness (feeling connected to others or not isolated), and intrinsic motivation (feeling autonomous about behavioral changes or not coerced) [52].

ElderTree is a multifaceted system focused on older adults' physical and mental health and quality of life. As reported in earlier ElderTree studies [28-30], the laptop system is a members-only website free of ads, with design features based on older users' feedback and best practices for older populations (eg, larger fonts or uncluttered screens) to optimize comprehension, navigation, and usability [53]. The ET-SD version follows these usability principles as well. Both systems substantially replicate ElderTree as described in an earlier study comparing ET-LT to an attention control [29,30], with modifications and enhancements to focus on the functional health of individuals with multiple morbidities and to align with the technical capabilities of the smart display platform.

System Content

ElderTree offers video content in the areas of functional movement, information and advice, mood and mental health, and entertainment, as well as social engagement and health tracking features. Video content is both originally produced and curated from high-quality external sources. Descriptions of each feature or function are listed in Table 2, and the home screen organization for both platforms is shown in Figure S1 in Multimedia Appendix 1: ElderTree screens and physical activity decision tree.

Table 2. Key features of the ElderTree eHealth intervention.

Feature or function	Description
"Let's Move" videos	Functional movement videos, in 3 assigned ability groupings based on participants' physical health screening and doctor approval.
"Tips & Info" videos	Short, practical information and advice on a wide range of topics related to physical and mental health (eg, "How Blood Pressure Works", "Finding Friends as an Older Adult", "Easy Ideas for Healthy Eating").
"Relax & Inspire" videos	Meditation, relaxation, and breath work videos for sleep, reducing stress, creativity, and more.
"Just for Fun" videos	Humor, music, and human interest are for pleasure (this content is located in "Relax & Inspire" on the smart display platform).
CalmConnect multisensory videos [54]	Program of short practice videos that combine rhythm, hand movement patterns, and facial expression cues, engaging the user physically, cognitively, and emotionally with the goal of strengthening social connectivity and mental health.
Wednesday Meetup	One-hour weekly facilitated group video meeting with a topic presentation (eg, balance, falls, and vision health) and small breakout rooms for socializing.
Weekly Survey	Tracking of 10 self-reported general health indicators (eg, sleep, mood, exercise), with results presented in graph form over time.
Thought of the Day	A new motivational or inspirational quote delivered daily at with the user's first visit to the intervention.
Prompts	Reminders to take the weekly health tracking survey; notifications of new content.
Featured content	On the home screen, new and existing content is highlighted to encourage exploring services and resources, and is continually rotated to keep ElderTree fresh.
Favorites	Bookmarking and retrieval feature.
System tutorials	Instructional videos for accessing ElderTree features and content.

The critical physical exercise content is located in ElderTree's "Let's Move" area, offering videos targeting balance, strength, endurance, and flexibility. After randomization, participants in both conditions were placed in one of three activity-level groups on the basis of their responses to the Exercise and Screening for You (EASY) Tool [38] and approval from their primary care physician (PCP), to ensure safety and accessibility. Figure S2 in Multimedia Appendix 1 shows the decision tree for assigning each participant to their group within the study arm. The three groups are as follows:

1. Group 0: restricted based on the EASY Tool and do not have approval from their PCP to use standing activity content on ElderTree. The fitness activities available to them are limited to gentle seated movements for coordination, dexterity, and mental stimulation (eg, "Wake Up Your Brain"). Also, in Let's Move, Group 0 has access to an 8-module course on managing chronic pain, developed by our research team.

2. Group 1: restricted based on the EASY Tool, but their PCP has given approval to engage in supported standing activities. For this group, we developed a collection of instructional and practice videos with a geriatrician expert in functional movement for older adults who have health conditions. The videos are available in all areas of fitness: balance, flexibility, strength, and endurance. Group 1 participants must view a safety video for each of the 4 fitness categories before access to the movement videos is unlocked. Group 1 also has access to all Group 0 content.

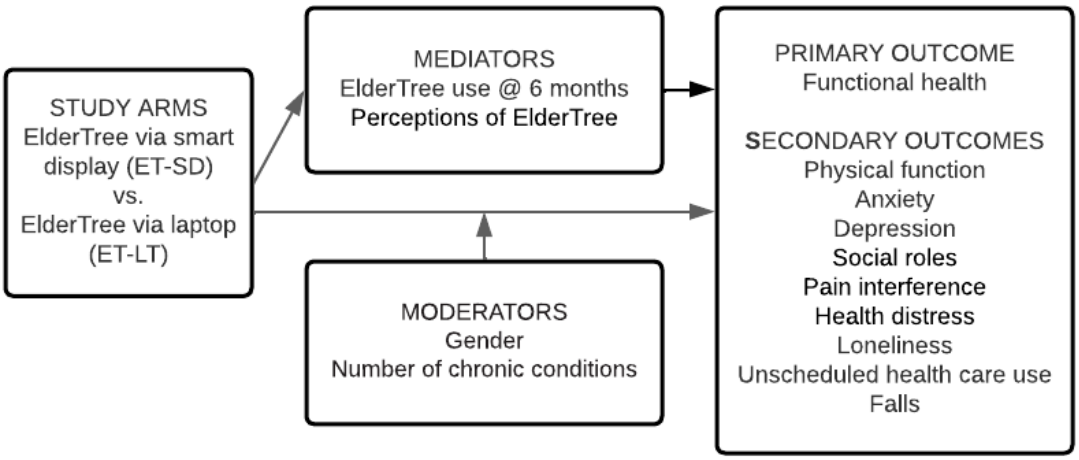
3. Group 2: no restrictions, based on the EASY Tool, and may use all the movement videos on ElderTree after viewing the safety videos in each of the 4 fitness categories. The Group 2 content includes all activities available to Groups 0 and 1, as well as videos provided by outside experts in fitness and functional movement for older adults. These externally sourced videos have been vetted by the study's geriatrician for safety, suitability, and quality. Playback times and challenge levels are

indicated in every video title to enable users to self-tailor their selections on any given day.

Outcomes

The primary outcome is differences between groups over time in functional health, a multifaceted variable that includes physical function, pain interference and intensity, fatigue, sleep disturbance, anxiety, depression, and satisfaction with one's social roles and activities. To tease apart these elements, the secondary outcomes include the functional health subscales of physical function, pain interference, anxiety, depression, and social role satisfaction. Additional secondary outcomes are health distress, loneliness, unscheduled health care use, and falls. Figure 1 diagrams the study logic.

Figure 1. Study logic.



Measures

Primary Outcome

The 29-item PROMIS (Patient-Reported Outcomes Measurement Information System)-29 v2.1 is used to measure functional health [55]. Items tapping physical function, pain interference with aspects of daily life, anxiety, depression, ability to participate in social roles and activities, fatigue, and sleep disturbance are scored on 5-point Likert scales, while a single 11-point item (range=0–10) rates pain intensity. The possible ranges, scored by providers of the measure [56], are 21.2–67.6 for a social-emotional cluster and 16.2–67.7 for a physical cluster of functional health, with higher scores indicating better functioning.

Secondary Outcomes

We are using PROMIS-43 v2.1 subscales to separately assess physical function, pain interference, anxiety, depression, and satisfaction with social roles and activities [57]. For each subscale, participants respond on a 5-point (1-5) Likert scale to 6 items modified from occurring "currently" to "in the past 7 days," for consistency with other survey items. For the physical function items (eg, "Are you able to go for a walk of at least 15 minutes?"), higher scores indicate poorer function (total possible range=22.9-56.9). For pain interference (eg, "How much did pain interfere with the things you usually do for fun?"), higher scores indicate greater interference (total possible range=41.6-75.6). Anxiety items include "I felt nervous" and "My worries overwhelmed me"; higher scores indicate greater anxiety (total possible range=40.3-81.6). Depression items include, "I felt like a failure" and "I felt unhappy"; higher scores indicate more depression (total possible range=41-79.4). For social roles items (eg, "I have to limit my regular activities with friends"), higher scores indicate more difficulty or limitation (total possible range=29-64.1).

Health distress is measured with the 4-item Lorig Health Distress Scale [58,59]. Sample items are how often in the past month a participant has been "discouraged by your health problems" and "fearful about your future health." Higher scores on the 6-point (0–5) Likert scale indicate greater distress. The total possible score is the mean of the 4 items (range=0 5).

Loneliness is assessed with the 5 Loneliness scale items in the NIH Toolbox Social Relationship scales item bank v2.0 [60]. Sample items include how often in the past month a participant has felt "alone and apart from others" and "left out". Scores are calculated by the scale developer; the possible range=37–85, with higher scores indicating greater loneliness.

For unscheduled health care visits, participants will report at each survey time point their number of urgent care clinic visits, emergency room visits, and overnight hospital stays in the past month.

The number of falls in the past 6 months, as well as the number requiring medical attention, will also be surveyed at each time point. A fall is defined in the survey as "when your body goes to the ground without being pushed."

Measures for all planned outcomes and their psychometrics are presented in Table 3.

Table 3. Outcome measures, the number of survey items, and psychometrics.

Variable	Measure	Items, n	Psychometrics
Primary outcome			
Functional health	PROMIS[a]-29 v2.1	29	α≥.94 [55]
Secondary outcomes			
Physical function	PROMIS-43 physical function subscale	6	α>.9 [57]
Pain interference	PROMIS-43 pain interference subscale	6	α>.9 [57]
Anxiety	PROMIS-43 anxiety subscale	6	α>.9 [57]
Depression	PROMIS-43 depression subscale	6	α>.9 [57]
Social roles	PROMIS-43 social roles subscale	6	α>.9 [57]
Health distress	Lorig Health Distress Scale	4	α>.87 [58]
Loneliness	NIH Toolbox	5	α≥.93 [60]
Number of unscheduled health care visits	N/A[b]	3	N/A
Falls	N/A	2	N/A

[a]PROMIS: Patient-Reported Outcomes Measurement Information System.

[b]N/A: not applicable.

Mediation, Moderation, and Covariates

We will test whether functional health at 12 months is mediated by participants' amount of ElderTree use and perceptions of ElderTree at 6 months. ElderTree use will be assessed via continuously collected system data. For perceptions of ElderTree, participants rate 18 items (eg, "It is easy to use," "It helped me learn more about my health issues") on a 4-point (1-4) Likert scale and answer 6 open-ended questions (eg, "What stopped you or hindered you from using ElderTree or the computer or smart system in general?"). We will also examine possible moderation due to gender and the number of chronic conditions at baseline. Finally, as potential covariates we will test baseline race and ethnicity, education level, and barriers to technology due to physical limitations (eg, vision or hearing challenges); those that significantly predict our primary outcome will be included in the final analysis.

Power Analysis and Sample Size

The primary hypothesis is that the intervention modality (voice activation vs typing and touching) will affect functional health. Based on PROMIS validation studies (eg, chronic pain, arthritis, and cancer), a difference of 3 points or more between study arms is considered to indicate a clinically meaningful difference [61]. The PROMIS website also gives the mean and SD of the T-score metric (mean 50, SD 10). Power calculations for this primary hypothesis were performed using the SAS procedure PROC GLMPOWER (SAS Version 9.4) [62]. Results indicated that 282 participants after attrition would be needed for 80% power (P<.05) to observe a difference score of 3 points between the two study arms at 12 months. In our original ElderTree study, 79% of the sample completed the 12-month survey [28], and in the subsequent study, 92% of participants did so [30]. We based our sample size on the more conservative numbers from the original study and planned to recruit a total of 356 participants, or 178 per arm, to achieve 282 after attrition.

With regard to power for moderation analyses, we ran a sensitivity analysis to compute the smallest effect size our study would be powered to find using 280 given 4 groups (eg, 2 study arms × 2 genders). With N=280, G*Power calculations [63] show our study would have a 95% chance (with P<.05) of observing a moderation effect as small as a Cohen d of 0.22.

Data Collection

Patient Surveys

Patients will complete surveys at baseline, 6, 12, and 18 months. Baseline surveys were collected at training and setup, and subsequent surveys will be mailed to patients with a return stamped envelope. Participants are encouraged to contact the study staff if questions arise. All 4 surveys will assess primary and secondary outcomes using the measures detailed above. At 6, 12, and 18 months, participants will also respond to the checklist of chronic conditions used for eligibility screening as well as answer items assessing their perceptions of the intervention. Demographics were gathered only at baseline.

ElderTree System Data

ElderTree usage data are automatically and continuously collected in time-stamped log files, including logins, services used, pages accessed, and weekly surveys completed.

In addition, data are collected from the weekly survey of self-rankings for medication adherence, falls, thinking and memory, mood, healthy meals, snacks and drinks, physical activity, quality time with others, sleep, pain, and balance.

Retention

We are promoting study retention by providing telephone and email support for patients' use of the technologies and by following up with patients to encourage them to return surveys. If a survey is not returned within 2 weeks, a research team member will call to check that the survey was received and

encourage the patient to complete and return it in the provided envelope. The date and time of the phone call will be recorded in REDCap, along with whether the researcher talked to the participant directly (vs left a message) and any information gathered during the conversation. If we cannot reach the participant, another copy of the survey will be sent with a personal note asking them to complete it or call us on our toll-free number if they have questions or are no longer interested.

Data Quality and Management

Surveys comprise standardized measures that have been validated for older adults. In addition, the following strategies, developed during our previous large RCTs with this population, are implemented to reduce errors and missing data: (1) surveys are sent via hard copy, with paid return envelopes; (2) visual formatting is simple and clear, in large print on uncluttered pages; (3) tables of items and response options are designed with line-by-line alternate shading for easy tracking; and (4) instructions are explicit as to how participants should respond if they feel a question does not apply or they do not know the answer. Participants are encouraged to call in with questions. Once a survey is returned, trained research staff will evaluate it within a week of receipt; if data issues are found (eg, missing responses, multiple responses to a single item), staff will contact the participant to resolve the error.

To mitigate the risk of breaches in patient confidentiality, all participants are assigned a unique code number. Participant contact information and survey data are housed electronically in REDCap. Survey data are double-entered by two different individuals to ensure accuracy. Paper files are stored in a locked room in locked cabinets and can be accessed only by authorized personnel. The database administrator provides access to study data at appropriate levels for various members of the research team.

Statistical Methods

Predictor and Outcome Assumptions

Participants were assigned at random, with constraints that study arms would have roughly equal proportions for key covariates (eg, race, education, baseline number of chronic conditions). The effect of key covariates on outcomes will be assessed for each model. We will assess whether there are main effects of recruitment sites or interactions with the study arm (ie, whether data can be pooled across sites). Variables will be examined using standard summary statistics, visualizations, and tests for normality and homoscedasticity. Data will be transformed as needed.

Missing Data

With regard to survey data, in the previous ElderTree RCT of older adults coping with at least 3 high-risk chronic conditions, 320 of 344 participants (93%) completed the 6-month survey, 309 (89.8%) completed the 12-month survey, and 298 (86.6%) participants completed the 18-month survey [30]. In completed surveys, data were missing on about 2% of core items. Occasional out-of-residency time is also expected for participants (eg, travel and hospitalizations). We encourage patients to take the intervention with them when possible, but absences without ElderTree will be addressed as covariates in our outcome models.

We expect rates of missing data in this study to be similar to those reported above for the ElderTree RCT. We will report rates of missing data by study arm and time point. We will also use logistic regression to predict missing data as part of our evaluation of missing data patterns.

Effects of Study Arm on Outcomes

Primary and secondary outcomes will be analyzed using an intention-to-treat approach that includes all observed data from all participants who were randomized to a study arm. These analyses will follow a model-based approach that assumes missing data for outcomes at specific time points are missing at random (MAR) [64]. Specifically, a linear mixed model [65-68] will be used to examine the effects of the study arm (ET-SD vs ET-LT, a between-subjects factor) on the primary outcome, functional health, over time. Linear mixed models will also assess the effects of the study arm on each of the secondary outcomes over time (ie, an interaction of the between-subjects factor of the study arm and the within-subjects factor of time of measurement). Count variables that lack sufficient variability to be treated as count data (negative binomial distribution) will be treated as dichotomous variables and run using a binomial distribution in the linear mixed model.

Supplemental sensitivity analyses [69] will also be conducted to assess the robustness of conclusions to our assumption that missing data are MAR. Specifically, we will use comparable linear mixed-effects models to examine the effects of the study arm using only complete cases, as would be appropriate if data were missing completely at random. To address the possibility that the data are missing not at random, we will use both the Diggle-Kenward approach (which assumes that dropout is a function of time-specific outcomes) and the Wu-Carroll approach (which assumes that dropout is a function of one's developmental trajectory) [66-68,70].

Mediation of Effects of Study Arm on Primary Outcome

We predict effects of the study arm on functional health will be mediated by the amount of ElderTree use and perceptions of ElderTree at the 6-month midpoint. We will use structural equation modeling with separate models for the social-emotional and physical components of functional health.

Moderation of Study Arm on Primary Outcome

We predict that the effects of the study arm on functional health will be moderated by gender and the number of chronic conditions at baseline. We will use linear mixed models, testing each moderator separately, to examine the moderator-by-arm interaction while accounting for time.

Ethical Considerations

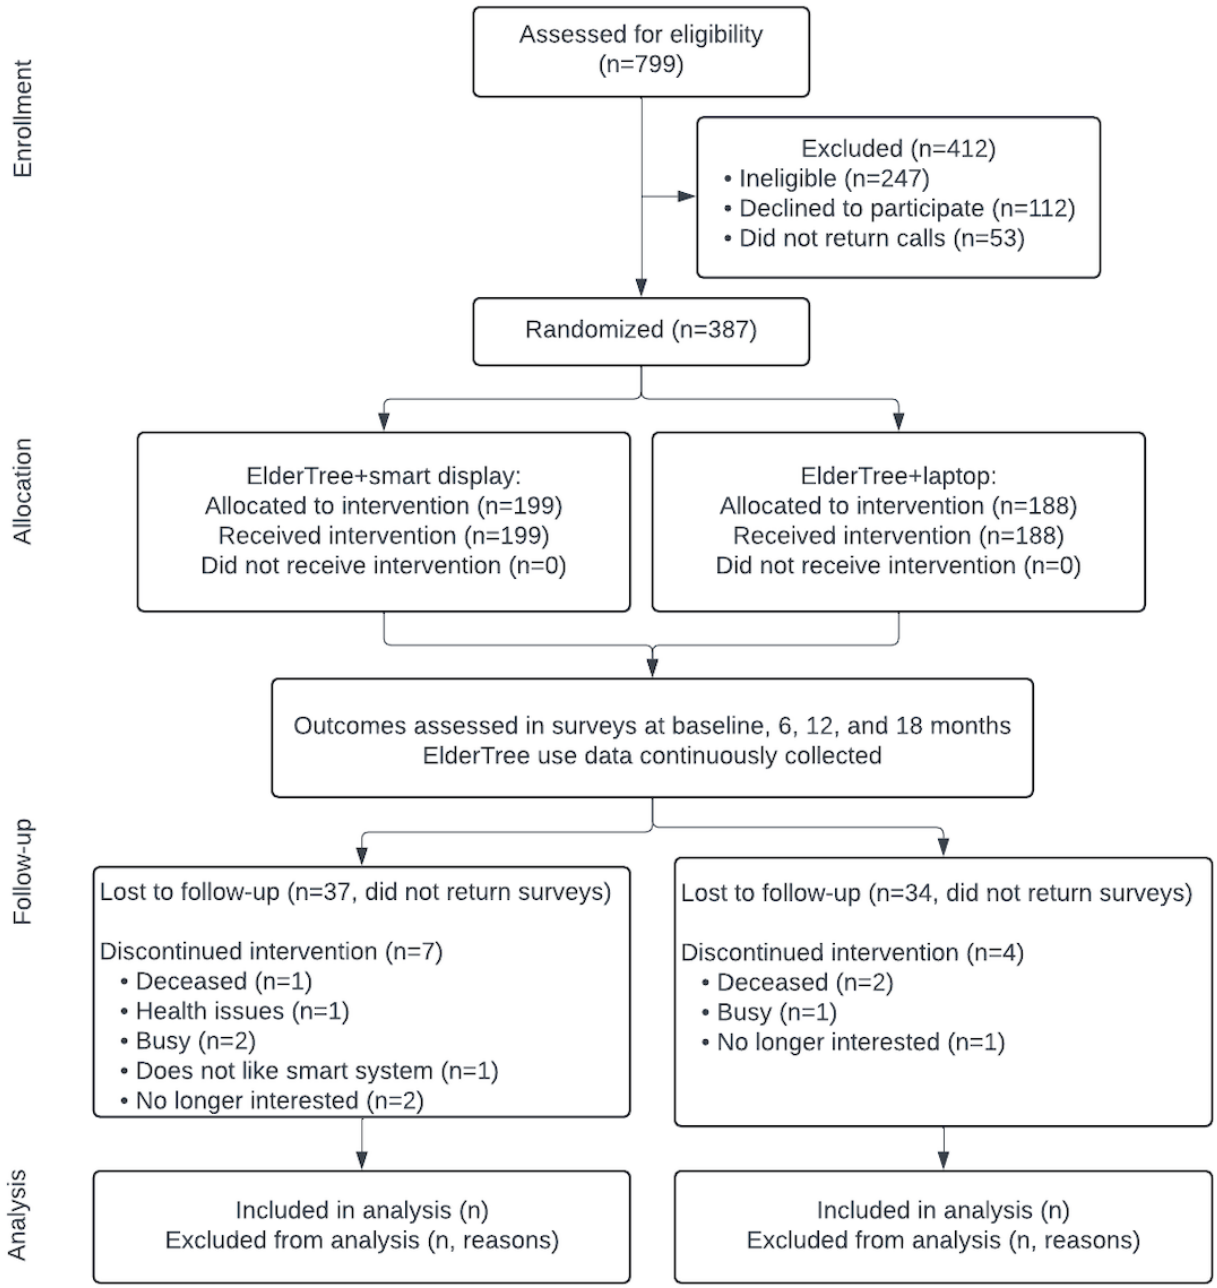
This study protocol received ethical approval from the University of Wisconsin Health Sciences and Minimal Risk Research institutional review board (reference number 2020-0984) and has been registered at ClinicalTrials.gov (NCT05240534). Consent forms were mailed to potential participants and research staff walked through informed consent

over the phone. Participation was voluntary and participants could opt out at any time. Only a small number of research staff has access to patient data and all outcomes and usage data are deidentified. Participants were paid US $10 for each outcome survey completed and received a free laptop or smart display and internet service for 12 months if needed.

Results

As of May 2024, a total of 387 new participants have been enrolled, concluding recruitment 2 months earlier than originally scheduled. The 12-month intervention period will end in May 2025, and data collection will end in November 2025. Findings will be disseminated via peer-reviewed publications. Figure 2 shows the status of participants throughout the trial. Interim numbers are shown in the Follow-up section, as the intervention and data collection are not yet complete. The final numbers for the Analysis section will be reported in the main outcome publication.

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) flow diagram.



Discussion

Anticipated Findings

The central question of this study is whether a voice-activated smart system will be better than a laptop for delivering an intervention for functional health to older adults with ≥5 chronic conditions. The prediction is that those randomized to access the intervention via a voice-activated smart display will show more use of the intervention than those randomized to access it via a laptop and that greater use will lead to more positive

change over time in the primary and secondary health-related outcomes.

Few studies thus far have rigorously tested smart displays as a platform for health interventions for older adults. A 2024 scoping review found 22 studies (published between 2010 and 2022) examining community-dwelling older adults' use of personal voice assistants [26]. The overall conclusion was that many older adults found the devices convenient and easier to use than a computer for basic tasks like reminders or checking the weather, but they sometimes struggled to make themselves understood or to remember the necessary commands. As the authors noted, all of these studies were exploratory, and none examined effects on quality of life or health-related outcomes.

Since then, 2 studies have examined socio-emotional outcomes of older adults' uses of smart devices, but one lacked any comparison group (examining pre-post changes only) [71], and the other compared a smart speaker (audio only) versus a smart display (audio + screen) [72]. While both found that frequent use of smart systems was associated with positive socio-emotional changes (eg, reductions in loneliness), it is possible the same changes would have occurred with laptop use. A third, nonrandomized study examined whether a smartphone health intervention for older adults would be more effective if participants agreed to add a smart speaker with extra functions (eg, medication reminders, exercise programs, quizzes) [73]. There were no differences between the 2 self-selected groups in changes over time in depression or 5 of 6 health outcomes; only dietary diversity showed greater improvements in the group that agreed to have the smart speaker as well as the smartphone.

In sum, despite claims about the possibility that voice interactivity may increase the accessibility and effectiveness of health interventions for older adults, our project is one of the first randomized trials comparing a smart display versus a laptop for delivering an intervention for older adults, who face complex health challenges. As in any study, there are strengths and limitations.

The first strength lies in the methodological rigor involved in a randomized trial that followed 356 older adults over 12 months with a postintervention follow-up at 18 months. Another strength is that we can gather objective, ongoing data about participants' uses of the intervention, rather than relying on their recollections. Next is our recruitment of older adults with 5 or more comorbid conditions, given the need for effective interventions that will engage this sizable, high-risk population. In addition, the focus on functional health is a core determinant of older adults' ability to remain independent.

There are also a number of limitations. One is that this iteration of ElderTree, like those that came before it, was developed before the widespread availability of large language models and artificial intelligence (AI) interactivity. Although participants can interact with ElderTree on the smart speaker by voice, they must do so using specific commands, rather than the intuitive, conversational exchanges now made possible by AI. A second limitation is the absence of a randomized control group that does not receive access to ElderTree: we prioritized adequate power to detect a difference between the 2 intervention groups but will not be able to assess whether both improve outcomes relative to treatment as usual. Next is that we rely on participants' perceptions of their functional health, rather than using clinical data or direct assessment of their functional movement. We regard these limitations as invitations for further research, particularly research that would probe older adults' uses and responses to digital devices that are much more interactive and responsive to voice commands, given AI advances.

Conclusion

Whether the theoretical advantages of voice activation translate to improved effectiveness of eHealth interventions has yet to be determined. Although technologies are constantly developing, the issue of talking versus typing for health interventions for older adults is fundamental and supersedes specific devices. In this way, if ElderTree on the smart display does outperform the laptop in terms of use and health-related outcomes, this would have important implications for the design of future health interventions for this population.

Acknowledgments

This project was funded by a grant (4R33HL151870-02) from the National Heart, Lung, and Blood Institute, and supported by the Clinical and Translational Science Award (CTSA) program through the National Institutes of Health's National Center for Advancing Translational Sciences grant (UL1TR002373). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health. The authors wish to thank the research and technology staff at CHESS for their care and dedication regarding all aspects of this project: Kaitlyn Brown, Lynne Cotter, Dave Gustafson Jr, Hannah Lehr, Adam Maus, Sam Nowak, Sydney Saunders, Jen Stoughton, Kasey Thompson, Olivia Vjorn, Judy Woodburn, Katherine Wright, and Matthew Wright.

Data Availability

Following the completion of the final analysis, the datasets generated or analyzed during this study will be available from the corresponding author on reasonable request.

Conflicts of Interest

DHG Sr. has a small shareholder interest in CHESS Health, a corporation that develops health care technology for patients and family members struggling with addiction; this relationship is managed by DHF Sr and the University of Wisconsin–Madison's Conflict of Interest Committee. The authors have no other conflicts to report.

Abstract

Background: While access to pre-exposure prophylaxis (PrEP) is an important tool for reducing HIV incidence in the United States, disparities in uptake by race, sex, socioeconomic status, and geography persist. In 2018, the US South accounted for more than half of all new HIV diagnoses but only one-third of PrEP users. PrEP use in North Carolina (NC) similarly lags, with uptake being the lowest among young, sexual and gender minority populations, who account for nearly two-thirds of the state's incident infections. The PrEP-to-need ratio, a metric of PrEP equity that measures PrEP uptake relative to new HIV diagnoses, highlights disparities in PrEP uptake among specific demographic groups such as women and Black, Hispanic, and Southern people, indicating that these groups are underserved relative to their epidemic need. Despite behavioral risk overlap of incident sexually transmitted infections (STIs) and HIV, in NC, PrEP is only offered at a few primarily urban health department–affiliated STI clinics. The lack of robust health care infrastructure in these areas presents challenges for HIV prevention services.

Objective: This protocol describes a randomized controlled trial of a multilevel PrEP intervention recruiting from rural and periurban STI clinics.

Methods: This trial aims to enroll up to 336 participants and randomly assign them 1:1 to either the intervention or control group. The intervention consists of access to a digital health app, linkage to a remote PrEP navigator, and the option of referral to telehealth-based PrEP services. Persons randomly assigned to the control condition will receive an enhanced standard of care, including access to a limited version of the digital health app. All participants will be followed up on quarterly for at least 3 months. The primary outcome is the initiation of PrEP within 3 months of an index STI clinic visit; secondary outcomes evaluate PrEP care engagement and adherence, incident HIV and bacterial STI infections, PrEP stigma, and cost-effectiveness. Binary outcome analyses will estimate the proportion of participants achieving an event (eg, PrEP uptake) in each arm and a probability difference and the corresponding 95% CI to compare the intervention versus control arm at each time point. Continuous end points will use nonparametric Wilcoxon rank sum tests comparing the intervention and control groups.

Results: Enrollment opened on August 31, 2023, at 15 health departments in NC and subsequently expanded to 21 facilities in 20 counties by July 2024. Completion of the enrollment and data collection phases is expected by May 2025. Results will be published thereafter.

Conclusions: This study directly addresses multiple barriers to PrEP use in rural and periurban areas of the Southeastern United States and can inform policy and programming that seek to expand PrEP access and promote use in underserved communities.

Introduction

Background

To meaningfully reduce HIV incidence, the United States needs integrated, scalable, and cost-effective prevention strategies. Despite the high efficacy of HIV pre-exposure prophylaxis (PrEP), only approximately one-third of PrEP-eligible people nationwide have received a prescription for PrEP; regional and racial disparities have been well characterized and mirror similar disparities in HIV care [1-5]. In 2021, the US South accounted for 52% of new HIV diagnoses but only 38% of PrEP users [6-8]. Coverage of those assigned male sex at birth with PrEP indications was reported by the Centers for Disease Control and Prevention (CDC) as 41% in 2022 but only 12.8% among Black and African American individuals [5]. In North Carolina (NC), the state-level PrEP coverage estimate is 30%, which belies the wide variability from urban to rural areas [9]. Indeed, in NC, where an estimated 1 in 112 residents will acquire HIV in their lifetime [10,11], PrEP use remains below the US average [6,11]. Similar to other states in the Southern region, PrEP uptake is lowest among young, sexual and gender minority men, who account for 76% of new HIV infections in NC [12]. Among the 15 NC counties with the highest rate of HIV diagnoses [13-23], 6 have nonmetropolitan designation, and 8 are small or medium metropolitan areas [12,24]. The lack of a robust health care infrastructure, including scarce HIV care providers, in these areas presents challenges for the sustainable expansion of HIV prevention services.

Similarly to most of the United States, NC's HIV statistics track alongside those of sexually transmitted infections (STIs) [13], with a disproportionately high burden among rural, young, sexual and gender minority men. Previous studies have demonstrated the potential role of STI clinics as effective PrEP linkage sites but have been limited to urban settings [14-23,25]. Despite behavioral risk overlap of incident bacterial STIs and HIV, PrEP is only offered at a few primarily urban health department–affiliated STI clinics in NC [26,27]. STI clinics are a logical entry point for PrEP services, but ineffective integration in rural STI clinics reflects heterogeneity in clinic structure and staffing—PrEP services require additional human resources and longitudinal engagement to be effective [28]. Leveraging STI clinics as an on-ramp to PrEP presents a compelling opportunity to capitalize on STI service encounters and address disparities in PrEP access for rural residents [15-17].

Multilevel impediments to PrEP scale-up in rural NC include provider shortages, intersectional stigmas, and lack of PrEP knowledge among providers and patients [29-33]. These challenges are compounded by poverty and incomplete insurance coverage of PrEP and PrEP services [34,35]. Building on collaborations with state and local partners, we will implement a multilevel intervention in partnership with rural county health departments and health care organizations that links PrEP and STI services to address PrEP use barriers while working within clinic operational limits and competing demands on physical and human resources. This intervention combines multiple evidence-based interventions, including PrEP navigation services [36-38], access to a digital health platform (HealthMpowerment) [39-42] that connects users to tailored social and informational support for PrEP initiation and persistence [43,44], and referral to telehealth PrEP services [45-48].

Research Aims

Our objective is to determine the effectiveness and cost-effectiveness of the proposed PrEP linkage strategy in 2 aims. Our primary effectiveness outcome is PrEP uptake within 3 months of an STI clinic visit, defined as confirmed receipt of PrEP prescription or evidence of detectable tenofovir diphosphate in the blood, evaluated through a randomized controlled trial (RCT). Secondary outcomes evaluate PrEP uptake within 6 months of an STI clinic visit, 3- and 6-month PrEP care engagement and adherence, incident HIV or STI infections, and PrEP stigma.

We will examine implementation outcomes as exploratory outcomes, capturing process indicators, including intervention costs, fidelity, and acceptability, to inform future refinement. We will use decision analytic modeling to determine the cost-effectiveness of the proposed intervention over a range of assumptions and inputs, as well as developing a budget impact analysis. Specifically, intervention effectiveness and prospectively collected cost data will be used to model cost per new PrEP initiation. Budget impact analyses will identify drivers of cost, informing strategy refinement for program staffing and scale-up.

This project is supported via a milestone-based funding mechanism, wherein if predefined effectiveness, implementation, and development milestones are met within the initial phase, we will pursue a second phase, in which we will use intervention mapping to refine the proposed strategy and expand implementation in a nonrandomized fashion with updated cost-effectiveness modeling. The second phase is not described further in this paper as the development and finalization of that protocol are dependent on this trial's outcomes.

This trial has been registered with ClinicalTrials.gov (NCT05984030), which includes reporting of all relevant items

from the World Health Organization Trial Registration Data Set.

Methods

Protocol Adaptations

We present our methods according to 2 participant recruitment stages: stage I, which focused exclusively on young, sexual and gender minority men seeking STI services from health department–affiliated STI clinics, and stage II, which reflects an amended protocol with modifications made in response to participant enrollment challenges and feedback from collaborating sites. Changes in stage II of protocol implementation include (1) expanding collaborating sites beyond the initially identified 15 health department–affiliated STI clinics, (2) offering a US $5 incentive for completing the brief screening questionnaire, (3) shortening the follow-up period to 3 months for participants enrolled in the final quarter of the study recruitment period, and (4) expanding eligibility criteria to include women assigned female at birth.

Expanding to women more closely aligns with 2021 CDC recommendations, including discussing PrEP with all persons with an STI in the previous 6 months, and reflects the evolving focus on PrEP for women put forth by the CDC, particularly racial minority women in the Southeastern United States. Among new HIV cases in women in the Southern region of the United States, Black women account for 67% of new HIV infections and 72% of new diagnoses among women reporting heterosexual sex [49]. Increasing PrEP use among cisgender women has the potential to significantly impact the spread of HIV in rural and periurban NC and contributes to a broader public health strategy aimed at reducing new HIV infections across various demographics. To explore the potential for our intervention to expand PrEP care to a broader population in NC, we conducted a change in scope that adapted our eligibility criteria to encompass women.

Study Design (Stage 1)

This RCT of a multilevel PrEP intervention strategy will open with recruitment of those assigned male sex at birth seeking sexual health services from rural and periurban NC STI clinics (Figure 1). Participants are randomly assigned 1:1 to the intervention or control condition. All participants regardless of study arm complete study measures and activities at enrollment and the 3- and 6-month follow-up time points, with a subset of participants enrolled in the first 6 months of recruitment also completing a 12-month follow-up assessment (Table 1). The timing of participant follow-up activities mimics the CDC-recommended frequency of testing, which includes screening for bacterial STIs every 3 months among men who have sex with men or among patients with ongoing risk behaviors [50,51]. Therefore, HIV and STI testing will be completed as part of patients' routine care at established STI clinics (not administered through this study). The HealthMpowerment app and study staff will help facilitate participants' return to the STI clinics for HIV and STI testing by providing in-app appointment reminders, SMS text messages, and phone calls as needed. Quarterly surveys will assess participants' adherence to CDC-recommended testing frequency.

Cost data and implementation outcomes are collected throughout study implementation examining organization-level determinants of success via surveys and in-depth interviews with participants, clinic staff, health care providers, and other key stakeholders for PrEP expansion.

Figure 1. Study schema—aims 1 and 2, years 1 to 3. PrEP: pre-exposure prophylaxis.

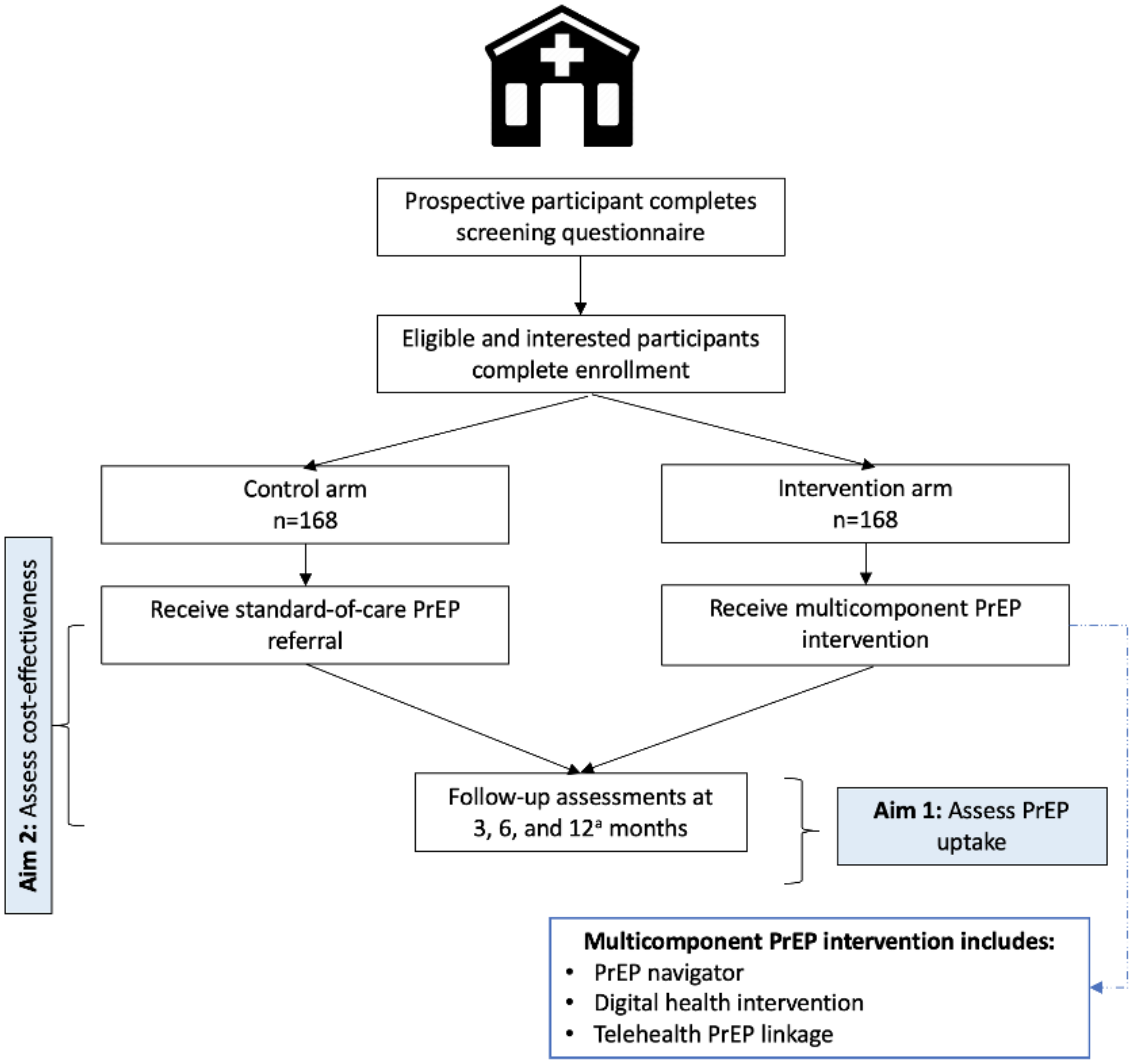

Table 1. Participant assessment timeline.

	Screening	Baseline	3-month follow-up	6-month follow-up	12-month follow-up
Screening questionnaire	✓

[a]HIPAA: Health Insurance Portability and Accountability Act.

[b]CASI: computer-assisted self-interview.

[c]Participants enrolled in approximately the final quarter of study enrollment will only be followed up on for 3 months.

[d]Only applies to participants who enroll during the first 6 months of study recruitment.

[e]DBS: dried blood spot.

[f]A subset of up to 50 participants will complete an in-depth interview following their 3- or 6-month study visit.

Study Design (Stage 2)

The updated study design incorporates a shortened follow-up period to extend the enrollment window, allowing for a greater number of participants to contribute to the primary outcome of PrEP uptake assessed at 3 months. Randomization and intervention procedures remain unchanged, and study measure assessments are completed at baseline and 3 months (Table 1).

Eligibility

For stage I, RCT-eligible participants must (1) be assigned male sex at birth, (2) report sexual activity with a male individual in the previous 12 months, (3) report recent HIV testing (within the previous 90 days) and not be known to be HIV positive at screening or enrollment via self-report, (4) be aged 18 to 39 years, (5) have daily smartphone access, (6) be English speaking, and (7) deny recent PrEP use (defined as not having taken oral PrEP or received injectable PrEP within the previous 90 days).

For stage II, the eligibility criteria were updated to reflect the eligibility of persons regardless of sex assigned at birth. All other eligibility criteria from stage I remain unchanged.

We will also conduct qualitative interviews with up to 50 clinic staff members, providers, and other relevant stakeholders for PrEP provision or relevant to the proposed intervention. Interviewees will be purposively sampled to ensure a diversity of clinic roles and responsibilities relevant to STI and sexual health services and referrals, diversity in leadership level, and representation across all participating clinics.

STI Clinic Selection

We initially identified 15 health department–affiliated STI clinics in relatively high–HIV burden, rural, or periurban counties across NC. Counties were selected in coordination with partners in the NC Department of Health and Human Services using county-level 2019 to 2021 HIV and STI data (reported to the State Laboratory of Public Health). Specifically, we examined HIV and STI testing volume and test positivity rates by reported race or ethnicity among men aged <40 years, prioritizing counties with higher rates of HIV and non-HIV STIs ranked by county without a predefined cutoff. We also reviewed the National Center for Health Statistics urban-rural classification scheme focusing on rural counties, as well as those designated as small (<250,000) or medium (<1 million) metropolitan areas [45-47]. We refer to all locations where STI services are offered as *clinics* or *STI clinics*; however, these locations may also include extensions of clinic services, such as mobile testing or service delivery within other outreach events.

Clinics were contacted with information about the study and an invitation to participate. The study team met with clinics who responded; clinics that decided to participate provided signed letters of support indicating commitment to collaborate and outlining expected roles and responsibilities. At the time of study launch, none of the initial 15 participating STI clinics offered PrEP navigation services or had “in-house” providers prescribing PrEP. Only 7% (1/15) of the participating clinics offered referral to a colocated primary care clinic that could prescribe PrEP. Of the remaining 14 initial collaborating clinics that did not offer in-house PrEP services, a minority provided patients with passive referral to services in the community (eg, the clinic shared the name or names of private practice providers that may offer PrEP services). Starting in March 2024, a total of 6 more clinics were added as collaborating sites under protocol version 3.0. None of these clinics offered PrEP navigation services or had “in-house” providers prescribing PrEP.

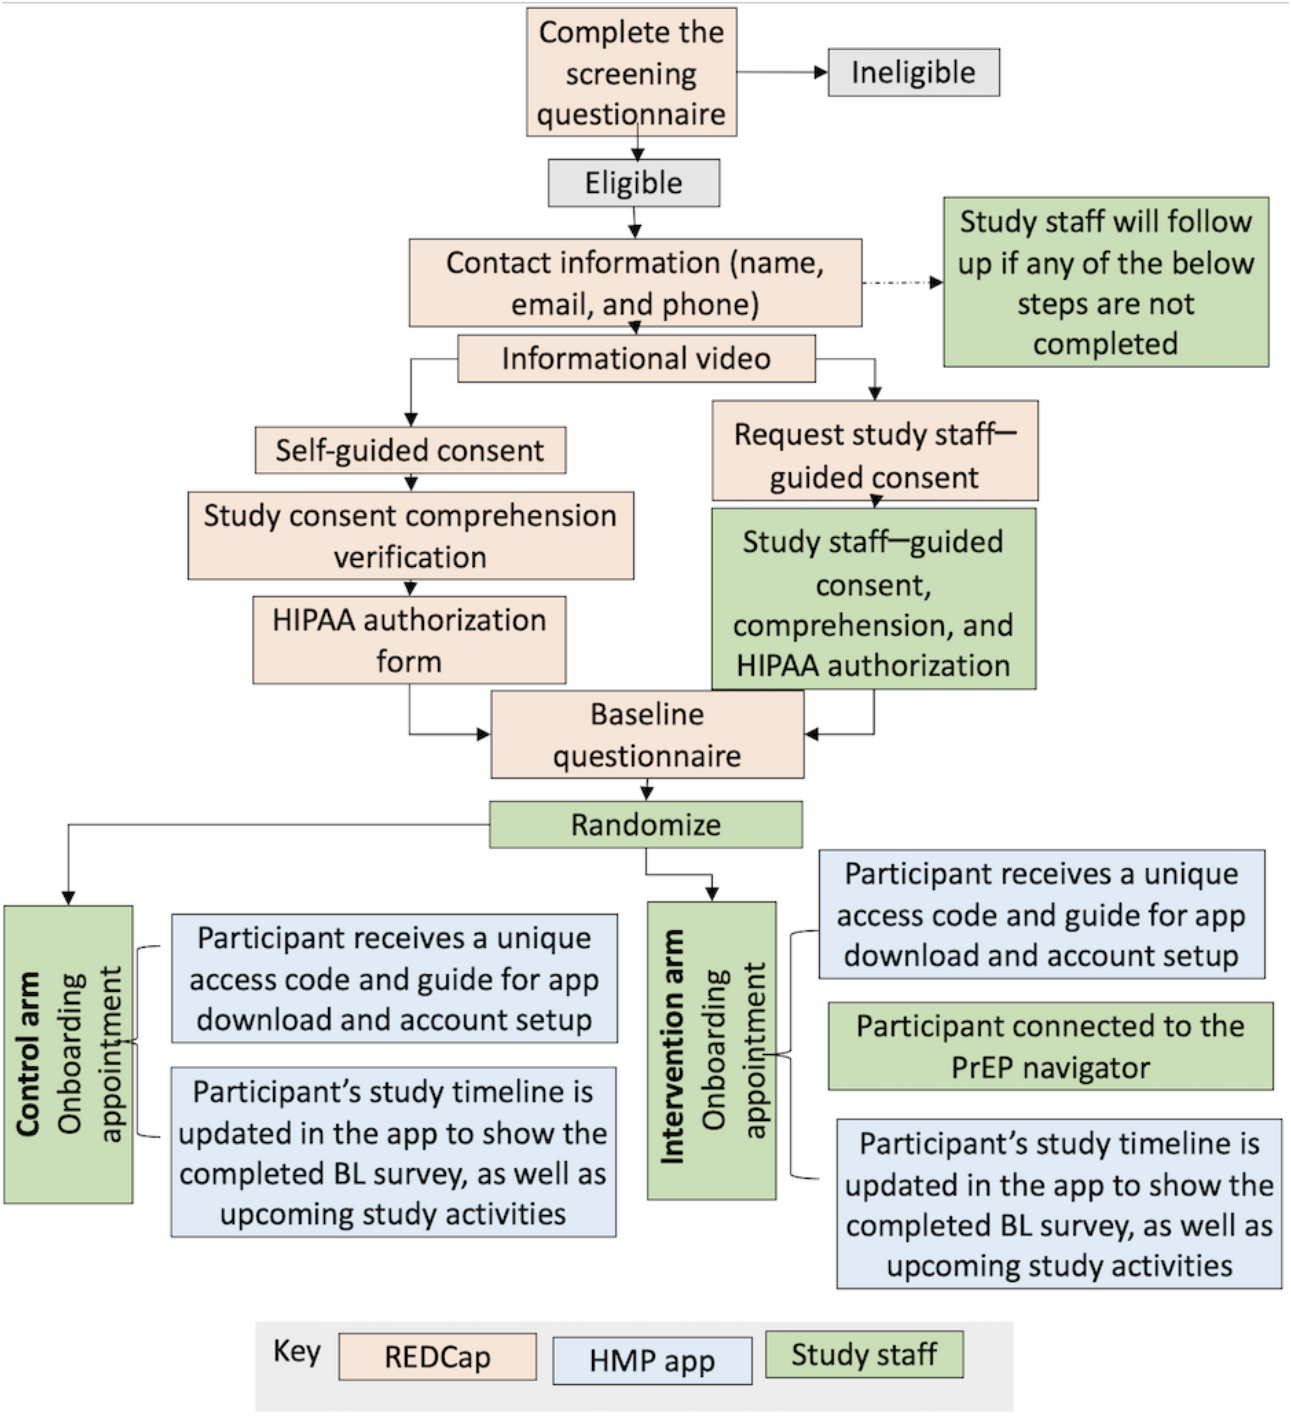
Sample Size and Statistical Power

On the basis of historical clinic volumes and patient demographics, we expect that >7400 patients will present for care across the sites during the study enrollment period, with 20% to 35% being study eligible. Power calculations were based on the study’s primary outcome (PrEP uptake within 3 months of STI clinic visits). PrEP use among the target population has not been estimated previously as there is currently little to no availability of PrEP in rural NC settings. Assuming that 2.5% of eligible patients start PrEP within 3 months in the control arm, we calculated statistical power to detect a range of small to large effect sizes from 5% to 15% increases in PrEP uptake under a range of possible sample sizes and assuming 10% missing data or attrition at 3 months. At a total sample size of 336 given our design and assumptions, we will have >88% statistical power to detect medium (10%) and large (15%) effect sizes and 80% statistical power to detect a moderate (7.5%) effect size with a 5% type-I error rate (SAS; version 9.4 [SAS Institute]).

Randomization and Enrollment

After providing written informed consent electronically and completing baseline surveys, participants will be randomly assigned 1:1 to the control or intervention condition at enrollment using blocked randomization stratified by county, with randomly ordered blocks of sizes 4 and 6 (Figure 2). There will be no masking to assigned arms. Randomization assignments will be automated through the study database. Arm assignment is then disclosed to participants by study staff during study onboarding. The onboarding session includes orientation to study app features for all participants and, for those randomly assigned to the intervention arm, an introduction to the remote PrEP navigator.

Figure 2. Participant enrollment flow. (Note: Dependent on their enrollment date, only a subset of participants will be asked to complete 6 and 12-month study activities.) BL: baseline; HIPAA: Health Insurance Portability and Accountability Act; HMP: HealthMpowerment; PrEP: pre-exposure prophylaxis; REDCap: Research Electronic Data Capture.

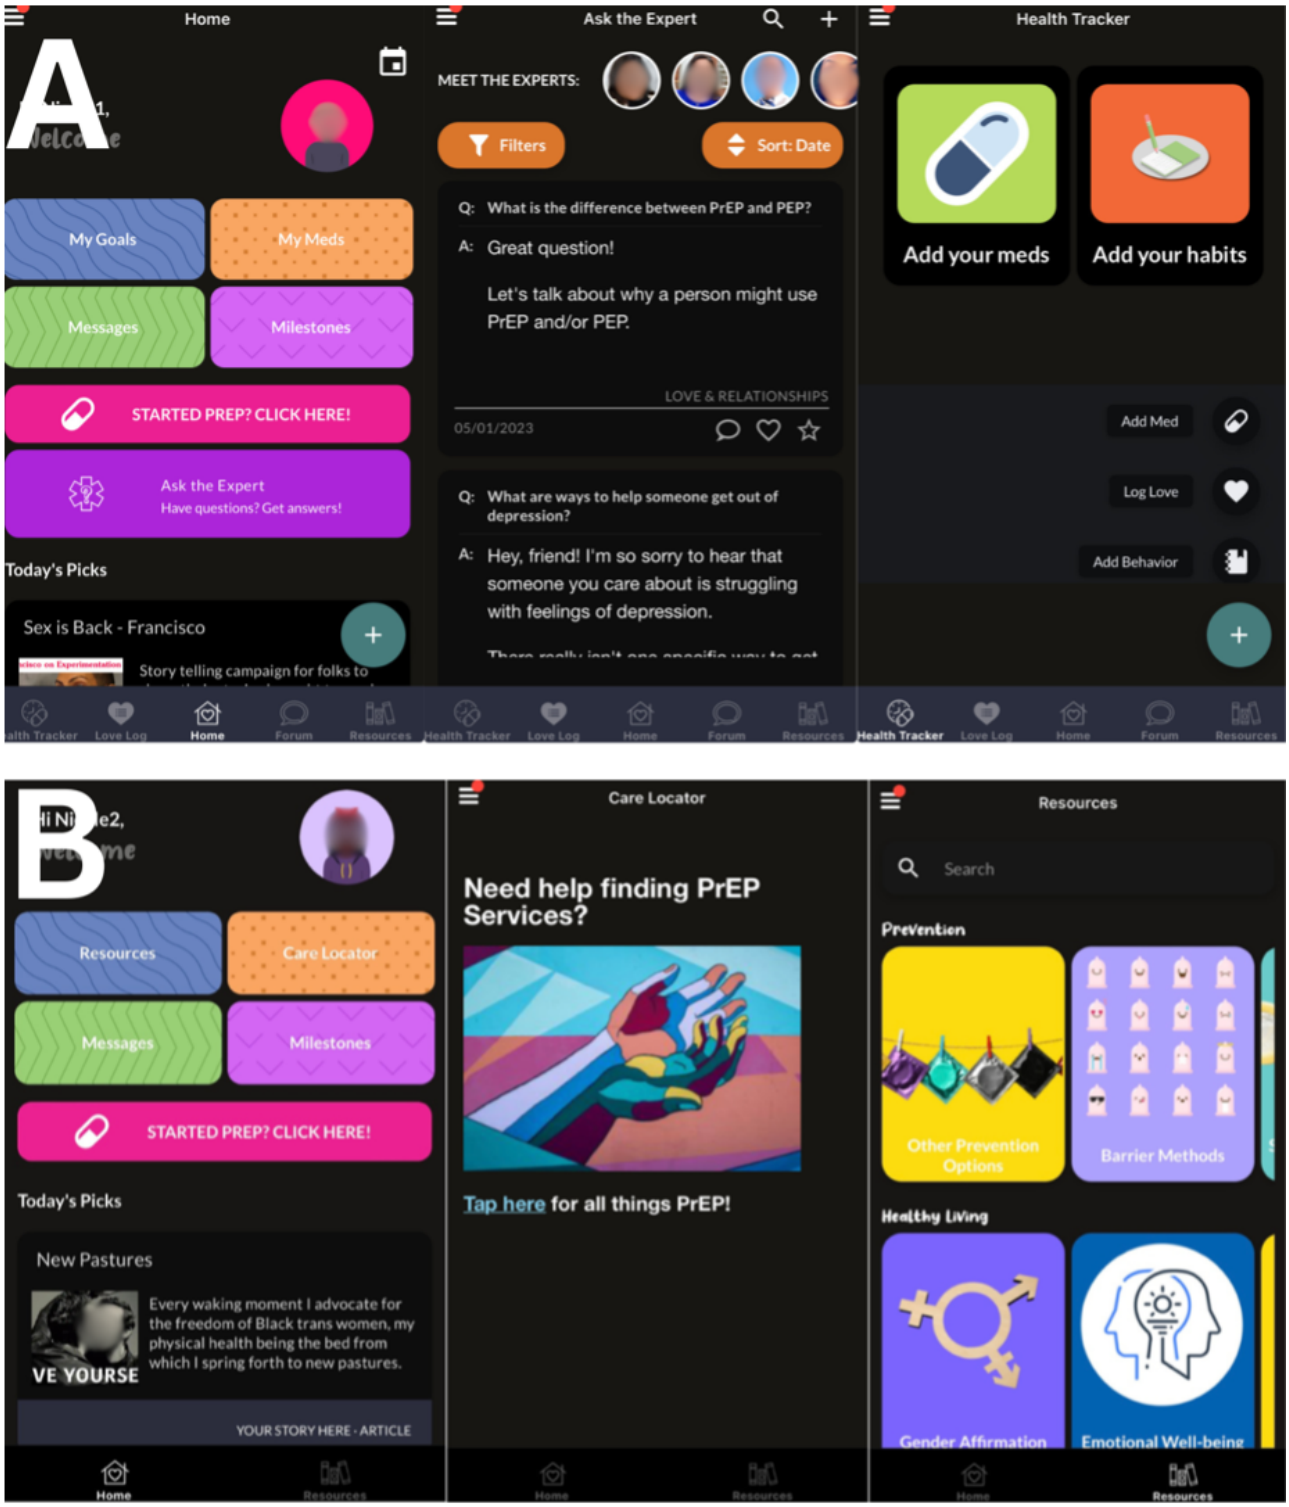


Intervention Arm

Overview

Participants randomly assigned to the intervention arm will receive standard PrEP referral services identical to those available to persons in the control condition (see the following sections), as well as a multilevel intervention with 3 components, all of which they engage with remotely: a PrEP navigator to address potential barriers to PrEP uptake and use and facilitate linkage to PrEP services if interested, referral to telehealth PrEP services as an option for linking to PrEP care, and a Health Insurance Portability and Accountability Act (HIPAA)–compliant web-based digital health intervention app (see additional information regarding app privacy in the *Ethical Considerations* and *Data Quality and Monitoring* sections; Figure 3A).

Figure 3. Screenshots from the HealthMpowerment app—(A) enhanced version of the HealthMpowerment app for the intervention condition and (B) limited version of the HealthMpowerment app for the control condition. PEP: postexposure prophylaxis; PrEP: pre-exposure prophylaxis.



PrEP Navigation

PrEP navigators will connect with participants immediately following app onboarding. Navigator services are available to participants for the first 6 months of participation (active intervention period) and include assessing participant awareness of an interest in PrEP, referral to PrEP care, helping participants engage in PrEP care (including assisting with appointment scheduling, reminders, and other provider access issues), and assisting with completing necessary paperwork for insurance and application for drug assistance programs as needed. PrEP navigators undergo study- and navigator-specific trainings.

PrEP navigators were recruited through relevant recruitment channels and listserves commonly used by professionals in the HIV prevention sector. Preference was given to applicants with experience in sexual health; lesbian, gay, bisexual, transgender, and queer health; health insurance; digital health or telehealth; and patient navigation. In addition, candidates with experience

collaborating with regulatory bodies and research study teams and in academic-community partnership settings were preferred.

PrEP Linkage

PrEP navigators can link interested participants to preexisting local or telehealth PrEP services, although neither are provided, financed, or staffed by the study. Participants referred to telehealth services will receive these PrEP services via the technology platform or service that the provider typically uses. PrEP clinical eligibility, visit frequency, monitoring of laboratory tests, and all other PrEP management will be at the discretion of the PrEP provider. Before enrollment, all participants will sign a HIPAA authorization form permitting study staff to access their medical records pertaining to PrEP care delivery.

Digital Health Intervention App

HealthMpowerment is an HIV status–neutral, theory-informed, HIPAA-compliant digital health intervention that supports sexual health and risk reduction among young, sexual and gender minority men [52-54]. HealthMpowerment is guided by the Integrated Behavior Model [55], facilitating examination of the individual and structural determinants of health (eg, stigma and discrimination, health literacy, and poverty) and psychological distress (eg, depression, anxiety, and loneliness) that hinder adoption of HIV-preventive behaviors. The app provides a range of resources addressing these social determinants for persons at all stages of readiness to initiate PrEP, as well as ongoing support and resources for those who do initiate PrEP. All information on the app is available to all participants. The app also recommends specific content to individuals based on their voluntary responses to questions and activities within the app. As part of PrEP-monitoring features, participants can indicate how PrEP was prescribed (ie, daily oral, event-driven oral, or injectable), as well as indicate the dates on which PrEP was taken or, in the case of injectable PrEP, received. HealthMpowerment was first found effective in a statewide RCT [42,53] in NC, which found that greater HealthMpowerment engagement was significantly associated with fewer episodes of condomless anal sex; stigma reduction; and greater provider communication, HIV status disclosure to partners, and HIV care outcomes (eg, engagement in care and adherence) [53,56].

The content included in this version of the app was selected from a broader content library developed and used in previous studies involving similar populations. The app's design, interface, and features were developed and user tested by a community advisory board comprising racially and ethnically diverse, young, sexual and gender minority groups. In addition, the app's content is dynamic, with updates made based on user engagement analytics and ongoing developments in the field.

Control Arm

Persons randomly assigned to the control arm will receive an enhanced standard of care, pairing existing referral systems with access to the core educational resources of the HealthMpowerment app. For this study, access to publicly available PrEP locator resources and tailored information on PrEP and HIV prevention will be accessible from within the app (Figure 3B). This comparator condition of an enhanced standard of care control was selected to balance the dual goals of establishing effectiveness and ethical obligations to provide all participants with information regarding available PrEP services and basic PrEP education.

Study Procedures

All study staff will be trained in and follow a detailed study-specific procedure manual and topic-specific standard operating procedures (SOPs) that were informed by the Division of AIDS Site Clinical Operations and Research Essentials Manual [57].

Recruitment

The protocol uses clinic-based recruitment at participating STI clinics. Posters, 1-page flyers, and palm cards with scannable QR codes will be posted throughout the clinic waiting areas, on bulletin boards, and in patient rooms. The study will also be promoted through word of mouth via health professionals, administrative staff, and community outreach personnel associated with each site. Clinic and study staff may also bring recruitment materials to community-based events they attend on behalf of the clinic (eg, health fairs and blood drives) with information about the study.

Scannable QR codes will lead to a web-based screener, which allows potential participants to learn about the study and their eligibility discretely. As of July 17, 2024, prospective participants that complete the screening questionnaire are offered a US $5 e–gift card. Individuals who are not eligible based on screening criteria, duplicate entries, or choosing not to proceed will be thanked and rerouted to a public web page. Prospective participants will be asked to grant permission for study staff to contact them and to provide preferred contact information before they are routed to a brief video describing the research basics and specific study objectives.

Participant Management and Retention

We will collect multiple forms of participant contact information and study-related communication preferences (eg, email and phone or SMS text messaging) as part of study enrollment. The HealthMpowerment app supports participant retention through a timeline that displays upcoming study activities and a 2-way secure messaging feature for participants and study staff. All participants will receive compensation throughout the course of their participation.

Data Sources and Collection Methods

Data sources and collection methods are described in this section and summarized in Table 2. The study will use electronic data capture tools (REDCap [Research Electronic Data Capture; Vanderbilt University]) hosted at Florida State University for all primary data collection and participant management purposes [58,59]. REDCap is a secure, web-based software platform designed to support data capture, audit, monitoring, and export for research studies. Study screeners, assessments, and in-depth interviews will all be completed remotely via secure HIPAA-compliant platforms for survey administration and phone and videoconferencing.

Table 2. Data sources and collection methods.

Data source and collection method	Primary effectiveness	Cost-effectiveness
CASI[a] surveys—in the clinic or web-based	✓	
Whole blood collection samples—self-collected blood sample	✓	
Qualitative notes and transcripts—interviews and intervention mapping	✓	✓
Digital health intervention paradata—entered into the app by participants, study staff, and PrEP[b] navigators	✓	
Clinic observations—project receipts and personnel salary		✓
Time-and-motion logs		✓
HIV and STI[c] test results—electronic health record and data or Lapcorp or Quest or CELR[d] or participant-provided records	✓	
PrEP care history—electronic health record data or participant-provided records	✓	✓

[a]CASI: computer-assisted self-interview.

[b]PrEP: pre-exposure prophylaxis.

[c]STI: sexually transmitted infection.

[d]CELR: Clinical and Environmental Laboratory Results.

HIV and STI Result Abstraction From Electronic Health Records

Participants will be encouraged to receive HIV and STI testing at intervals consistent with CDC recommendations (quarterly testing for men who have sex with men and annual testing for sexually active women) [50]. HIV and STI testing will be completed as part of participants' routine care at the STI clinic site, not administered through the study or by study staff. Collaborating clinics or PrEP providers will be responsible for specimen collection, processing, and handling of indicated treatment and treatment referral as appropriate. Proof of a nonreactive (negative) HIV assay is required for study enrollment, but no prospective testing is required, nor are participants incentivized to complete these tests. Participants who receive an HIV diagnosis while enrolled in the study will be study stopped. Individuals may choose to keep the digital health app installed on their phone. All test results will be extracted from clinical records. Clinics will either provide study staff with direct access to the participant's HIV and STI results or upload the results to a secure survey via REDCap.

Specimen Collection

Dried blood spot (DBS) specimens will be used to detect the presence of PrEP metabolites in participants' blood and will be administered at months 3 and 6 depending on participants' enrollment date. Participants can choose to have a DBS kit mailed directly to them (at an address of their choice) or opt for the kit to be mailed to their local health department and pick it up in person. Following an illustrated step-by-step instruction card, participants use a single-use lancet to collect blood onto specialized paper cards, and then they return the sample using a preaddressed, prepaid shipping envelope. DBS specimens will be tested for the presence and levels of tenofovir diphosphate and emtricitabine triphosphate to inform PrEP exposure and prevention-effective use as correlated with survey and available medical record data regarding PrEP medication and intended dosing strategy [60,61].

Study Assessments

Computer-assisted self-interview survey assessments from REDCap will be sent to participants via the HealthMpowerment app at baseline and 3 and 6 months, with a 12-month brief assessment for a subset of participants. Participants enrolled in approximately the final quarter of enrollment will only complete the 3-month survey, reflecting the shorter follow-up period for this group. Survey domains include sociodemographic data, sexual behaviors, PrEP use, self-reported STI and HIV testing outcomes, and perceived or experienced PrEP stigma.

Clinic Assessments

Understanding the organizational environment from which participants will be recruited is crucial to interpret outcomes and potential for scale-up and sustainability. We will conduct assessments of all participating clinics to evaluate staffing, patient volume, hours of operation, and available services. These assessments will be conducted using a combination of in-person and remote interactions. We will also ask relevant stakeholders about intervention acceptability and organizational factors that may influence PrEP provision and integration of services, including organizational readiness for change, support climate, and intervention value fit [62-64]. We will also monitor relevant policy changes, such as those pertaining to insurance, PrEP coverage, or recommendations for use that may serve as external influences relevant to our observed outcomes.

Qualitative In-Depth Interviews

Up to 50 participants will complete an in-depth interview following their 3- or 6-month assessment contextualizing their experience with study participation, perceived accessibility of PrEP before and after study enrollment, evaluation of the acceptability of this enhanced PrEP access model (if randomly assigned to the intervention arm), unmet PrEP-related health service needs and barriers, experience initiating PrEP (if relevant), experience using the study-related intervention components (app, PrEP navigator, and telehealth for PrEP), and other topics as raised by participants (Multimedia Appendix 1).

Participant interviews will be conducted remotely via phone or videoconference platform. Participants will be purposively sampled to ensure diversity in areas such as PrEP initiation status, recruitment clinic, age, and race.

In addition, we will engage up to 50 other stakeholders, including health department–affiliated clinic staff, health care providers, and other stakeholders relevant for PrEP services, for in-depth interviews. Interview topics may include experiences and challenges with being part of a participating clinic for this study, perceived accessibility of PrEP for the target patient population before and after study implementation, perceived strengths and drawbacks of this PrEP access model, suggested changes to this strategy, and unmet PrEP-related health service needs and barriers among the participant population. Stakeholder interviews will be conducted in person or remotely via phone or videoconference platform after consent by trained research staff using a semistructured interview guide (Multimedia Appendix 2). Each interview will be digitally recorded and transcribed for analysis.

Cost-Effectiveness

We will build a decision model to estimate the budget impact and compare the cost-effectiveness and population outcomes of our multilevel PrEP intervention to those of the standard of care.

Specifically, costs will be collected prospectively in 2 ways: microcosting and time-and-motion logs. Microcosting involves "direct enumeration" for consumed inputs [65], an ingredient-based approach. We will further quantify resources associated with the development and implementation of our intervention (eg, costs associated with the adaptation of the HealthMpowerment app and personnel training). Following established methods, we will measure non–research-related costs associated with the intervention and control arms to estimate the incremental cost per additional person starting PrEP. Cost data will be available through contractual information with developers, clinic and project receipts, and NC Department of Health and Human Services supply chain partners. We will also extract data from project expenditure and management records, including purchase logs and human resource records. Time-and-motion assessments record how the involved parties (eg, navigators and providers) divide time among PrEP-related tasks, reliably apportioning effort relevant to implementing the intervention.

Outcomes and Data Analysis

Our primary outcome (PrEP uptake) is assessed through self-reported PrEP use (oral or injection) on a follow-up survey or on the app and verified by at least one of the following: (1) an uploaded photo or image demonstrating a PrEP prescription, (2) any indication of the presence of tenofovir diphosphate or emtricitabine triphosphate in DBS, or (3) staff-abstracted electronic medical record of PrEP prescription issued or prescriber notation of PrEP being initiated (Multimedia Appendix 3).

Outcome Analysis

Analyses will be conducted for all primary and secondary outcomes using the following general procedures. Basic descriptive statistics will be calculated. Frequency tables will be presented for the categorical variables, and means, SDs, and percentiles (25th, 50th, and 75th) will be provided for the continuous variables. For each binary outcome, we will estimate the probability of achieving the event (eg, PrEP uptake) in each arm and a probability difference and the corresponding 95% CI to compare the intervention versus control arms at each time point (3-, 6-, and 12-month follow-ups). For continuous end points, we will use a nonparametric Wilcoxon rank sum test to compare the intervention and control arms. For count data variables (eg, number of unprotected sex acts), we will use small analysis methods for count data (eg, exact Poisson regression).

To address missing data, we will review the frequency of missing and nonmissing values for all variables at baseline and the 3-, 6-, and 12-month follow-ups. We will conduct missing value analyses to determine whether persons with missing values are systematically different from those without missing values and whether the probability of having missing values differs by arm. If this assessment of the frequency and imbalance of missing data suggests that bias may be introduced, we will use inverse probability of observation weights or multiple imputation to address the missing data. If there is chance imbalance in the measured baseline covariates between those randomly assigned to the intervention and control groups, we will conduct sensitivity analyses applying stabilized inverse probability treatment weights.

The primary outcome of PrEP uptake is measured at the 3-month follow-up. The effectiveness of the intervention will be estimated as the difference in probability of starting PrEP within 3 months of an index STI clinic visit comparing patients randomly assigned to the intervention and control groups.

Secondary effectiveness outcomes include PrEP uptake at 6 months, PrEP care engagement, PrEP use, PrEP adherence [66-68], incident STIs, incident HIV, and PrEP stigma [69,70] (all at both 3 and 6 months). All analyses will follow the specifications described previously.

PrEP adherence at 3 and 6 months will be assessed using PrEP metabolite levels and self-reported 30-day adherence as 2 separate outcomes. We will use standard-of-care quarterly STI and HIV testing results to examine differential rates of incident STIs adjusting for testing frequency given potential increased testing frequency among PrEP initiators [71,72].

Exploratory outcomes will report the effectiveness of the intervention (defined previously) as measured using PrEP uptake at the 3-month follow-up stratified by sex assigned at birth.

We will also examine additional exploratory implementation outcomes, including process indicators to inform intervention implementation, optimization, and scale-up. We will measure acceptability of the implementation strategies for providers and clinic directors, feasibility of the intervention, and intervention satisfaction among patients and providers using validated scales [73-76] for outcome assessment, as well as measuring cost-effectiveness.

To measure the acceptability [73,77,78] of the intervention and explore clinic-level influences on implementation feasibility at each clinic, we will interview providers and clinic directors. We will assess factors such as provider burden of intervention, adequacy and timing of training, supervision or support structure, organizational readiness for change (quantitative scale and qualitative interviews) [62], management support (qualitative interviews), implementation climate (quantitative scale and qualitative interviews) [63], and intervention value fit (quantitative scale and qualitative interviews) [64]. We will use facility audit data, including county population, patient panel size and demographics, number and training level of clinic staff, staff-to-patient ratio, daily patient volume, opening hours, and local access to PrEP to contextualize determinants.

Feasibility measures will assess patient engagement with the intervention, including uptake of elements (ie, linkage to insurance if not durably insured at enrollment, use of telehealth PrEP, and interactions with PrEP navigators). We will examine the percentage of enrolled participants in the intervention arm who are engaged by the PrEP navigator within 2 weeks of enrollment. We will also examine app-specific engagement, including successful app installation, account creation and log-in, total number of log-ins, and time spent on the app.

Measurement of patient satisfaction [74,79,80] with the intervention includes qualitative (in-depth interview data) and quantitative (eg, System Usability Scale [75]) assessments. We will conduct interviews with a subset of patients regarding their experiences with the intervention. This sample will include a mix of persons with variable HealthMpowerment engagement and PrEP uptake. We will ask about satisfaction with clinician interactions as part of STI or PrEP care. As a quantitative assessment, all participants will complete a satisfaction scale at quarterly follow-up visits [81].

Analysis of implementation outcome measures will include qualitative analysis. Transcripts from participants and providers or clinic staff members will be analyzed separately and reviewed for quality. Interview transcripts will be thematically analyzed following a combination of deductive and inductive analytic approaches. An initial codebook will be developed based on a priori concepts driven by the theoretical underpinnings used to develop the interview guide. All textual data will then be read thoroughly to summarize first impressions. Emerging themes will be incorporated into the codebook. Preexisting codes may be modified based on interview transcripts. Transcripts will be coded iteratively using qualitative analysis software. In total, 2 researchers will code the interviews separately to assess intercoder reliability. The codebook will be revised and updated. Analysis of the coded data will include investigation of relationships between codes, coding matrices, and mapping of codes and themes. Data from qualitative interviews will be triangulated with the quantitative data to gain a more complete understanding of the factors underlying implementation. For example, if our survey data show that clinics with lower fidelity tended to score low on the implementation climate scale, we will examine our qualitative data for indications of what aspects of the leadership or climate may have contributed.

Our primary cost-effectiveness outcome is the incremental cost per additional person started on PrEP (the primary study outcome) in the intervention versus control condition.

We will conduct a budget impact analysis of the cost in US dollars of the intervention overall, providing decision makers with estimates of the financial feasibility of the intervention [82,83].

All models will include sensitivity analyses to examine the potential impact of varying cost and effectiveness assumptions, accounting for parameter uncertainty [84] and capturing input uncertainty (eg, PrEP adherence and intervention cost and effectiveness). The upper and lower bounds will be based on trial data, literature, or expert opinion. The results represent an average across simulated model runs with an estimated uncertainty range.

We will report incremental cost-effectiveness ratios. The analyses will take the perspective of the health system and public payers.

Study Monitoring and Adverse Event Reporting

The purpose of study monitoring is to verify that the rights and well-being of human participants are protected; the reported trial data are accurate, complete, and verifiable from source documents; and the trial is conducted in compliance with the currently approved protocol and amendments, with good clinical practice, and with all applicable regulatory requirements. This study will follow a detailed clinical quality monitoring plan that specifies the frequency and types of data that will be reviewed (case report forms, regulatory documents, study staff training records, and medical and laboratory records) to accomplish these monitoring activities. External monitoring for this study will be conducted biannually through the North Carolina Translational and Clinical Sciences Institute monitoring service in accordance with established International Conference of Harmonization Good Clinical Practice Guidelines and Title 21 of the Code of Federal Regulations. This review includes quality assurance (QA) and study monitoring, such as regulatory file review, informed consent review, patient eligibility confirmation, protocol compliance review, assessment of safety reporting requirements, and review of training records.

In addition, a study monitoring committee (SMC) will be constituted before initiation of the study. This committee will include, at a minimum, 2 HIV clinicians or research investigators not directly involved in the study and a community representative. At least one representative from the National Institutes of Health (NIH; study sponsor or funder) will be invited to attend the biannual meetings. SMC members will review cumulative study reports, including reports of adverse events (AEs), social harms, and unanticipated problems. The SMC will assess study conduct, adequacy of the delivery of the intervention package, ascertainment of PrEP uptake outcomes, and other related data to ensure adequate collection of primary and key secondary outcome data.

There are no plans for additional interim analyses beyond standard monitoring and reporting, and there are no explicit, prespecified stopping guidelines for the trial. The study sponsor and funder retain the right to terminate the trial.

As a behavioral intervention that does not include an investigational product, standard AE reporting will not be undertaken for this study. The study team will monitor for and track serious and nonserious AEs related or possibly related to study procedures or participation in the study. Study participants will be instructed on how to contact the study staff to report any AEs they may experience at any time between enrollment and the follow-up assessments. AEs will also be actively assessed in all follow-up quarterly assessments. Should a participant report experiencing an AE that they perceive to be related to their study participation, research staff will contact the participant to assess the severity and appropriate resolution action.

Ethical Considerations

This study, including the protocol, the informed consent documents, and all participant-facing materials, has been reviewed and approved by the University of North Carolina (UNC) Biomedical Institutional Review Board (IRB; 22-3058), who is responsible for the oversight of the study. Any subsequent modifications will be reviewed and approved by the UNC IRB before implementation. Annual IRB reporting and review is required for the duration of the study.

Eligible participants will have the choice to complete a self-guided electronic informed consent form following the informational video before enrollment or complete a staff-guided electronic informed consent form (via a HIPAA-compliant videoconferencing platform or phone call) before enrollment (Multimedia Appendix 4). All participants will be required to complete comprehension questions to ensure that they adequately understand the research, risks, and benefits and that they can opt out of study participation at any time before providing an electronic signature. All prospective participants who provide informed consent will be required to review and digitally sign a HIPAA release form (Multimedia Appendix 5).

All participants will be assigned a unique participant ID number. Participant-related study information will be identified only through the participant ID on all participant case report forms, audio files, transcripts, and computer-assisted self-interview files. Participant names and other personally identifying information will not be used on any study documents and will be redacted from interview transcripts.

Participants will receive digital cash incentives through the Tango payout platform for completing study visits (surveys, DBS kits, and interviews) as follows: US $60 for enrollment activities (baseline survey and enrollment), US $40 for the 3-month survey, US $50 for the 3-month whole blood self-collection kit, US $40 for the 6-month survey, US $50 for the 6-month whole blood self-collection kit, US $40 for the 12-month survey, and US $50 for the qualitative exit interview. Participants can choose their preferred gift card from a reward catalog.

We will secure study data with all appropriate physical, electronic, and operational protections following our data collection and handling SOP. All data files will have encryption and strong password protection, and files will be stored and managed using HIPAA-compliant, secure servers and cloud-based participant management software. Participant names and their participant IDs will be stored in separate tabs in REDCap accessible only to designated study staff and site monitors. Any files that are not specific to a single participant (eg, laboratory sample manifest) will be stored securely on a university-managed, HIPAA-compliant server. Original source documents for individual participants will be maintained at the UNC study site and will be accessible only to the study staff.

Data Quality and Monitoring

The clinical quality monitoring plan outlines the regular quality control (QC) and QA checks that are completed by the study team and external study monitor. Internal quality management activities ensure that research staff perform the study-required work correctly per the protocol requirements and in real time. Quality management activities also support good clinical practice compliance, human participant protection, and adherence to protocol requirements and site SOPs. Internal QC and QA monitoring and reporting consists of standardized methods and tools for QA and QC checks, as well as mechanisms for summarizing and disseminating the gathered information. Quality management checks will be implemented throughout the data collection process to quickly identify and rectify potential problems. Survey instruments will use skip patterns and built-in checks to minimize discrepant and unrealistic answers. Standard data-cleaning procedures will be used before analyses, including outlier detection and graphical representation of the data.

Data Dissemination

The results of this research will be disseminated via publication in peer-reviewed journals; conference presentations; and direct presentation to other interested stakeholders involved in HIV prevention and STI care provision, programming, and policy generation. The protocol is available for public review at ClinicalTrials.gov (NCT05984030).

Written publication guidelines for authorship eligibility will follow the criteria recommended by the International Committee of Medical Journal Editors (substantial contribution, participation in writing, approval of final version, and accountability) [85].

Lay summaries and infographics of study findings and implications will also be created for a general public audience and distributed via social media channels, as well as to participating clinics. When participants are asked for consent for the study to maintain their preferred contact information, they are informed that this information may be used to inform them of the study results. Thus, primary results and lay summaries will be individually shared back with participants unless they opt out of receiving this communication.

No participant names or other identifying information will be used in any dissemination materials, published or otherwise. The final deidentified dataset will be maintained by the study primary investigators and may be shared with other investigators for the completion of secondary data analysis following the establishment of acceptable data-sharing or data use agreements per the requirements of the US NIH (funder or sponsor) and UNC at Chapel Hill (grantee).

Results

Enrollment opened on August 31, 2023, at 15 health department–affiliated clinics in NC and subsequently expanded to 21 facilities in 20 counties by July 2024. Completion of the enrollment and data collection phase is expected by May 2025. As of January 2, 2024, a total of 17 persons have been enrolled. We have conducted 13 PrEP trainings, reaching a total of 106 providers and clinic staff members, as well as organizing 15 refresher trainings to promote continued understanding and study engagement among clinics. We have conducted 33 qualitative interviews among study participants, clinicians, and stakeholders. In addition to the customized HealthMpowerment study app, we have developed a PrEP navigation manual that also includes a compiled list of county-specific resources. The conclusion of phase I of this study is expected by May 2025, with results to be published thereafter.

Discussion

Novel Strategies to Address Barriers to PrEP Uptake

This study hypothesizes that leveraging STI clinics as an on-ramp to PrEP will serve as an effective opportunity to capitalize on STI service encounters and address disparities in PrEP access across rural and periurban environments in NC. As infrastructure for providing PrEP in rural NC STI clinics is currently extremely limited, no previous published studies have assessed PrEP uptake in these settings. In some settings, the diverse needs of potential PrEP recipients may exceed what can be reasonably provided by rural STI clinic staff in stand-alone, frequently understaffed clinics. Developing and testing a pathway to PrEP that complements clinic resources and workflow, including linking to remote PrEP navigation and offering high-quality STI testing services or monitoring for PrEP users, is an appealing strategy that could leverage rural STI clinics as a cost-effective on-ramp to sustained PrEP services. We believe that hybridizing components of multiple-effect PrEP uptake strategies, such as access to PrEP navigation and implementation of a virtual PrEP strategy supported by digital health interventions such as HealthMpowerment, may help support PrEP initiation in patient populations that would otherwise face barriers to obtaining and pursuing in-person PrEP service referrals [36,37].

In NC, men assigned male sex at birth who have sex with other men continue to represent a disproportionate majority of new HIV acquisitions. However, as we expanded within rural NC communities and engaged with the rural providers who staff the participating clinics, we recognized the disconnect between this focused recruitment strategy among persons seeking services at STI clinics and the importance of discussing HIV prevention, and PrEP specifically, with all patients. Our expansion to women will offer unique insights into the challenges and opportunities of engaging with this population within rural STI clinics.

Importantly, in this phase of the study, we are screening persons into a research study, not a PrEP referral process or pathway. As such, challenges with the implementation of the study, including recruitment, do not necessarily reflect barriers to linkage to remote navigation and digital health applications that would be implemented were this model to be scaled. Furthermore, although the randomized nature of our approach offers a more robust evaluation of potential efficacy, this design could influence willingness to enroll or engage with study materials. However, the process of referring all persons seeking STI services to PrEP navigation services using a scannable code or offering access to an informational app for those interested, as reflected in the study recruitment process, may indeed be a strategy used in future implementations if our intervention is shown to be effective in improving uptake of PrEP.

Potential Limitations and Future Directions

The external validity of the intervention may be challenging to establish when implemented outside the context of the research study. Participants are provided with a modest monetary incentive for initial engagement, which could influence their motivation to take part initially. In addition, the provision of ongoing incentives for study activities may impact their continued willingness to participate. This potential limitation will be further investigated through qualitative research aimed at exploring the motivation behind participants' decision to engage in the study. Importantly, this study was designed explicitly to address challenges related to PrEP access for persons accessing STI services in rural areas in which PrEP providers and general PrEP services are scarce, and thus, the generalizability, including the acceptability of this approach, may not be immediately relevant to other contexts with more concentrated service delivery options and more widely available, robust PrEP referral and linkage opportunities. The potential expansion or modification of this approach to other similarly resource-constrained settings within and outside the United States will be an important next step but is beyond the scope of this pilot. Incorporating PrEP services into STI clinics presents unique implementation challenges. Barriers at the provider (eg, knowledge and self-efficacy), clinic (eg, budget constraints and understaffing), and structural (eg, limitations in capability for long-term follow-up) levels complicate PrEP scale-up in rural STI clinic settings [86]. However, per CDC recommendations, screening for bacterial STIs should occur at least every 6 months for all sexually active patients and every 3 months among men who have sex with men or persons with ongoing risk behaviors [50,51]. By including budget impact analyses, this study informs program planning and sustainability of the proposed intervention strategy. As public health agencies and providers endeavor to increase PrEP uptake, understanding of the comparative value of alternative strategies, particularly among populations with high HIV incidence and low PrEP use, is urgently needed. Successful implementation and scale-up of the proposed intervention relies on understanding the main drivers of clinic-level costs and demonstrating that an integrated strategy for PrEP and STIs may be more cost-effective than providing these services separately, particularly if optimized models of centralized resources (eg, PrEP navigation and telehealth) and local services (eg, regular HIV and STI testing) can be identified. Ultimately, this study will assess the effectiveness, acceptability, feasibility, and cost-effectiveness of a model to colocate STI services and PrEP access in rural and periurban settings and provide critical information about ways to tailor this service delivery model. A pilot study to assess feasibility

was not conducted before the full-scale RCT, as the R61 mechanism of the NIH is designed to be informative. This study builds on existing preliminary research that supports the use of PrEP navigators, remote provision of PrEP delivery, and DBS monitoring and draws from extensive literature examining the challenges of HIV care among this population. Further directions of this work will include engaging with state and local stakeholders to refine the PrEP intervention and expanding the refined implementation strategy to all persons who enroll at a participating clinic.

Acknowledgments

This trial is supported by funding through the National Institutes of Health (NIH) National Institute of Allergy and Infectious Diseases Division of AIDS (R61AI174285) and the Center for AIDS Research (P30AI50410). The content of this publication is solely the responsibility of the authors and does not necessarily represent the official views of the NIH. SER received additional support from Doris Duke Charitable Foundation grant 2020143. Staff at the NIH National Institute of Allergy and Infectious Diseases (sponsor) reviewed and provided feedback on the study protocol, including the study design, and reviewed this manuscript. The sponsor will continue to provide study oversight without any role in study data collection, management, or analysis.

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

SER was the principal investigator and contributed to study concept and design, protocol development and writing, manuscript drafting and revision, lead and oversight over all study activities, and lead for telehealth pre-exposure prophylaxis (PrEP) service development and implementation.

EF was the study coordinator and contributed to protocol development and writing, and manuscript revision; served as the lead for the development and coordination of all partnering clinic activities; and the lead for the development and implementation of participant recruitment, enrollment, and retention activities.

OM was the research assistant and contributed to manuscript drafting and revision.

NB was the data manager and contributed to the design, programming, and implementation of data collection tools; ongoing data analytic monitoring reports and data quality control procedures; participant recruitment, enrollment, and follow-up; and manuscript drafting and revision.

JS was the data system designer and served as the lead for the conceptualization and design of fully integrated data systems for participant screening, enrollment, and follow-up; contributed to the design, programming, and implementation of data collection tools; design of integrated data–monitoring reporting tool; and manuscript revision.

AW was the PrEP navigator and served as lead for the development and implementation of PrEP navigation protocols and intervention components, the development and maintenance of tracking procedures for clinic-based PrEP services and referral procedures, and manuscript revision.

VM was the HIV and Sexually Transmitted Disease state medical director and contributed to the study concept and design, ongoing expert consultations to align study-specific procedures with state-level HIV and sexually transmitted infection services and PrEP expansion initiatives, and manuscript revision.

SD was the chief medical officer of North Carolina Medicaid and contributed study concept and design, ongoing expert consultations to align study-specific procedures with state-level HIV and sexually transmitted infection services and PrEP expansion initiatives, and manuscript revision.

JE was a coinvestigator and contributed to the study concept and design; served as lead study statistician and epidemiologist for informing randomization scheme, statistical methodologies, sample size estimation, and scientific rigor; and contributed to protocol development and manuscript revision.

LBH-W was a coinvestigator study concept and design, protocol development, original creation of the HealthMpowerment digital health intervention, and manuscript revision.

CBH was a coinvestigator and contributed to the study concept, design and protocol development; served as lead for the development, implementation, and evaluation of clinic-based PrEP service training and technical support; and contributed to survey design and manuscript revision.

BP was a coinvestigator and contributed to the study concept and design; served as lead for implementation science design and evaluation components; and contributed to manuscript revision.

KEM was the principal investigator and contributed to the study concept and design; served as lead and oversight over all study activities, protocol development and writing; contributed to manuscript drafting and revision; and served as lead for qualitative research methodology components.

Abstract

Background: The 5-Cog paradigm is a 5-minute brief cognitive assessment coupled with a clinical decision support tool designed to improve clinicians' early detection of cognitive impairment, including dementia, in their diverse older primary care patients. The 5-Cog battery uses picture- and symbol-based assessments and a questionnaire. It is low cost, simple, minimizes literacy bias, and is culturally fair. The decision support component of the paradigm helps nudge appropriate care provider response to an abnormal 5-Cog battery.

Objective: The objective of our study is to evaluate the effectiveness, implementation, and cost of the 5-Cog paradigm.

Methods: We will enroll 6600 older patients with cognitive concerns from 22 primary care clinics in the Bronx, New York, and in multiple locations in Indiana for this hybrid type 1 effectiveness-implementation trial. We will analyze the effectiveness of the 5-Cog paradigm to increase the rate of new diagnoses of mild cognitive impairment syndrome or dementia using a pragmatic, cluster randomized clinical trial design. The secondary outcome is the ordering of new tests, treatments, and referrals for cognitive indications within 90 days after the study visit. The 5-Cog's decision support component will be deployed as an electronic medical record feature. We will analyze the 5-Cog's implementation process, context, and outcomes through the Consolidated Framework

for Implementation Research using a mixed methods design (surveys and interviews). The study will also examine cost-effectiveness from societal and payer (Medicare) perspectives by estimating the cost per additional dementia diagnosis.

Results: The study is funded by the National Institute of Neurological Disorders and Stroke of the National Institutes of Health (2U01NS105565). The protocol was approved by the Albert Einstein College of Medicine Institutional Review Board in September 2022. A validation study was completed to select cut scores for the 5-Cog battery. Among the 76 patients enrolled, the resulting clinical diagnoses were as follows: dementia in 32 (42%); mild cognitive impairment in 28 (37%); subjective cognitive concerns without objective cognitive impairment in 12 (16%); no cognitive diagnosis assigned in 2 (3%). The mean scores were Picture-Based Memory Impairment Screen 5.8 (SD 2.7), Symbol Match 27.2 (SD 18.2), and Subjective Motoric Cognitive Risk 2.4 (SD 1.7). The cut scores for an abnormal or positive result on the 5-Cog components were as follows: Picture-Based Memory Impairment Screen ≤6 (range 0-8), Symbol Match ≤25 (range 0-65), and Subjective Motoric Cognitive Risk >5 (range 0-7). As of December 2024, a total of 12 clinics had completed the onboarding processes, and 2369 patients had been enrolled.

Conclusions: The findings of this study will facilitate the rapid adaptation and dissemination of this effective and practical clinical tool across diverse primary care clinical settings.

Introduction

Background and Rationale

Problem and Progress

Alzheimer disease and related dementias (ADRD) affect approximately 57 million people globally, a figure projected to rise to 152 million by 2050 [1,2]. Studies have long noted deficiencies and delays in individuals receiving a dementia diagnosis [3-12]. The World Health Organization's Global Action Plan on Dementia includes a focus on the right to a timely dementia diagnosis to enable better planning, treatment, care, support, and quality of life [13]; for example, timely diagnosis can help individuals avoid preventable accidents and injuries leading to care escalation and can reduce distress for patients and caregivers [9,14-16]. In addition, several studies have estimated a potential cost saving of approximately US $10,000 per timely diagnosis because of delayed institutionalization, with the expectation that improved health and quality of life related to early diagnosis could result in even more cost savings [17].

Studies have repeatedly noted that delay and deficiency in diagnosis disproportionately impacts individuals from historically minoritized racial and ethnic groups as well as those from socioeconomically disadvantaged backgrounds [3-12]; for example, a recent nationally representative study found that a higher proportion of non-Hispanic Black and Hispanic individuals had a missed or delayed clinical dementia diagnosis compared to non-Hispanic White individuals (46% and 54% vs 41%; P<.001). This is thought to be an underestimate of the impact because the study relied on claims-based data, and non-Hispanic Black and Hispanic individuals may be less likely to access care that generates claims [18].

Experts recommend robust, multifaceted strategies to close these diagnosis gaps [15,17,19-24]; interventions must address implementation ("the actively planned process of putting evidence to use or integrating new interventions within a specific setting." [25]) and dissemination ("the targeted distribution of information and intervention materials to a specific public health or clinical practice audience" [26]) challenges as much as they aim to achieve high clinical accuracy and quality [20,21,27-31]. The Consortium for Detecting Cognitive Impairment, Including Dementia, a collaborative research effort directed and funded by the National Institute of Neurological Disorders and Stroke and the National Institute on Aging of the National Institutes of Health (NIH), has produced promising paradigms to meet this need. As part of this effort, our team at the Albert Einstein College of Medicine and Montefiore Medical Center (hereinafter Montefiore Einstein clinics) in the Bronx, New York, United States, developed the 5-Cog paradigm [32,33]. In a randomized controlled trial (RCT) of 1200 older adults with cognitive concerns at an urban primary care clinic in a primarily Black and Hispanic community, we showed that the 5-Cog paradigm improves dementia care, most notably by increasing the rate of diagnosis of mild cognitive impairment (MCI) and dementia [33]. This detection and diagnosis increases opportunity for primary care providers (PCPs), patients, and patients' families to intervene to potentially slow or prevent progression to dementia or, for individuals who do progress, to prepare in advance to meet the complex caregiving and clinical challenges to come [34].

Hence, our research questions for this cluster randomized trial were as follows:

- Can a brief cognitive assessment paired with a clinical decision tree (5-Cog paradigm) increase the rate of new diagnoses of MCI syndrome or dementia in primary care patients presenting with cognitive concerns in real-world settings, across broad patient groups (hence its categorization as a pragmatic trial [35])?

- What are the determinants of the 5-Cog's impact in these settings?

Updates to the 5-Cog Paradigm for This Trial

The 5-Cog paradigm (brief cognitive assessment battery and decision support tool) worked well in our initial trial. However, building on implementation reflections from that trial [27] as well as feedback from local primary care stakeholders, we have made 2 refinements to the 5-Cog paradigm to improve clinical utility and aid future dissemination. We substituted the gait speed measurement component of the 5-Cog with a questionnaire that assesses mobility and cognition. In addition, we modified the 5-Cog decision support component to capitalize on electronic medical record (EMR) capabilities and better align the 5-Cog paradigm with existing care provider workflows. All these modifications are described in detail in the following subsection (The 5-Cog Paradigm) and in the Interventions section.

The 5-Cog Paradigm

The 5-Cog paradigm is composed of a 5-minute brief cognitive assessment (the 5-Cog battery) combined with an EMR-embedded clinical decision support tool. The 5-Cog battery was granted US copyright registration effective December 14, 2023.

Clinical decision support provides timely information, usually at the point of care, to inform and improve decisions about a patient's care [36].

The first of the 3 items in the 5-Cog battery is the Picture-Based Memory Impairment Screen (PMIS), created by Verghese et al [37], which uses 4 pictures to test free and cued recall after a delay of at least 2 minutes. Administration and scoring have been previously described [38]. This screener was selected because of ease of use (simple to administer after minimal training and does not require specialized technology), freedom from literacy bias (uses photographs of items instead of words), and cultural fairness (photographs were chosen and validated for consistent recognition by patients in the relevant cultural milieu). In our validation study, PMIS was shown to have high validity for distinguishing older adults with cognitive impairment from those without, regardless of age, sex, education, or presence of depression (sensitivity and specificity >90%) as well as excellent reliability (intraclass correlation 0.91) [37,38].

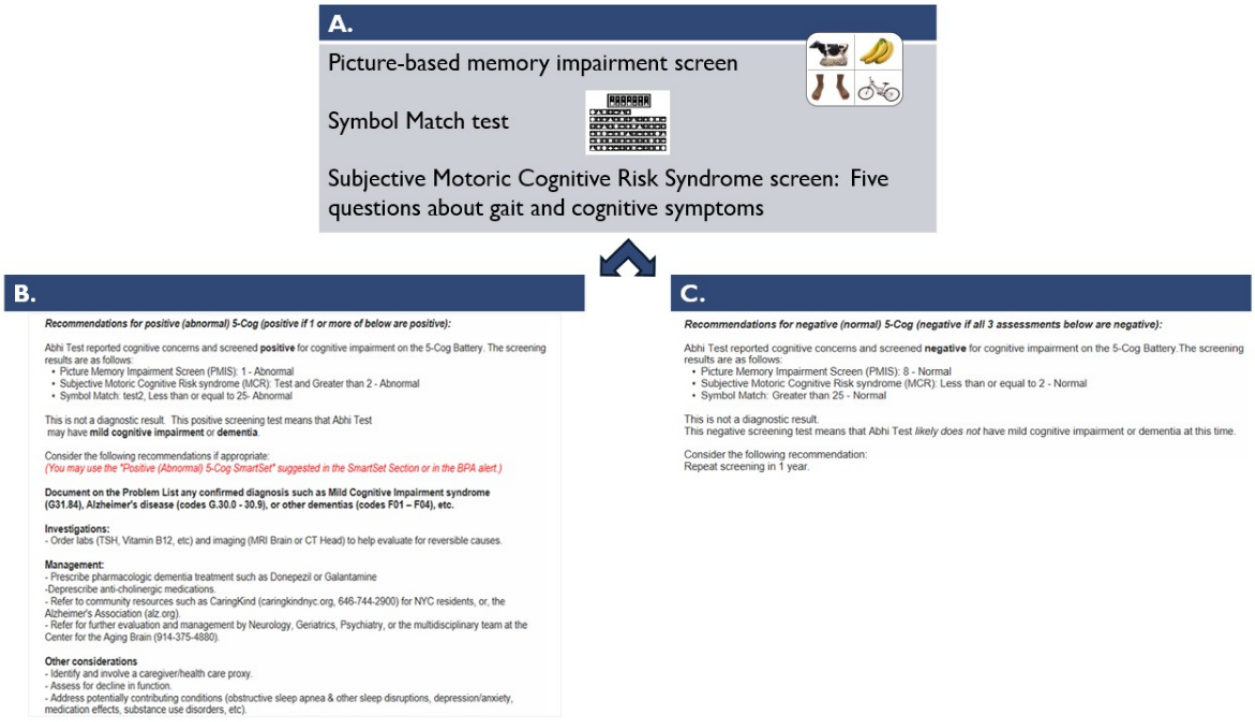
The second item in the 5-Cog battery is the Symbol Match [39], developed by one of our coinvestigators (EFW). It is an oral timed transcription task created to identify difficulties with divided attention, visual scanning, tracking, and motor speed. It requires individuals to quickly substitute (verbalize) numbers for an array of symbols using a key provided at the top of the page. After a practice run with 7 symbols, individuals are given 90 seconds to correctly name as many items as they can as quickly as they can without making a mistake. The number of correct oral substitutions at the end of 90 seconds is the participant's score. Individuals who complete the task before the time limit receive a ceiling score of 65. Internal validation within our study population suggested 25 as the optimal cutoff score to identify cognitive impairment (refer to the Results section for details). The Symbol Match was chosen because of ease of use (requires no specialized equipment and minimal training to administer) [39]. The 90-second Symbol Match correlates highly with the established Symbol Digit Modalities Task [40,41], which can detect nonmemory impairments and functional changes [42]. This feature allows Symbol Match to detect patients with nonmemory impairments that may not be identified by the PMIS [39].

Finally, the 5-Cog incorporates an assessment of gait. The motoric cognitive risk (MCR) syndrome, first described by Verghese et al [43], and defined as slow gait in the presence of cognitive concerns, has been extensively validated to predict an elevated risk of dementia independent of other cognitive assessments [43-47]. Traditionally, the MCR syndrome assessment involves the measurement of gait speed. Given that gait speed is not routinely tested in current primary care environments and that it may present a barrier for 5-Cog implementation, we modified this assessment. For this study, we will be assessing the Subjective MCR (sMCR) screening tool, developed by Ayers et al [48], which uses the patient's subjective reports of mobility and cognitive concerns via a 5-item questionnaire, rather than having a tester measure gait speed. Responses to these 5 questions are used to derive a weighted score that is used to define sMCR. Administration and scoring have been previously described [48]. We found the sMCR approach to have excellent discriminative validity versus objective MCR (defined using gait speed) and excellent predictive validity for incident dementia; in our validation study, participants who met the sMCR criteria had a >2-fold increased risk of developing dementia [48].

The 5-Cog paradigm's EMR-based decision support tool includes 2 components: documentation of the patient's 5-Cog battery result and recommended next steps that may be appropriate for further diagnosis or management of the patient's cognitive concerns (clinical decision support). This "nudge" supports and supplements the provider's own clinical decision–making process [49,50]. In this study, the decision support tool incorporates 3 additional features that make it resemble other EMR-based decision support systems: first, the 5-Cog result will be listed among other clinical practice advisories that contain information tailored to each patient regarding time-sensitive care needs. Second, providers will receive 5-Cog results through an interruptive alert when they access the patient's chart (as they do in cases of other clinical issues that can impact patient safety). Finally, the decision support tool will include a direct link to orders for the next steps in care. This reduces clinician cognitive load by providing a menu of options (such as appropriate laboratory, imaging, and referral orders) and minimizes clicks by consolidating these options in one place.

Our 5-Cog 1.0 protocol [32] can be referenced for additional detail on the development and design of the 5-Cog paradigm. Figure 1 depicts the 2 components of the 5-Cog paradigm.

Figure 1. (A) The 5-Cog battery (5-min cognitive assessment). (B) Decision support for a patient with a positive 5-Cog result. (C) Decision support for a patient with a negative 5-Cog result. EMR: electronic medical record.



Implementation Study

The United States Institute of Medicine (now the National Academy of Medicine) estimated a 17-year gap from when a clinical innovation is proven effective to when it is routinely implemented in clinical care [51]. Given that cognitive impairment detection paradigms are not adopted widely in primary care, it is important to systematically identify and address potential factors that influence implementation outcomes, that is, implementation determinants [52]. Our implementation measurements for the 5-Cog will be guided by the Consolidated Framework for Implementation Research (CFIR). The CFIR is an established implementation science theoretical framework for identifying implementation determinants [53,54]. We chose the CFIR because it facilitates the identification of implementation determinants that influence implementation outcomes either positively as facilitators or negatively as barriers [55-58]. Each CFIR construct is well defined, has established measures, and can be depicted in rich qualitative detail. The CFIR is practical because it is often used to both explore and subsequently optimize future implementation contexts and processes [59]. As with many implementation science frameworks, the CFIR does not mandate a specific data collection methodology [53]; studies applying the CFIR have used quantitative only, qualitative only, or mixed methods approaches [59]. We have chosen a mixed methods strategy to examine implementation contexts, processes, and outcomes. The study approach is based on the broader epistemology of critical realism [60] and more specifically the realist evaluation framework [61] wherein quantitatively measured implementation outcomes are explained by analyzing the relationships between implementation context and process factors. We will use the CFIR to identify implementation determinants through qualitative processes (interviews). We will use quantitative measures—the Acceptability of Intervention Measure (AIM), the Feasibility of Intervention Measure (FIM), and the Intervention Appropriateness Measure (IAM) [62]—to measure implementation outcomes. We will then analyze all findings using the CFIR as a lens to examine the relationships between these outcomes and implementation context and process factors [54,59].

Cost-Effectiveness Assessment

Currently, Medicare reimburses cognitive impairment assessments for older adults as part of their annual wellness visit (AWV) [22]. However, there is no standardized required form and output for this assessment. For health systems that would like to implement the 5-Cog for the AWV, questions may arise regarding its impact on costs. The 5-Cog battery is a low-cost intervention, requiring simple paper-and-pencil tools that are easily adapted to digital formats and minimal training to administer. For the 5-Cog decision support component, we anticipate programming and workflows to be translatable between EMR systems with a 1-time, upfront customization and without recurring software or staffing costs. Thus, the 5-Cog's direct expenses predominantly include staffing costs (eg, salaries, benefits, and travel expenses for workers administering the 5-Cog). Given the short duration and minimal supplies cost of the 5-Cog, indirect expenses (eg, scheduling, record keeping, facility overhead, and equipment depreciation) and opportunity costs (eg, forgoing other billable care) are anticipated to be minimal. Investigators have previously reported costs associated with both community health workers (CHWs) and practice facilitators throughout Indiana and the Midwest in the United States [63]. There may also be costs associated with dementia care actions resulting from the use of the 5-Cog. However, these follow-up costs may be offset by cost savings resulting from earlier dementia care intervention [64].

The goal of our budget impact analysis (BIA) [65-67] and cost-effectiveness analysis (CEA) [68] is to understand the cost per cognitive case identified from a societal and payer (eg, Medicare) perspective to facilitate informed dissemination (per the CFIR model). The study design for estimating the financial effects involves addressing several issues, many predetermined by BIA and CEA best practices and the Consolidated Health Economic Evaluation Reporting Standards [65-68]. The BIA will determine financial planning and affordability, and the CEA will determine the effectiveness and value of the 5-Cog compared to enhanced usual care. The BIA can be used to determine financial adoption and scalability for national implementation.

Trial Design

Given the problems of underdiagnosis and undertreatment of dementia, which are expected to worsen with the growing number of aging adults globally [69], we chose a hybrid type 1 effectiveness-implementation design for this trial. In this design, the primary emphasis is on testing the intervention, with a secondary emphasis on exploring implementation-related factors [55]. We chose this design because it would be premature to conduct an implementation-only trial, given that the 5-Cog has previously been studied in 1200 individuals in only 1 urban primary care setting. The hybrid type 1 effectiveness-implementation design allows us to confirm the effectiveness of our intervention, while also hastening its potential to make needed impact in the "real world" through incorporating implementation examination prospectively [55]. The clinical effectiveness (in this case, meaning the degree of beneficial effect [70]) component of the trial will be completed using a pragmatic, cluster randomized design (randomized at the level of the clinic) with intervention clinics receiving the 5-Cog paradigm and control clinics receiving enhanced usual care (cognitive concern information and cognitive impairment detection education provided but no detection approach or clinical decision support tool implemented).

Objectives

This trial's three aims are to (1) test whether the 5-Cog paradigm used in primary care patients with cognitive concerns in diverse urban and rural environments and including individuals from racial and ethnic minority groups and those with socioeconomically disadvantaged backgrounds leads to an increased rate of MCI and dementia diagnoses; (2) explore the implementation context, process, and outcomes of the 5-Cog paradigm in diverse primary care clinics using mixed methods guided by the CFIR; and (3) assess the cost-effectiveness of the 5-Cog paradigm.

We hypothesize that this trial will demonstrate the 5-Cog paradigm's effectiveness in increasing the diagnosis of MCI in dementia and primary care, its cost-effectiveness in achieving this outcome, and the range of factors shaping its successful implementation across diverse primary care settings.

Methods

Participants, Interventions, and Outcomes

Study Setting

The study is being carried out at primary care clinics affiliated with 2 large academic health systems: Montefiore Medical Center and Albert Einstein College of Medicine (hereafter referred to as Montefiore-Einstein) in the Bronx, New York, and Indiana University Health (IUH) in Indiana.

The Montefiore-Einstein clinics serve an urban population primarily composed of individuals from historically minoritized racial and ethnic groups (Hispanic/Latino and Black populations). Of note, these clinics serve Bronx County, which ranks last (62 out of 62) among New York State counties on health-related indicators [71] and has a significant poverty rate, affecting 1 in 4 older adults [72]. The IUH clinics are situated across both urban and rural settings. Within this network, 12 (75%) of the 16 selected clinics are located in regions scoring >60 on the national area deprivation index (score range 0-100; higher scores indicate higher deprivation) [73,74]. Notably, 2 (17%) of these 12 clinics are in areas with an area deprivation index score of >91, underscoring the profound level of need of these communities. Indiana health-related indicators show higher premature death, lower life expectancy, lower PCP and mental health provider availability, and lower median household income than the US average [74].

The study procedures are completed by research assistants (RAs), who are trained as CHWs and embedded in the clinics. This approach was chosen for its pragmatic value, reflecting reality in primary care settings in which CHWs are incorporated into clinical teams and may complete other screening questionnaires with patients [75,76] and because the 5-Cog components have been shown to be practical and feasible for administration by individuals who are not medical professionals and with minimal training [37,44,77]. The RAs at Montefiore-Einstein are bilingual in English and Spanish because of the high proportion of Spanish-speaking participants at this site. All study materials were translated from English into Spanish and back translated to ensure language fidelity.

Eligibility and Screening

Clinics are eligible to participate if they provide primary care (internal medicine or family medicine), not specialty care. Clinics primarily serving as residency teaching sites are excluded.

In keeping with the pragmatic nature of the trial, our individual-level eligibility criteria are designed to ensure that enrolled patients are those who would receive this intervention if it were part of usual care [78-80]. The 5-Cog intervention was designed to improve dementia diagnosis in ambulatory primary care settings. Individuals are excluded if they have a prior diagnosis of dementia or reside in a nursing home. Nursing home residents are excluded because they already have a high prevalence of diagnosed dementia (60%-90%) [81] and largely do not receive primary care from ambulatory clinics because of their mobility and cognitive limitations [82]. To be eligible

for our 5-Cog effectiveness study, individuals must be aged ≥65 years, have no prior diagnosis of dementia, speak English (Montefiore-Einstein or IUH) or Spanish (Montefiore-Einstein only), have a scheduled primary care office visit, and endorse a cognitive concern via a subjective cognitive concern questionnaire (SCQ) [32,83]. Initial screening is completed by RAs via prospective EMR review of patients scheduled at each clinic and confirmed through screening telephone calls.

Implementation study participants will be recruited from among patients, caregivers, clinicians, clinic staff, clinical leaders, clinical informatics staff, and administrative leaders. The exclusion criteria are the same as those for the effectiveness study.

Textbox 1 lists the complete individual-level inclusion and exclusion criteria, including the SCQ.

Textbox 1. Inclusion and exclusion criteria.

Effectiveness study

- Individual-level inclusion criteria
  - Aged ≥65 years
  - English or Spanish speaking (Albert Einstein College of Medicine and Montefiore Medical Center will enroll English- and Spanish-speaking patients; Indiana University Health will enroll only English-speaking patients)
  - Have a cognitive concern: subjective cognitive concern questionnaire result is positive (≥1 of the following: "Are you concerned about your memory?"—the chosen response is yes; "Are your loved ones concerned about your memory?"—the chosen response is yes; and "Is your mind as clear as it used to be?"—the chosen response is no)
- Individual-level exclusion criteria
  - Prior diagnosis of dementia (as recorded in the electronic medical record or reported by primary care provider; the prior diagnosis of mild cognitive impairment is not an exclusion criterion, but the effectiveness outcome is only counted if a participant previously diagnosed with mild cognitive impairment is assigned a new diagnosis of dementia)
  - Nursing facility resident

Implementation study

- Individual-level inclusion criteria
  - Patients who have undergone the 5-Cog battery, caregivers of these patients, clinicians, clinic staff, clinical leaders, clinical informatics staff, and administrative leaders at each of the randomized primary care practices
  - Ability to provide informed consent
- Individual-level exclusion criteria
  - Prior diagnosis of dementia (as recorded in the electronic medical record or reported by primary care provider; the prior diagnosis of mild cognitive impairment is not an exclusion)
  - Nursing facility resident

Recruitment of Clinics and Patients

The study team actively recruited clinics in the Bronx and Indiana to participate through contacting their administrative leadership to discuss the study. Generally, 1 to 3 meetings were held with clinic leadership and practicing clinicians to introduce the study and secure the clinic's commitment to participate.

All individual patient recruitment for the effectiveness study is passive. RAs review a clinic's scheduled patients via the EMR to determine which patients seem to meet the eligibility criteria and contact potentially eligible patients by telephone within 1 week before their scheduled office visit. The patient is informed that the caller is working with the patient's primary care practice to assess cognitive concerns. The patient is asked to confirm that they plan to keep their upcoming clinic appointment. If they have decided to change the appointment, cognitive concerns are not assessed. If the patient confirms their scheduled appointment, the RA administers the SCQ (Textbox 1). The patient is free to decline to answer, at which point the call is ended. When the patient answers the questions, the results are documented in the EMR. In the clinics randomized to the control arm, patients who have answered the SCQ are considered recruited; and if their SCQ result is positive, they are considered enrolled once they show up to their scheduled clinic appointment. In the clinics randomized to the intervention arm, patients with a positive cognitive concern are invited to undergo additional cognitive screening (the 5-Cog battery) at the clinic on the day of their office visit, just before they see their care provider. Patients who agree are considered recruited, with enrollment confirmed once they complete their scheduled office visit. In both arms, patients who do not show up to their scheduled clinic appointment after a positive SCQ result are not considered enrolled. If these patients have another scheduled clinic appointment during the study period at their clinic, they are eligible to be rerecruited and enrolled at this time (RAs will call and confirm SCQ responses before this visit).

Implementation study participants will be actively recruited from intervention sites through snowball sampling among different types of key informants mentioned previously. In addition, we will collect quantitative implementation surveys from as many clinicians and staff as possible at the intervention clinics.

Participant Timeline

The 22 participating clinics were randomized in year 1 of the study. These clinics are onboarded in waves throughout the 5-year study period. The time period over which each clinic will experience active study recruitment (with the goal of enrolling 300 patients per clinic) is anticipated to vary from 3 to 12 months, depending on clinic size.

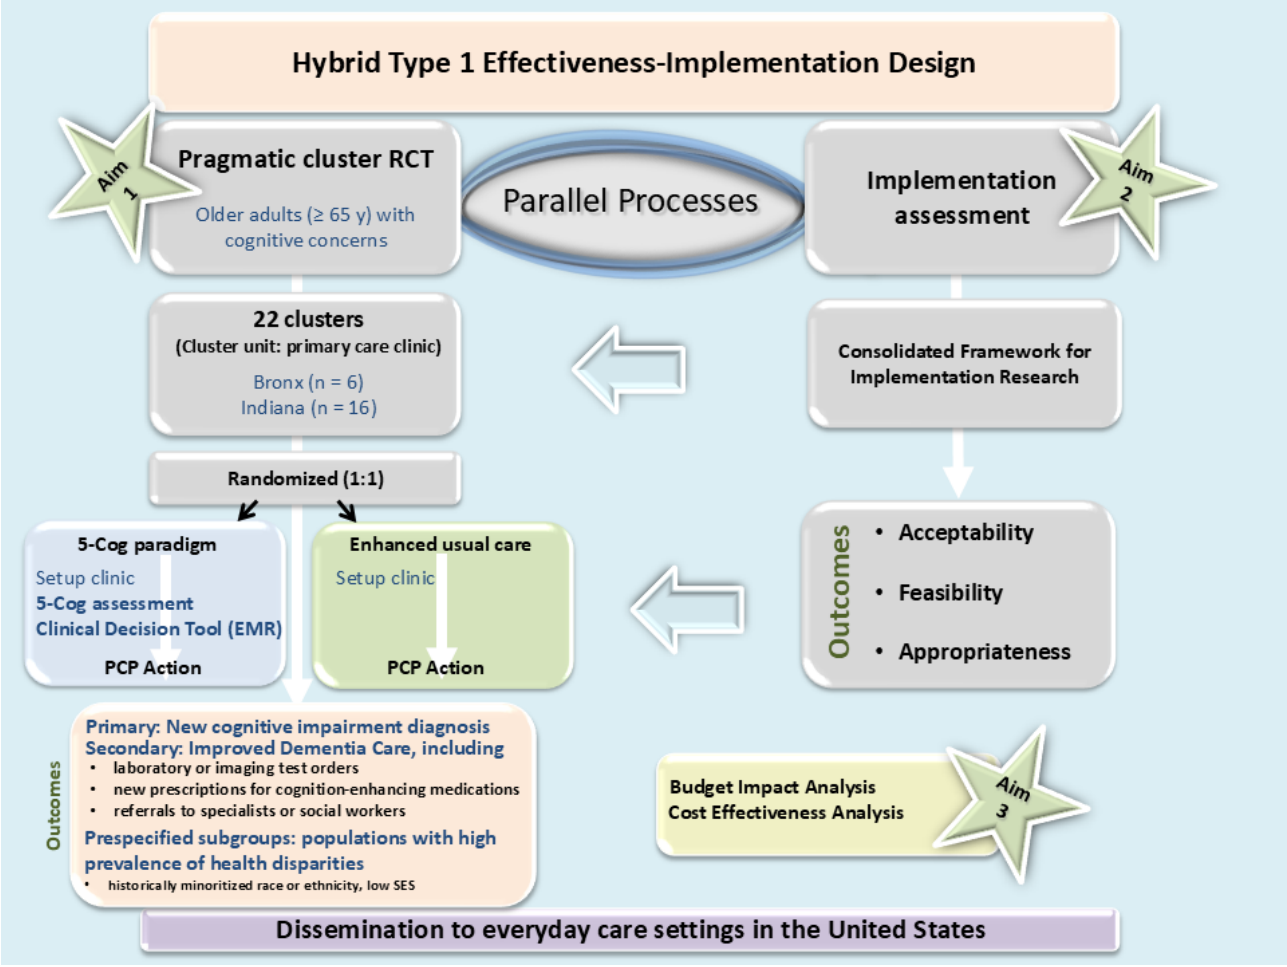
For individual patients in the effectiveness study, the initial screening and recruitment telephone call takes place within 1 week before a patient's scheduled primary care visit and takes 10 to 15 minutes. Patients are then considered enrolled when they complete their scheduled PCP clinic appointment.

At the intervention clinics, participating patients are asked to arrive up to 1 hour early for their scheduled visit to allow sufficient time for undergoing the 5-Cog battery before meeting their care provider. The 5-minute assessment is completed at the clinic before the appointment.

In both intervention and control groups, patients remain enrolled for 90 days. Study outcomes are ascertained at 90 days (primary and secondary end points), at which point the enrolled patients are considered to have completed participation. This time window was selected because >95% of physician actions for dementia care were completed within this period in our initial trial [33].

Implementation study participants are enrolled when they consent to participate in a survey or an interview, and their enrollment is completed at its conclusion. Figure 2 depicts the study flow.

Figure 2. Study flow. EMR: electronic medical record; PCP: primary care provider; RCT: randomized controlled trial; SES: socioeconomic status.



Planned Sample Size

The planned effectiveness study sample size is 6600 enrolled patients, including approximately 300 (4.56%) from each of the 22 participating clinics (Bronx: n=6, 27%; Indiana: n=16, 73%).

For the implementation interviews, we will use snowball sampling to identify the most relevant informants across clinics of different sizes. We anticipate conducting up to 6 implementation interviews per practice for a maximum total sample size of 132 participants or until thematic saturation is reached over the 5-year study period. We will disseminate the quantitative implementation surveys to the clinicians and staff at the intervention clinics.

Interventions in the Intervention Arm (5-Cog Battery With Decision Support Tool)

On the day of the patient's scheduled clinic visit, an RA meets the patient upon their entry into the clinic waiting area in preparation to complete the 5-Cog with them before their PCP visit. The RA escorts the patient through clinic registration. At the same time, the RA communicates with the clinical team to let them know that the patient will undergo the 5-Cog battery before being ready to see their care provider.

The RA administers the 5-Cog (refer to the Introduction section and Figure 1 for more details on the 5-Cog) in a private space within the clinic and then brings the patient back to the waiting area. Next, the RA informs the clinical team that the patient has completed the 5-Cog battery and is ready to be integrated back into the usual clinical workflow. The RA then completes documentation of the battery results in the EMR (and in the study database). The 5-Cog decision support recommendations are harmonized across sites for a positive 5-Cog result, as they are for a negative 5-Cog result (Figure 1).

Montefiore-Einstein and IUH use 2 different EMR systems: Epic (version 100.2412.0.0) and Cerner (version 2024.3), respectively. Unique features within each EMR are used to capture and house the 5-Cog results, create alerts, and present the results and decision support recommendations to the care providers.

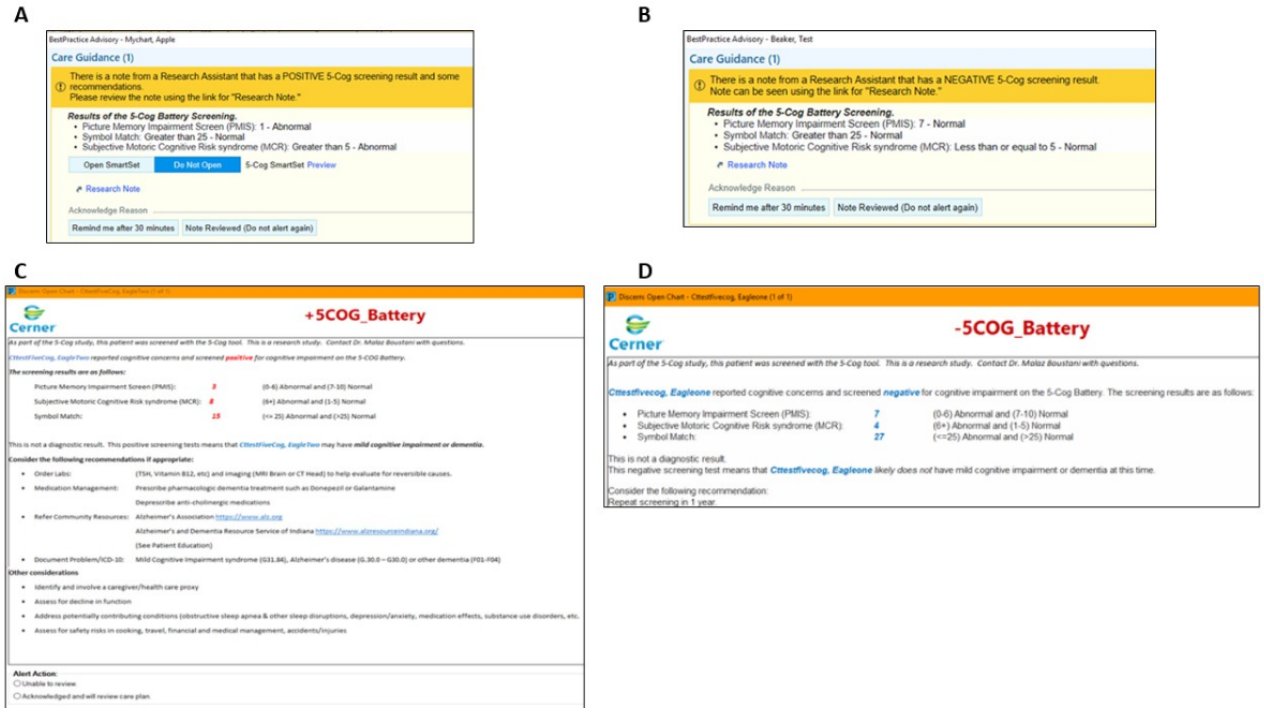
At Montefiore-Einstein, the RA creates a "research note." Here, they input the 5-Cog battery component scores by selecting from a drop-down list for each assessment. They also manually select the appropriate decision support arm (for positive vs negative 5-Cog result) using a quick-text feature. The EMR then responds to the results of the 5-Cog assessments, using structured data elements. Thus, the values that the RA enters for the three 5-Cog battery components trigger a preprogrammed tailored care provider alert, a "best practice advisory" (BPA). If the result of any of the 3 assessments indicates potential cognitive impairment, a "positive 5-Cog" BPA is triggered. If the results do not indicate potential cognitive impairment a "negative 5-Cog" BPA gets triggered. The BPA is "interruptive"; as soon as the care provider accesses the patient's medical record for the current visit in the EMR, they are shown the alert on their screen. The BPA contains the 5-Cog result with a hyperlink to the research note.

At IUH, the RA inputs the 5-Cog battery result into an EMR-based flowsheet through ad hoc documentation. Specifically, these results are entered into the "Results Review - Clinical Assessment" tab. The EMR is programmed to automatically trigger the appropriate decision support content based on the 5-Cog battery result. As at Montefiore-Einstein, a customized, interruptive alert is displayed to the provider. At IUH, the alert itself contains the 5-Cog result, along with all decision support recommendations.

In both IUH and Montefiore-Einstein EMR flows, care providers must respond to the interruptive alert, acknowledging it in some way. The options for this vary by EMR. At both sites, the alert for patients with a positive 5-Cog result also facilitates linking to an order set. This allows the care provider to efficiently and comprehensively select clinical actions that may be relevant to the patient's further cognitive care.

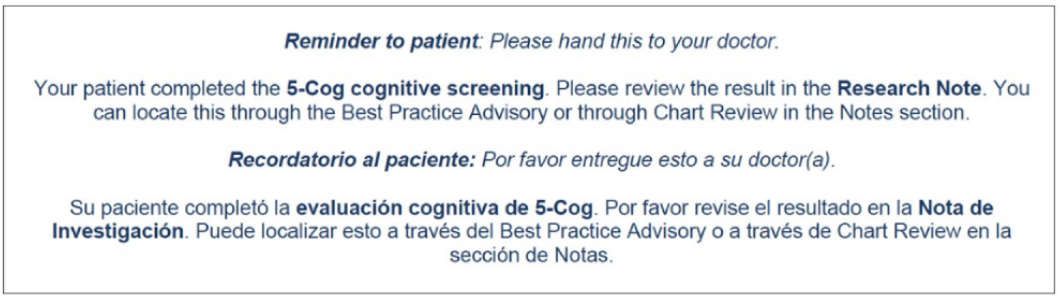
Figure 3 depicts a sample of the Montefiore-Einstein and IUH EMR alerts.

Figure 3. Electronic medical record (EMR)–based provider alerts for the intervention sites at the Albert Einstein College of Medicine and Montefiore Medical Center (Montefiore-Einstein; Epic EMR system) and Indiana University Health (IUH; Cerner EMR system). (A) Montefiore-Einstein: positive 5-Cog result. (B) Montefiore-Einstein: negative 5-Cog result. (C) IUH: positive 5-Cog result. (D) IUH: negative 5-Cog result.



At both sites, a paper token (Figure 4) is used as an additional feature to help ensure that care providers review the patients' 5-Cog results. Patients are handed this token after they complete the 5-Cog battery and are asked to hand it to their care provider at their scheduled visit, generally within 30 minutes after the 5-Cog battery administration.

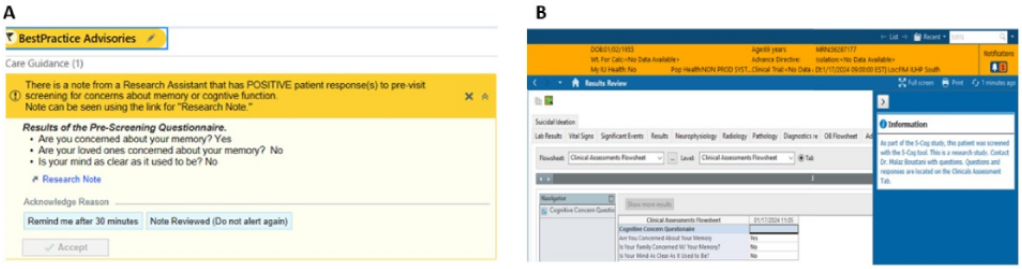
Figure 4. Token to alert care provider for patient's 5-Cog participation.



Interventions in the Control Arm (Enhanced Usual Care)

Patients are screened via telephone using the SCQ, as described in the Recruitment of Clinics and Patients subsection. RAs input results into the EMR. Care providers receive positive SCQ results through noninterruptive alerts. Figure 5 presents images of the alerts at Montefiore-Einstein and at IUH. We are calling this arm "enhanced usual care" because care provider are informed about the presence of a cognitive concern in their patient in this group. In addition, as at the intervention sites, care providers at the enhanced usual care sites receive preparatory education (described in the next subsection). The care providers at the control and intervention sites do not overlap.

Figure 5. Electronic medical record (EMR)–based care provider alerts for the control sites at the (A) Albert Einstein College of Medicine and Montefiore Medical Center (Epic EMR system) and (B) Indiana University Health (Cerner EMR system).



Care Provider Education and Preparation in Both Arms

Care providers at both control and intervention sites receive Microsoft PowerPoint presentations on the 5-Cog study. The presentations review the background to the study and then explain the study interventions that will be carried out at the sites (SCQ and new EMR features at both sites; 5-Cog at intervention sites). The presentations last 10 to 15 minutes at the control sites, and 25 to 30 minutes (to allow education about the 5-Cog battery) at the intervention sites. These presentations are provided 2 to 4 weeks before study start at a regularly scheduled clinic staff meeting. In addition to this education, care providers are given brochures that review cognitive impairment detection, diagnosis, treatment, and billing and invited to contact study staff at any time with questions. Finally, they are given tip sheets summarizing the new EMR features. At the intervention sites, care providers are updated on study progress via a monthly email or an informal in-person check-in by a study leader.

Of note, at both intervention and control sites, members of the interprofessional clinic leadership team (administrative and nursing managers) are provided with education on the study procedures and flow so that they can be prepared to assist and appropriately direct any patients who have questions about the study. At the intervention sites, members of the interprofessional clinic leadership team are also engaged in a session to plan clinic-customized logistical workflows to minimize interruptions to the clinic's operations during the course of the study. These workflows, along with a background to the study, are presented to the full interprofessional clinic staff before study initiation.

Interventions for the Implementation Study

From the intervention sites, a subset of patients (after the completion of study procedures and clinic visit) and providers will be invited to complete interviews to assess implementation issues. We will adapt the semistructured CFIR interview question guide. Interviews will be conducted, recorded, and analyzed by study staff trained in qualitative interviewing. We will aim to include patients with both positive and negative 5-Cog results. PCPs and clinical staff at the intervention sites will be asked to complete quantitative surveys containing 3 standardized 4-item measures: the AIM, FIM, and IAM [62]. The implementation outcomes measures are written at a fifth grade reading level; therefore, no specialized training is needed for administration, scoring, or interpretation. Finally, we will retain and later analyze recordings and field notes from our preimplementation stages (initial conversations with clinics and readiness presentations) through the completion of the project. This analysis will assess the barriers and facilitators to primary care sites' buy-in for study engagement. We will also use

summary reports to discern trends in care provider responses to the EMR-based alerts.

Interventions for the Cost-Effectiveness Study

Billing and actuarial data will be extracted from the EMR for cost estimation. In parallel fashion to the intervention sites, costs are also collected at the control sites. Standardized cost calculators previously developed by investigators [67,84] will also be used to facilitate microcosting (measuring detailed resource use and unit costs to obtain precise estimates [85]) applicable to the 5-Cog paradigm. We will evaluate the cost of implementing and sustaining the 5-Cog paradigm by accounting for and itemizing specific program characteristics. We will evaluate differences in 5-Cog costs of care on the desired study outcomes compared to enhanced usual care.

Effectiveness Study: Primary Outcomes

The primary outcome is a new diagnosis of MCI or dementia within 90 days after study enrollment. Patients who enter the study with a known diagnosis of MCI will only be counted as meeting the primary outcome if they receive a new diagnosis of dementia. We chose diagnosis as the primary outcome for 2 reasons. First, a new diagnosis was a common outcome in our 5-Cog 1.0 study, and we want to validate this finding [33]. Second, this outcome is highly relevant to patients and PCPs: knowing their cognitive diagnosis has been shown to be important to patients and family members [34,86,87]; moreover, diagnostic clarity facilitates appropriate psychoeducation, resource connections, tailored medical treatment, and caregiver activation [88,89].

Effectiveness Study: Secondary Outcomes

The secondary outcome is a composite: “improved dementia care” within 90 days after study enrollment. “Improved dementia care” is defined by any of the following actions that are relevant to dementia diagnostic assessment and care: orders for dementia-related laboratory or imaging tests; a new prescription for cognition-enhancing medication or the deprescribing of anticholinergic medication; or referrals to a dementia specialist clinician, a nurse navigator, a social worker, or a community-based organization for related supports. We are including this composite outcome because a new diagnosis without subsequent action is less likely to improve patient outcomes. The aforementioned components are highly relevant to both PCPs and patients [90,91]. The actions described are only counted as an outcome if a cognitive indication (eg, memory loss or MCI) is entered as the indication in the EMR. Tests or referrals without indications entered or performed for any other medical reasons are not counted as outcomes. Prescription of dementia medications will always be counted because these medications inherently indicate cognitive impairment. For anticholinergic deprescribing, actions will be counted via a comparison of EMR-extracted medication lists from the 90 days before and after study enrollment. Charts will be reviewed for clinician notation on whether deprescribing (discontinuation or nonrenewal) was due to a cognitive indication [92]. We will consider the medications listed under “Drugs with strong anticholinergic properties” in the American Geriatrics Society Beers Criteria [93].

All primary and secondary outcomes are collected prospectively from the EMR. Textbox 2 presents a summary of the primary and secondary outcomes.

Textbox 2. Study outcomes.

Primary outcome: new cognitive diagnosis (with associated International Classification of Diseases, Tenth Revision, code [94])

- Vascular dementia with or without modifiers (F01)
- Dementia in other diseases with or without modifiers (F02)
- Unspecified dementia with or without modifiers (F03)
- Mild cognitive impairment or minor neurocognitive disorder (unless patient entered study already having this diagnosis; G31.84)
- Alzheimer's disease with late onset (G30.1)
- Other Alzheimer's disease (G30.8)
- Alzheimer's disease, unspecified (G30.9)
- Frontotemporal dementia (G31.09)
- Lewy body dementia (G31.83)
- Dementia associated with alcoholism (F10.27)
- Unspecified with psychoactive substance–induced persistent dementia (F19.97)
- Variant Creutzfeldt-Jakob disease (A81.01)
- Creutzfeldt-Jakob disease, unspecified (A81.00)
- Other Creutzfeldt-Jakob disease (A81.09)

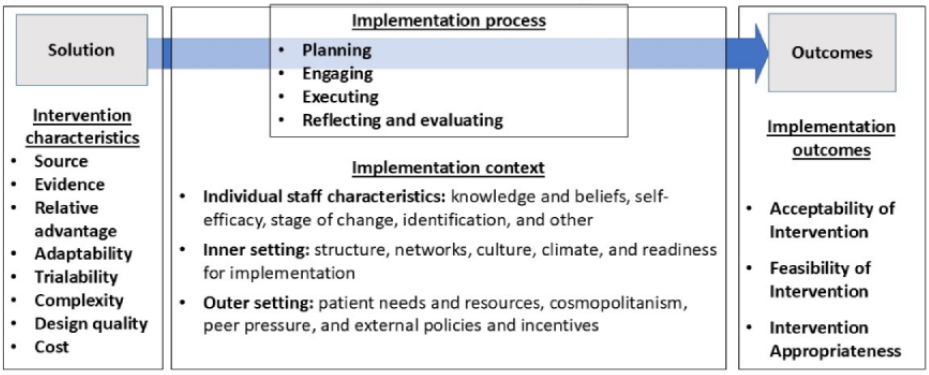
Composite secondary outcome: "improved dementia care" through relevant actions

- Medications: donepezil, rivastigmine, galantamine, memantine, donepezil-memantine, antiamyloid monoclonal antibody infusions, and any other Food and Drug Administration–approved medications for dementia
- Deprescribing anticholinergic medications: discontinuation or nonrenewal of any of the 41 medications in table 7 ("Drugs with strong anticholinergic properties") of the American Geriatrics Society Beers Criteria [93]
- Laboratory tests (cognitive indication only): thyroid-stimulating hormone, vitamin B12, glycated hemoglobin, complete blood count, basic metabolic panel, liver tests, HIV antigen and antibody combination, and syphilis immunoglobulin G and immunoglobulin M antibody with reflex
- Imaging tests (cognitive indication only): computerized tomography (head without contrast) and magnetic resonance imaging (brain without contrast)
- Specialist referrals for cognitive evaluation: geriatrics, neurology, neuropsychology, psychiatry, geriatric psychiatry, and social work
- Community referrals: Alzheimer's Association or local support organization

Implementation Outcomes

We will begin recruiting implementation study participants after approximately 1 month of patient involvement at each study site, once a "steady state" has been established. We will vary time points for the collection of implementation outcomes throughout our engagement at each clinic in anticipation that informant responses may shift with varied exposure to the 5-Cog. Surveys will assess the implementation outcomes of acceptance, feasibility, and appropriateness, which are considered "leading indicators" of implementation success. These will be measured using the AIM, FIM, and IAM, as noted in the Interventions for the Implementation Study subsection [62,95]. The results of the surveys will be computed using descriptive statistics (central tendency and variability) and, after checking for assumptions (eg, high interclass intraclass correlation), aggregated at the clinic level across all respondents. We will also collect and analyze EMR engagement data (eg, the rates and types of responses to alerts and the use of order sets) to assess the acceptance of EMR tools. In addition, we will collect field notes with observations about the study sites and observations from informal conversations with clinic staff during the study period to better understand the implementation context. Figure 6 summarizes the implementation constructs and the CFIR outcome measurement model for the study.

Figure 6. Consolidated Framework for Implementation Research (CFIR) Measurement Model.



Cost-Effectiveness Outcomes

The cost calculator includes parametric models of cost inputs; cost model outcomes from this study will thus allow scenario analyses [67,84]. The proposed calculator will incorporate both the direct costs of the intervention (test administration, staffing costs, etc) and costs associated with interventions prompted by the 5-Cog (brain imaging, specialist referral, laboratory tests, etc). The cost calculator will thus enable others to determine 5-Cog delivery costs and implementation specifics such as the cost of hiring at future implementation sites. Data collected for the BIA will determine financial planning and affordability, while data collected for the CEA will determine the effectiveness and value of the 5-Cog paradigm compared to enhanced usual care.

Exploratory Outcomes

Medical billing for cognitive impairment detection paradigms may be an important component of sustainability [22] because PCPs often lack sufficient resources to support the effort required to care for patients with complex needs [96]. The 5-Cog may have benefit in enhancing billing opportunities because it incorporates 5 minutes of cognitive testing and may add to the level of medical complexity of a visit. As noted, one of the 5-Cog 2.0 study interventions—implemented at both 5-Cog and control sites—is provider education on billing for cognitive impairment detection, diagnosis, and treatment. Although the 5-Cog study does not include PCP billing interventions as part of its aims, we will monitor and compare the rates of use of "cognitive" billing codes (eg, Medicare AWV and current procedural terminology codes 96136 and 96138 [97]) between the 5-Cog and enhanced usual care sites. At the 5-Cog sites, we will examine whether the use of "cognitive" billing codes is associated with 5-Cog paradigm administration.

Assignment of Interventions

Sequence Generation

As in other pragmatic cluster randomized trials [98], we randomize at the clinic level. Commitment to join the study was sought from clinics. Once an adequate number of clinics (n=22) were identified, they were randomized. Computer-generated randomization assigned primary care practices in a 1:1 ratio within each site (the Bronx and Indiana) to either the 5-Cog paradigm or control arm. Randomization was stratified within each arm by clinic size (number of PCPs).

Allocation Concealment Mechanism

Randomization is central, computer generated, and not vulnerable to researcher influence. The study statisticians are blinded to interventions and other aspects of the trial.

Implementation

The 22 clinic clusters will be phased in gradually for logistical reasons, following a standardized procedure at each clinic: an overview presentation for leadership, a readiness presentation for providers and staff, and then study initiation.

Masking

Blinding of patients or PCPs at 5-Cog sites will not be feasible due to the nature of the intervention. However, the outcome is EMR based, and data abstractors will be blinded to allocation. Standardized checklists will be used for outcome measurement to further minimize bias. Statisticians will not be involved in the intervention delivery.

Data Collection, Management, and Analysis

Data Collection Methods

Data will be collected from 2 sources (refer to the following subsections).

EMR Data

We will collect EMR data on trial-enrolled patients aged ≥65 years receiving care in the participating practices after obtaining consent from the practice leadership and receiving a waiver from the institutional review board (IRB). Outcomes will be extracted and aggregated from the EMR. Deidentified analytic databases will be created and analyzed by investigators.

Feedback From Care Providers, Staff, and Patients

Data on clinician and practice staff perceptions of the intervention and factors that facilitated or impeded implementation and sustainability will be obtained through digital surveys and in-person interviews with key informants. Data on patient perceptions and experiences with the 5-Cog will be obtained through in-person, telephone, and video call platform interviews. Data collection will be the responsibility of the clinical trial staff at the site under the supervision of the site investigators. The investigator will be responsible for ensuring the accuracy, completeness, legibility, and timeliness of the data reported. All source documents will be completed in a neat, legible manner to ensure accurate interpretation of

data. Hard copies of the study visit worksheets will be provided for use as source document worksheets for recording data for each participant consented and enrolled in the study. Data recorded in the electronic case report form derived from the source documents will be consistent with the data recorded on the source documents. All effectiveness and implementation data will be entered into REDCap (Research Electronic Data Capture; version 14.0.31; Vanderbilt University), a 21 CFR Part 11–compliant data capture system provided by the Albert Einstein College of Medicine through an NIH grant (UM1TR004400). The data system includes password protection and internal quality checks, such as automatic range checks, to identify data that seem inconsistent, incomplete, or inaccurate.

Data Management

Data collected for this study will be analyzed and stored at the Albert Einstein College of Medicine via REDCap. These data will be available through web-based registration to researchers for future analyses after the completion of our pragmatic clinical trial and publication of the main results. For resource-sharing approval, collaborators—both internal and external—will be required to register on the web and submit a resource transfer agreement. Requests can be submitted electronically to expedite research progress. Requests will also be reviewed by the steering committee at regularly scheduled meetings.

Effectiveness Study: Statistical Plan

The baseline characteristics of the clinical sites as well as individual enrolled patients will be examined after the baseline measurement time point at the halfway point of target enrollment. It is possible that baseline differences between the groups or missing data will limit the value of data analysis of measurements. Effects on the power to detect differences in the primary outcome will be evaluated and communicated to the principal investigators (PIs), data safety monitoring board (DSMB), and NIH. Given the monitoring plans outlined in the Monitoring subsection, it is exceedingly unlikely that there will be baseline differences between the groups of a magnitude that could threaten the validity of the study.

We will evaluate the clinical effectiveness of the 5-Cog paradigm on new cognitive impairment detection by comparing the proportion of “new MCI and dementia diagnoses” by PCPs within 90 days after the clinic encounter in the 5-Cog paradigm group versus the enhanced usual care group using generalized linear mixed effects (GLME) models with a logit link to account for clinic-clustered data [99]. Using these models, odds ratios of new MCI and dementia diagnoses between the 5-Cog paradigm and enhanced usual care arms will be calculated and tested. We chose a 90-day cutoff because the majority of PCP actions occurred within the first 30 days in our recent RCT [33]. The 22 clinics are cluster randomized to either the 5-Cog paradigm or enhanced usual care arm, which can result in correlated data due to clustering of patients within clinics. This issue will be handled using random effects in the mixed models. Proportions of new MCI and dementia diagnoses for each treatment group will also be reported. We will perform an intention-to-treat analysis. As a secondary approach, we will also perform a per-protocol analysis. All estimates will be reported together with their 95% CIs. The same method will be used for the secondary outcome (“improved dementia care”).

Stratified analyses across the 22 sites will be performed for groups impacted by health disparities, as designated by the NIH, including those from racial and ethnic minority groups (Black and Hispanic individuals) and individuals from socioeconomically disadvantaged backgrounds. Interactions between race and ethnicity and socioeconomic status (SES) will also be explored by stratified analyses by the combination of the 2 factors and by including the 2 factors and their product as well as interactions with the treatment groups in the GLME model for all enrolled patients. We will compare 5-Cog results by location in sensitivity analyses to detect any health care system–based variations.

All sample size and power calculations were performed using 2-tailed tests with a significance level of α=.05. The within-cluster intraclass correlation in this cluster randomized trial is assumed to be 0.05 based on prior studies [100]. On the basis of our RCT data, the proportions of “new MCI and dementia diagnoses” are expected to be 14% and 2% among the 5-Cog and control arms, respectively. The proportions of “improved dementia care” are expected to be 21% and 7% among the 5-Cog and control arms, respectively. In our total sample (N=6600), we have >99% power to detect the overall effectiveness of the 5-Cog paradigm on “new MCI and dementia diagnoses” and the secondary outcome of “improved dementia care.” Sample size determination was based on the primary outcome among individuals from racial and ethnic minority groups (2112/6600, 32%) and those with low SES (3750/6600, 56.82%). Assuming that 80% (1400/1800) of the participants in the 6 Bronx clinics are from racial and ethnic minority groups, and 75% (1350/1800) have low SES, as well as 14% (672/4800) and 50% (2400/4800), respectively, in the 16 Indiana clinics, 300 patients per cluster (clinic) will enable the detection of the effect of the 5-Cog paradigm on new MCI and dementia diagnoses with 81% power among individuals from racial and ethnic minority groups and 99% power among those with low SES.

Our outcomes are ascertained from the EMR by blinded assessors and do not require repeat in-person assessments. This will minimize missing data issues. We will implement robust EMR-based data management processes to further minimize missing data. Cluster sites are not contiguous, and patients within a cluster are assigned to specific PCPs who do not work across sites. Any intentional or unintentional contamination will be monitored by the data team, including by comparing enrolled patient lists across the sites.

Implementation Study: Statistical Plan

Interview data will undergo content analysis to identify and score implementation barriers or facilitators. Qualitative content analysis will be performed primarily using a deductive approach, starting from a developed theoretical model—the CFIR—and its associated hypotheses and then examining data to disconfirm or confirm these hypotheses [101]. The analysis will also allow for the inductive development of new themes, categories, and relationships as they arise from the data [102]. Deductive data analysis will be guided by the CFIR constructs and their

definitions such that units of qualitative data (sentences or passages) are assigned to ≥1 codes reflecting the CFIR constructs [102]. We will use NVivo 15 (Lumivero) to manage and code qualitative data. For each implementation interview, there will be an artificial intelligence–generated transcript that will be manually reviewed by study staff before it is moved into NVivo. To guide systematic coding, a codebook will be developed. A multiple-analyst team will be trained and tested on its application. Analysts will code a random subset of interviews together during training and then assigned at a ratio of 2 to 3 per transcript for either all or a subset of transcripts, depending on the original level of coding agreement (ie, interrater reliability) [103,104]. Subsequent coding discussions will be held intermittently for the calibration and discussion of difficult cases and disagreements. Interrater reliability will be computed in NVivo at the start, middle, and end of coding, with retraining and adjustments to the plan depending on the results. Inductively, we will allow for the emergence of new codes and subcodes [104]. We will also use applied thematic analysis [105] to identify patterns within and between codes. As much as possible, data analysis will occur in parallel with data collection, enabling us to adjust data collection procedures to capture emerging and unexpected phenomena, as well as perform member checking with informants willing to complete follow-up interviews to review and validate our coding of their initial interviews. Within each CFIR code, for each implementation context or process element, the assigned analyst will add a rating on a scale ranging from +3 (strong facilitator) to −3 (strong barrier) [54]. Analysts will be trained to use evidence from interviews and not personal opinions to rate each driver [102].

RAs in Indiana and the Bronx will be trained by coinvestigators to reliably collect implementation process data from a combination of documents, field notes, and interviews, with select staff responsible for the implementation process. To capture implementation data monthly, while minimizing staff burden, we will use the Prospectively Reported Implementation Update and Score [106]. The analysts will reconstruct these data into process maps or workflow diagrams depicting key historic moments, process variations, and players [54,59,102].

Linking Implementation to Effectiveness Analysis

Examining how stakeholder-level factors impact and are impacted by the 5-Cog implementation is critical because implementation can be influenced by stakeholders' characteristics, attitudes, intentions, and motivations. Stakeholder-level factors are also shaped by organizational factors [107]. Following the guidance of Damschroder and Hagedorn [58], we will link identified and rated (+3 to −3) context and implementation process drivers to implementation outcomes. Our analytical approach is as follows: we will derive clinic-level mean and variability measures of the AIM, FIM, and IAM scales and examine whether these implementation measures are associated with cognitive impairment detection by using GLME models with a logit link, treating the mean and variability measures of the AIM, FIM, or IAM as independent variables [108]. This analysis will determine how detection rates are associated with the levels or variabilities in implementation acceptance, perceived feasibility, and appropriateness within each clinic. We will explore whether and how context variables account for 5-Cog effects on outcomes by including quantitative context measures and interactions with the intervention group as independent variables in the GLME models from the effectiveness analysis [108]. We will then develop a thematic matrix that includes characteristics derived from stakeholder surveys and emerging themes from our qualitative data for each 5-Cog clinic site and conduct side-by-side comparisons—at system, organizational, and staff levels—of the factors that were identified as facilitating or hindering 5-Cog implementation. We will note common and unique factors for each clinic or location. This will generate a list of relevant system-, organizational-, and staff-level factors and processes organized by level of consensus (ie, identified by >1 source) and operational salience (ie, identified as critical for implementation). We will use this list to generate a heuristic model to inform future implementation strategies [54,55].

CEA and Economic Impact

Using data from the BIA cost-tracking tool, the cost-effectiveness ratio [109,110] "numerator" will account for site personnel and other costs at both intervention and control sites. The denominator will represent the number of cognitive impairment cases identified at the 5-Cog and control sites. In summary, the cost-effectiveness ratio represents the incremental cost of the 5-Cog intervention compared to enhanced usual care to achieve a clinically meaningful change, divided by the difference in effectiveness, to determine the cost per cognitive impairment case identified. This is expressed as follows:

Cost-effectiveness ratio = intervention costs + Δ (health care costs) / Δ health outcomes (5-Cog) – Δ health outcomes (enhanced usual care comparison group)

To assess uncertainty in our analysis, we will follow the recommendations of the International Society for Pharmacoeconomics and Outcomes Research and the Society for Medical Decision Making Modeling Good Research Practices Task Force [63,65-68,111]. Variability of inputs across study sites with differing levels of social determinants of health will be included in analyses [112]. Differences in intervention and health care costs due to secondary procedures will be assessed individually using negative binomial regression and reported with a 95% CI. Only statistically significant differences from the regression analyses will be incorporated into the cost-effectiveness ratio. Differences in health outcomes will be assessed as described in the Effectiveness Study: Statistical Plan subsection, and the estimate of the GLME model, if significant, will be incorporated into the cost-effectiveness ratio. Costs will be discounted at a 3% annual rate for the trial period, as recommended by the Second Panel on Cost-Effectiveness in Health and Medicine [113].

Monitoring

Data Monitoring

Each clinical site will perform internal quality management of study conduct, data collection, documentation, and completion. All sites will follow a common quality management plan. Before we began data collection, the PIs and the DSMB chair reconfirmed that our sites have appropriate safety measures in

place. The DSMB met with the entire research team to review the study protocols. Particular attention was paid to outcome definition, study design, procedures for recording and reporting adverse events (AEs), informed consent procedures, and documentation. At its initial meeting, the DSMB approved the protocol and formulated its operating procedures (eg, meeting schedule, report deadlines for the study statistician, unblinding policy, and guidelines for releasing interim data to the investigators). At this meeting, the plans for interim monitoring for efficacy and futility were presented to the DSMB to aid in trial oversight. We will train competent staff to conduct the assessments and ensure that they understand the data collection procedures and process as well as AE reporting requirements.

Effectiveness Study: Monitoring for Harms

Patients who receive care at the practices randomized to implement the 5-Cog paradigm may experience minimal risk through their participation. It is possible that patients may feel shame, anxiety, and some emotional discomfort when completing the cognitive assessment; however, this may be the case with the standard of care cognitive assessment as well and may not be specific to the intervention arm. In addition, in our ADRD screening trial that evaluated the potential benefits and harms of ADRD screening, there were no differences between the screened and control groups in quality of life, depressive symptoms, or anxiety [114,115]. That trial also assessed the impact of this early diagnosis on participants' quality of life and care and found no negative impact on quality of life, depression, anxiety, health care use, or independence at home [114,115]. The risk of potential harm such as stigma is not known. However, the early detection of ADRD is considered part of the standard of care, and screening for ADRD is part of the AWV covered by Medicare because of the significant potential benefits.

Implementation Study: Monitoring for Harms

Answering questions on surveys and participation in interviews with trained personnel involve minimal psychological, social, or other risks. We do not expect any AEs during these noninvasive assessments.

Full Study: Monitoring for Harms

Safety oversight will be under the direction of a DSMB composed of individuals with the appropriate expertise. We will set up a data safety monitoring plan, which will be monitored by the PIs and DSMB. The PIs will also conduct data and safety monitoring and will regularly monitor study progress, goal achievement, and overall research direction in consultation with the coinvestigators. Members of the DSMB will be independent from the study conduct and free of conflicts of interest. The DSMB, which will meet at least semiannually to assess safety and efficacy data from each study arm, will operate under the rules of an approved charter that was written and reviewed at its organizational meeting. The DSMB will provide its input to the National Institute of Neurological Disorders and Stroke and NIH staff.

AEs will be monitored on an ongoing basis by the study managers through self-initiated reports from participants or patients, observations of research and clinic staff at the intervention sites, biannual review of acute care use among enrolled patients, and review of EMR data at 90-day outcome collection for any medical records or notes of medical, psychological, or stress symptoms possibly related to the administration of the 5-Cog battery. In addition, a list of hospitalizations and emergency department visits (for any reason) occurring within 90 days after the clinic visit will be generated by the EMR system, which will be reviewed by the PIs and study investigators. All AEs not otherwise precluded per the protocol will be captured on the appropriate case report form. Information to be collected includes event description, time of onset, clinician's assessment of severity, relationship to study procedures (assessed only by those with the training and authority to make a diagnosis), and time of resolution or stabilization. All AEs occurring during the study will be documented appropriately regardless of their relationship to the intervention and followed until adequately resolved. Any preexisting medical or psychiatric conditions at screening will be considered baseline and not reported as an AE. However, any deterioration in a patient's clinical or psychological condition during the assessment will be recorded as an AE. Changes in AE severity will be documented to assess the duration of the event at each severity level. For AEs characterized as intermittent, the onset and duration of each episode will be documented. New diagnoses of MCI or dementia may result in psychological stress for patients that may not be captured in the EMR. Hence, we will also assess these more subtle psychological symptoms during the implementation interviews.

Auditing

Quality control procedures will be implemented. In the implementation study only, regarding informed consent, study staff will review both the documentation of the consenting process and a percentage of the completed consent documents to evaluate compliance with good clinical practice, accuracy, and completeness. Feedback will be provided to the study team to ensure that proper consenting procedures are followed. To assess data accuracy (the level of correctness of stored information [116]), site staff will compare a representative sample of source data against the database, focusing on key data points. The study team will review protocol deviations on an ongoing basis and implement corrective actions if deviations reach a concerning level. Should independent monitoring become necessary, the PIs will provide direct access to all trial-related sites, source data and documents, and reports for monitoring and auditing by the funding agency and inspection by local and regulatory authorities.

Ethical Considerations

The Albert Einstein College of Medicine IRB approved this study (2022-14144) and serves as the IRB of record for both sites under a reliance agreement with the Indiana University IRB. This study will be conducted in accordance with federal publication and data-sharing policies and regulations. Regarding consent for participants, we received a waiver of informed consent from individual patients from the IRB to maintain the pragmatic design of the clinical trial. For the implementation part of the study, consent is obtained from all participants before

completion of any study measures. Participants who consent for the implementation study receive US $25 in compensation for completed interviews. Outcomes will be extracted and aggregated from the EMR and will be deidentified. After the study is completed, the deidentified, archived data will be transmitted to and stored in a data repository with protections in place for patient confidentiality.

Results

The grant was funded, and the protocol received IRB approval, in September 2022.

Effectiveness Study

A validation cohort of 76 older patients (mean age 76.5, SD 7.72 y; n=50, 66% women) from dementia centers at Montefiore Einstein was evaluated with the 5-Cog battery to determine optimal cut scores. This was completed by July 2023. Among these 76 patients evaluated by the multidisciplinary care provider team at these centers (neuropsychology, neurology, and geriatrics), the resulting clinical diagnoses were as follows: 32 (42%) had a diagnosis of dementia, 28 (37%) MCI, 12 (16%) subjective cognitive concerns without objective cognitive impairment, and 2 (3%) had no cognitive diagnosis assigned. The mean scores on the PMIS were 5.8 (SD 2.7), Symbol Match 27.2 (SD 18.2), and sMCR 2.4 (SD 1.7). We correlated performance on the individual 5-Cog battery tests with the Blessed Information-Memory-Concentration Test scores (range 0-32; higher scores indicate worse performance), an omnibus test of general mental status (mean 10.3, SD 6.8). The PMIS (Pearson r=−0.76; P<.001) and Symbol Match (r=−0.69; P<.001) showed excellent correlation with Blessed scores. While the sMCR was not correlated with Blessed scores (r=0.008; P=.95), it was correlated (r=−0.34; P=.007) with walking speed (mean 72.3, SD 25.3 cm/s) in this sample. The PMIS was correlated (r=−0.59; P<.001) with the 5-item memory recall subtest on the Blessed Information-Memory-Concentration Test (mean 2.9, SD 1.84; higher scores indicate worse performance). Symbol Match was correlated (r=0.88; P<.001) with the Symbol Digit Modalities Task score (mean 21.2, SD 14.6; lower scores indicate worse performance).

As we examined the sensitivity and specificity data to choose cut scores, we chose to favor sensitivity to minimize missing individuals with true disease in this sample of patients considered high risk because of their cognitive concerns. The cut scores for a *positive* result on the 5-Cog components were as follows: PMIS ≤6 (range 0-8), Symbol Match ≤25 (range 0-65), and sMCR >5 (range 0-7). There was a high rate of completion of the PMIS (75/76, 99%), Symbol Match (76/76, 100%), and sMCR (74/76, 97%) tests on the 5-Cog battery, indicating high acceptability and feasibility of administration of the 5-Cog battery in populations with cognitive impairments.

The DSMB met in July 2023, approved the protocol and data safety monitoring plan, and authorized study enrollment. By October 2023, all 22 clinics had agreed to participate and been randomized. By November 2023, decision support tool integration into the EMRs had been finalized. As of December 2024, a total of 12 clinics had completed onboarding processes (refer to the Methods section, Care Provider Education and Preparation subsection), and 2369 patients had been enrolled.

Implementation Study

We have completed 6 implementation interviews and 23 implementation surveys over 12 clinic sites.

Cost-Effectiveness Study

5-Cog 2.0 investigators have already collected procedure and health care cost estimate data for Montefiore-Einstein for a 5-Cog 1.0 CEA. Preliminary results suggest that the 5-Cog paradigm is a cost-effective option compared to “enhanced usual care” for the early detection of cognitive impairment in primary care (H Congivaram, BS, unpublished data, December 2024). Investigators have begun collecting cost estimates for 5-Cog procedures and resulting health care costs in the IUH system, as these were not previously collected.

Discussion

Anticipated Findings

The results of this 5-Cog 2.0 RCT will provide additional evidence that the 5-Cog paradigm is effective in improving dementia diagnosis. At the same time, the implementation portion of this study will provide critical information about the context, facilitators, and barriers to using the 5-Cog successfully, while the cost-effectiveness portion of this study will offer a practical analysis of the cost implications of the paradigm. Taken together, these study outcomes will allow informed, tailored, and rapid adaptation and dissemination of the 5-Cog paradigm to diverse primary care environments.

Meeting the ongoing and anticipated growing need for timely dementia diagnosis and care has been a focus of much study. Despite the availability of high-quality tools for dementia detection [22], significant gaps remain in real-world application, and the rates and timeliness of diagnosis remain unacceptably low [28,117,118]. This translates to clinical “blind spots” for care providers and missed opportunities for patients. These gaps are even more pronounced among individuals from historically minoritized racial and ethnic groups [5,119]. The 5-Cog paradigm is poised to effectively bridge these gaps. The 5-Cog itself is designed for widespread applicability, with characteristics that make it appropriate for individuals from various cultural, linguistic, and literacy backgrounds [32,33]. The 5-Cog’s simple, fast format also makes it easily adaptable in resource-limited environments in contrast to some cognitive assessment tools that require specialized training or equipment to administer [120,121]. Although the evidence for decision support systems to improve clinical practice is mixed [50,122], the 5-Cog paradigm does build on prior evidence of the efficacy of decision supports in dementia detection [123,124].

Strengths and Limitations

This study has several strengths. Its results are anticipated to have improved generalizability compared to prior studies for several reasons: its large sample size; the racially and ethnically diverse patient population being enrolled; and the pragmatic nature (using local CHW staff, colocation in patients’ usual sites of care, and a waiver of written informed consent), which

may help reduce the hesitancy of individuals from historically marginalized groups to participate in the trial [125]. While the characteristics and specifications of primary care clinic sites will vary, the urban and rural primary care clinic sites in the 5-Cog study are typical of primary care clinics in the United States, especially those that serve underserved individuals from historically minoritized groups. Prior studies of decision supports in dementia were limited by a small sample size and a lack of active control groups [50,122]. The 5-Cog 2.0 study overcomes these limitations. Another strength of this study is that the BIA will form the basis of a tool that can be used to tailor financial adoption and scalability in different practice settings for national implementation. Finally, this study's unique hybrid effectiveness-implementation design will rapidly generate actionable data to advance progress in closing dementia care gaps. This study is anticipated to have a few limitations. Although the inclusion criteria are intentionally liberal in this pragmatic trial, the trial may not address dementia care gaps for the subset of patients who lack insight into their cognitive impairments and deny having them and are therefore not eligible for the trial. Implementation analyses will allow an exploration of whether and how the 5-Cog can support PCPs' clinical approach to this subset of patients who do not recognize their own cognitive decline. A limitation of the CEA is that the time horizon is relatively short, and long-term sustainability will need to be assessed in future studies.

Anticipated Dissemination Strategy

The information gained about the 5-Cog paradigm, including details of the EMR-embedded clinical decision support and incorporation into medical billing systems, in this pragmatic trial will enable future implementation in everyday clinical settings across the United States for routinely detecting cognitive impairment, including dementia. For dissemination, this trial has been registered at ClinicalTrials.gov (NCT05515224), and results information from this trial will be submitted to ClinicalTrials.gov. Every attempt will be made to publish the results in peer-reviewed journals. Final research data will be shared openly and in a timely manner: data from this study may be requested from other researchers 1 year after the completion of the primary end point by contacting Albert Einstein College of Medicine. For dissemination of the 5-Cog paradigm itself, the 5-Cog forms and administration instructions will be made available on a publicly facing website. 5-Cog team members anticipate making presentations at national conferences of clinical, educational, and administrative leaders in dementia care to facilitate the dissemination of the paradigm.

Future Directions

Although there will not be a "one-size-fits-all" solution to detecting cognitive impairment across the country, we anticipate that elements of the 5-Cog battery can be adapted in distinct sites and further studied; for instance, pictures in the PMIS may need to be updated to account for local cultural and ethnic factors. We also anticipate that, as new knowledge regarding MCI and dementia and treatments emerges in the future, we will have to update the 5-Cog decision tree and adapt to other EMR systems. Finally, the results of this study will provide the foundation for further study of the 5-Cog assessment for use in the increasingly common collaborative dementia care models [15,30,126-128], as a screening paradigm for population health models [129,130], and to evaluate the impact of early detection on clinical care and outcomes.

Acknowledgments

The authors wish to acknowledge the IT specialists from the Indiana University Health Cerner team and the Montefiore- Einstein Epic team who helped integrate the 5-Cog battery into the respective EMRs; the community health workers and research assistants from both sites who provided input and refinement to anticipated study procedures and processes; Indiana University Health team members Andrea Burkhardt and Julie Maier who contributed substantially to protocol development before moving to other departments; and the study data safety monitoring board members Alexia Mary Torke, Amy Ehrlich, and Claudene George. This work is funded by a grant from the National Institute of Neurological Disorders and Stroke of the National Institutes of Health (2U01NS105565).

Data Availability

The data that support the findings of this study will not be publicly available due to reasons of confidentiality. On reasonable request to the corresponding author, individual deidentified participant data (including data dictionaries) will be made available via a REDCap (Research Electronic Data Capture) web-based database, after review and approval of a methodologically sound proposal, with a signed data access agreement, in line with ethics committee requirements.

Authors' Contributions

JV and MB were responsible for conceptualization and funding acquisition. EA, DA, AH, and PY were responsible for data curation. CW and HX were responsible for formal analysis. JV, MB, JZ, RBRC, AT, EA, EFW, AA, KF, CW, DA, DDF, JMW, HC, NRF, DS, HX, AH, RJH, MM-V, CN, and PD were responsible for methodology. EA, MM-V, PY, NRF, AH, RBRC, EFW, AA, and CN were responsible for project administration. JV, MB, and AA were responsible for resources. RBRC, DS, and PD were responsible for software. JV, MB, NRF, JZ, EFW, and RJH were responsible for supervision. RBRC, PY, EA, EFW, and DS were responsible for visualization. RBRC, EA, JV, and MB wrote the original draft. EA, JV, MB, NRF, EFW, AT, AA, PY, CW, JZ, KF, DS, RJH, HX, DDF, JMW, HC, MM-V, CN, PD, AH, and DA reviewed and edited the manuscript.

Conflicts of Interest

JV serves on the editorial boards of the Journal of the American Geriatrics Society and the Journals of Gerontology, Series A: Medical Sciences. He serves as a scientific adviser for Catch U, Inc, and MedRhythms, Inc. JV, EA, and EFW hold a copyright for the 5-Cog battery (TX9340781). MB serves as chief scientific officer and cofounder of Blue Agilis, Inc and chief health officer of DigiCare Realized, Inc. He has equity interest in Blue Agilis, Inc and DigiCare Realized, Inc (he sold his equity in Preferred Population Health Management, LLC and MyShift, Inc [previously known as RestUp, LLC]). He serves as an advisory board member for Eli Lilly and Company, Eisai Inc, Merck & Co, Inc, Biogen, Inc, and Genentech, Inc. MB's conflicts have been reviewed by Indiana University and have been appropriately managed to maintain objectivity. All other authors declare no conflicts of interest.

Abstract

Background: The human papillomavirus (HPV) vaccine is an effective way to prevent HPV and its associated cancers. Provider recommendation has been shown to be one of the most successful strategies for increasing the uptake of the HPV vaccine; however, more training and resources are needed to help boost health care providers' confidence and communication skills in recommending the HPV vaccine to their patients, particularly in underserved Hispanic communities where vaccination rates among all ages are lower.

Objective: This study aims to compare HPV educational and professional skills intervention effectiveness on improving provider recommendations and patient communication strategies with health care providers serving the El Paso United States–Mexico border region.

Methods: We will conduct a randomized, blinded, multiple posttest-only controlled behavioral trial using a parallel group design that will examine the effectiveness of a fully automated, web-based, culturally tailored HPV education and professional skills intervention containing unique reading material and video role-play, as compared to a standard Centers for Disease Control and Prevention fact sheet and video about general communication skills. Participants were recruited using a purposive sampling technique, both internet-based and in-person outreach events. Study data are being collected and managed using REDCap (Research Electronic Data Capture; Vanderbilt University) hosted at the University of Texas at El Paso. Chi-square analyses, ANOVA, and other statistical tests will be used with 2-tail α to reject null hypotheses at .05 to analyze the self-assessed outcome data. The Mauchly test of sphericity for each ANOVA and the Huynh-Feldt epsilon test or Greenhouse-Geisser correction to the degrees of freedom of the F-ratio will be reported for each significant effect. We may use multiple imputation procedures to handle the missing data (if applicable). This study is being conducted in the west Texas or southeast New Mexico region of the United States. Chi-square analyses will be used to assess associations between variables reported on the baseline provider knowledge, attitudes, and practice scales. We seek to examine self-assessed changes in provider attitudes and behaviors regarding HPV vaccine recommendation 1 month after receiving our unique multimedia and culturally tailored intervention.

Results: Research and data collection for this clinical trial began in December 2023. Participant recruitment was closed by May 2024 (N=128), with final data collection expected to be completed by December 2024.

Conclusions: This study team decided to report on the intervention protocol to help ensure transparency in the research process and facilitate the improvement of the research design. Tailored web-based educational programs for health care professionals, designed to address regional and patient population characteristics, may be a promising approach to enhancing the real-world implementation of clinical practice guidelines.

Introduction

Overview

The human papillomavirus (HPV) is a primarily sexually transmitted infection that affects approximately 40 million Americans and is associated with 6 types of cancer [1]. A total of 3 HPV vaccines (nonvalent, quadrivalent, and bivalent) have been developed, licensed, and shown to be effective in preventing high-risk HPV infection. Current immunization guidelines recommend that children aged 11-12 years initiate a 2-dose HPV vaccine series but can begin as early as 9 years of age. Young adults older than the age of 15 years with no previous history of HPV vaccination can start a 3-dose series; the 9-valent HPV vaccine is also approved to protect against 73% of HPV-associated cancers for adults older than 26 years of age [2]. Although national vaccination rates in the United States have steadily increased over the years, vaccination rates for adolescents remain well below the 80% designated target goal set forth by Healthy People 2030 [3]. The need for this vaccine is particularly salient considering the high direct and indirect costs of HPV and associated cancers in the United States; for example, Ong et al [4] found that the average cost of HPV-related cancer and other diseases was approximately US $38,056 per case.

HPV Health Care Provider Recommendation Practices

Recent studies reveal that receiving a recommendation from a health care provider is a crucial factor influencing HPV vaccine uptake among parents of vaccine-eligible children and adults themselves [5-8]. However, in a study currently under review, many health care providers have reported that while they have sufficient knowledge and understanding about HPV and its treatment and prevention, they often lack the confidence to effectively communicate about HPV and recommend the vaccine to their patients. Similarly, some populations, such as adults, men, and sexual minority individuals (members of the LGBTQ+ [lesbian, gay, bisexual, transgender, and queer/questioning] community), are less likely to be encouraged to get vaccinated and tend to have inaccurate perceptions of the importance of vaccination [9]. Due to the need to improve training and resources for health care providers concerning HPV vaccine recommendation (in addition to the recommendation of other salient vaccines such as influenza and meningococcal vaccines [10,11]), researchers have explored the effectiveness of several approaches, theories, and foci when recommending HPV vaccination. The combined use of the presumptive approach (in which the provider assumes parents will vaccinate their child rather than communicating that the HPV vaccine is optional), along with motivational interviewing and a fact sheet for vaccine-hesitant clients, results in higher perceived levels of parental HPV vaccine acceptance [5]. Furthermore, studies [6,7] emphasize the importance of providing recommendations that "announce" the need for the HPV vaccine in a manner that is brief, easy to understand, and focused on cancer prevention.

Beyond the need for improved HPV vaccine recommendations among health care providers' nationwide, enhancing communication strategies is particularly important for health care providers practicing with racial minority populations, such as predominantly Hispanic populations residing along the United States–Mexico border. Recent literature has identified both barriers and facilitators that exist in trying to increase HPV vaccine uptake in a diverse and predominantly Hispanic community [12]. Similarly, a recent quantitative study revealed that HPV vaccine acceptability in Hispanic young adults is associated with several factors, including the number of HPV informational sources, number of HPV discussions, health care provider recommendations, having a health care provider with similar characteristics, and family vaccine perceptions [12]. Another study found that culture-based factors such as familism and trusted sources of information can predict HPV vaccine acceptance [13]. Additionally, Xu et al [14] demonstrated that patient-provider health communication strategies aimed at enhancing HPV vaccine uptake among racial minority patients must be culturally tailored for the intended population, while including approaches that increase provider self-efficacy, use persistent language, reframing vaccine conversation focus from sex to cancer, and working with the community to culturally sensitize vaccine-related language. All these findings highlight the importance of receiving HPV vaccine recommendations from health care providers in a culturally competent manner, as well as the importance of family in shaping perceptions and behaviors related to vaccinations.

Web-Based Health Care Professional Educational Interventions

To improve patient care and population health outcomes, health care providers rely on clinical practice guidelines (CPGs) to stay current with evidence-based recommendations [15]. However, the dissemination and implementation of guidelines, such as those for HPV vaccination and screening, vary across health professionals. While traditional print-based delivery methods for CPGs have largely shifted to digital platforms, digitizing guidelines on medical authority websites (eg, the Centers for Disease Control and Prevention [CDC]) have improved the access for health professionals. Despite improved access, time constraints often make it difficult for providers to actively search for and apply these guidelines without additional support. The absence of supportive modules that assist with real-world implementation, such as HPV recommendation practices, creates barriers to addressing gaps in care. Notably, research has shown that web-based medical educational modules can be as effective as in-person training in helping health care providers implement CPGs more efficiently [16].

Intervention Theoretical Framework

Elements of the Health Belief Model have been examined as predictors of HPV vaccine acceptance and uptake among adults in the United States–Mexico border region in a previous study conducted by the researchers [13]. This model demonstrates that a broad range of intersectional factors play a role in an individual's health choices and behaviors, such as perceived benefits (in this case, the belief that the HPV vaccine will prevent infection and cancer) and perceived severity, which have both been associated with HPV vaccine acceptance [13]. Frietze et al [13] also studied perceived safety and perceived harm as predictors of acceptance and uptake. Therefore, the proposed intervention has incorporated 4 tenets of the Health Belief Model (perceived benefits, severity, safety, and harm) into the intervention to increase provider vaccine recommendation practices and strategies. The tailored intervention also builds on educational models including HPV biology, epidemiology, and disease morbidity, coupled with role-played conversations in clinical video vignettes using the "announcement" approach, in which the health care provider works from the presumption that patients or parents will accept the vaccine. The research question is, will health care providers receiving a web-based, culturally tailored, HPV-specific professional skills intervention report stronger HPV prevention recommendation behaviors at 0-3-6 months post intervention, compared to health care providers receiving a web-based intervention using publicly available CDC HPV provider materials and general communication skills modules?

Research Aims and Hypothesis

This study is guided by 2 aims. Aim 1 is to assess the knowledge, practices, and beliefs of emerging and current health care providers in the Paso del Norte Region related to HPV prevention, HPV vaccine, and HPV-associated cancers. Aim 2 is to facilitate the prevention of HPV-associated cancers in the Paso del Norte Region through strengthened recommendation of the HPV vaccine and screening by health care providers.

It is hypothesized that health care providers receiving a web-based, culturally tailored, HPV-specific professional skills intervention will report higher between-group changes in proportions on the HPV health care provider (HCP) practices scale at 0, 3, and 6 months post intervention, compared to health care providers receiving the standard web-based CDC HPV provider materials and communication skills active control intervention.

Methods

Ethical Considerations

This study was approved by the University of Texas at El Paso institutional review board (#1441487). Participation in the study was voluntary and confidential. All potential participants who were screened and met eligibility were invited to join the study and provided informed consent. Informed consent covered primary and secondary data collection procedures and data analysis and dissemination following the completion of the study. Participants consented to relinquish the ownership of anonymous data to the research team for dissemination (primary and secondary analysis). All study data will be deidentified and survey responses will be anonymous. Participants are compensated in the form of a US $30 electronic gift card for the completion of the initial survey and a US $10 electronic gift card for the completion of each of the follow-up surveys (US $50 total throughout the course of the study). The study information sheet made clear to participants that they were free to withdraw from the study at any time with no consequence to them, and withdrawal protocols with contact information were included.

Study Trial Design

We will conduct a mixed (within-between) subjects longitudinal design in which participants are randomly assigned to 1 of the 2 conditions and will be assessed over 3 time points using a parallel group design to examine the effectiveness of a tailored versus a standard HPV education and professional skills intervention. Emerging and current health care providers will be randomly assigned to 1 of the 2 conditions. (1) Treatment condition in which they will receive a tailored Education and Professional Skills Intervention and (2) control condition in which they will receive general, publicly available (ie, CDC) information about HPV and communication skills. Participants will then be followed over 3- and 6-month time frames, and group differences will be assessed. Furthermore, this clinical trial protocol will follow the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) to report the internet-based educational modules (behaviorally based treatment) [17]. The completed itemized checklist instrument is provided in Multimedia Appendix 1.

Study Setting

The intervention is internet based, and participants will complete the survey using personally owned computers, tablets, or cell phones. This study is based on, deployed in, and will reach health care providers primarily in the Paso Del Norte Region, which includes El Paso County, Texas, and Southern New

Mexico, including Dona Ana County, and the cities of Alamogordo, Hobbs, Artesia, Roswell, and Lovington. The population is predominantly Hispanic, with 82.9% (718,964/867,239) of the population of El Paso County, Texas, identifying as Hispanic or of Latin ancestry, and 50.2% (1,061,413/2,114,371) of the population of the State of New Mexico identifying as Hispanic or of Latin ancestry [18,19].

Community Advisory Board

A community advisory board was formed, as community advisory boards have previously demonstrated to be effective when planning health-related programs and interventions to facilitate meaningful and structured engagement with local community members [20]. Our community advisory board consisted of a formalized collective of community members, research stakeholders, regional clinical partners, and other academics from several institutions, including The University of Texas at El Paso, Texas Tech University Health Sciences Center El Paso, and New Mexico State University. The community advisory board was instrumental in providing insight into the local community while providing insight to develop equitable partnerships with the community. The community advisory board has been involved in all phases of the intervention development, from the reconnaissance phase to the intervention's development, and will remain a vital component of the intervention until the study has concluded and results are evaluated. To date, the community advisory board has met periodically and has been provided with a report of ongoing project-related activities and project progression. All community advisory board feedback and suggestions have been taken into consideration and retro fed back into project-related activities.

Acceptability, Pretest, and Pilot

All components of the clinical trial (survey, control and experimental intervention modules, recruitment plan, and communications) underwent multiple rounds of review and revision by members of the research team. In addition, the intervention and survey were pilot-tested with a small group (n=7) of health care providers in training or in practice, and feedback from those individuals was incorporated into the final products. For example, demographic questions such as participant gender were changed to reflect participant's concerns on gender identity (to include nonbinary and gender nonconforming individuals). For example, "Which of the following best describes your gender identity: male, female, transgender male, transgender female, gender variant/nonconforming, prefer not to answer," and an "other" option which permits text entry. In addition, the pilot test helped to clarify questions regarding previous HPV infections: "How likely do you think it is that you have ever been infected with HPV?" and "How likely do you think it is that your current or recent partner(s) has (have) ever been infected with HPV?" A question was added to elicit the zip code in which the participant primarily practices or trains in, and the amount of time it would take to complete the study was adjusted.

Consolidated Standards of Reporting Trials Flow Diagram

Progress through the phases of this planned randomized trial (ie, enrollment, intervention allocation, follow-up, and data analysis) will be visually represented using the CONSORT (Consolidated Standards of Reporting Trials) flow diagram [17]. A participant is considered to have completed the study if they have completed the initial postintervention assessment and the 3-month and 6-month follow-up assessments.

Intervention Materials

The intervention materials and survey were developed and produced by members of the research team based on, and in alignment with, a health care provider survey and a community needs assessment conducted under the larger parent study [13,21]. HPV knowledge, practices, and beliefs will be assessed, as was done previously in formative research, with additional questions that further assess in-depth provider recommendation behaviors for HPV vaccination that is inclusive of vaccine-eligible age groups and genders. We will also inquire about provider comfort in communicating with patients about sexual health topics, vaccines, and cancer.

Participants will be randomly assigned to 1 of the 2 conditions: (1) the treatment condition, in which they receive the tailored HPV Education and Professional Skills Intervention, and (2) the control condition, in which they receive the General Education and Professional Skills Intervention. An internet-based platform will be developed to deploy the HPV Education and Professional Skills Intervention to emerging or current health care providers. The platform will be comprised of training modules divided into 3 sections paralleled among control and experimental groups—a document to be read, a video to be watched, and an activity to complete. Participants will take 15-30 minutes to complete all 3 sections of the module.

Control Group Materials

The control group (active comparator) will receive the General HPV Education and Communication Skills Intervention materials, which will be comprised of a 3-page PDF document, a web-based video, and 4 rank-order multiple-choice questions to answer. The PDF document will be a standard, publicly available HPV fact sheet from the CDC. The video contains information on improving basic communication skills as would occur in a business or interpersonal setting. The multiple-choice questions will ask the participant to select their preferred mode of communication (ie, email, text, phone call, or face-to-face) in different scenarios.

Experimental Group Materials

The experimental treatment group will receive the tailored HPV Education and Communication Skills Intervention materials, which comprised the same categories of content as in the control intervention. In this case, the 3-page PDF document is modeled after the CDC HPV fact sheet but includes data from the first phase of our program and informs the reader of important and relevant research findings from our region. The video was produced in-house and scripted to focus on improving provider communication with patients, specifically regarding HPV, the HPV vaccine, and addressing vaccine hesitancy. The

multiple-choice questions are presented as clinical vignettes with response options that address patient concerns, and participants will rank them in terms of their perceived effectiveness.

Thus, the control module will engage participants to improve general communication skills and increase baseline knowledge about HPV, HPV vaccine, and HPV-associated cancers. The experimental intervention module, in contrast, will specifically engage participants to improve patient-provider communication and strengthen HPV vaccine recommendations through (1) identifying critical points of discussion regarding the HPV vaccine and patient health; (2) encouraging discourse on vaccines that are optional (eg, influenza) for patients; (3) sharing best practices for discussing vaccines with patients or parents who are vaccine-hesitant; (4) increasing provider understanding about generalized and region or culture-specific reasons for vaccine hesitancy among patients; and (6) facilitating increased knowledge about HPV, the vaccine, and its cancer relevance.

Surveys are to be delivered 3 and 6 months after the initial intervention, and the survey will again evaluate provider knowledge, practices, and beliefs regarding HPV, HPV vaccine, and cancer and will also specifically assess changes in provider behavior since the intervention. Uptake of the HPV vaccine by the provider or their children, assuming eligibility, will be tracked, as will provider recommendation behaviors and levels of comfort in interacting with patients when issues of sexual health, vaccine hesitancy, or cancer prevention arise.

Study Outcome Measures

Provider Practices

The primary outcome of interest is between-group changes in proportions of provider practices. This will be measured on the 8-item HPV HCP practices scale (HCP vaccine recommendations, HCP screening recommendations, and HCP communication practices) scored on a Likert scale from never (1) to always (5). A composite score is developed that creates an average score for HCP vaccine recommendations, HCP screening recommendations, and HCP communication practices. Postintervention practices of health care providers will determine change in both strength and frequency of recommending the HPV vaccine to patients.

The secondary outcomes of interest include understanding provider beliefs and provider knowledge. These will be measured on previously validated scales adapted from the Vaccine Attitudes and Knowledge Survey (VAKS) [13,21].

Provider Beliefs

Provider beliefs (ie, attitudes toward HPV vaccine) will be measured using the 9-item HPV vaccine attitudes scale (perceived safety, perceived harm, and perceived effectiveness) scored on a Likert scale from strongly disagree (1) to strongly agree (5). A composite score is developed which creates an average score for perceived safety, perceived harm, and perceived effectiveness.

Provider Knowledge

Provider knowledge about HPV and the HPV vaccine will be measured using a previously adapted 14-item HPV knowledge scale scored as true (1) or false (0) [13,21]. A composite score is developed which creates an average score for 14 items and then multiplying by 100 to calculate a percentage.

Participants

Participants will be recruited from the health care provider population in El Paso County, Texas, and Southern New Mexico. Both current (in practice) and emerging (in training) practitioners in the professions of medicine (ie, doctor of medicine, doctor of osteopathic medicine, physician assistant, nurse practitioner, pharmacy, or nursing) are eligible to participate in the study. To qualify, participants must be a current (in practice) or emerging (in training—student, resident, or fellow) health care provider, be between the ages of 18 and 65 years, be working, training, or living in the Paso del Norte Region (ie, El Paso County, TX-Southern New Mexico), have computer or internet literacy and access to an electronic device with internet access (eg, cell phone, tablet, and computer), and have the authorization to recommend the HPV vaccine. Participants will be excluded from the study if they are not affiliated with the El Paso United States–Mexico border region, have not previously participated in phases I or II of the larger parent research project, do not identify as a current or emerging health care provider, decline or are unable to participate in the full intervention and follow-up time points, or are unable to complete participation and activities in the English language.

Recruitment

Recruitment took place over 6 months, from December 2023 to May 2024. No critical secular events fell into this study period. Participants who were eligible and agreed to participate in the study will be active in the project for 7 months post-initial recruitment. This time frame starts at the time of recruitment and ends at the final 6-month follow-up time point. Researchers used a purposive sampling technique to recruit participants through multimedia (ie, print and email) and professional network contacts. The study participants were recruited from (1) the main campus and some regional clinical hubs of the Burrell College of Osteopathic Medicine; (2) the University of Texas at El Paso College of Health Sciences, College of Nursing, and School of Pharmacy; (3) federally qualified health centers in the Paso del Norte Region; (4) private provider clinics; and (5) other health care workers and professional network connections that provide training and services to the Paso del Norte region residents. Special attention will be given to recruit practitioners in the specialties of pediatrics, family medicine, and obstetrics and gynecology due to their increased familiarity with vaccines, HPV, and cancer. All participation is entirely web-based. Once the participant is deemed eligible and agrees to participate, they will be provided with a study information sheet outlining that their participation is voluntary, and they can opt out at any time. Participants will be compensated for their time with a US $30 electronic gift card after completion of the initial training session and surveys (~30 minutes). Participants will receive email reminders to complete each of the 2 follow-up survey sessions at 3 and 6 months after

completing the initial intervention, as well as an additional US $10 electronic gift card for participating in the follow-up survey sessions (~20 minutes per survey questionnaire).

Randomization, Treatment Allocation, and Concealment

Sequence Generation

After determining eligibility, we will randomize participants on a 1:1 basis to intervention groups (experimental vs control) while controlling for the potential bias introduced by factors of sex, age, and career stage. To achieve this goal, we will use a randomization table within the REDCap (Research Electronic Data Capture; Vanderbilt University) platform to create balanced treatment groups based on these factors and reduce the effect of selection bias [22].

Concealment

This study is double masked (ie, participant and outcomes assessor). Participants will be randomly assigned to treatment and control groups; they will not be made aware of other participants' receipt of treatment or control materials. Participants will be asked not to discuss this project outside of the intervention; delivery of the intervention or other educational materials will be internet-based, limiting the ability of participants to interact with one another during the study. Furthermore, to reduce bias in the implementation and assessment of the clinical trial (eg, outcome assessor), participant information and pre-post survey responses will be maintained separately from the assignment and delivery of the intervention.

Measures

All the survey questionnaire measures or instruments will be made available electronically in English.

Screening Questionnaire

Participants completed a screening questionnaire delivered via the REDCap platform to determine their eligibility to participate in the study or intervention [22]. The questionnaire will assess items such as age, geographical location, and health care provider education status (ie, MD, DO, PA, NP, PharmD, or RN) of the potential participant. The questionnaire will also assess their comfort with auditory and visual content in the English language, and if they had prior participation in the earlier phase of this study. The screening questionnaire requires approximately 3 to 5 minutes to complete. Upon successful completion of the screening questions, participants will read and sign the consent form indicating that they agree to participate in the study.

Demographic and Background Questionnaire

The demographic and background questionnaire via the REDCap platform will gather demographic information (eg, age, gender, ethnicity, and income), as well as information about family composition, HPV vaccination status, trusted sources for medical information, general feelings about vaccines, trust in the government, and experiences with the recent COVID-19 endemic [22]. The demographic survey will only be administered at baseline prior to administering the intervention. The demographics survey requires approximately 5 to 8 minutes to complete.

Postassessment

A post-assessment via the REDCap platform will be administered at baseline (immediately following intervention), 3 months, and 6 months [22]. The post-assessment will include a modified version of the VAKS [13,21] to self-assess factors that influence levels of comfort in discussing HPV-related topics, patient-provider communication about HPV, vaccines, cancer risk, and additional questions designed to evaluate the impact of the interventions and the actual changes in practice in terms of vaccine uptake, patient communication, and vaccine recommendation behavior. Moreover, the outcome variables are included in the post-assessments such as the self-assessment of the proportions of provider practices (as indexed by the HCP practices scale), provider beliefs (as indexed by the HPV vaccine attitudes scale), and provider knowledge (as indexed by the HPV knowledge scale). These will be measured on previously published scales adapted from the VAKS [13,21]. In a previous study that administered the VAKS, Cronbach α ranged from 0.70 to 0.90 for the various scales included in the survey [13]. The post-assessment requires approximately 25-30 minutes to complete.

Data Collection and Management

All study data will be collected using REDCap [22], a password-secured internet-based software application system developed to design and manage web-based databases and surveys, hosted at The University of Texas at El Paso. All data collected will be deidentified. REDCap will be maintained by the College of Science at The University of Texas at El Paso [22]. Data will remain stored for up to 5 years after completion of the study. Only the study team will have access to the data, as the team has received training on maintaining research data confidentiality, responsible conduct of research, and research ethics with human participants. Data will be accessed through password-protected and encrypted computers.

Analytical Methods

All statistical analyses will be conducted using SPSS (version 26.0; IBM Corp) and R (version 4.0.3; R Core Team) and will use 2-tail α to reject null hypotheses at .05. Prior to conducting analyses, data will be screened to ensure that statistical assumptions are met and any transformations or adjustments to the model will be used. We may use multiple imputation procedures to handle missing data. Descriptive statistics will be reported for demographic variables including age, sex, gender, and health professional degree or field. A power analysis estimating repeated measures within-between interaction, assuming a small effect size (f=0.15), determined that approximately 110 total participants are required to provide an 80% chance of detecting an effect between the 2 experimental conditions (tailored intervention vs active control) across 3 time points (0, 3, and 6 months postintervention). To account for an estimated 10%-15% attrition, at least 100 participants needed to be recruited.

Study Outcomes

The chi-square analyses will be used to assess associations between variables reported on the baseline provider knowledge, attitudes, and practice scales. Repeated measures mixed ANOVA with α set to .05 will examine whether change in our outcome variables (self-assessment of the proportions of provider practices, as indexed by the HCP practices scale), provider beliefs (as indexed by the HPV vaccine attitudes scale), and provider knowledge (as indexed by the HPV knowledge scale) is the result of the interaction between the experimental condition (tailored intervention vs active control) and time (at 3 time points) [23]. If no interaction emerges, we will conduct follow-up tests to determine whether any change in our outcome variables are due to one of the factors (experimental condition or time). We will calculate the Mauchly test of sphericity for each ANOVA, and the Huynh-Feldt epsilon test or Greenhouse-Geisser correction to the degrees of freedom of the *F*-ratio will be reported for each significant effect [23-25]. We may use multiple imputation procedures to handle missing data (if applicable).

Future Directions and Plans for Dissemination

Plans for the dissemination of our findings include publication in peer-reviewed scholarly journals and presentation at scientific conferences, but we are also committed to sharing our data with the community that supports and contributes to this work. For both providers and patients, it is important to base medical decision-making on relevant and up-to-date information. Our findings will also be shared with health care providers in practice and in training at the institutions and locations in which our participants were included. Data will be reported in aggregate form, with no identifying information shared. This data may further be incorporated into the curriculum followed by providers in training in the Paso del Norte region and beyond.

Results

Overview

A larger parent grant (NIH/NIMHD 2U54MD007592) was funded in October 2019. Data collection of this subproject, a provider-focused randomized controlled trial (RCT), began in December 2023, with a total of 128 participants recruited by the closing of recruitment in May 2024. Primary data collection was completed in December 2024. As of March 2025, data analysis is in progress, with publication of results anticipated in winter 2025.

Study Outcomes

Provider Practices

Results of the ANOVA model assessing the primary outcome of between-group changes in proportions of provider practices will be summarized and presented in tables and visuals.

Provider Beliefs and Provider Knowledge

Results of the ANOVA model assessing secondary outcomes of understanding provider beliefs and provider knowledge will be summarized and presented in tables and visuals.

Discussion

Principal Findings

The goal of this RCT was to develop and deploy an educational and professional skills intervention to increase health care provider HPV prevention recommendation scores. This is a critical factor in cancer prevention, and multiple factors contribute to the observation that, while HPV vaccine uptake in our region is higher than in many other regions, it still falls short of national targets. We anticipate finding that health care providers who receive our experimental intervention materials (culturally tailored videos specifically targeting effective HPV vaccine-related communication strategies) will demonstrate improved and more frequent HPV vaccination recommendation practices and behaviors with their patients, as compared to health care provider participants who receive the control materials (standard CDC-issued materials).

Comparison to Prior Work and Strengths

Our approach to intervention with health care providers is not particularly novel, nor is the intention to increase provider vaccine recommendations since it has been well-established that provider recommendation is one of the most critical factors in patient decisions to get vaccinated [26]. What is innovative in our approach, however, is how we engage with and tailor skills-based training for providers in our region. The initial evaluation of provider knowledge, practices, and beliefs about HPV and the HPV vaccine informed us that HPV-related knowledge among providers is high. An intervention that provides additional education on HPV, the vaccine, and cancer was thus likely to have limited benefit and would not be a valuable use of provider time. In contrast, our intervention focuses on supporting the professional development of providers in the domains of modifying their own behavior and improving communication with patients. Increasing provider awareness of biases in vaccine recommendation and delivery, increasing their comfort in discussions about sexual health topics, and supplying them with tools for addressing patient hesitancy associated with vaccination were determined by our group to be more likely to produce the desired results.

A second way in which our research is innovative is to focus on emerging health care providers. Engaging with this group has the potential to produce multiple positive outcomes, including (1) increased vaccine uptake since many individuals in this group are vaccine-eligible but remain unvaccinated, (2) normalization of vaccine-related discussions in patient care if this becomes a consistent component of provider training, and (3) strengthened vaccine recommendations as the providers themselves serve as role models for vaccination to their patients. Third, we are committed to improving vaccine recommendation behavior by providers that serve a binational, majority-Hispanic population that is medically underserved and faces multiple barriers to vaccination. Previous work has shown that Hispanic women have high HPV vaccine acceptability [27], but this may vary based on age and birth origin [28].

Limitations

This study recruited an internet population of health care providers in the United States–Mexico border region; therefore, findings may not directly translate to other health care provider populations nationally or globally. Furthermore, this intervention did not provide Continuing Medical Education (CME) credit, which would limit uptake outside of an RCT setting. Study participation involved a relatively large time commitment for providers in practice, which worked against recruitment and survey completion. We may, therefore, be somewhat limited in our ability to conduct subanalyses such as comparisons across provider specialties (eg, pediatrics vs family medicine) or other participant characteristics (eg, ethnicity or income level). As we have gathered data from health care providers in medicine, nursing, and pharmacy, different approaches to patient care in these professions may increase variability in the responses obtained. A pretest of HPV and vaccine-associated practices was not done in our study, and the use of solely self-reported data may be incomplete or may contain bias. Our random assignment of participants into control and experimental groups should protect against baseline group differences; however, we will still be able to determine the persistence of any changes in behavior regardless of participant starting point. If any group of providers demonstrates high vaccine recommendation rates at the onset of the study, it will be difficult to determine a statistically significant increase in behavior in response to the intervention. Still, identifying providers with strong recommendation practices will be of benefit to our project. Finally, we anticipate the loss of a limited number of participants through attrition over time for many possible reasons, perhaps reducing the power of our study and our data analysis capabilities at the 3- and 6-month time points.

Conclusions

To improve population health, it is essential to look beyond interventions aimed solely at patient populations. Web-based educational programs for health care professionals are promising tools for enhancing the real-world implementation of CPGs. Tailoring these provider-level interventions to account for regional and patient population characteristics can also improve patient-provider communication as clinical guidelines evolve. Until HPV and other vaccine-preventable infections are eradicated, collaboration between health researchers and providers is critical to delivering accessible and effective professional development interventions. Furthermore, beyond reporting research findings of such studies, reporting specific intervention protocols helps ensure transparency in the research process and facilitates the improvement of population health interventions.

Acknowledgments

The authors would like to thank the university and community partners, especially key representatives from local federally qualified health centers and both The University of Texas at El Paso College of Health Sciences and the College of Nursing, for assisting in the recruitment process. The authors would also like to thank all the members of the advisory committee for their contributions and support of the ongoing project. This paper was completed through funding (grant 2U54MD007592) by the National Institute on Minority Health and Health Disparities (NIMHD), a component of the National Institutes of Health (NIH). A Diversity Supplement supported author JM (grant 3U54MD007592-28S3) from the NIMHD/NIH. One of the authors (JIC) was supported by a research fellowship funded under the University of Texas Health Science Center at Houston (UTHealth) School of Public Health Cancer Education and Career Grant Development Program, National Cancer Institute/NIH Grant (T32/CA057712).

Data Availability

The datasets generated or analyzed during this study are not publicly available as they are stored in the REDCap (Research Electronic Data Capture) repository maintained by the University of Texas at El Paso and subject to institutional access restrictions but are available from the corresponding author on reasonable request.

Authors' Contributions

EMM, KG, and JIC conceptualized the study with critical input from KLL, MW, and JM. JIC, KLL, MW, and JM wrote the first draft, and EMM, KG, and JIC gave critical input throughout the study development and contributed to the paper revisions. All authors contributed and approved the final study. No artificial intelligence was used in any portion of the paper development.

Conflicts of Interest

None declared.

Abstract

Background: Postpartum mood and anxiety disorders (PMADs) are higher among pregnant military service women (26%) and military spouses (12.2%) compared to the civilian population (10%-15%). This is partly due to military-specific factors, including deployment, which are known to increase risk. Important risk factors for PMADs include sleep disturbances, defined as sleep deprivation, insomnia, or poor sleep quality, which are more are common among military-affiliated pregnant women.

Objective: This study describes a protocol for a new randomized controlled trial that aims to ameliorate the risk for PMADs through improving infant sleep or maternal sleep during the first 6 postdelivery months in a sample of military-affiliated women.

Methods: This study is a 6-month, parallel-arm, randomized controlled trial. Pregnant women (N=342) in the third trimester will be randomized at 1:1 ratio to use a smart bassinet (SB) or a standard commercially available bassinet (HALO BassiNest Swivel Sleeper 3.0; traditional bassinet [TB]) for up to 6 months after delivery. Participants will have their infants sleep in the bassinet, complete monthly web-based questionnaires, and record sleep data with diary and actigraphy for both the participants and their infants for 1 week each postpartum month. Blood samples will also be collected at baseline (late pregnancy) and at 3 months and 6 months post partum to assess immune functioning. The primary outcomes for this study will be postpartum mood (depressive and anxiety symptoms) and infant and maternal sleep. In addition, we are evaluating whether SB has a significant impact on immune functioning—a marker that physiologically connects sleep and mood symptoms.

Results: Recruitment for this study began in January 2025. Six separate mixed 2 (treatment vs control) × 6 (assessment period) multivariate analysis of variance and analysis of variance models will be conducted to test the hypotheses that SB will have a greater impact on infant and maternal sleep than TB, SB will be associated with a greater reduction in postpartum mood symptoms than TB, and immune system function will be less dysregulated in birthing individuals using SB compared to those using TB. Lastly, we will evaluate whether the elevated risk demonstrated by previously identified postpartum depression epigenetic biomarkers in the *TTC9B* and *HP1BP3* genes can be modified with an SB. We hypothesize that the elevated risk will be reduced in SB compared to that in TB.

Conclusions: At the conclusion of this project, we will have gained a thorough understanding of the capability of SB to positively affect infant and maternal sleep compared to the traditional sleep arrangement and its impact on maternal mood through 6 months post partum in military-affiliated women. The promotion of sleep health in both mothers and infants may be an accessible and amenable method to prevent PMADs.

Introduction

Postpartum mood and anxiety disorders (PMADs) are the most common and disabling complications of childbearing. They are often underdiagnosed and undertreated [1]. PMADs are recognized to seriously affect both mother and baby [2,3]. In fact, mental health conditions are a leading contributor to maternal morbidity, with suicide as a major cause of postpartum death. According to the Department of Defense, the number of females in the US military constituted 17.3% of the total force in 2021 [4]. Research indicates that the rate of PMADs in active-duty women can range from 20% to 26% [5-7], with slightly lower rates among military spouses at around 12.2%. Although these rates are similar to that reported in the civilian population (~10%-15%) [8-10], when other factors such as deployment are considered, the rates vary dramatically, reaching as high as 50% [11-16]. Women with spouses who are deployed have more frequent diagnoses of depressive disorders, sleep disorders, anxiety, acute stress reactions, and adjustment disorders compared to women without a deployed spouse. Despite these elevated risks, this segment of our population has been insufficiently evaluated as it pertains to PMAD risk and warrants further attention.

It is well appreciated that sleep disturbance is associated with both new and recurrent depressive and anxiety episodes in all populations, especially perinatal women [17-22]. Sleep disturbance often precedes the development of mood disorders [23,24]. Indeed, sleep issues lasting for at least 2 weeks increase the risk for the future development of mood disorders [25,26] and are a criterion for the diagnosis of depression in the Diagnostic and Statistical Manual of Mental Health Disorders, Fifth Edition, Text Revision (eg, major depressive disorder) [27]. Sleep disturbances, both in prevalence and severity, in military-affiliated women extend beyond what civilian women experience. Active-duty service members and their spouses experience unique stressors that often exacerbate sleep issues [28,29]. Despite this, there are limited empirical data regarding sleep disturbances among military-affiliated women.

Infant sleep problems further contribute to significant maternal sleep issues [30-32] and maternal mental health consequences, regardless of the mothers' depression history [32-34]. Mothers who report poor infant sleep behavior have significantly more depressive symptoms than mothers who report good infant sleep [35-37]. There is some evidence that maternal sleep quality is a mediator of this relationship [35]. Persistent, rather than transient, infant sleep issues contribute to maternal depression, poor sleep, and poor family functioning well into toddlerhood [33,38,39]. We propose that focusing and intervening on infant sleep is a viable pathway to improve maternal sleep and well-being.

Here, we describe the protocol for a randomized controlled trial (RCT; Clinical Trials.gov CT94252410690; Sleep Health and Mood in Newly Expectant Military Mothers [SHINE]) with the following aims.

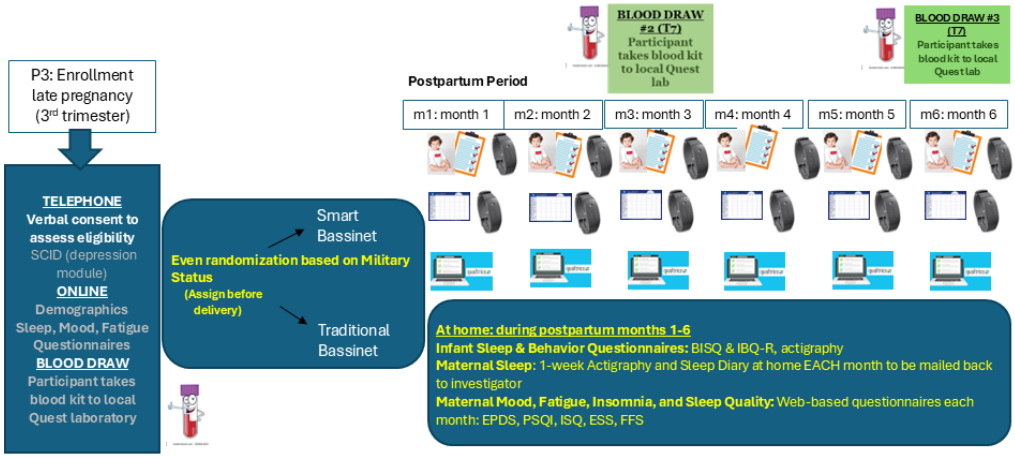
1. Determine whether the use of a smart bassinet (SB) augments infant sleep and improves maternal sleep during the first 6 months post partum compared to the use of a traditional bassinet (TB). (1) Hypothesis 1a: Infants who sleep in SB will have better sleep (ie, diary and Brief Infant Sleep Questionnaire as maternally reported) [40] than those who sleep in TB. Outcomes will include maternally reported sleep duration, awakenings, as well as objectively assessed (actigraphy) wake after sleep onset and sleep onset latency. (2) Hypothesis 1b: Mothers of infants who sleep in SB will have better subjectively reported (ie, diary and Pittsburgh Sleep Quality Index) and objectively assessed (actigraphy) sleep compared to those of infants who sleep in TB. Outcomes will be the same as those for infants.
2. Determine the effect of SB on maternal postpartum depressive and anxiety symptoms and evaluate the model that the association between SB and postpartum depressive symptoms is mediated by both infant and maternal sleep. (1) Hypothesis 2a: Mothers of infants who sleep in SB will have fewer postpartum depressive symptoms over time (ie, Edinburgh Postnatal Depression Scale) compared to those of infants who sleep in TB. (2) Hypothesis 2b: SB improves infant sleep, which then predicts better maternal sleep, and thereby predicts lower maternal depressive symptoms.
3. Compare the trajectory of immune system function from late pregnancy through post partum between participants with and without PMADs and between SB and TB groups. (1) Hypothesis 3a: Peripheral cytokines, immune cells, and stimulated cytokine profiles of women with PMADs assessed in late pregnancy and at 3 and 6 months post partum will indicate greater innate immune activity compared to those of women without PMADs. (2) Hypothesis 3b: Mothers of infants who sleep in SB will exhibit lesser innate immune dysfunction than mothers of infants who sleep in TB.
4. Exploratory aim: Evaluate whether the elevated risk demonstrated by previously identified PMAD epigenetic biomarkers at the TTC9B and HP1BP3 genes can be modified by using an SB. We hypothesize that the elevated risk will be reduced in the SB group compared to that in the TB group.

Methods

Study Design

This study is a 2-arm, parallel-group RCT. Participants will be randomized at 1:1 ratio to either SB group or TB group. Outcomes are assessed at 7 timepoints (Figure 1): late pregnancy (P3) and in postpartum months 1-6 (M1-M6).

Figure 1. Flowchart in this study. BISQ: Brief Infant Sleep Questionnaire; EPDS: Edinburgh Postnatal Depression Scale; ESS: Epworth Sleepiness Scale; FFS: Flinders Fatigue Scale; IBQ-R: Infant Behavior Questionnaire-Revised; ISQ: Insomnia Symptom Questionnaire; PSQI: Pittsburgh Sleep Quality Index; SCID: Structured Clinical Interview for Diagnostic and Statistical Manual of Mental Disorders-5.



Ethics Approval

This study has been approved by the institutional review board of the University of Colorado Colorado Springs (#2024-071) and the Office of Human Research Oversight (US Army Medical Research and Development Command). The SHINE trial was previously registered with Clinical Trials.gov (CT94252410690). This protocol follows recommendations from CONSORT (Consolidated Standards of Reporting Trials) 2010 statement checklist (Multimedia Appendix 1) and guide [41]. All participants will be required to provide informed written consent prior to enrollment. Participation is completely voluntary, and the participant has the right to withdraw at any time. All participants will be assigned a 6-digit ID number to be used so that all data collected will be deidentified. Participants will be compensated for their time. There are 7 timepoints in this study. At baseline (late pregnancy), participants will be compensated US $100; at postpartum months 1, 2, 4, and 5, they will be compensated US $50 for data collection, and at postpartum months 3 and 6, they will be compensated US $100. At baseline and at postpartum months 3 and 6, they will provide a blood sample.

Participants

At the time of recruitment (P3) (third trimester), participants will complete a screening survey to determine their eligibility. Eligible pregnant women (N=342) will be recruited nationwide. The inclusion criteria were pregnant military-affiliated individuals with a singleton gestation; age 18-45 years; ability to communicate in English during the screening process; access to a computer, smartphone, or tablet with internet service; willing to use the bassinet they are randomized to; and willing to travel to a local Quest Diagnostics (an insert description) for blood draw. The exclusion criteria were presence of a depressive or anxiety disorder assessed over videoconference using the Structured Clinical Interview for Diagnostic and Statistical Manual of Mental Disorders-5-Clinical Version mood disorders section [42]; current active suicidal ideation, medical or psychiatric instability, or active substance abuse or dependence during the last 90 days; plans to co-sleep with infant; younger than 18 years or older than 45 years; multiple gestations; type 1 diabetes; congenital fetal anomalies; tobacco use (current); self-reported, untreated comorbid sleep disorders, including narcolepsy, periodic leg movement disorder, or obstructive sleep apnea; and current use of psychotropic or sleep medications.

Procedures

Recruitment and Consent

Advertisement for this study will take place primarily online (social media) and through partner advocates (Postpartum Support International and Maternal Mental Health Leadership Alliance). Pregnant military-affiliated individuals who reside in the United States are eligible. Interested participants will contact the study coordinator for additional information and initial eligibility screening, including verification of military status.

Telephone Interview and Screening

Participants who meet initial inclusion criteria and have completed the consent and baseline questionnaires will be contacted for a telephone interview to assess further eligibility. The interview will contain items of the Structured Clinical Interview for Diagnostic and Statistical Manual of Mental Disorders-5-Clinical Version [42] and the Structured Clinical Interview for Sleep Disorders-Revised [43]. Eligible participants will be randomly assigned to either SB group or TB group. The SB will be shipped to the participants and returned after M6 at no expense to them. TB group participants will be shipped a standard bassinet (HALO BassiNest Swivel Sleeper) to keep. Mother-infant dyads (up to N=342) will be randomly assigned to conditions by using a random number generating program found on a widely used and reputable website [44]. We will perform 1:1 randomization. Variability in the length of bassinet usage may be impacted by size of infant, parental preference, or infant temperament. However, data will be collected through 6 months post partum.

Data Collection

For each assessment (Figure 1), all participants will receive an email with a REDCap (research electronic data capture) link for web-based data collection. All web-based survey data will be published in accordance with the CHERRIES (Checklist for Reporting Results of Internet E-Surveys) checklist. To mitigate

and minimize the possibility of missing data in the measures, we will program electronic questionnaires to prevent skipping questions. REDCap is a web application and back-end database model designed to support data capture for research studies. REDCap is an open-source tool developed by Vanderbilt University to build and manage web-based forms for data collection. REDCap was developed specifically based on guidance from the Health Insurance Portability and Accountability Act of 1996 security guidelines and contains features such as data encryption. In addition, participants will receive a monthly package containing 2 actigraphs, a baby's day diary, and a prepaid return envelope.

Adverse Events

Adverse events will be monitored monthly via questionnaires and during telephone contact at month 3 and month 6 (phone calls to remind them to get blood drawn). Further, participants will be asked to report to the research team immediately if they experience unwanted adverse effects during participation. These events will be recorded and included in human research ethics reports. The Edinburgh Postpartum Depression Scale [45] has a single item that denotes suicidal ideation. It will be flagged such that if the participant endorses the item, a telephone call from a clinical psychologist (LF) to the participant will be initiated to conduct a risk assessment and assist with triage, as necessary.

Measures and Materials

Table 1 describes the schedule of the study assessments for primary and secondary measures.

[a]PP: post partum.

[b]SCID: Structured Clinical Interview for Diagnostic and Statistical Manual of Mental Disorders-5.

Primary Infant Assessments

The mother will record infant sleep for 1 week per month in the baby's day diary [46]. Boxes are filled in daily for 1 week with symbols that correspond to when the infant is asleep, awake, awake and fussy, sucking, or feeding. This measure has been widely used and exhibits desirable reliability and validity [47,48]. The Brief Infant Sleep Questionnaire [40] is used to assess the infant's sleep during the past week. The Infant Behavior Questionnaire-Revised [49] will be used to allow mothers to report, on a 7-point scale, the frequency with which infants have enacted specific behaviors in common situations during the past week.

Primary Maternal Assessments

The Consensus Sleep Diary [50] will collect subjective sleep, while actigraphy will be contemporaneously used to derive objective sleep data. The Pittsburgh Sleep Quality Index [51] will measure habitual sleep quality. The Edinburgh Postnatal Depression Scale [52,53] will be used to assess changes in the depressive symptoms over time. The Generalized Anxiety Disorder Scale-7 items [54] and the Perinatal Anxiety Screening Scale [55] will be used to assess anxiety symptoms over time.

Participants will have their blood drawn (up to 20 mL) at enrollment, 3 months post partum, and 6 months post partum at a Quest Diagnostics laboratory near them (Figure 1). Briefly, blood collection kits with ethylenediaminetetraacetic acid tubes will be mailed to participants with a requisition form and a laboratory directive (from Quest) that provides the Quest Diagnostics Patient Service Center instructions on how to collect and process the study kit. Blood samples will be shipped in a temperature-controlled fashion to the Psychoneuroimmunology in Pregnancy & Postpartum (PIPPI) laboratory at Weill Cornell Medical College for analysis. Measurements of circulating cytokines, stimulated cell assays, and flow cytometry analysis will be conducted to evaluate the role of immune dysregulation.

Secondary Maternal Assessments

The Insomnia Symptom Questionnaire [56] is a self-report instrument that identifies a clinically relevant case definition of insomnia consistent with widely used insomnia classification criteria. It has 13 items, which identify sleep symptoms, frequency, duration, and related daytime impairment. Scoring indicates positive or negative for insomnia. The Epworth Sleepiness Scale [57] will assess daytime sleepiness. The Flinders Fatigue Scale [58] will assess daytime fatigue.

Measures in Both Mothers and Infants

Actigraphy watches (Phillips/Respironics and ActiGraph, LLC) will be provided to the dyad each month to collect objective sleep data. Data collection and interpretation will be consistent with previous reports [59-61]. For infants, watches will be placed on the right ankle in accordance with suggested guidelines [61-63].

Epigenetic Biomarker Testing

Blood Draw Collection

Upon enrollment, participants will be sent supplies from TruDiagnostic for blood collection, including a Tasso blood collection kit and a prepaid mailing kit to TruDiagnostic. Blood samples will be processed using the Illumina Human MethylEPIC beadchip. Methylation data for the *TTC9B*, *HP1BP3*, and *MS4A7* genes will be sent to Dr Zach Kaminsky who will use the published algorithm for predicting postpartum depression risk to determine if the participant's epigenetic methylation patterns are consistent with increased risk for postpartum depression. Participants will not be informed of their biomarker status, as we are still determining the clinical value of the biomarkers.

Immune Markers

Blood collection kits with ethylenediaminetetraacetic acid tubes will be mailed to participants with a requisition form and a laboratory directive (from Quest) that provides the Quest Diagnostics Patient Service Center instructions on how to collect and process the study kit. Aliquots of plasma and the second tube of whole blood will be shipped overnight to Weill Cornell Medicine. Peripheral blood mononuclear cell (PBMC) suspensions will be prepared within 24 hours of blood collection by low-density gradient centrifugation via Hermle Z300 (K#55085010) to avoid erythrophagy-related activation of the monocytes. PBMCs will be frozen and stored at –80 °C using 10% dimethylsulfoxide, thereby allowing all samples to be analyzed in parallel. Plasma will also be stored at –80 °C. In our prior studies, we have missing biological data (due to incomplete blood draws) in about 7% of the visits; we anticipate similar rates in this study.

Cytokine Analysis

Cytokine analysis will be performed under Dr Osborne's supervision in the PIPPI laboratory at Weill Cornell Medicine. Plasma cytokines will be measured using the Meso-Scale Discovery Ultrasensitive Proinflammatory Multiplex kit (Meso Scale Diagnostics LLC) according to the manufacturer's protocol in duplicate and read using the MS2400 imager (Meso Scale Diagnostics LLC). We will calculate the coefficient of variation for each woman's replicates when both have concentrations above the limit of detection.

Cell Preparation and Stimulation

Maternal PBMCs will be thawed in Roswell Park Memorial Institute 1640 medium and distributed into three 24-well multiplates (5×10^5 cells/well). Remaining cells will be aliquoted into two 5-mL culture tubes (2×10^6 cells/tube). Cells will be maintained in a humidified atmosphere of 95% air/5% CO_2 at 37 °C. After 24 hours, PBMCs in the 24-well plates will be treated with increasing concentrations of cortisol. Hydrocortisone stock solutions will be prepared by dissolving hydrocortisone in ethanol and then diluting with pyrogen-free sterile saline solution (NaCl 0.9%) to achieve equipotent final culture concentrations of 0.2 µg/mL (physiological plasma cortisol level) and 0.4 µg/mL (plasma cortisol level in high-stress status). PBMCs will be treated with a final cortisol concentration of 0, 0.2, and 0.4 µg /mL. Cells in the 5-mL culture tubes will be stimulated with phorbol myristate acetate (Sigma Aldrich) and ionomycin (Sigma Aldrich) in the presence of GolgiStop (Becton Dickinson) for 4 hours in 37 °C under a 5% CO_2 environment to stimulate T-effector cells. Following the

incubation periods, the supernatant from cortisol-stimulated cells will be collected and stored at –80 °C until assayed for interleukin (IL)-6, IL-10, IL-8, and IL-4 by using a commercial enzyme-linked immunosorbent assay. Cellular pellets will be resuspended and prepared for flow cytometry to assess the immune cell phenotype.

Flow Cytometry Analysis

Flow cytometry analysis will be performed on the BD LSRII instrument (BD Biosciences, 3 laser, 14 color) within the Cubillos-Ruiz laboratory adjacent to Dr Osborne's PIPPI laboratory. Additional analyses, as necessary, will occur in the Weill Cornell Flow Cytometry Core, which houses a BD AriaII sorter, 5 laser (355, 405, 488, 561, 640) capable of 4-way sorting; a BD Influx sorter, 6 laser (355, 405, 445, 488, 561, 640) capable of 6-way sorting; a BD Fortessa analyzer, 5 laser (355, 405, 488, 561, 640) 20 parameter and a BD FACSCelesta analyzer, and 3 laser (405, 488, 561) 14 parameter. Panel one will include membrane staining markers and will be performed using thawed PBMCs. Stained cells will be analyzed by 8-color flow cytometry (with anti-CD3 BV786, anti-CD4 Pe-Cy7, anti-CD8 BV605, anti-CD14 antigen-presenting cell, anti-CD25 phycoerythrin, anti-CD16 PerCp-Cy5.5, anti-CD56 fluorescein isothiocyanate, and anti-CD19 BV421; Becton Dickinson). We will use a gating method to measure subsets of monocytes, lymphocytes, natural killer cells, T-cells, B-cells, CD4+ T helper cells, and CD8+ cytotoxic T cells. Samples stimulated with phorbol 12-myristate 13-acetate and ionomycin will be stained using a T-cell specific panel and analyzed by 8-color flow cytometry (with anti-CD3 BV786, anti-CD4 Pe-Cy7, anti-CD45RO BV605, anti-IFN-γ antigen-presenting cell, anti-CD25 PE, anti-FoxP3 PerCp-Cy5.5, anti-IL-4 fluorescein isothiocyanate, and anti-IL-17A BV421; Becton Dickinson).

Process Measures

Treatment Expectation Questionnaire

An adapted version of the Treatment Expectation Questionnaire [64] will be administered at month 3 and month 6 to assess the mother's expectations of benefits, satisfaction with condition, and fears. This measure asks about expectations regarding symptom relief, improvement, and benefits from using the specific bassinet. It allows for comparison of the impact of multidimensional expectations across different conditions. Open-ended comment boxes will be provided for mothers to report experiences, adverse events, or other comments.

Patient Adherence

Various items will be collected to determine patient adherence: (1) self-reported adherence assessed using an adapted survey checklist provided by Dr Stremler, (2) self-report data on bassinet usage, (3) pictures of bassinet use by participants, and (4) comment boxes to explain nonadherence.

Additional Factors to Consider and Use as Covariates

These include (1) presence of spouse/partner and other children at home [36,65-67]; (2) type of feeding [68-70]; (3) infant variables such as acid reflux, colic, and gestational age; (4) consistency of bedtime routine [71-73] and when moved to a crib; (5) history of childhood trauma in the mother via the Childhood Trauma Questionnaire [74], as prior trauma is highly correlated with depressive episodes, especially in new mothers [75,76] and negatively affects sleep [77]; and (6) type of delivery, complications, or time spent in neonatal intensive care unit.

Statistical Analysis

Power

Power analyses were performed using $P<.05$ (2-tailed) at .80 power, based on recommended guidelines [78-80]. The power analyses were conducted for each statistical technique to be pursued in aims 1 to 3: mixed (between-subjects and within-subjects) multivariate analysis of variance (MANOVA), mixed (between-subjects and within-subjects) analysis of variance, independent 2-sided *t* test, dependent 2-sided *t* test, correlation, and the mediational models involving structural equation modeling (based on the β coefficient). The pilot study collected similar measures from pregnant/postpartum women with a history of major depressive disorder who used SB or HALO TB. Hence, the power analyses were based on pilot sleep and mood data. Calculations revealed an average effect size across all postpartum timepoints (T1 to T6) between the treatment and control groups on the following measures: infant sleep (d=0.39), postpartum sleep quality (d=0.27), and postpartum depression (d=0.33). Based on these effect sizes, a sample size of 208 participants is needed for infant sleep, 434 participants for postpartum sleep quality, and 286 participants for postpartum depression to attain statistical significance. Thus, a final sample size of 393 participants will be targeted (allowing for an attrition rate of 15%).

Randomization

AL generated the random sequence by using a random number generating program found on a widely used and reputable website [44]. We performed 1:1 randomization, stratifying for antidepressant use (actively taking or not). The study coordinator is responsible for the assignment based on the random sequence. This is not a blinded study, as there are distinct differences between the 2 bassinets.

Intention-To-Treat Analyses

Intention-to-treat analyses [81,82] will be conducted to understand the extent to which participants who satisfy the inclusion criteria for enrollment and are therefore randomized to one of the two conditions (intention-to-treat population) are similar to participants who provided complete data across the measurement rounds (actually treated sample). The purpose of intention-to-treat analyses is to scrutinize whether the conclusions drawn from the RCT remain robust even after considering participant attrition across time [81]. We will adhere to the recommended guidelines for performing multiple imputation on clinical research data [83].

Mean Differences

Initial analyses will be performed to verify that the random assignment procedure successfully equalized participants between the treatment and control groups on the preintervention variables. Thus, MANOVA will compare these 2 groups on the entire set of preintervention baseline measures. A chi-square

test will verify that both groups have the same distribution of infant boys and girls. As participants will be randomized to groups using a random number generator, baseline equivalency of the 2 groups is anticipated.

Six separate mixed 2 (treatment vs control) × 6 (assessment period) MANOVA models will be conducted. Specifically, to assess hypothesis 1a (aim 1), the model (model 1) will be applied to the infant sleep quality outcome measures. To address hypothesis 1b (aim 1), the analysis (model 2) will be applied to maternal postpartum sleep quality outcome measures. To evaluate hypothesis 2a (aim 2), the model (model 3) will be applied to the maternal postpartum depression outcomes. To examine hypothesis 3a (aim 3), the model (model 4) will be estimated on the measures involving peripheral cytokines, immune cells, and stimulated cytokine profiles. To examine hypothesis 3b (aim 3), the model (model 5) will be undertaken on the measures of T-cell dysfunction. Furthermore, to examine the exploratory aim, the model (model 6) will be estimated on the epigenetic biomarkers.

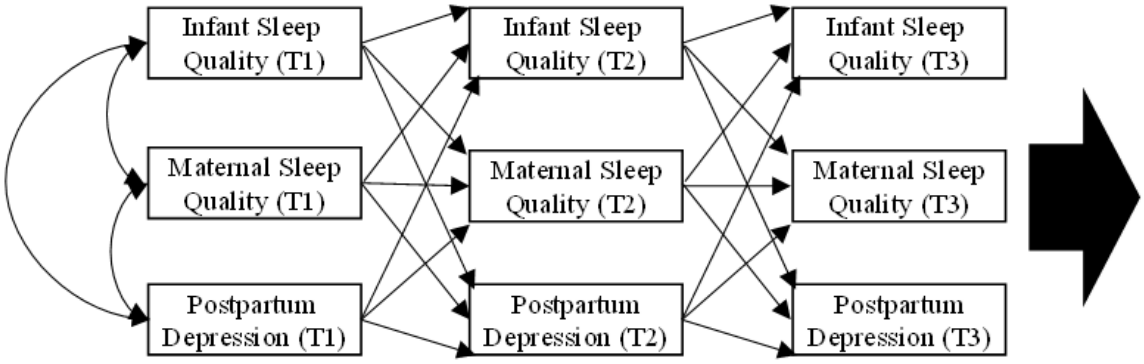
In each of the mixed MANOVA models, several follow-up analyses will be conducted to examine the results. First, a mixed (between-subjects and within-subjects) analysis of variance will be applied on each specific outcome. Second, independent 2-sided *t* tests will assess mean differences between the treatment and control group (at each timepoint) on each outcome. Third, dependent 2-sided *t* tests will permit scrutiny of the temporal change in mean scores between every 2 timepoints on every outcome. Fourth, the longitudinal trajectories across the entire 6-month period for both the treatment and control groups will be graphed using 95% CIs to provide a visual tool to offer insights to understand the effectiveness of the RCT.

Prior to conducting analyses, the normal distribution of all the measures will be inspected. If a variable is evidenced to be nonnormally distributed, then the bootstrapping variant of these statistical techniques instead will be performed to obtain corrected *P* values [84].

Mediational Analyses

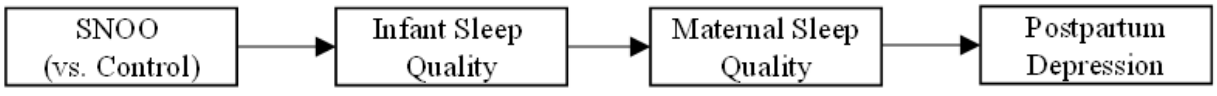
Cross-lagged panel designs will be pursued to make inferences about the temporal priority of a set of measures assessed longitudinally [85-87]. Accordingly, cross-lagged panel models permit the opportunity to determine the temporal precedence of antecedents and consequents in the set of constructs [86]: infant sleep quality, maternal sleep quality, and postpartum depression. The depiction of the proposed cross-lagged panel model to be tested is shown in Figure 2.

Figure 2. Cross-lagged panel model. For diagrammatic clarity, not displayed but will be estimated as part of the model are the constructs for postpartum months 3 (T4), 4 (T5), and 5 (T6), the correlations across constructs in every measurement round, and predictive error terms.



The cross-lagged panel model findings in the above model are expected to help inform how to specify the mediational model for hypothesis 2b. We propose that the cross-lagged panel model will evidence the following significant temporal cross-lagged directions that are consistent with hypothesis 2b: SB versus TB→infant sleep→maternal sleep→postpartum depression. Thus, a longitudinal mediational model, incorporating the intervention factor, will be specified and estimated (Figure 3). This mediational model tests and proposes that following underlying mechanism: SB group (vs the control group) will improve infant sleep quality, which would then predict better maternal sleep quality and finally contribute to lower maternal postpartum depression. All the outcomes of aim 1 are incorporated into the aim 2 mediational model to provide comprehensive and compelling insights that will statistically connect all the psychosocial constructs and understand the underlying process of this RCT.

Figure 3. Mediational model. For diagrammatic clarity, not displayed but will be estimated as part of the model are the predictive error terms. SNOO: smart bassinet.



The cross-lagged panel model and the meditational model each will be estimated with structural equation modeling [88]. The overall adequacy of these structural equation models will be assessed using fit indices [89-91]. A nonsignificant model chi-square test is desired to signify that the model approximates the underlying data, but this index tends to be sensitive to sample size [92]. Thus, additionally interpreted will be the comparative fit index and the Tucker-Lewis index, with higher values, preferably above 0.90, indicative of a good-fitting model [93,94]. The root mean-square error of approximation is sufficiently sensitive in detecting model misspecifications and provides a 90% CI [95]. Values below 0.05 indicate close fit, between 0.05 and 0.08 fair fit, between 0.08 and 0.10 mediocre fit, and above 0.10 poor fit [95].

If the fit indices for a model would be judged satisfactory, then the magnitude of the direct paths and the *P* values of these paths will be interpreted [96]. In the mediational model, the statistical significance of these mediational processes starting from the SB intervention (vs control) to infant sleep quality to maternal sleep quality and finally to postpartum depression with be evaluated in tests of indirect effects to determine whether the mediational process is significant beyond chance [88]. As recommended for structural equation models [96], bootstrapping with bias-corrected CIs will be applied to adjust for potential nonnormality of the variables.

Statistical Analyses for Immune Measurements

The initial statistical approach will include a descriptive cross-sectional analysis at each timepoint, both for quality assurance and to attain a better understanding of the distributions of the immune cell and cytokine profile variables for use in subsequent analyses, including the need for any transformations (ie, logarithmic transformation to symmetrize the residuals). Factor analysis will be employed as a means of data reduction to probe latent cytokine profiles reflected across the manifest indicators (eg, tumor necrosis factor-α, IL-6, IL-1β). We will first compare levels of a combined score of peripheral innate immune cytokines and frequency of maternal immune cells between women who do and do not develop PMADs in separate models to evaluate cross-sectional effects, employing a multivariable linear regression model to adjust for relevant covariates (eg, gestational age, BMI). Similar models will be repeated for maternal cytokines and innate cell recruiting factors as produced by the stimulated cells. Second, we will test whether the magnitude of group difference varies across the study period in a longitudinal analysis. We will fit a generalized linear population-average model estimated using generalized estimating equations with exchangeable working correlation structure to account for within-women correlation of mood measures. The model will include the relevant immune markers identified in the cross-sectional analyses, indicators for visit and group, as well as any relevant interaction terms (immune marker by group or immune marker by visit). The models will adjust for baseline severity of depressive symptoms and psychotropic medication use. Standard model checking will be performed, and the most parsimonious model will be selected based on the Akaike information criterion or quasi-likelihood information criterion for generalized estimating equations models. To test the within-group effects of severity of PMAD symptoms, the dichotomous group variable will be replaced by continuous Edinburgh Postpartum Depression Scale and Generalized Anxiety Disorder Scale-7 item scores in analytic models and restricted to only the subset of women with significant PMAD symptoms.

Missing Data

Attrition in our prior studies has been approximately 15%, and we have accounted for that in our planned sample size. In addition, in our prior studies, we have missing biological data (due to incomplete blood draws) in about 7% of the visits; we anticipate similar rates in this study, which will use the same approach. Given the prospective nature of our study, we will carefully evaluate missingness. If identified, we will employ one of the two strategies to handle missing data. The first approach relies on a technical assumption of missing at random and involves inclusion of covariates related to missingness in all analyses. Full information maximum likelihood performs well under ignorable missing data conditions such as missing at random. A second strategy we will use is multiple imputation. Although this has the potential to yield biased estimates dependent on the nature of missingness [97], we will employ this approach to implement sensitivity analysis under plausible assumption of missing not at random to examine the robustness of our inference [98].

Results

This project was funded in June 2024 and approved by the institutional review board of University of Colorado Colorado Springs (#2024-071) and by the Office of Human Research Oversight in February 2024. Recruitment for this study began in January 2025. We anticipate that the data analysis for the primary and secondary aims will be completed by July 2028. The methodology for the web-based surveys will be reported according to the CHERRIES checklist before the submission of any manuscript. The results from this trial will be used to extend SB efficacy in larger military cohorts and in women experiencing active perinatal mood disorders.

Discussion

Implications of SHINE

At the conclusion of this project, we will have gained a thorough understanding of how SB affects infant and maternal sleep compared to TB and its association with maternal mood through 6 months post partum in military-affiliated women. We will also significantly extend our current knowledge regarding the biological mechanisms associated with PMADs and how they may be modified by behavioral interventions. Future directions will include evaluations of women with current depressive disorders, women with a history of depression but not actively depressed, women with and without a history of trauma, and women who deliver prematurely to determine if SB can mitigate depressive symptomatology over the course of 12 months. This is a primary goal, as PMAD is a serious public health concern.

Limitations

This study will, however, have important limitations that warrant discussion. The study goal is to determine whether SB can prevent or reduce the reoccurrence of PMADs and not for use as an active treatment. Hence, we chose to exclude participants with active psychopathology at enrollment. We focused on at-risk participants. Those with active psychopathology are not at-risk—they have it. Moreover, we felt that it was a matter of safety. Recruiting participants from across the United States restricts the ability of our team to manage or treat an actively depressed mother. Ethically, we believe that we needed to demonstrate that SB can mitigate or prevent PMADs before evaluating whether it can treat active PMADs. However, if a participant develops PMAD at post partum, they will remain in the study and be referred for treatment. To clarify, we are only excluding women with a positive diagnosis of SCID; women with a history of PMAD or who are effectively treated will be included. This decision comes with some concerns. One is that we may have too small of a magnitude or range of mood symptoms to observe a true positive effect of SB on mood symptoms. In other words, the population will be too mentally normal/healthy. We believe, however, that the diverse sample will provide enough variability in mood symptoms, especially since a greater percentage of active-duty women and military spouses experience mental health conditions and at a higher rate than civilians [99-101]. If we notice that the rate of PMAD symptoms is limited or if we are excluding too many participants due to active psychopathology, we may alter the design to include active psychopathology. Another limitation is that the study requires participants to have access to the internet; therefore, individuals of low socioeconomic status and certain racial/ethnic groups may potentially be excluded from the study [102]. However, low-income Americans have made gains in technology and access to the internet, which is likely to continue in the future. A primary goal of this study is to have a diverse sample of racial and ethnic backgrounds. Recruiting and retaining a broad range of participants, particularly those of low socioeconomic status, has been challenging, with recent calls to enhance representation [103,104]. In order to provide an equitable interpretation of the data, the participants need to be diverse and accurately reflect the population of the United States. Therefore, a major emphasis will be on recruiting a diverse and representative sample of military-affiliated participants. Although attrition has been a minimal issue in our studies, we are cognizant of the duration and expectations of the protocol. Thus, our group will maintain regular contact and troubleshoot, if necessary, to enhance retention.

Conclusions

Pregnant active-duty and military spouses are an underserved population. Data suggest that persistent, rather than transient, infant sleep issues contribute to maternal depression, poor maternal sleep, and poor family functioning. We contend that to achieve the goal of reducing PMADs among new military-affiliated mothers, sufficient and efficient sleep is crucial. Understanding that there are few nonpharmacologic interventions that significantly improve infant or maternal sleep highlights the need for these data. This will be the first study to assess sleep methodically and longitudinally from infants who sleep in an SB and their mothers versus those who sleep in a TB and their mothers and how sleep from both individuals interacts to affect postpartum mood. We hypothesize that this study will indicate that SB may indeed reduce PMADs in military-affiliated mothers.

Abstract

Background: Young adults (15-24 years old) living with HIV may experience pressure both from HIV infection and social role change problems, resulting in a series of psychological problems such as depression and anxiety. Effective psychological intervention can improve their mental health and quality of life.

Objective: The study aims to explore the effectiveness of VR-based mental intervention on young adults living with HIV. The application and advantages of virtual reality (VR) in children's psychotherapy provide new ideas for psychological intervention for young adults living with HIV.

Methods: We use the qualitative interviews and questionnaire results as well as guided by classical psychotherapy to create a personalized psychological intervention system for young adults living with HIV through VR technology, which is based on the long-term AIDS treatment cohort and infectious diseases cohort of children. We use the mental scales and biochemical indexes as the outcomes, conducting a prospective randomized controlled trial to verify the feasibility and effectiveness of the VR psychological intervention system.

Results: The study began enrollment in September 2023. To date, 160 participants have finished the baseline questionnaires.

Conclusions: The study results might provide a scientific basis for accurate psychological treatment among young adults living with HIV in the future.

Introduction

According to the latest data from the joint United Nations Program on HIV/AIDS (UNAIDS), an average of about 4000 people were newly diagnosed with HIV globally per day in 2021. Young people aged 15-24 years old accounted for 31% of new HIV infections. In the Asia-Pacific region, about 260,000 young people were newly diagnosed with HIV in 2021, accounting for 17.3% of the global increase, second only to Africa [1]. The mental health of people living with HIV/AIDS is an important part of the quality of life, and infection-related stigma makes people living with HIV/AIDS face 2-3 times more anxiety and depression than the general population [2-4]. Young people living with HIV face pressure from social adaptation, such as personal growth and role change, as well as disease pressure caused by the incurability and stigma of HIV infection [5]. Studies on young people aged 10-24 years old living with HIV showed that 21% of them had depression symptoms and 14% had anxiety, and the proportion interval of suicidal ideation was from 4.4% to 24.4%, and those with long-term suicidal ideation ranged from 9.26% to 33.33% [6-9]. So, how to carry out effective psychological intervention for young people living with HIV is very important.

There are many forms of psychological intervention, and numerous interventions are intended to support mental health, mainly by way of face-to-face and group-based intervention, internet intervention, and mobile remote intervention. Regardless of the form of psychological intervention, it is based on the theoretical framework or theoretical basis. Common theoretical bases include cognitive behavioral therapy (CBT) and dialectical behavior therapy (DBT) [10]. Previous studies proved the effectiveness of CBT or DBT in the way of face-to-face intervention. Synder et al [11] conducted a group-based psychological intervention study on people living with HIV aged between 16 and 24 years of CBT. The results showed that the self-perceived social support of the intervention group was higher than that of the control group, but the difference was not statistically significant (P=.20) [11]. Bedics et al [12] conducted a 1-year DBT treatment on 101 women with borderline personality disorder, which showed that DBT therapy could reduce suicidal behaviors and nonsuicidal self-injury behaviors. Burton et al [13] conducted a psychological intervention with DBT therapy, suggesting that the depression clinical scores had improved of the participants in the intervention group. DBT therapy has achieved some effects in helping improve behavioral problems in children [14] and alcohol problems among college students [15]. However, face-to-face and group-based CBT or DBT needs to be carried out by professionals, and the existing qualified health care providers and infrastructures are limited in meeting the challenge in China.

Studies in developed countries have shown the feasibility and efficacy of using mHealth to provide counseling and services to improve mental health in diverse populations. Mohr et al [16] conducted a self-control psychological intervention in the general population by mobile phone, and the results showed that depression and anxiety decreased over time [16]. The research team conducted a randomized controlled psychological intervention trial on 300 adults living with HIV on the WeChat public platform. At 3 and 6 months after the intervention, the depression level and suicide ideation rate of the experimental group were reduced compared with the control group (P=.02) [17,18]. However, there is no study focusing on mental intervention among young people living with HIV. At the same time, studies showed that compliance with remote Internet or mobile phone intervention is poor, and patients are unable to concentrate during the intervention process, which makes it difficult to ensure the effective implementation of the intervention.

Virtual reality (VR) provides a variety of sensory stimuli to people through the computer-generated virtual environment, enabling people to interact with the virtual environment naturally to achieve a sense of immersion and experience in the real environment [19]. Falconer et al [20] used VR technology to set virtual scenes to treat patients with depression and found that the depression decreased after the intervention, and the improvement effect was still maintained one month after the end of the experiment. Based on the mindfulness-based program (MBP), Modrego-Alarcón et al [21] conducted a study on the stress level of 280 college students through VR equipment. The results showed that the experimental group had increased relaxation and decreased stress levels compared with the control group (P=.006) [21]. Navarro-Haro et al [22] combined DBT therapy with VR to guide mindfulness training. The results showed that the impulse to commit suicide, self-harm, give up treatment, and use drugs in the experimental group was reduced after the intervention [22]. However, most of the existing studies are small-scale pilot studies on general adults or adolescents with adverse psychological conditions, and there is little study on young people living with HIV.

In summary, the proposed study intends to address the issues of prevalent mental health problems in young people living with HIV and to innovatively use VR to provide integrated and culturally appropriate intervention for mental health improvement.

Methods

Goal and Objectives

The objectives of the project are (1) using DBT as the theoretical framework, based on VR technology to carry out the individualized psychological intervention for young people living with HIV; and (2) A 1:1 prospective randomized controlled trial (RCT) will be conducted to verify the effectiveness of VR psychological intervention on reducing depression and anxiety in young people living with HIV.

Intervention Design

Development of A VR Intervention System

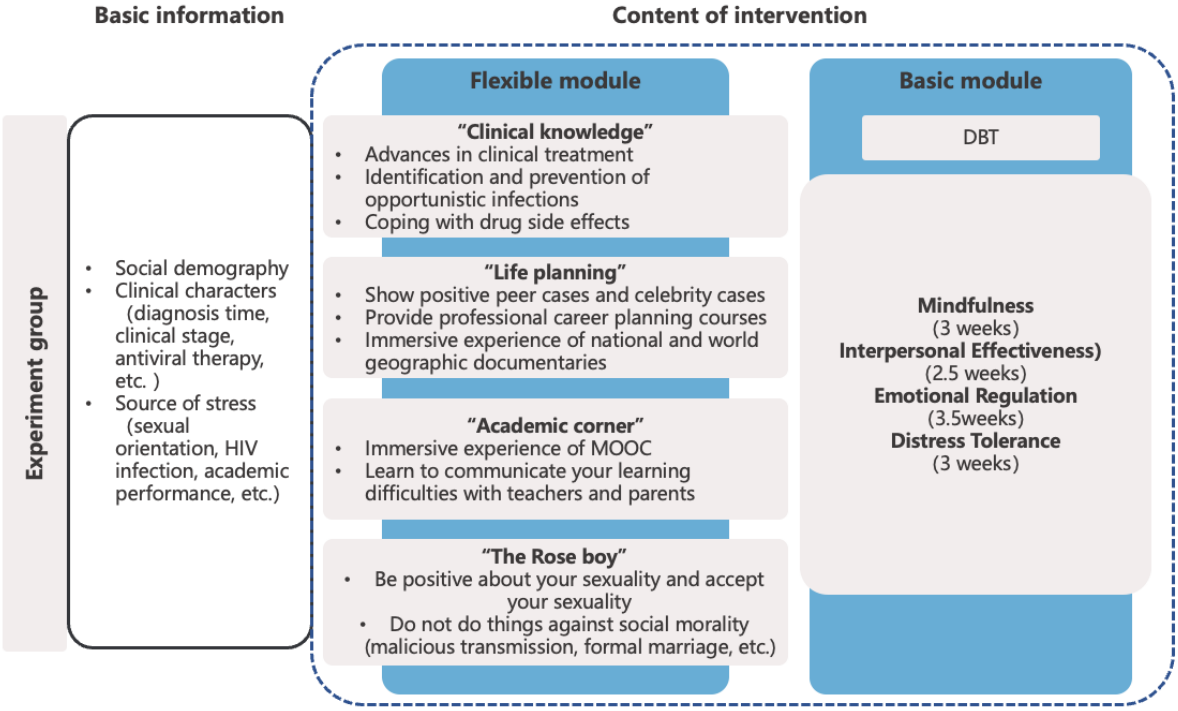
Content of the Intervention

The proposed study is guided by DBT and combined with the actual needs and unique characteristics of young people living with HIV to develop a specialized psychological intervention system suitable for the characteristics of this population.

The actual needs of mental health among young people living with HIV were collected based on literature and qualitative interviews with young people living with HIV. The outline of the qualitative interview mainly included (1) basic information and (2) The main source of stress (infection, drug side-effect, income, life expectancy).

Study subjects in the experimental group received 2 modules of psychological intervention. Module 1 was the basic intervention module, mainly the DBT treatment course, which covers 4 parts: mindfulness, distress tolerance, emotional regulation, and interpersonal effectiveness. The second module is a flexible intervention module applicable to the actual needs of young people living with HIV. As shown in Figure 1.

Figure 1. Psychological intervention content in the experimental group. MOOC: Massive Open Online Courses. DBT: dialectical behavior therapy.



Intervention Delivery

We set up a user management platform as the support for the intervention. The function of the platform included (1) information management: a complete record with a unique number is generated when each research object is enrolled. The researcher is the system administrator and can add and modify the relevant information of the patient, such as fixed number, basic personal information (deprivatized), clinical and therapeutic information, psychological assessment scale, etc. The system is associated with the VR intervention software, which can record and synchronize the completion of the intervention course of the research object, and the administrator can view and export the corresponding data through the number.

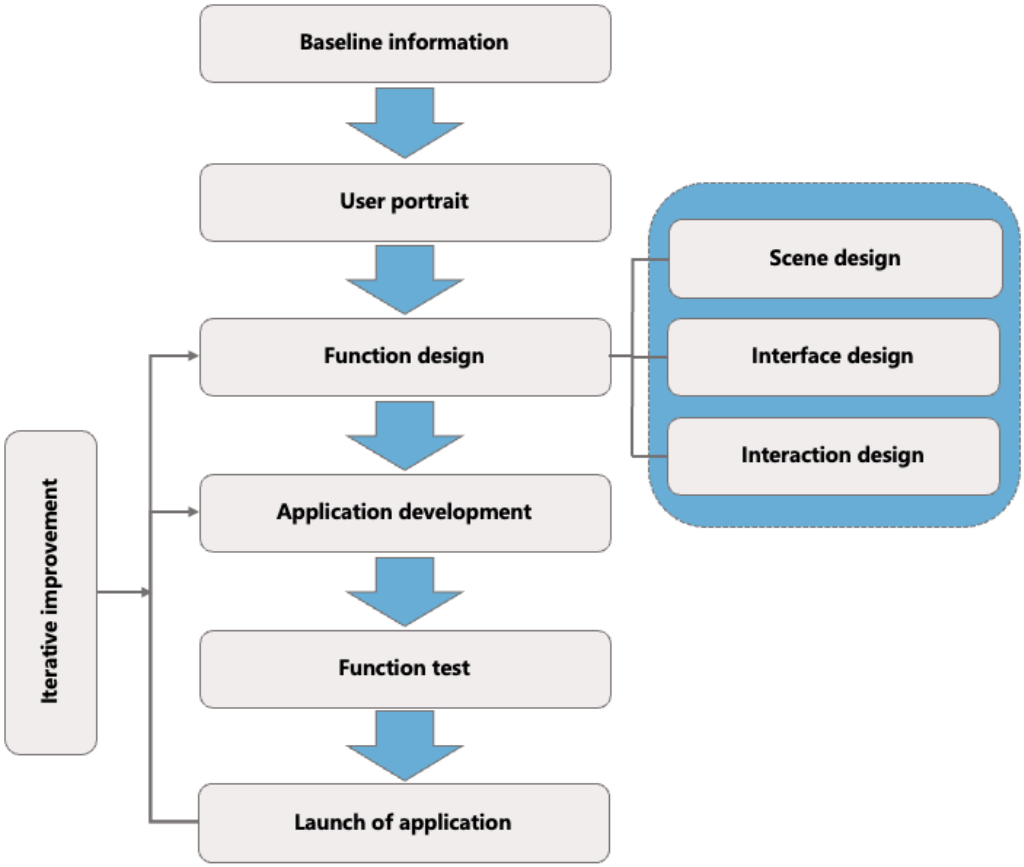
(2) Upload and update intervention resources: the intervention content involved in VR software forms a "resource library" in the management system, and the user portrait is generated when the subject is enrolled in the corresponding intervention content. The user portrait is the virtualization of real users and the category of research objects extracted; that is, the entire psychological intervention system is a big picture. Against this background, different types of subjects receive psychological intervention corresponding to their characteristics to achieve personalized customization. In the course of the experiment, the researchers continuously improved and updated the intervention resources.

(3) The intervention goal setting and process supervision: researchers use motivation type interview (motivational interviewing [MI]) to help subjects set up goals, regularly to supervise the completion of the intervention for subjects, and set a message to remind, intervention to ensure compliance.

VR Application Development

VR application development mainly includes 3 stages. First, Scene design is a virtual scene in which the participants experience psychological intervention therapy. This study mainly includes 2 scenes: natural landscape and indoor landscape. The natural landscape was used as the environment for participants to immerse in mindfulness and other skills training. The indoor landscape, including the home environment and the consultation environment, was used for the explanation and learning of psychological intervention courses. Second, regarding interface design, this study follows the principle of consistency of interface structure and style, choosing simple graphical design language and interface style with comfort and color sense. The icon uses a simple 2-dimensional graphic simulation to represent the functional form, which is convenient for the participant to identify and quickly associate the icon function, reducing the possibility of wrong selection. Third, interaction design refers to the use of VR hardware devices such as glasses and gamepads to realize the interaction of subjects in the scene. For example, when the participant enters the "family scene," he or she can move freely and roam in panorama; through the button control of indoor lighting and curtains, choose the bedroom, living room, consulting room, etc, to carry out the study of psychological courses. As shown in Figure 2.

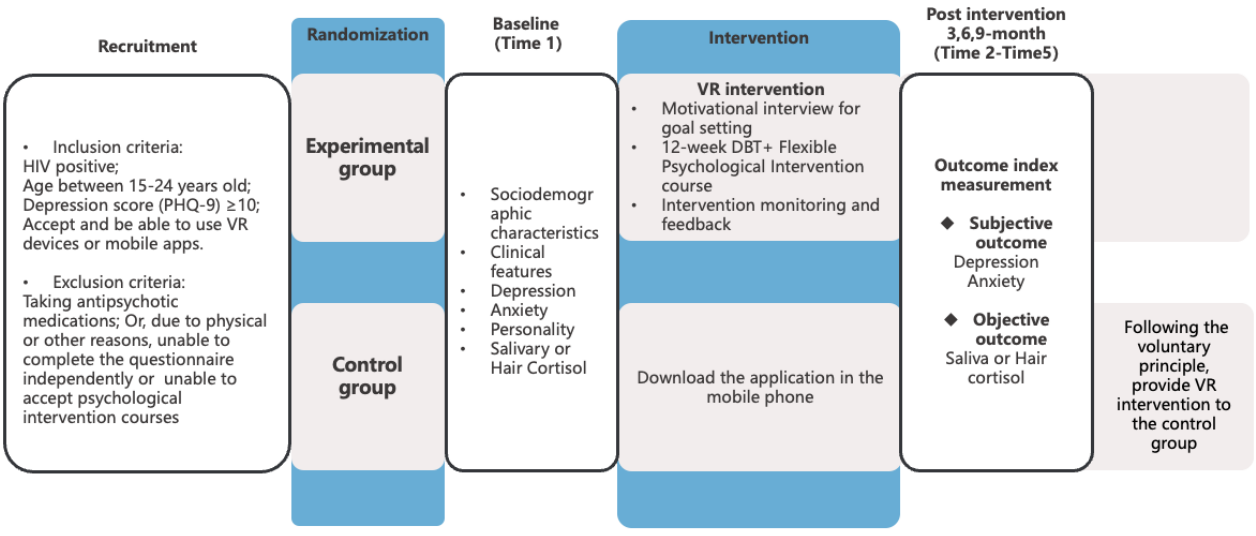
Figure 2. Virtual reality (VR) system development.



Verify the Effectiveness of VR Psychological Intervention

A 1:1 RCT will be conducted to verify the effectiveness of VR psychological intervention in reducing depression and anxiety in young people living with HIV. The RCT was not possible to blind the participants. The study lasted for 12 months. According to the inclusion and exclusion criteria, the participants are randomly divided into an experimental group and a control group. The experimental group received VR psychological intervention for 3 months, and the control group received non-VR mobile phone intervention for the same period. Data will be collected at 5 time points: baseline, postintervention, 3 months, 6 months, and 9 months after intervention, as shown in Figure 3.

Figure 3. The process of the intervention. PHQ-9: Patient Health Questionnaire-9. VR: virtual reality. DBT: dialectical behavior therapy.



Measurement

Depression score was measured by the Patient Health Questionnaire-9 (PHQ-9). PHQ-9 is shorter but has demonstrated both good reliability and validity in the Chinese populations [23,24]. The scale consists of 9 items, such as “Little interest or pleasure in doing things” and “Feeling down,

depressed, or hopeless," to measure the depressive status of the participants over the previous 2 weeks. Each item was rated on a 4-point Likert scale ranging from 0 (not at all) to 3 (nearly every day), providing a 0 to 27 total severity score, with higher scores indicating increased depressive symptoms [25].

Anxiety was measured by the Self-rating Anxiety Scale (SAS) that assesses anxiety in the last week with the Chinese version [26,27]. SAS has 20 items with responses of a 4-point Likert scale (1="never or rarely," 2="sometimes," 3="most of the time," 4="almost every day"). The total score ranges from 20-80, with 50 as a cutoff point, 50-59 being considered mild anxiety, 60-69 as moderate anxiety, and ≥70 as severe anxiety.

Study Participants

Inclusion criteria were a positive HIV test, age 15-24 years, depression score (PHQ-9)≥10 (with depressive symptoms), accepting and being able to use VR devices or mobile apps. Exclusion criteria were taking antipsychotic drugs or, for physical or other reasons, being unable to complete surveys or questionnaires independently, or being unable to accept psychological intervention courses.

Recruitment

The recruitment location is mainly based on Beijing Ditan Hospital Capital Medical University, which is treating 11,735 people in 2023. After clinic doctors have completed all the treatment procedures, researchers will distribute research leaflets to them to introduce the research project and invite them to participate. If the young people living with HIV agree to participate, the program's researchers will invite the participants to a separate room to be screened for enrollment conditions.

The staff will present the informed consent form of this study and inform the content of the informed consent form, including the introduction of the project, the benefits and possible risks of participating in this study, and the voluntary principle. The research subjects will be asked to sign the informed consent form after they have fully understood it.

Baseline Information Collection

The collection of baseline information in this study included 2 items: filling out questionnaires and retaining biological samples. A self-designed questionnaire was used to collect baseline information, including sociodemographic characteristics, medication and treatment information, clinical indicators, and mental health scale evaluation. The electronic questionnaire data can be downloaded directly, which is convenient to timely grasp or correct the information of infected people enrolled on the same day, and ensure the quality of data. To facilitate data collection, improve work efficiency, and improve data collection quality, electronic questionnaires were used at baseline and 3 follow-up visits.

Sample Size Calculation and Group Randomization

The sample size was calculated according to depression, the main outcome indicator of this study. Participants with PHQ-9 depression scale score ≥10 were classified as having depressive symptoms. It is expected that after intervention, the proportion of depression in the intervention group will be reduced by 20% compared with that in the control group. A bilateral test with a sample size ratio of the test group and control group as 1:1, test efficacy (1-β) as 0.9, and α as .05 was adopted, and a loss rate of 20% is expected. Through the calculation of PASS software (NCSS), 145 study subjects need to be included, and finally, 160 study subjects are rounded up, including 80 in the experimental group and 80 in the control group.

To ensure the balance between the experimental group and the control group, the block randomization method was adopted, code was written in R (R Foundation for Statistical Computing), random numbers were generated according to random seeds, and randomization was carried out to make the allocation of each treatment group more balanced and meet the research requirements. According to the order in which the subjects were enrolled, each participant was given a random number generated by the above random scheme. According to the group corresponding to the random number, the subjects were randomly assigned to the experimental group and the control group.

Quality Control

To improve the compliance of young people living with HIV, this study conducted regular telephone communication with the permission of the study subjects based on unified management through the user management platform to understand the intervention and treatment of the study subjects and give more humanistic care.

To ensure privacy and reduce reporting bias, this study was conducted anonymously, and the VR intervention was free during the study. The fixed and unique number assigned to each research subject when they were enrolled was used as the basis for information matching. After each collection of questionnaires, data was downloaded and backed up on the same day, and the questionnaire platform data was deleted in time. The downloaded questionnaires were formed into a special database and stored encrypted in an unconnected computer for safekeeping by the project leader. At the same time, the VR intervention software and the intervention program of the control group are regularly maintained, network security is regularly checked, user information is protected in many aspects, and security information is set in the application, such as adding mobile phone number association, email association, secret security issues, and the relevant computer professionals are supervised.

Statistical Analysis

Quantitative data were analyzed using SD or demographic characteristics of composition comparison baseline. The *t* test, ANOVA, or rank sum test were used for hypothesis testing of quantitative data. The chi-square test or Fisher exact probability method was used to test the hypothesis of qualitative data. The effect size would also be calculated. In this study, the intervention effect of the VR psychological intervention system was analyzed using generalized estimating equations (GEE). During the follow-up, the attrition diagram in each group would be plotted over time. In this study, binary classification PHQ-9 is used as the outcome variable, which belongs to longitudinal data, and there is a certain correlation between the data. When conducting statistical analysis of such data, the data correlation should be fully considered. Therefore, GEE was used to analyze

the intervention effect to correct for the correlation between data caused by repeated measurements at multiple time points.

Study Significance

The clinical cohort supported by this study is a long-term antiviral treatment cohort, which can ensure the sample size and representativeness of the enrolled participants. The research team includes experts and scholars from various disciplines, including epidemiology and health statistics, clinical medicine, psychology, computer science, technology, etc, to provide professional guidance for the design of a psychological intervention department and the implementation of mental health intervention. The case managers in the research team are from Beijing Red Ribbon Home and have rich experience in providing psychological support for people living with HIV. The Home of Red Ribbon was previously known as the Home of Red Ribbon of Beijing Ditan Hospital, which was established in 1999. On January 5, 2005, the Home of Red Ribbon was registered with the Beijing Municipal Civil Affairs Bureau as the first civil society organization in China specializing in comprehensive HIV/AIDS care. It has 6 independent branches focusing on medical support, self-help of HIV-positive people, volunteer service, social assistance, online publicity, and legal aid. Its purpose is to provide comprehensive support and services for people living with HIV by pooling strength from all social strata, carrying out a variety of HIV prevention and control measures, and health awareness campaigns for enhanced public understanding of HIV.

This study innovatively applied modern VR technology to psychological intervention for young people living with HIV, which provides a new idea for our country to carry out psychological treatment. As a special group, people living with HIV are in urgent need of effective psychological guidance and sensitivity for privacy. This study combines VR technology with psychological intervention, uses an immersive 3D virtual environment to overcome the disadvantages of 2D mobile phone intervention, and avoids the privacy exposure that may be caused by offline medical treatment. It can provide data support and a scientific basis for solving the mental health problems of young people living with HIV in the future.

Ethical Considerations

This study was part of a research project that had been approved by the ethics committee of Beijing Ditan Hospital of Capital Medical University (Approval number: 2024-012). All individual participants were provided oral informed consent at the time of enrolment.

Results

This study was funded by the Capital Medical University Research Development Fund (grant PYZ22138) in April 2023. The enrollment started in September 2023. The data analysis is expected to be finished in April 2025.

Discussion

This study innovatively transcends traditional intervention models to conduct a prospective randomized controlled trial of VR-based psychological intervention for young people living with HIV in China. The research results will provide the effectiveness of VR-based mental intervention among young people living with HIV.

This research might provide yields practical data that advocates for the integration of mental health services into the standardized treatment model for HIV, as well as the wider implementation of psychological intervention services within domestic HIV-designated medical institutions and other health care facilities lacking specialized psychological consultation clinics.

The limitation of the study was that the population involved in this study mainly were young people living with HIV, which might cause a selection bias. However, young HIV-positive people were a group with a high proportion of HIV prevalence in China, so the study results still were representative of the effectiveness of the VR intervention and had good prospects of the intervention expanding in China.

The study population needs to be expanded to include people with chronic diseases to achieve effective mental intervention based on VR technology in the future.

Acknowledgments

We thank the participants who were recruited in the research. We acknowledge the support provided by (1) the Beijing Municipal Administration of Hospitals' Ascent Plan (DFL20191802), (2) the Beijing Municipal Administration of Hospitals Clinical Medicine Development of Special Funding Support (ZYLX202126), (3) the High-level public health technical personnel construction project (2022-3-036), and (4) the Capital Medical University Research Development Fund (PYZ22138). AI was not used in any portion of the manuscript writing.

Data Availability

The datasets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

HZ wrote the first draft of the manuscript. YS and JH conducted the field research management and collected field study data. HZ, Zhao H, and FZ critically reviewed and edited the manuscript. The author group was entirely responsible for study design, data collection, and data analysis. We declare that all authors have read and approved the final manuscript.

Abstract

Background: The worldwide rise in the prevalence of noncommunicable diseases has increased the recognition of the need to identify modifiable risk factors for preventing and managing these diseases. The office worker, as a representative group of physically inactive workers, is exposed to risk factors for metabolic syndrome, which is a primary driver of noncommunicable diseases. The use of virtual reality (VR) exergames may offer a potential solution to the problem of increasing noncommunicable disease prevalence, as it can help individuals increase their physical activity levels while providing a more immersive experience.

Objective: This exploratory study aims to examine the interventional efficacy of at-home immersive VR exergames on metabolic syndrome biomarkers among office workers. Additionally, it seeks to investigate the impacts of at-home immersive VR exergames on the active and sedentary behaviors of office workers.

Methods: A 3-arm, single-blinded pilot randomized controlled trial will be conducted to examine the therapeutic effects of at-home immersive VR exergames. A total of 120 Chinese office workers, engaging in less than 150 minutes per week of moderate to vigorous intensity physical activity, will be recruited via a convenience sampling method. The participants, who will be tested over a 12-week period, will be randomly assigned to one of three groups: (1) the VR exergame intervention group, (2) the regular physical activity control group, and (3) the nonexercise control group. Throughout the 12-week trial, three categories of variables will be collected across the three groups: clinical risk factors associated with metabolic syndrome, active and sedentary behaviors, and demographics. To analyze variance among the groups, a mixed linear model will be applied to assess the efficacy of each group. Differences in metabolic syndrome clinical risk factors among all groups will be used to evaluate the effects of at-home

immersive VR exergames. Changes in active and sedentary behaviors will also be used to determine the impacts of VR exergames on metabolic syndrome.

Results: The ethics committee of Guangzhou University, China, approved this study on September 25, 2024. Participant recruitment will begin in early 2025 and continue for approximately 3 months. Data will be analyzed after the 12-week trial is completed, with full results expected to be presented in early 2026.

Conclusions: This study explores an emerging topic by applying an at-home immersive VR exergame intervention, potentially contributing to understanding the effects of an exergame program on metabolic syndrome risk among office workers.

Introduction

Noncommunicable diseases, such as cancer, cardiovascular diseases, diabetes, and heart disease, constitute the foremost cause of death internationally [1]. Noncommunicable diseases accounted for 63% or 36 million global deaths in 2008, which increased to 74% in 2019 [2,3]. The increasing prevalence of noncommunicable disease deaths worldwide has increased the need to identify modifiable risks in preventing and managing these diseases.

Metabolic syndrome is a common chronic disease characterized by the co-occurrence of several major biomarkers, including high-density lipoprotein cholesterol (HDL-C), low-density lipoprotein cholesterol (LDL-C), impaired fasting glucose, insulin, triglycerides, blood pressure, waist circumference, and BMI [4,5]. Moreover, as a route to many noncommunicable diseases, such as cancer, cardiovascular diseases, and type 2 diabetes [6-8], metabolic syndrome plays a pivotal role in health status. For example, several systematic reviews have shown that individuals with metabolic syndrome are approximately two to five times more susceptible to developing cardiovascular disease and type 2 diabetes [9-11]. Although metabolic syndrome is one of the threats to a healthy life [12], its prevalence is increasing globally [13]. For example, a study conducted in the United States reported an increase of more than 35% in the prevalence of metabolic syndrome among US adults from 1988-1994 to 2007-2012 [14]. A systematic review reported that approximately 20% of the adult population in most Asian Pacific countries is struggling with a metabolic syndrome epidemic [15]. However, as an effective approach to mitigate the risk and treatment of metabolic syndrome, physical activity is facing a worrisome status across all countries [16,17].

Employed adults, the largest population in the world, spend a large portion of their waking time in the workplace [18,19]. Especially in desk-based workplaces, most of this time is spent sitting [20-22]. For example, in desk-based workplaces, Japanese workers spend approximately 70% of their time sitting with a low level of physical activity [23]. With the ongoing advancement of technology, the worldwide phenomenon of physical inactivity among employed adults has been occurring increasingly in recent decades [24]. An example study conducted in China revealed that the energy expenditure of occupational activity decreased by more than 22% and that the energy expenditure of domestic activity decreased by more than 51% over 9 years [25]. Other studies in the United States reported a steadily increasing trend of low-activity occupations of 76% from 1950 to 2000 [26] and a decreasing occupation-related caloric expenditure of more than 124 calories per day from 1960 to 2008 [27]. Prolonged sitting time adversely affects cardiometabolic health among office workers, an already at-risk population for metabolic syndrome [28]. For example, a study conducted in Central Iran reported that approximately 36% of office workers had metabolic syndrome [29]. Other studies have revealed that approximately one in ten office workers are at risk of metabolic syndrome in Korea [30] and Great Britain [31]. Physical activity promotion interventions have a strong positive impact on people with metabolic syndrome [32]. Nevertheless, several factors, such as the nature of the job and lack of motivation and time [33-35] for exercise, remain key barriers for office workers to adhere to an active lifestyle. Consequently, gym attendance rates are low even among people paying for membership [36], and more than 75% of people fail to keep their health target for more than 3 years [37].

Exergames are defined as video games that require players to be physically engaged in them to play [38,39]. Several systematic and narrative reviews have provided preliminary evidence for the correlations between playing exergames and users' physical activities [40,41]. For example, the contribution of exergames to increasing older adults' health and wellness through physical activity has been validated [41]. Previous studies have demonstrated that exergames can be used as interventions to increase physical activity, particularly among obese individuals [42]. With the ongoing advancement of virtual reality (VR) technology, exergames have become more immersive for users. The concept of immersion is defined as "users' engagement with a VR system that results in being in a flow state" [43]. Owing to the technology limitations of conventional VR, several shortages have been presented to users, such as difficulty in producing dynamic natural environments and interaction deficiencies in human-environment simulations. In contrast, with the development of visualizations and interactions with virtual environments, new immersive VR methods can address these limitations and lead to more accurate

and efficient virtual environment assessments [44]. Additionally, its new application in exergame areas has already shown potential for promoting the health and well-being of some disabled youth [45]. Nevertheless, research on the health impact of immersive exergames remains rare. A search of the terms "immersive exergame" or "video game," "physical activity" or "exercise," "cardiometabolic" or "metabolic syndrome," and "office worker" produced 0 results in the Scopus database as of May 6, 2024 [46]. Thus, using immersive exergames to promote physical activity in relation to cardiometabolic health is still in its infancy among office workers, with a need for increased knowledge about this topic. Therefore, as the first randomized controlled trial (RCT), to the best of our knowledge, the purpose of this study is to examine the effects of at-home immersive VR exergames on clinical risk factors among office workers, an already at-risk population for metabolic syndrome.

Methods

Study Design

RCTs, a top-level research methodology in the area of evidence-based medicine [47], have played a significant role in evaluating the effects of lifestyle changes on metabolic syndrome [48-50]. This protocol is a longitudinal pilot study that uses a 3-arm parallel-group RCT to examine the interventional efficacy of an at-home immersive VR exergame on several clinical risk factors of metabolic syndrome among office workers. On the basis of prior research on exercise and physical activity interventions [48,51], a 12-week duration was selected for this trial, as it is a commonly used period for evaluating the efficacy of interventions targeting metabolic syndrome. Several clinical risk factors for metabolic syndrome, as well as active and sedentary behavior, will be monitored in three stages during this 12-week trial. Stage 1 will be at the start of the trial, Stage 2 at week 6, and Stage 3 at the end of the trial. The therapeutic effects of the at-home immersive VR exergame intervention for metabolic syndrome will be evaluated by comparing these risk factors among three groups: the VR exergame intervention group, the regular physical activity control group, and the nonexercise control group. The study follows two checklists: the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials Statement for Randomized Controlled Trials of Electronic and Mobile Health Applications and Online TeleHealth) [52] and the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials; Multimedia Appendices 1 and 2) [53,54].

Participant Recruitment

For this exploratory study, a convenience sampling method will be used to recruit 120 office workers from six office-oriented information technology companies in Guangzhou City, Guangdong Province, located in Southern China. This group represents a high proportion of physically inactive individuals [55,56] and is at greater risk of developing metabolic syndrome [56-58]. Recruitment emails will be sent to participants via the Tencent Enterprise Mailbox [59], a platform that allows companies to create email accounts with their corporate domain. This platform serves as a communication and office tool to support enterprises in providing unified notifications to office workers and to support office workers in providing timely and efficient feedback. The inclusion criteria for participants are office workers who are 16-60 years old (based on the standard age of the Labor Law of the People's Republic of China), capable of standing and exercising, and have no history of heart disease, cancer, or dementia. Additionally, participants should be interested in playing with the exergames and willing to adhere to a 12-week intervention exergame treatment because of the nature of the trial.

This research aims to examine the effects of at-home immersive VR exergames on the clinical risk factors for metabolic syndrome. Hence, individuals who are already engaged in more than 150 minutes per week of moderate to vigorous intensity physical activity will be excluded [60]. Additionally, pharmacological treatments, such as metabolic syndrome–related medicines (insulin sensitizers and biguanides, orlistat, sibutramine, etc), some surgeries (bariatric surgery), and traditional Chinese medicine (herbal medicine of ginseng, berberine, bitter melon, etc), are the other exclusion criteria because of their potential to influence cardiometabolic outcomes [61,62].

First, to encourage participation, some basic information related to exercise for health and immersive VR exergames will be introduced to potential participants. After a detailed explanation of what is needed during the trial, a precheck of the inclusion and exclusion criteria will be asked to identify eligible participants. Then, participants who meet the criteria will be instructed to review the information and provide informed consent and assent for this study. Given the nature of the clinical risk factors to be collected, a data collection center will be arranged at a cooperative clinic, and its address will be shared with all the participants for data collection and allocation of experimental equipment and material at the start of the trial.

Intervention and Control Groups

Following RCT guidelines [63,64], participants will be randomized into three equal groups: (1) the at-home immersive VR exergame intervention group, (2) the regular physical activity control group, and (3) the nonexercise control group. Including both the regular physical activity and nonexercise control groups will help determine whether VR exergame intervention offers unique benefits beyond those achieved through traditional exercise or no intervention. This design allows us to isolate the specific effects of immersive VR exergames. The at-home immersive VR exergame intervention includes a 12-week trial of exercise using Meta Quest 2, as shown in Figure 1. The Meta Quest 2 device is a valid tool that has been used in previous studies to support physical activity [65-68]. A VR headset and 2 handheld controllers are contained in the Meta Quest 2 set. Several active aerobic game apps will be installed on headset devices. These apps include the following [69]: Beat Saber (exercise: full-body, aerobic), Synth Riders (exercise: dance, aerobic), OhShape (exercise: dance, aerobic), Ragnarock (exercise: arms, shoulders, aerobic), Dance Central (exercise: dance, aerobic), Until You Fall (exercise: back, shoulders, arms, aerobic), In Death: Unchained (exercise: arms and shoulders, endurance/aerobic), and Space Pirate Trainer (exercise: full-body, aerobic). In these immersive games, the

users can present their body movements in the game world from a first-person perspective. Moreover, they are all designed to motivate users to participate in physical movements with various categories of motivational affordances. For example, Beat Saber is a rhythm game in which users need to move their bodies to slice blocks at an exact angle. Physical activities such as arm waving, moving, and squatting with an accelerating speed are motivated in the game with affordances of rank, point, and record. The participants in the VR exergame intervention group will be instructed to play one or more of these exergames for at least 150 minutes per week, which is in line with the World Health Organization's physical activity guidelines [60]. They will be requested to record the frequency and duration of their exergaming sessions. Participants in the regular physical activity control group will engage in a physical activity routine similar in duration and intensity to the VR exergame intervention. Participants in the nonexercise control group will not receive any specific exercise instructions. All groups will be advised to maintain regular eating and working habits without making significant changes throughout the 12-week trial. After completing the trial, participants in both control groups will be offered the same procedures as the intervention group, but their data will not be collected.

Measures

This exploratory pilot study aims to test the intervention of at-home immersive VR exergame on metabolic syndrome. Two variables, including clinical risk factors for metabolic syndrome and active and sedentary behaviors, will be measured throughout the three stages of the trial. Demographic information will be collected only at stage 1. Major clinical risk factors are objectively measured from participants' blood tests and a sphygmomanometer. The Global Physical Activity Questionnaire (GPAQ) will be used to measure participants' active and sedentary behaviors. A summary of the stages, measures, and indicators is shown in Table 1.

Table 1. Summary of stages, measures, and indicators.

Measures and indicators	Timeline		
	Stage 1	Stage 2	Stage 3
Demographics			
Age, gender	✓		
Clinical risk factors			
HDL-C[a]	✓	✓	✓
LDL-C[b]	✓	✓	✓
Impaired fasting glucose	✓	✓	✓
Insulin	✓	✓	✓
Triglycerides	✓	✓	✓
Blood pressure	✓	✓	✓
Waist circumference	✓	✓	✓
BMI	✓	✓	✓
Active and sedentary behaviors			
Exercise time (including exergaming time)	✓	✓	✓
Sedentary time	✓	✓	✓

[a]HDL-C: high-density lipoprotein cholesterol.

[b]LDL-C: low-density lipoprotein cholesterol.

To test the therapeutic effect of this intervention, primary clinical risk factors for metabolic syndrome, including blood tests for HDL-C, LDL-C, impaired fasting glucose, insulin, and triglycerides, along with sphygmomanometry of blood pressure, waist circumference, and BMI, will be measured [4,70,71]. Owing to several merits of immersive VR exergames, such as physical engagement [38,39], the nature of immersion, and attractiveness [43], the use of VR exergames may have a significant effect on behaviors, such as exercise and sitting time [72]. Therefore, we use the GPAQ to observe the changes in active and sedentary behaviors produced by immersive VR exergames. Moreover, the validity of the GPAQ has been proven for monitoring physical activity in health promotion research [73]. The whole questionnaire includes 16 items for 3 intensities (light, moderate, and vigorous intensity) of physical activity and sedentary behavior during work, transport, and leisure time [74]. The paper form will be printed and passed to participants to assess the changes in active and sedentary behaviors during the trial.

Study Procedure

Each group in this study will consist of 40 randomly allocated participants (using a simple computer-generated random number sequence managed by JZ), and the trial will be conducted in a single-blinded structure. In this three-arm study, participants will receive the VR exergame intervention, regular physical activity, or no exercise at all. The participants will inherently be aware of their assigned activity. However, they will be blinded to the specific study hypotheses and the detailed objectives regarding comparing the 3 groups. To reduce perceived differences, participants in both control groups will receive VR exergame devices after completing the trial, but no data will be collected from this phase. Additionally, outcome assessors and data analysts will remain blinded to group assignments to prevent bias in data collection and analysis. This single-blind design helps reduce bias in the interpretation of the study results, even though participants are aware of their assigned activity.

The comprehensive framework for this protocol consists of 3 stages over 12 weeks and the allocation of items for each stage is shown in Table 2. In stage 1, when participants arrive at the data collection center, experiment coordinators will distribute and explain the manual booklet to all participants, which includes a description of the procedures, requirements, and address for inquiries. After participants have confirmed the contents and requirements of the manual, the experiment coordinators and clinic nurses will collect demographics, clinical risk factors, and GPAQ from all participants as the baseline data. A Meta Quest 2 set of equipment (entire trial), GPAQ questionnaire (0 to 6 weeks), and a recording sheet of exergaming time (0 to 6 weeks) will be additionally assigned to the VR exergame intervention group. In stage 2, the GPAQ questionnaire (7 to 12 weeks) will be assigned to all 3 groups and a recording sheet of exergaming time (7 to 12 weeks) will be additionally assigned to the VR exergame intervention group. In stage 3, only the Meta Quest 2 set of equipment will be assigned to both control groups. The necessary items for each stage will be passed to participants when they arrive at the data collection center.

Table 2. Timeline and allocation of items.

	Stage 1[a]	Stage 2[b]	Stage 3[c]
VR[d] exergame intervention group	• Manual booklet • Demographic questionnaire • GPAQ[e] • Meta Quest 2 set • Recording sheet of exergaming time	• GPAQ • Recording sheet of exergaming time	—[f]

[a]Start of the trial.

[b]Week 6 of the trial.

[c]End of the trial.

[d]VR: virtual reality.

[e]GPAQ: Global Physical Activity Questionnaire.

[f]Not applicable.

All participants will be asked to visit the data collection center in three stages for data collection and experimental material allocation. The self-reported GPAQ questionnaire will be completed by all participants at home, as it is a convenient at-home format for exploring impacts on active and sedentary behavior. The VR exergame intervention group will record the frequency and duration of their exergaming sessions, the regular physical activity control group will track their daily exercise routines, and the nonexercise control group will report any physical activities they perform beyond their baseline. Participants will be asked to bring all self-report sheets to the data collection center at stages 2 and 3. Coordinators will collect and summarize all the completed questionnaires and recording sheets for data processing. Major clinical risk factors are objectively measured from participants' metabolic syndrome biomarkers, which are operated by professional nurses at the data collection center (cooperative clinic). Since there is a fasting biomarker for testing metabolic syndrome, all participants are required not to consume any food or drink 12 hours before blood sample collection in the morning. After the major clinical risk factor data from all the participants for the entire trial are collected, the experiment coordinators will visit and obtain the data from the data collection center.

Analyses

After 12 weeks of the trial, 3 categories of data, including demographic, clinical risk factor, and active and sedentary behavior data, will have been collected. Regarding descriptive statistics for each indicator, the changes in clinical risk factors during the first 6 weeks, the last 6 weeks, and the entire 12-week trial will be calculated and presented as the means, SDs, and quartiles to show differences. Active and sedentary behavior will be presented as minutes of weekly light, moderate, and vigorous-intensity physical activity, and sedentary time will be obtained from the self-reported GPAQ items. Demographic variables will be presented as sum values or percentages. Additionally, the diagnosis of metabolic syndrome for all groups of participants will be summarized into sums and percentages at each stage according to the definition from a World Health Organization consultation report (high levels of insulin and impaired fasting glucose, together with at least two of the following items: HDL-C concentration less than 35 mg/dL for men [39 mg/dL for women], triglyceride concentration greater than 150 mg/dL, a waist circumference greater than 37 inches, BMI greater than 30 kg/m^2, systolic blood pressure greater than 140 mm Hg and diastolic blood pressure greater than 90 mm Hg) [4,70].

As it will be adjusted for demographic variables, the linear mixed model, which is recommended in the literature for individually assigned RCTs [75], will be used as an analysis method for determining the effects of the intervention. In cases where participants drop out or are nonadherent, missing data will be handled via multiple imputation techniques. The primary outcome assessed is the change in clinical risk factors for metabolic syndrome, including HDL-C, LDL-C, triglycerides, blood pressure, waist circumference, BMI, impaired fasting glucose, and insulin. The linear mixed model will compare these clinical risk factors across the 3 groups—VR exergame intervention, regular physical activity control, and nonexercise control groups—over three stages. The model will also assess the interaction between groups and time to determine whether the VR exergame intervention has different or additional effects compared with regular physical activity and no physical activity. Adherence to the intervention will be assessed through daily self-report logs for all participants and included as a covariate to account for variations in engagement with the interventions. Additionally, sensitivity analyses will be conducted to examine the potential impact of varying adherence levels on metabolic outcomes. This approach ensures that adherence variations are properly considered when the study's results are interpreted. In this study, the intervention or control groups are fixed factors,

and demographic factors would be considered as random factors for accommodating variabilities within or between participants. All available data will be imported into Stata (version SE 15.1; Stata Corp) for analysis, and the significance level will be set at $P<.05$. As this is an exploratory pilot study, the primary objective is to assess feasibility and gather preliminary data. Given the lack of prior studies using immersive VR exergames in this context, conducting a power analysis would be speculative. The focus of this pilot is to generate effect size estimates and assess practical considerations, which will inform the design of a future, fully powered RCT. In the larger RCT, a formal power analysis will be conducted using the data generated from this pilot study.

Ethical Considerations

This study was approved by the Institutional Ethics Committee of Guangzhou University, China (2024-112; September 25, 2024). Initially, potential participants will be provided with basic information regarding the benefits of exercise for health and immersive VR exergames. Subsequently, interested individuals will receive a detailed explanation of the study process, and they will be asked to sign the informed consent and assent forms. In addition, some personal information is required during this trial, including name, age, gender, email address, home address, and phone number for the purpose of marking data, sending the results of blood tests and diagnosis of metabolic syndrome, or analyses (eg, as covariates). All participant information will be collected directly by the experiment coordinator (JZ) to ensure the privacy of their personal information. Strict measures will be implemented to manage and store all the collected data. To compensate for participation, participants will be rewarded with RMB 150 (approximately US $21) for completing each stage, whereas participants who complete all the processes of the trial will be rewarded with RMB 500 (approximately US $71). All incentives will be sent via a registered postal cash envelope. For visiting the data collection center at each stage, transportation fees will also be reimbursed.

Results

This study was approved by the ethics committee of Guangzhou University, China, as of September 25, 2024. The completion of participant recruitment and the initiation of the intervention or control trial are anticipated by the middle of 2025. The full processes of this trial, including data analysis and paper writing, are expected to be completed in early 2026.

Discussion

Principal Findings

Our findings will reveal whether the clinical risk factors for metabolic syndrome within the intervention group significantly improved after a 12-week exergaming intervention compared with those in the two control groups. The increase in the time engaged in physical activity (all types of light, moderate, and vigorous intensity) and the decrease in the time spent in sedentary behavior will also be evaluated.

The phenomenon of physical inactivity among employed adults has been occurring increasingly worldwide because of the development of society and technology in recent decades [16,17]. Consequently, the population of employed adults at risk for metabolic syndrome is growing across the globe [14,15]. Several primary factors, such as a lack of motivation, weather restrictions, and busy schedules for work, social lives, and family, have been reported as key barriers to physical activity [34]. Notably, at-home immersive VR exergames can provide several advantages to address these barriers to physical inactivity for employed adults. However, to our knowledge, few studies have explored the health effects of immersive exergames. This study is the first RCT and aims to examine the effectiveness of at-home immersive VR exergame interventions for improving metabolic syndrome. Our hypotheses were based on several advantages of at-home immersive VR exergames. The first benefit to exergames is engagement and enjoyment, as various types of motivational affordances (eg, points, leaderboard, and badges) were found within the gaming process along with several positive psychological effects (eg, joyfulness) [76]. The second advantage is the convenience of at-home exercise, which can mitigate weather restrictions and fit into a flexible schedule. In addition, exergames also have positive impacts on both physical health and cognition [77], which may offer pathways to improve rehabilitation and wellness [41]. Although these positive results have been reported, there is also some evidence that these positive impacts from exergames may be temporary [78].

Strengths and Limitations

This study has several limitations. First, the possibility of VR sickness resulting from individual differences [79] may result in variable exercise time, which can indirectly influence the primary clinical risk factors for metabolic syndrome and bias the efficacy of the intervention. Second, the unsupervised process of self-recorded exercise time and self-reported GPAQ items may produce inexact data about trial results. Third, according to trial length within exercise or physical activity studies, 12 weeks to 1 year is the range for determining interventional efficacy for comprehensive metabolic syndrome risk factors [48,51]. The 12-week trial for this study is consistent with the minimum length threshold, but a longer treatment period may produce more robust and efficacious results. Additionally, our participants will be recruited from Guangzhou, China, where particular life habits and social conventions, such as long work hours [80] and food habits [81], may produce results with limited generalizability. Although these limitations exist, the strengths of this study include its RCT design, the use of clinical measures of risk factors for metabolic syndrome, the novel examination of the impacts of exergames on promoting physical activity and metabolic syndrome, and the improvement of health conditions within the at-risk population of office workers.

Conclusions

The use of at-home immersive VR exergames for improving metabolic syndrome is an emerging topic for promoting physical activity related to cardiometabolic health. The primary aim of this proposed study is to assess the feasibility and preliminary

effects of an at-home immersive VR exergame intervention on the clinical risk factors for metabolic syndrome. The results of using at-home immersive VR exergames may contribute to promoting office workers' health conditions and help reduce the burden of metabolic syndrome risk among a large and increasingly sedentary population. These results will inform the design and implementation of a larger-scale, fully powered RCT. This exploratory pilot RCT will provide data regarding the intervention's practicality and initial effectiveness, which will guide future research efforts.

Abstract

Background: Cognitive stimulation therapy is a group-based psychological treatment for people with dementia as well as those with mild cognitive impairment (MCI) and is shown to improve both cognition and quality of life. Previous studies have indicated the potential to benefit from the use of technological devices in group interventions.

Objective: The pilot study aimed to assess the effectiveness of a tablet- and group-based multicomponent cognitive stimulation therapy (MCST) for enhancing cognitive functions among older adults with MCI. The following study aims to report the protocol for a trial evaluating whether the MCST program is affecting individuals with MCI.

Methods: In the first study, 30 individuals with MCI participated in 10 sessions of the tablet- and group-based MCST group. A subsequent protocol study will compare tablet-based MCST, tablet-based cognitive stimulation therapy, and control groups among 93 individuals with MCI. All participants will be recruited from older adults living in semiurban communities. Intervention groups will be facilitated by trained therapists, nurses, or psychologists. The study will be assessed by a pre- and posttest evaluation, including computer-based neuropsychological tests and electroencephalography assessment. The effects of several indicators, such as cognitive functions, behavioral, and emotional, will be analyzed as being indexed by their neurophysiological data.

Results: The pilot study showed significant cognitive improvement (P<.001), reduced depression (P=.002), and decreased state anxiety (P=.001) post intervention. Quality of life remained unchanged (P=.18). The randomized controlled trial study was funded in March 2023. Enrolling began in August 2023 and was completed in December 2023. The data analysis was started, and the results are expected to be published by mid- to late-2025.

Conclusions: The study is the first tablet-group–based MCST for older adults with MCI in middle-income countries. It will provide deeper insight into participants' neuropsychological data, thus identifying specific processes underlying physiologically measured positive outcomes. Furthermore, the project will deliver solid and integrative results to mental health professionals in terms of knowledge and guidance for implementing the tablet- and group-based MCST in people with MCI.

Introduction

Mild cognitive impairment (MCI) is the stage between normal aging and dementia, including probable Alzheimer disease, characterized by noticeable cognitive deficits that do not impair daily functioning significantly [1-3]. The cognitive domains affected by MCI include learning and memory, language, visuospatial abilities, executive functions, and psychomotor skills. Notably, evident impairment in any of these domains is sufficient for an MCI diagnosis [4]. Furthermore, particular deficits in emotions such as anger, sadness, and fear have been observed in individuals with MCI, with anxiety being more prevalent in clinical samples than in community-based ones [5,6]. In addition, subjective cognitive decline has been linked to anxiety symptoms, independently increasing the risk of MCI or dementia [7]. Depression is also associated with early cognitive impairment, but patients with depression typically do not exhibit the memory deficits observed in MCI or dementia [8,9].

Group-based cognitive stimulation therapy (CST) has been shown to improve both cognitive functions and quality of life in older adults with dementia or MCI [10,11]. The guiding principles of CST were adapted to create 15 fundamental principles of individual-centered CST, including mental stimulation, reminiscence, learning and communication stimulation, and a person-centered approach. The program includes various activity sessions encompassing different areas such as life history, current affairs, creative tasks, games, and cognitive challenges [12,13]. The belief that continuous participation in various mental activities improves cognitive and social functioning underpins cognitive stimulation treatments [14]. Furthermore, Silva and colleagues [15] discovered that in MCI or mild dementia, a cognitive stimulation program could account for the improved cognition response observed. These data reveal that the lower the cognitive damage, the better the neuroplastic capacity and ability to learn, and the greater the potential to induce neurogenesis. Therefore, cognitive interventions should be implemented at the earliest stages of cognitive impairment [15].

Recent studies on tablet-based intervention with cognitive stimulation have focused on the feasibility, acceptability, and cognitive and psychosocial effects of the computerized cognitive stimulation (CCS) and computerized cognitive engagement programs. Both treatments were efficient and acceptable, allowing patients with MCI to improve in several aspects of their cognitive and psychosocial functioning. Still, the effect sizes on cognition, such as free recall and the Trail Making Test part A, were moderate, favoring the CCS group [16]. A further study explored whether CCS induced differential effects in older adults with MCI according to the degree of white matter hyperintensities, were separated into no-to-little and moderate-to-severe groups. Following the session, both groups improved on numerous cognitive tests but not in mood and psychosocial features except for motivation [17]. Previous research suggested that the effectiveness of tablet-based CST on cognition, emotion, or psychosocial outcomes should be investigated [17]. Furthermore, the increased computerization of intervention programs is a step toward treatment uniformity. Computer-based intervention methods are cost-effective, noninvasive, and simple to execute, requiring little human and financial resources [18]. In particular, tablet-based CST should also be further examined in middle-income or developing countries since the expected findings will close the gaps and expand the generalizability of the theories and therapeutic technologies.

In addition, extant research shows that CST is effective in enhancing cognitive functions in people with mild dementia investigated by using the resting-state functional magnetic resonance imaging technique [19] that provided solid evidence of enhancement in the neuronal networks in terms of structures and functionalities by using a group CST. Nonetheless, the previous research came with methodology limitations regarding the small sample sizes and comparison between groups. Furthermore, there is a lack of studies to show the effect of changes in neurobiological features in older adults with MCI. Thus, this study aims to monitor the effectiveness of tablet-based CST using neuroimaging techniques in people with MCI.

The underlying neurobiological factors contributing to MCI involve changes in neurotransmitters, including the noradrenergic, serotonergic, and dopaminergic systems [20]. Notably, the cholinergic system, particularly acetylcholine, plays a crucial role in cognitive function, with its decline correlating with cognitive impairment. Electroencephalography (EEG) measures have revealed alterations in brain activity patterns among individuals with MCI, including increased beta-two power and notable changes in the theta, alpha, and delta frequencies [21]. Atrophy of the hippocampus and the medial temporal lobe regions, along with hypometabolism in specific brain areas, are indicative of MCI [22]. Specifically, electrophysiological recordings and event-related potentials (ERPs) provide valuable insights into cognitive functioning. P300 latency delays have been observed in people living with MCI, and abnormalities in N400 and P600 components are associated with a higher risk of developing Alzheimer disease [23-26]. These EEG and ERP components could potentially serve as biomarkers for monitoring brain change in people with MCI.

Accordingly, the first study aims to evaluate the effects of the tablet- and group-based multicomponent cognitive stimulation therapy (MCST) program on cognition and emotions in older adults with MCI. The program draws on CST principles and multisensory stimulation techniques to create tailored activity

sessions that target cognitive function and emotions. This study hypothesizes that the intervention positively affects cognition and emotions in older adults with MCI after the intervention.

The following study aims to assess how a tablet-based MCST program, with or without multisensory integration (MSI), affects cognitive functions, emotions, and quality of life in older adults with MCI, comparing experimental and control groups designed as parallel groups. Changes in EEG and ERPs will be examined before and after the intervention. The cognitive domains targeted as primary outcomes for improvement include learning and memory, language, visuospatial abilities, executive functions, and psychomotor skills as well as emotions. Specific brain locations are associated with these domains, and the study aims to enhance the functioning of these regions to counteract the cognitive decline observed in MCI. The protocol study hypothesizes that the intervention will improve cognitive functions, emotions, and behaviors in older adults with MCI, outperforming an active comparator and control group. Expected EEG and ERP changes may reveal brain activity patterns tied to cognitive improvements, focusing on frequency bands and ERPs.

Methods

Overview

The pilot and protocol for a randomized controlled trial (RCT) intervention study have been approved by the Burapha University institutional review board (IRB4-191/2566). The study was conducted according to the Guideline for Good Clinical Practice and the Declaration of Helsinki [27]. Following the gold standard in research on intervention effectiveness—the CONSORT (Consolidated Standards of Reporting Trials; checklist provided in Multimedia Appendix 1), the RCT study design, including the proximal and distal outcomes, has been preregistered in the Thai Clinical Trials Registry (reference TCTR20230829004).

This project consisted of 2 studies. The first study involved a pilot of the MCST intervention and effective assessment of cognitive functions in older adults, which began in August 2023. The next study is the RCT, with recruitment starting in September 2023. The intervention and data collection were done over 14 weeks.

Study 1: Pilot Study

Study Design

This study investigates the efficacy of the tablet- and group-based MCST program, using a 1-group pretest-posttest design. Participants were randomly assigned to 3 subgroups, and dependent variables were measured both before and after the implementation of the program.

Participants

In total, 30 older adults participated as volunteers in the experiment. Participants ranged from 60 to 75 (mean 66.14, SD 4.72 years) years of age with normal or corrected normal vision, no color blindness or weakness, and no history of mental illness or neuropathy. Thai native speakers were capable of reading and comprehending writing. All participants were assessed using the Thai version of the Montreal Cognitive Assessment (MoCA-T) to assess cognitive impairment [28], the subjective memory complaint scale to assess complaints of defective memory [29], the Chula Index Scale and Activities of Daily Living to assess normal activities of daily living [30], and the Clinical Dementia Rating Scale to assess the absence of dementia [31]. These assessments are established screening tools as criteria for detecting MCI [32].

Participant characteristics show that among them, MCI was presented (MoCA-T scores between 17 and 24), 20% (6/30) were male and 80% (24/30) were female. Participants' occupations varied as 43% (13/30) were farmers, 10% (3/30) were freelancers, 10% (3/30) were sellers, 13% (4/30) were retired government officers, and 23% (7/30) were unemployed. Regarding health conditions, 23% (7/30) of participants had diabetes, while 40% (12/30) reported having hypertension. An additional 20% (6/30) reported other diseases. In terms of vision, 57% (17/30) of participants wore glasses and 43% (13/30) did not wear glasses.

Intervention

The MCST interventional program was adapted from group CST for MCI with 10 sessions and once a week over a period of 10 weeks [10]. The intervention is presented in the RCT study and shown in Table 1.

Table 1. Cognitive stimulation therapy sessions adapted to Thai culture.

Session	Theme	Activities
1	Physical activity	Finger exercise and using a touch screen and learning to navigate the tablet
2	Music and sound	Stimulating auditory and visual senses using old music and sounds from daily life
3	Childhood	Pictures of singers, actors, or celebrities from the past
4	Food and cooking	Different kinds of foods, recipes, and methods of cooking; being creative
5	Travel	Current affairs, places and sounds, well-known destinations and talking about the hometown
6	Occupations	People's jobs, using word games and word association
7	Sports	Sporting events, matching the picture to the word, senses, and sounds
8	Shopping	Using money, prices, and calculation
9	Household	Categorizing objects
10	Team games	Number games

Assessments

The results of the effectiveness of the tablet-based group intervention were evaluated. At the pre-and postintervention assessment, participants were asked to examine the MoCA-T, Thai geriatric depression scale (TGDS), State-Trait Anxiety Inventory (STAI)–state, and Older People's Quality of Life Questionnaire (OPQoL)-Brief (refer to Outcome Measures section for further details).

Data Analysis

Because the sample size in this study was not large enough to permit the assumption of normality on the study variables, the nonparametric test was used. The Wilcoxon signed-rank test was used to examine the effects of the tablet- and group-based MCST on cognition, emotions, and quality of life. The rank-biserial correlation coefficient (r_B) was considered as effect size and is interpreted the same as the r coefficient, such as trivial (<0.10), small (0.10), moderate (0.30), and large (0.50) [33]. The JASP (Jeffreys's Amazing Statistics Program; Version 0.16.2.0; University of Amsterdam), an open-source statistics program, was used for paired samples and effect size analysis [34].

Study 2: RCT

Overview

The RCT aims to assess the effects of the tablet-group–based MCST program on cognitive functions and emotions and quality of life based on the differences between experimental groups with and without MSI compared with a control group, and the changes observed in EEG and ERPs during the pre- and posttest interventions. The study hypothesizes that the intervention affects cognitive functions positively in older adults with MCI after the intervention compared with an active comparator and a control group. Furthermore, it is hypothesized that the intervention improves emotion and behavior in older adults with MCI after the intervention compared with an active comparator and control group. Changes in brain waves are also expected to reveal brain activity patterns associated with cognitive improvement, focusing on frequency bands and ERPs.

Trial Design

This research uses an RCT design with an experimental group, an active comparator group, and a control group. Participants are randomly assigned to 1 of the 3 study conditions. Each participant is randomly allocated 1:1:1 to an intervention or control condition. The study is designed as a randomized, controlled trial with 3 parallel groups. Randomization will be performed by Random Allocation Software (Isfahan University of Medical Sciences) [35].

Participants

Inclusion Criteria

Participants eligible for inclusion must meet the following criteria: (1) language proficiency: participants must be native speakers of the Thai language [32]; (2) age range: the study focuses on individuals aged 60 years or older; (3) objective memory performance: inclusion is based on objective memory impairment assessments [32] using well-established evaluation tools, including the MoCA-T and clinical dementia rating [36]; (4) subjective memory complaints [32]; (5) handedness: participants must be right-handed, as confirmed by the Edinburgh Handedness Inventory; (6) color vision: normal color vision is a requirement, evaluated using the Ishihara Plate Test; (7) health status: individuals with no chronic illnesses, deafness, blindness, or an diagnosed neurological disorder are eligible to participate; (8) cognitive status: eligible participants should not exhibit signs of dementia [32]; (9) reading ability: prospective participants are expected to be capable of reading and comprehending written material; and (10) computer proficiency: participants should be able to use computer devices effectively for the study activities.

Exclusion Criteria

The following criteria will lead to exclusion from participation: (1) a diagnosis of dementia: individuals diagnosed with dementia after participating in the study, irrespective of severity, will not be included in the study; (2) systemic illness: participants with concurrent systemic illnesses that could potentially confound the study outcomes will be excluded; and (3) refusal to participate: individuals who decline to participate or express

their unwillingness to engage in the study will not be considered for inclusion.

Sample Size

The sample size in the study was estimated using the G*Power program [37]. The required sample size considering an α=.05, a Cohen *d*=0.50 (medium magnitude for the effect size) [17,38], and power=0.95, is 26 or 27 participants in each condition, that is, a total of around 80 participants. Assuming a loss of 15% [17,38,39], in the event, the final sample consists of 93 participants, approximately 31 participants in each condition.

Recruitment

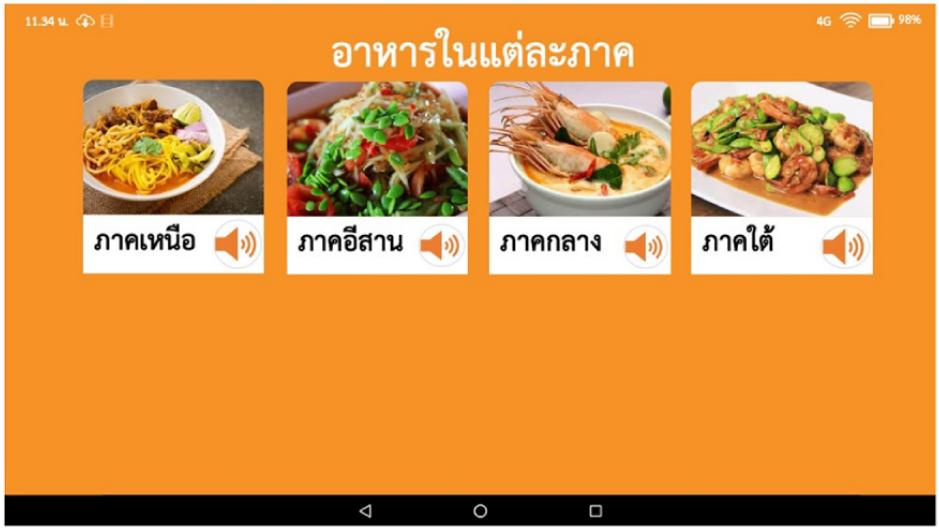
Older adults with MCI will be recruited via communities such as clubs for older adults and elderly schools in the semiurban area of Chonburi province, Thailand. Announcements regarding the study will be disseminated through radio and social media platforms (Line Messenger [Line Corporation], Facebook [Meta], and so on). Individuals who express interest will receive information and undergo a screening test. If they meet the inclusion criteria, they will be enrolled in this study.

Interventions and Control Group

Experiment Intervention

The interventional program was adapted from group CST for MCI with 10 sessions [10], the group CST principle [11,13,40], and adapting CST to other cultures [12,38]. Specifically, the program also adopted audiovisual temporal discrimination training to improve MSI [41], which was included in sessions as shown in Table 1 and Figure 1. Participants will be asked to use a 10-inch tablet with an Android operating system (Google) that has the computerized multicomponent cognitive stimulation app for each session installed so that they can participate in all activities. Intervention groups will be facilitated by trained therapists, nurses, or psychologists. Further details of the MCST intervention and the manual can be found on the website [42].

Figure 1. Screenshots of the computerized multicomponent cognitive stimulation app (screenshots present kinds of foods in different regions of Thailand).



Active Comparator

The comparator group is similar to the MCST intervention group but excludes MSI training, receiving only tablet-group–based CST. Each session will be like a structured session in the MCST intervention group.

Control Group

The participants in this group will not receive the treatment. They will be measured once at the start and then a second time 2 months later.

Data Collection

The study will take place at the Center of Excellence in Cognitive Science, which is part of the College of Research Methodology and Cognitive Science at Burapha University. Demographic and clinical information about age, gender, education, marital status, occupation, diseases, and physical issues will be self-reported at baseline. The results of the effectiveness of the tablet-based group intervention will be evaluated. The outcomes will be evaluated using measures of cognitive functions and brain waves, including EEG and ERP techniques that are recorded while participants perform the tasks.

At the beginning of the EEG and ERP assessment, participants will be asked to wear the neuro handset to correct the EEG resting-state data which will be measured during eyes-closed and eyes-open sessions at 5 minutes. Afterward, the EEG will be recorded while participants are performing the computerized neuropsychological tasks.

Cognitive functions and MSI tasks will use computer-based tasks to access neuropsychological data using PsychoPy software (Open Science Tools Ltd). Individuals will participate in a different sequence when dealing with order effects and time-related factors, changing the order by using counterbalancing. Furthermore, for each task, participants will rest for around 2 minutes before beginning the next task.

Electroencephalogram recordings on the Emotiv EPOC Flex saline and 10-20 layout 32-channel system will be recorded. The reference electrodes are located at the common-mode sensor (left side) and driven-right-leg (right side) sensor. All signals will be filtered automatically with a high-pass filter of 0.2 Hz and a low-pass filter of 45 Hz using a digital fifth-order sync filter and a sampling rate of 128 Hz, and the electrode impedance will be kept to at least 80% using EMOTIV PRO software to monitor EEG quality before recording and to collect the data [43].

Furthermore, after enrollment, the participants will be informed about the experimentation schedule, and the preconditions of the experiment such as proper sleep, and avoiding drinks like coffee and alcohol. Participants are required to shampoo their hair but avoid applying gel or lotion. Before starting the experiment, the researcher will confirm the participant's preparation before the experiment [44].

Outcomes Measures

Primary Outcomes

Learning, Memory, EEG, and ERP Components

The first running requires participants to learn and recall word pairs. The examination contains a variety of 12 pairs of words, such as related words, unrelated words, and name-word pairings. Participants are told to memorize unrelated word pairings (eg, hospital and lawyer). To test later, they are asked to recall those pairs of words. The total time for the test is approximately 10 minutes. A significant change in the recall numbers, EEG and ERP parameters (P<.05) is expected.

Executive Function Scores, EEG, and ERP Components

A standardized form of the Wisconsin Card Sorting Test, Berg Card Sorting Test will be used with the card sorting task using a 64-card deck. Participants are told to press the 1, 2, 3, or 4 keys that they believe match the card at the bottom of the screen. The cards' figures differ in color, number, and shape. The classification rule changes every 5 cards. Participants can complete the Wisconsin Card Sorting Test-64 within 10-15 minutes. The scoring includes percentage errors (%), perseverative responses (%), perseverative errors (%), nonperseverative errors (%), conceptual level responses (%), categories completed, trials to complete the first category, failure to maintain set, and learning to learn [45]. A statistically significant change in the EEG and ERP parameters (P<.05) is expected.

Language Scores, EEG, and ERP Components

The verbal fluency test is a short test of verbal functioning. It typically consists of 2 tasks, that is, category and letter fluency. Participants are given 1 minute to produce as many unique words as possible that are within a semantic category (category fluency: animal and fruit) and start with a given letter (letter fluency: words beginning with the letter Koh and letter Aoh in Thai). The participant's score in each task is the number of unique correct words [46]. For example, participants answered for animals such as dogs, cats, and monkeys, scoring 3 points for the category. The total time for the test is approximately 5 minutes. A statistically significant increase in fluency scores and EEG and ERP parameters (P<.05) is expected.

Visuospatial, EEG, and ERP Components

In the Corsi block-tapping task, participants were instructed to tap the blocks in the same serial order as presented (2 trials per sequence length ranging from 2 to 9 blocks). Participants receive 2 trials per level, starting from 2 to 9 lengths. Measures are the span (number in the longest correct sequence with the possible number from 2 to 9), the score (number of correctly reproduced sequences with the potential number from 2 to 9), and the product (span×score) [47]. The total time for the test is approximately 2-5 minutes. On the mental rotation task, participants are asked whether 2 objects rotated relative to one another (geometrical forms) are identical or mirror images [48,49]. The task consists of 69 stimuli, and each correct answer is worth 1 point, making a total of 69 points. Participants can complete the test within 5-10 minutes. A statistically significant

increase in all scores, EEG, and ERP parameters (P<.05) is expected.

Psychomotor, EEG, and ERP Components

In total, 2 reaction time tasks will be used, namely, the Deary-Liewald reaction time task and the number's reaction time box. In the simple reaction time test participants had to press a button or key in response to a single stimulus. The choice reaction time has 4 stimuli, and participants are asked to press the button corresponding to the correct response. The interstimulus interval ranged between 1 and 3 seconds and will be randomized within these boundaries. The task will record each trial's response time and the interstimulus interval for measuring [50]. The total time for the test is approximately 3-5 minutes. A statistically significant decrease in response time and total error, EEG, and ERP parameters (P<.05) is expected.

MSI, EEG, and ERP Components

The audiovisual task consisted of three conditions—2 control conditions (1 beep and 1 flash; 2 beeps and 2 flashes) and the illusion condition (2 beeps and 1 flash; 1 beep and 2 flashes). The auditory and visual stimuli will be presented simultaneously in the control conditions. The visual flash will be delivered simultaneously with the first auditory beep in the illusion condition. In each condition, the stimulus onset asynchronies used are between 150 and 300 milliseconds [51]. For a total of 80 stimuli, participants take approximately 2-3 minutes. Response time and the total error will be assessed. A statistically significant decrease in response time and total error and EEG and ERP parameters (P<.05) is expected.

The MoCA-T

The MoCA-T version 8 is the most frequently used screening test, and it was produced as a quick screening tool for MCI and dementia in its early phases. The visuospatial (5 points), naming (3 points), attention (6 points), language (3 points), abstract (2 points), memory (5 points), and orientation (6 points) abilities are assessed on this examination. When an assessment was completed, all scores were totaled out of a possible overall of 30. Higher scores indicated more significant cognitive function. The internal consistency of the MoCA-T was excellent (Cronbach α=0.91) [28]. It is expected to see a statistically significant increase (P<.05) in global cognition.

The TGDS-15

The TGDS-15 is a structured self-report scale that assesses depression symptoms over the previous week. The scale contains 15 items, with responses chosen as agreeing or disagreeing. The scale has a cutoff point for depression, which is 0-5 for no depression, 6-10 for suggestive of depression, and 11-15 for depression [52,53]. The Cronbach α coefficient of The TGDS-15 was 0.83, which showed high internal consistency [53]. It is expected to see a statistically significant decrease (P<.05) in depressive symptoms.

The STAI

On the State Anxiety Inventory Form Y-I scale, the STAI-state has the 20-item Thai version and has been validated by Thapinta [54]. Participants are asked how often, during the last 2 weeks, they have been bothered by each of the 30 questions of generalized anxiety disorder. Response options are "not at all," "for several days," "more than half the time," and "nearly every day," scored as 0, 1, 2, and 3, respectively. Therefore, the scores range from 0 to 80, with scores of ≥20, ≥40, and ≥60 representing mild, moderate, and severe anxiety symptom levels, respectively. The Cronbach α coefficient of the Thai STAI-state was 0.90, which showed high internal consistency [54]. A statistically significant decrease (P<.05) in the state anxiety symptom is expected.

Secondary Outcomes

The OPQoL-Brief in the Thai version [55] consists of 13 questions that are scored strongly agree=1, agree=2, disagree=4, and strongly disagree=5. The items are added together to get a total OPQoL-Brief score, and then positive items are reverse coded, such that higher scores imply better QoL. The entire sum score varies from 13 to 65. The Cronbach α coefficient of OPQoL-Brief was 0.94, showing that the first and the second questionnaire responses with a 2-week interval were highly stable [55]. A statistically significant increase (P<.05) in the OPQoL-Brief score is expected.

Data Analysis

As part of demographic and behavioral data, the means and SDs will be calculated to explain the general description such as age, gender, education, MoCA-T, TGDS-15, STAI-state, and OPQoL-Brief. Cognitive function scores of the 3 groups will be compared using 1-way analysis of covariance (ANCOVA) to examine differences in posttest scores of various neuropsychological tests controlling for pretest scores. The test involves computing an F-ratio large enough to indicate significant mean differences. Furthermore, ANCOVA is customary to measure the effect size with partial ω^2. In addition, post hoc analyses were performed using the Bonferroni Test.

In total, 4 EEG frequency bands' relative powers will be analyzed, and the latency and amplitude of ERP components will also be assessed. Furthermore, the EEG data collected will be cleaned and manipulated using the EEGLAB toolbox in the MATLAB environment. One-way ANCOVA will be applied to examine differences in the EEG and ERP posttest of various components among intervention groups (MCST, CST, and control) controlling for pretest scores.

Ethical Considerations

The study was approved by the Burapha University institutional review board (approval IRB4-191/2566; issue date: August 11, 2023; valid until date: August 11, 2024). It was also registered with the Thai Clinical Trials Registry (dated August 29, 2023; TCTR20230829004). All participants provided informed consent. All data will be anonymized. The participants were provided travel compensation (US $33 per participant).

Results

Pilot Study

The participants showed significantly improved global cognition as measured by the MoCA-T (P<.001), depression as measured by the TGDS (P=.002), and state anxiety as measured by the STAI-state (P<.001) but not in the quality of life as measured

by the OPQoL-Brief (*P*=.18). Furthermore, effect sizes among significant measures were large (r_B: 0.85-1.00; Table 2).

Table 2. Assessment results for older adults with mild cognitive impairment who completed both pre- and posttests.

Measure	Pretest (n=30), mean (SD)	Posttest (n=30), mean (SD)	Wilcoxon Signed Ranks Test		Effect sizes[a] (95% CI)
			Z value	*P* value	
MoCA-T[b]	19.50 (2.13)	23.13 (2.71)	4.70	<.001	1.00 (1.00 to 1.00)
TGDS[c]	3.53 (1.89)	2.40 (1.10)	2.99	.002	.85 (0.61 to 0.95)
STAI[d]-state	43.37 (5.40)	37.30 (5.87)	3.96	.001	.87 (0.73 to 0.94)
OPQoL[e]-Brief	52.47 (10.83)	56.00 (5.97)	1.33	.18	.28 (–0.13 to 0.61)

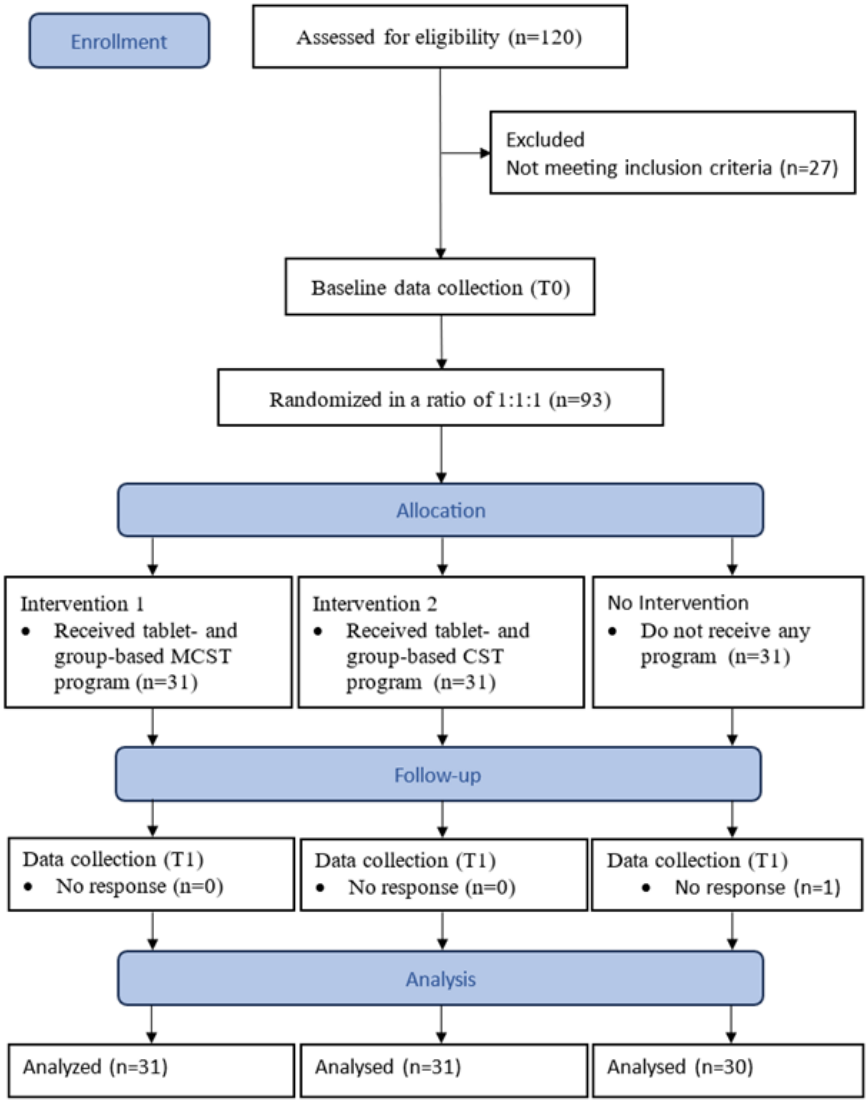
The RCT

In the RCT, the project secured funding in March 2023, started in April 2023, and received recommendations and approval from the Burapha University institutional review board in August 2023. Baseline data collection was conducted in September 2023, and the postintervention data collection started in December 2023. From baseline, we have data from 93 older adults with MCI. Results from the study will be available in mid- to late-2025 at the earliest and will be published in peer-reviewed international and national journals, as well as presented at relevant conferences. An overview of the trial flow is presented in Figure 2.

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) flow diagram. CST: cognitive stimulation therapy; MCST: multicomponent cognitive stimulation therapy; T0: baseline for pretreatment assessment (ie, week 0); T1: the week immediately after the intervention (ie, week 10).



Discussion

Findings From the Pilot Study

The pilot study determined the cognitive function, emotions, and quality of life among older adults with MCI in Thailand. Such improvement was attributed to the tablet- and group-based MCST for 45 minutes per session and once a week over a period of 10 weeks aimed at improving their cognition, emotions, and quality of life. Findings showed that older people with MCI showed improvement in global cognitive function, as proven by scores on MoCA-T. Furthermore, this study also indicated a reduction in depression and anxiety, as demonstrated by scores on TGDS and STAI-state. However, the intervention cannot enhance the quality of life among participants. These findings support that the tablet- and group-based MCST program effectively improves global cognitive function and emotions in older adults with MCI.

The study findings align with previous research regarding CCS using tablet-PCs and social interactions among older adults with MCI [16,17]. A recent study employed the KODRO app (Altera-Group) on Android tablets, incorporating functions like cognitive games, communication tools, and entertainment features to engage various cognitive domains in participants with MCI. The investigation demonstrates that CCS using tablet-PCs enhances cognitive function [16], consistent with meta-analytical findings indicating cognitive training's positive impact on global cognitive function, memory, and working memory in older patients with MCI [56]. Further evaluation of specific cognitive domains will involve neuropsychological assessments and EEG in older adults with MCI.

In terms of emotion, depression and anxiety are common in people with MCI [57-59]. Fascinatingly, emotional symptoms, such as depression and anxiety, decreased following the session. Contrary to the previous study [16], there was unchanged postintervention. Nonetheless, other findings found that not only cognitive functions but also depression and anxiety were improved in people with MCI after they participated in the computerized cognitive training program [60]. The MCST program's social interaction through discussions and games may explain the findings, aligning with research showing that social engagement enhances cognitive interventions. This discovery aligns with previous research, indicating that social

interaction has the potential to modify the outcome of cognitive intervention programs [61].

In contrast to our hypotheses, this study had no significant effect on the participants' quality of life. Perhaps because all of our participants were aware of their diagnosis and expressed low satisfaction with their cognition and physical well-being, no change in their quality of life was seen after postintervention. It has been shown that patients with MCI who are aware of their diagnosis or have high memory complaints have a poorer quality of life than those who are oblivious to their diagnosis or have low memory complaints [62,63]. However, previous studies showed that reminiscence therapy improved cognitive performance and quality of life, supporting CST's use for cognitive decline [64]. Cognitive stimulation benefits daily activities in MCI [10], while another study reported enhanced social, physical, and mental health [65]. Londos et al [66] noted the quality of life gains from goal-oriented rehabilitation, though self and mood subscales showed no significant change. This suggests that enhancing the quality of life in patients with MCI who are aware of their diagnosis may require more targeted interventions.

Principal Results for the RCT Study

The protocol for the RCT study introduces a comprehensive cognitive intervention program designed to address cognitive functions in older adults with MCI. The proposed program is tailored to target both cognitive domains and MSI. The study hypothesizes that the intervention has a positive effect on cognitive performance in older adults with MCI compared with an active comparator and a control group. In addition, it is anticipated that changes in brainwaves, with a focus on frequency bands and ERPs, are also expected to reveal patterns of brain activity associated with cognitive improvement. This study's contribution lies in its novel approach to combining CST and MSI training to address those cognitive deficits associated with MCI. The inclusion of tablet-based interventions and interactive sessions adds a technological dimension to traditional cognitive interventions, thereby potentially enhancing engagement and outcomes.

The study draws upon established principles from CST and MSI techniques. The cognitive stimulation program is designed based on group-based CST and multisensory stimulation approaches. CST has been shown to improve cognitive function and quality of life in individuals with dementia or MCI [10,11]. Furthermore, the group-based cognitive stimulation program, which involves social support from friends and group activities, is critical for mental health and adherence to health-promoting behaviors. It can reduce feelings of loneliness and isolation, which are common in older adults with MCI. The guiding principles of CST were adapted to create 15 fundamental principles of individual CST, including mental stimulation, reminiscence, learning, and communication stimulation, using a person-centered approach [12,13].

The study uses an RCT design with experimental, active comparator, and control groups. The primary objectives are to evaluate the effects of the computerized multicomponent cognitive stimulation program on cognitive functions in older adults with MCI and to explore the changes in the EEG and ERP components following the interventions. The study's structured design, preregistration, and adherence to ethical standards ensure a robust methodology.

The cognitive domains targeted for improvement encompass learning and memory, language, visuospatial abilities, executive functions, psychomotor skills, and emotions. The study integrates various neuropsychological tasks to assess these domains, evaluating the intervention's impact comprehensively. The expected improvements in these domains align with the program's focus on CST principles and MSI, which have shown promise in enhancing both cognitive functions and quality of life. It is crucial to have a tablet-based intervention that boosts self-confidence and reduces depression and anxiety. This can involve personalized training, support groups, and skill-building activities to manage cognitive stimulation. For example, previous research has demonstrated that the feasibility and acceptability of the CCS program and computerized cognitive engagement programs were efficient and acceptable, allowing patients with MCI to improve in several aspects of cognitive and psychosocial functioning [16,17]. Computerized technology is cost-effective, and simple to execute, requiring little human and financial resources [18]. In addition, implementing this intervention in middle-income countries may face challenges like setup costs and limited digital infrastructure. However, these barriers can be mitigated through local adaptations and partnerships with community organizations that support technology access and training, making tablet-based programs more applicable across diverse socioeconomic settings [67]. Furthermore, CCS is being used more widely as a standard approach for delivering nonpharmacological interventions to older adults, but determining the effectiveness of nonpharmacological therapies can be challenging [68]. They lack an appraisal of brain activities and a neuropsychological evaluation that correlates with the specific cognitive functions in people with MCI.

The study's use of EEG and ERP measures to examine neurobiological correlations of MCI adds welcome depth to the investigation. The alterations in brain activity patterns and the ERP components associated with MCI and cognitive impairment contribute to understanding the underlying mechanisms of the condition and identifying potential biomarkers for assessing and monitoring the relevance of the study to treatment. For instance, previous research shows that the EEG of resting-state conditions and a simple cognitive task are important as likely biomarkers for discriminating between healthy, MCI, and Alzheimer groups [69]. It is consistent with Fauzan and Amran [21], finding that when the EEG resting-state measure of the MCI group was compared with typical healthy aging, the theta and alpha increases were more prevalent, showing symptoms of cognitive impairment in MCI, and a decrease in the delta is associated with cognitive decline. In patients with MCI, P300 latency was delayed significantly [26]. P300 latency was related significantly to disease severity in people with probable Alzheimer disease. P300 latency had the highest correlation coefficients with cognitive measurement [23,24]. Furthermore, the N400 component could be connected to verbal memory and learning. The N400 amplitude correlates negatively with semantic expectancy and is inversely proportional to the

semantic processing load. P600 has also been linked to memory encoding and retrieval processes [25].

As a result, EEG is a valuable technology for collecting biomedical data from participants pre- and posttest to compare the difference in brain waves after participating in the experiments. However, the limitations of this research are the research design and instrument. The planned follow-up does not take into account that the study may not provide information about the long-term benefits and hazards of medical interventions. Furthermore, EEG data will be collected using the Emotiv Flex which is not capable of native hardware event-marking that can lead to an effect on time-lock stimuli to EEG data [43].

Limitations and Future Implications

The limitations of this study include its short-term focus, which may capture primarily immediate outcomes while potentially overlooking long-term effectiveness. In addition, the results may have limited generalizability, as they are based on a general population sample and may not extend to specific MCI subtypes. The predominance of female or male participants further limits generalizability, highlighting the need for larger studies to explore potential sex-related variations in response.

Further implications will contribute to knowledge, including developing a novel tablet- and group-based MCST program that combines CST with MSI to improve cognitive functions in older adults with MCI. Using EEG and ERP markers to measure cognitive functions and MSI will provide an assessment of the intervention's effectiveness. The EEG-recorded results will give a greater understanding of participants' tablet- and group-based therapeutic data, allowing for the identification of particular mechanisms, such as changes in cognition and emotion, that were found to improve in the pilot study.

Conclusions

To summarize, the pilot study on older adults with MCI in Thailand revealed significant improvements in cognitive function and emotions following a tablet- and group-based MCST program. The intervention, conducted over 10 weeks for 45 minutes per session, notably enhanced global cognitive function while reducing depression and anxiety levels. These findings corroborate previous research on CCS among patients with MCI. However, contrary to expectations, the MCST program did not yield significant improvements in participants' quality of life, likely influenced by their awareness of diagnosis and dissatisfaction with cognition and physical well-being. Nonetheless, the study underscores the importance of cognitive interventions and highlights the need for further exploration into specific cognitive domains among older adults with MCI. Further research employing neuropsychological assessments and EEG may provide deeper insights into the mechanisms underlying cognitive performance enhancement in this population.

Acknowledgments

This research is funded by National Research Council of Thailand (Contract N41A660157), and it is part of the research project entitled "Development of Computerized Multicomponent Cognitive Stimulation for Improving Cognitive Functions in Older Adults with Mild Cognitive Impairment: A Multimodal Investigation Using Neuropsychological and EEG/ERP Assessment."

Abstract

Background: The persistent high prevalence of e-cigarette use among young adults remains a significant public health concern, with limited evidence and guidance on effective vaping cessation programs targeting this population.

Objective: This study aims to outline the study design and protocol of a pilot randomized controlled trial aimed at investigating feasibility and assessing whether media literacy education or financial incentives enhance the effectiveness of evidence-based text message support in promoting vaping abstinence among young adult e-cigarette users.

Methods: The pilot study uses a 4-arm (1:1:1:1) randomized controlled trial design to assess the potential impact of different combinations of media literacy education, financial incentives, and text message support on vaping abstinence over a 3-month period. The first month serves as a preparatory phase for quitting, followed by 2 months focused on abstinence. A total of 80 individuals, aged 19-29 years, who have used e-cigarettes within the past 30 days, have internet access, and express interest in quitting vaping within the next 30 days, will be enrolled. Eligible individuals will be randomized into one of the four study groups: (1) Text Message, (2) Media Literacy, (3) Financial Incentive, and (4) Combined. All participants, regardless of group assignment, will receive text message support. Participants will be followed for 12 weeks, with abstinence status assessed at week 12, as well as during remote check-ins at weeks 6, 8, and 10. Feasibility measures include recruitment rate, reach, engagement, and retention. Other outcomes of interest include self-reported 7-day abstinence and changes in nicotine dependence and media literacy scores. Exit interviews will be conducted with those who complete the study to explore facilitators of and barriers to participation and engagement in vaping cessation, which will inform future program refinement and uptake.

Results: Recruitment for the study commenced in December 2023 and concluded in August 2024. A total of 40 participants were randomized into these groups: 9 for Text Message, 11 for Media Literacy, 10 for Financial Incentive, and 10 for the Combined group. The final assessment was completed in November 2024, and analyses are currently ongoing.

Conclusions: The findings from this trial could provide valuable insights into the design and uptake of vaping cessation strategies among the young adult population.

Introduction

E-cigarettes have emerged as the most commonly used tobacco product among young individuals [1,2], rapidly becoming a public health concern in the United States, particularly among youth and young adults [3]. Data from the 2021 National Center for Health Statistics reported that e-cigarette use (ie, vaping) was highest among young adults aged 18-24 years, with 11% (approximately 3.4 million people) using e-cigarettes, compared with an overall adult rate of 4.5% [4]. The 2023 National Center for Health Statistics reported an increase in overall adult e-cigarette use to 6.5% [5]. Similarly, another study using the 2021 Behavioral Risk Factor Surveillance System Survey observed a high prevalence of e-cigarette use among US adults (6.9%, 95% CI 6.7%-7.1%), particularly among young adults aged 18-24 years (18%) [6]. The accessibility of vaping products has significantly increased, largely driven by marketing efforts featuring appealing flavors targeted at this population [7]. Moreover, the influence of social media and influencers has contributed to the widespread prevalence of vaping [8,9]. Given the persistently high rates of e-cigarette use, especially among young adults, it is critical to explore the feasibility and effectiveness of targeted cessation programs for this group.

Although marketed as a safer alternative to combustible cigarettes [1,7], evidence suggests that vaping still poses health risks [10,11]. Vaping has been associated with increases in both blood pressure and heart rates [12]. Nicotine, a toxic and highly addictive substance found in e-cigarettes, contributes to these risks, with concentrations varying widely depending on the type of devices, their power, and the brands and models. Notably, nicotine levels in e-cigarettes have increased from 1.7% in 2017 to 5.0% in 2022 [13]. However, critical questions regarding both the short-term and long-term health effects of e-cigarette use remain unanswered [14-16].

Vaping cessation efforts among young adults often yield poor results, with many experiencing failed attempts [17,18]. Data indicate that 53.4% of current young e-cigarette users express an intention to quit, and 67.4% report attempts to do so [19], yet successful cessation rates remain low [20]. Despite a strong desire to quit, many struggle to stop vaping. Evidence-based behavioral vaping cessation programs are scarce compared with pharmacological interventions, such as nicotine replacement therapies [21-23] or vape concentration tapering [24]. Moreover, the implementation and reach of these behavioral programs remain a challenge, particularly among youth and young adult populations [25].

Three recent studies have reported on the effectiveness of behavioral vaping cessation programs using text message support or financial incentives. For example, Raiff et al [26] conducted a pre-post intervention study with 8 college students, finding that all participants quit vaping during the 2-week intervention period, using a remotely delivered program with financial incentives to reinforce abstinence. However, in a feasibility trial involving 27 young adults, Palmer et al [27] found no significant difference in vaping abstinence between the contingency management and monitoring control groups, despite the positive feedback about the intervention program. Another study examined a vaping cessation text message program called This is Quitting [28], which provides social support for quitting. In a randomized clinical trial (RCT) involving 2588 young adults aged 18-24 years, participants in the This is Quitting group were 1.39 times more likely to quit vaping compared with those in the control group [29]. The urgent need for evidence-based behavioral vaping cessation initiatives among this population is critical to addressing this public health concern.

Vaping often appeals to younger populations through marketing campaigns that highlight various flavors and glamorize the practice [7]. Companies also use manipulative strategies like social media influencers and product placement, particularly targeting communities with lower levels of vaping-related media literacy, who tend to be more susceptible to vaping [30]. Although limited evidence exists on the direct impact of media literacy programs on vaping cessation, integrating such programs into vaping cessation initiatives may help promote abstinence by (1) promoting positive behavioral norms (educating people about the true risks of vaping can foster a social environment where quitting is seen as important and achievable [31]); (2) encouraging peer advocacy and mentoring (by understanding marketing tactics and gaining skills to debunk misinformation, individuals can become more effective in supporting their peer to quit vaping [32]); and (3) enhancing self-efficacy against vaping triggers (media literacy can help individuals recognize and avoid triggers that encourage vaping, such as targeted advertising or social media content that normalizes the behaviors [33]). In addition, although media literacy programs are primarily designed for youth for educational and prevention purposes, young adults may also benefit from the content due to the close age proximity between these groups.

Contingency management is a well-established behavioral intervention in which individuals receive reinforcement, such as financial incentives, contingent upon predetermined outcomes [25]. Financial incentives have been shown to be effective in

promoting healthy behaviors [34] and improving the reach and engagement of evidence-based programs as part of an implementation strategy [35]. Numerous studies have demonstrated the success of financial incentives in encouraging behavior changes [36,37]. Rooted in health promotion economic theory, financial incentives enhance the perceived benefits of abstaining from unhealthy behaviors, thereby bolstering motivation for change [36].

Peer influence plays an important role in vaping behaviors, with family and friend use cited as key reasons for vaping initiation [38]. In addition, vaping for "entertainment" purposes is prevalent among younger populations [39]. Peer support strategies have been shown to be effective [40,41], especially in promoting cigarette smoking cessation in youth and young adults [42,43]. Platforms like SMS text messaging and social media have shown promise as peer support tools [44-46]. Specifically, peer support delivered through text message (eg, This is Quitting) has demonstrated effectiveness in vaping cessation across multiple studies [29,47,48], capitalizing on the widespread use of these communication methods among young adults.

The objective of this paper is to outline the design and methodology of a pilot RCT investigating feasibility and assessing whether media literacy education or financial incentives enhance the effectiveness of evidence-based text message support in promoting vaping abstinence among young adult e-cigarette users.

Methods

Study Design

This pilot study uses a 4-arm RCT design to assess whether media literacy education or financial incentives can enhance vaping abstinence when combined with text message support over a 3-month trial period. The first month involves a preparatory phase for quitting, followed by 2 months focused on maintaining abstinence from vaping. Eligible participants will be randomly assigned to one of four groups in a 1:1:1:1 ratio: (1) Text Message (text message support), (2) Media Literacy (text message support and media literacy education), (3) Financial Incentive (text message support and financial incentives), and (4) Combined (text message support, media literacy education, and financial incentives).

All 4 groups will receive evidence-based text message support (ie, This is Quitting). In addition, to develop and assess the process of conducting biospecimen collection (ie, urine) and analysis, a subsample of 20 participants (5 participants from each study group) will be contacted in order of enrollment until the target is met at baseline. These participants will be asked to provide urine samples both at baseline and at the conclusion of the study. The samples will be shipped to the Division of Laboratory Sciences at the Centers for Disease Control and Prevention for biomarker analyses to evaluate exposures to tobacco-related toxicants from e-cigarette use.

The trial protocol has been reported in accordance with the SPIRIT (Standard Protocol Items Recommendations for Interventional Trials) 2013 checklist [49] (Multimedia Appendix 1).

Participants and Eligibility Criteria

Eligible participants are individuals who: (1) are aged 19-29 years (the minimum age is set at 19 to align with the legal age of majority in Nebraska); (2) have used e-cigarettes within the past 30 days, consistent with previous behavioral vaping cessation trials targeting youth and young adults [29,50]; (3) have access to the internet; and (4) are interested in quitting vaping within the next 30 days. Individuals who self-report as currently pregnant or planning to become pregnant within the next 3 months, or who are currently enrolled in other behavioral or medical vaping cessation programs, will be excluded.

Sample Size Justification

As this pilot RCT aims to assess the feasibility of a future large-scale study, a sample size of 80 (n=20 in each arm) is considered sufficient, following the flat rule of thumb for pilot trials with continuous outcomes of interest (eg, feasibility outcomes), which typically recommend group sizes ranging from 12 to 35 participants [51]. This sample size also takes into account available resources such as time and budget [52].

Recruitment and Sample Selection

We will recruit a total of 80 participants using a population health management approach [53,54], a comprehensive strategy that involves identifying subpopulations of individuals from an existing pool who would benefit from a given evidence-based intervention. This approach includes examining the characteristics of these populations using electronic health record (EHR) data. The potential participant pool will be limited to patients who have opted in to be contacted for research studies in the EHR system at Nebraska Medicine.

Specifically, we will collaborate with EHR Data Access Core at the University of Nebraska Medical Center to first generate a list of potentially eligible participants, filtering for age and using smart text data to determine the vaping or smoking status, as young adults are more likely to engage in multiple tobacco products at the same time [55]. A study invitation email, containing a link to an eligibility screening, will then be sent to individuals on this potential participant list by the study team. In this email, interested individuals will be directed to complete web-based screening questions via Research Electronic Data Capture (REDCap; Vanderbilt University) to assess their eligibility. Eligible participants will then be contacted by research staff members on days 1, 3, 7, 14, and 21 (if no response) after the completion of screening to schedule an in-person baseline visit.

If the recruitment goal of 80 participants is not met after exhausting the initial participant list, the research team will directly contact potential participants via phone calls. In addition, we will implement a social media recruitment strategy by posting study advertisements on platforms such as Facebook (Meta), Instagram (Meta), or X (formerly Twitter). We recognize that there may be differences between participants recruited from various sources (EHR vs social media) and will account

for these differences in the reporting of trial results and the planning of future large-scale studies.

Interventions

Text Message Support

Grounded in social cognitive theory and designed as a compassionate, nonjudgmental companion, the text message program "This is Quitting" is an evidence-based, cost-free, and personalized initiative by the Truth Initiative, aimed at helping young individuals quit vaping. Most of the support messages are contributed by other users, reinforcing perceived social norms and providing communal encouragement for quitting. A recent RCT involving 2588 young adults aged 18-24 years found that participants receiving text message support were significantly more likely to achieve vaping abstinence compared with the control group (odds ratio [OR] 1.39; 95% CI 1.15-1.68; *P*<.001) at the 7-month follow-up [29]. Participants will retain full access to the text message program even after completing the study.

Participants in this study will receive 1 message per day for the week leading up to their quit date and for 8 weeks following it.

Media Literacy

Media Education for Sensible Evaluation and Nurturing Substance-free Experiences (MediaSense) [56] is an evidence-informed antivaping media literacy education program designed to prevent and reduce vaping among adolescents and young adults. Developed by our research team, the program draws on the social influence framework and incorporates guidance from the Centers for Disease Control and Prevention and Food and Drug Administration tobacco and vaping prevention guides, as well as an extensive review of evidence-based prevention programs and identified vaping risk factors. The MediaSense program consists of 9 web-based modules covering a range of topics, including (1) understanding what e-cigarettes are and how they work; (2) exploring the health impact of e-cigarettes; (3) understanding the role of marketing and advertisement in promoting e-cigarettes; (4) dispelling myths and revealing facts about e-cigarette marketing; and (5) learning how to deconstruct vaping advertisements. These e-learning modules aim to transform participants' knowledge, attitudes, and beliefs regarding e-cigarette use while emphasizing vaping-related media literacy and developing skills to critically deconstruct e-cigarette advertisements.

In our previous study that examined the effect of MediaSense on vaping prevention among middle and high school students (n=384), we observed significant results. Specifically, vaping media literacy scores improved, with mean scores increasing from 2.3 (SD 2.3) to 3.4 (SD 2.4) (*P*<.001). In addition, there was a decrease in the perception of vaping harm (adjusted OR 1.6 95% CI 1.1-1.22) and a reduction in vaping susceptibility (adjusted OR 0.7, 95% CI 0.5-1.0; *P*=.04) [56], indicating a reduced likelihood of students considering vaping.

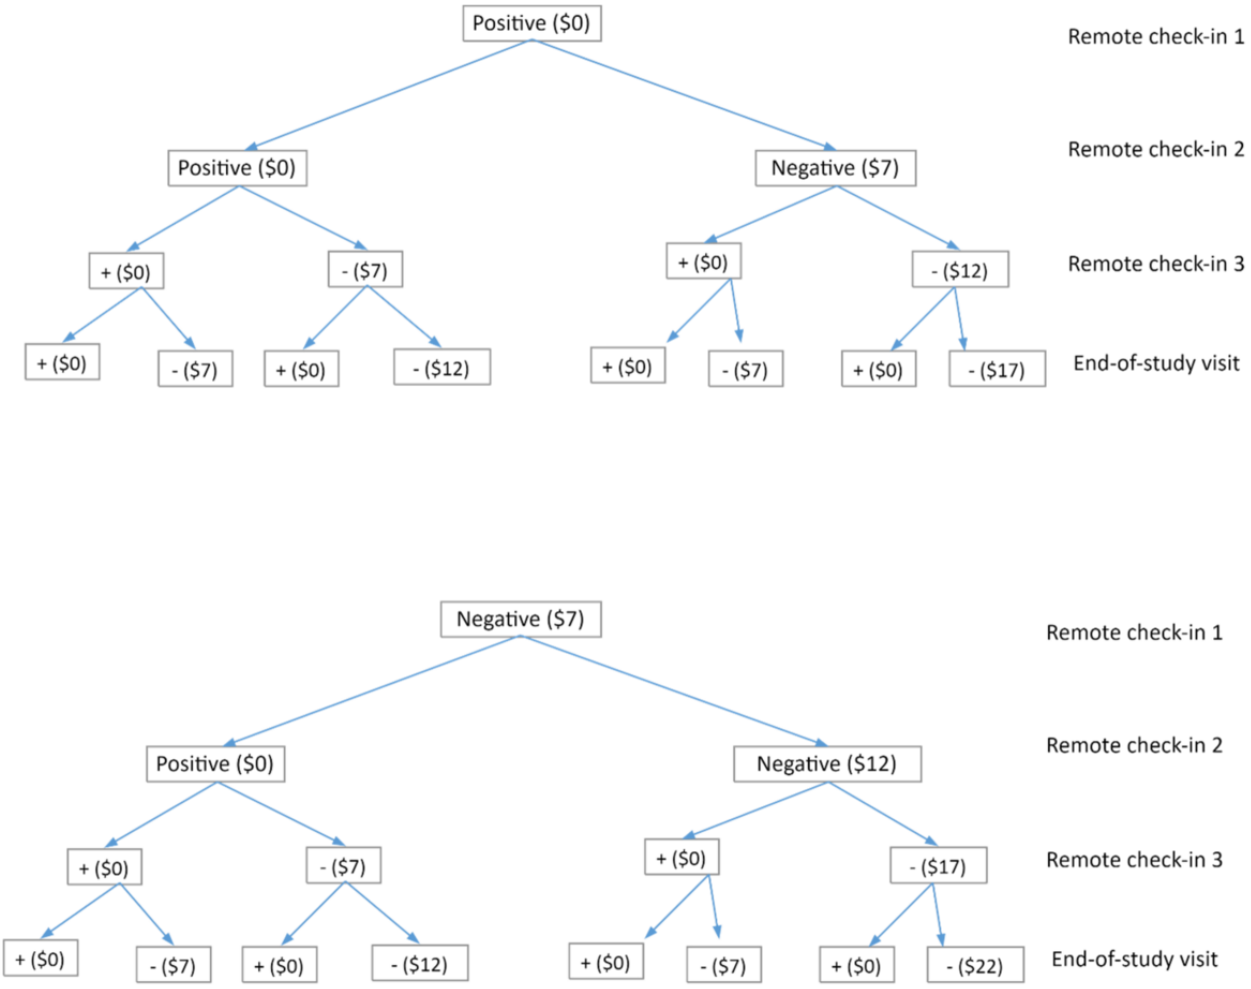
In this study, participants assigned to Media Literacy or Combined will complete these self-paced modules during the 1-month quitting preparatory phase and will be required to take a short quiz at the end of each module. These quizzes confirm module completion and assess participants' understanding of the education materials. Each module will take approximately 10 minutes to complete.

Financial Incentives

Participants will receive US $3 for each saliva sample submission, regardless of testing results, at week 6, week 8, week 10, and week 12 during the 2-month abstinence phase. In addition, they will earn escalating bonuses for each negative sample. The bonus will start at US $7 and increase by US $5 for each subsequent negative sample, that will be, US $7 for week 6, US $12 for week 8, US $17 for week 10, and US $22 for week 12. However, a reset contingency will be applied, meaning the bonus amount will revert to the initial US $7 if a sample is missing or tests positive for cotinine (refer to Figure 1).

Participants can earn up to $70 in total upon completing all 4 saliva sample submissions. They will be informed of their earnings after completing each scheduled task (ie, immediate reward) and will receive all payments as a 1-time disbursement at the conclusion of the study. The rationale behind the timing and amount of the incentives is to minimize the risk of inhibiting intrinsic motivation [57], as modest incentives (up to US $70) are less likely to undermine intrinsic motivation compared with the larger rewards typically offered in smoking cessation programs (eg, US $1185) [58].

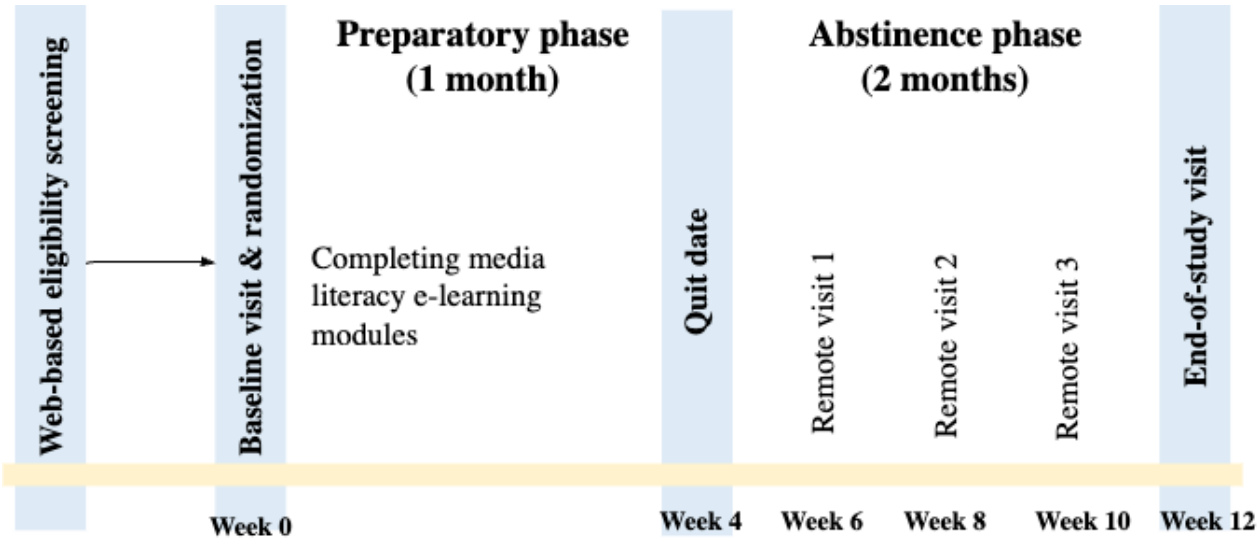
Figure 1. Financial reward decision flow. Values were negative (-) or positive (+).



Study Timeline and Data Collection

The study will span a duration of 3 months, consisting of a 1-month quitting preparatory phase (weeks 1-4) and a 2-month abstinence phase (weeks 5-12; Figure 2). Throughout the quitting preparatory phase, participants assigned to the Media Literacy or Combined groups will be directed to complete the web-based media literacy education modules by their quit date, Meanwhile, participants in the Text Message or Financial Incentive groups will be encouraged to prepare for quitting but not to quit before the specified quite date.

Figure 2. Study assessment timepoint.



Baseline Visit

This assessment will include a demonstration and facilitation of the saliva test, which participants will perform themselves at baseline and final study visits, as well as during remote check-ins. Participants will also sign a precommitment pledge (a psychological strategy to help individuals stick with their goals) and complete the baseline survey.

Following these activities, research staff members will conduct randomization using predetermined blocks of 4 and 8, with a computer-generated algorithm, to assign participants to one of the study groups. Participants will also be asked to specify a quit date (no later than 1 month after the baseline visit, which serves as the quitting preparatory phase), register for the text message program, and schedule the 3 remote check-ins for saliva testing.

Remote Check-Ins

During the abstinence phase, participants will engage in a total of 3 video calls, scheduled for week 6, week 8, and week 10. During each live video call, participants will receive instructions on how to complete the saliva sample collection on their own and submit the results. Specifically, they will be directed to open a new test kit and record their participant ID, visit number, date, and time on the kit. Participants will then perform the saliva test, allowing approximately 10 minutes for processing. In addition to verbally providing the test results (positive or negative) to the research staff members, participants will be required to take a picture of the results, including their participant ID, visit number, date, and time, and send it to the research staff members before concluding the call. Each video call will last no longer than 20 minutes. The primary purpose of these remote check-ins is to maintain participants' engagement and monitor their abstinence progress until the final study visit at week 12.

End-of-Study Visit

At the end-of-study visit (week 12), which may be conducted either remotely or in person, participants will provide the results of saliva testing and complete the end-of-study survey. Participants who provided a urine sample at the study baseline will be asked to attend the final visit in person for urine sample collection.

Exit Interview

For quality improvement and future modification and adoption of vaping cessation programs, we will conduct exit interviews with participants (n=8-12; 2-3 participants from each group) who have completed the study via video call. The interview guide will be developed based on the Pragmatic Robust Implementation and Sustainability Framework [59] to identify the barriers and facilitators of participating in a vaping cessation program and achieving abstinence goals.

Measures

Feasibility Outcome

As this is a pilot trial, our primary objective is to assess the feasibility of implementation. Specifically, we will use study records to measure the following: (1) recruitment rate, defined as the proportion of eligible individuals who consent to participate; (2) reach, assessed by the representativeness of sociodemographic characteristics among screened and enrolled individuals; (3) engagement, measured by the proportion of participants completing remote check-ins, and the proportion of participants in the Media Literacy or Combined groups who complete the media literacy e-learning modules; (4) retention, evaluated by the number of participants who withdraw from study, and the completeness of the end-of-study assessment; and (5) the number and proportion of participant providing a urine sample from each group at baseline and the end of study.

Cessation Outcome

The primary cessation outcome for this study is biochemically verified vaping abstinence, determined through the iScreen saliva cotinine test conducted at the end-of-study assessment. A negative cotinine result will be indicated by a cutoff of <30 ng/mL [60].

Additional Outcome

Additional outcomes of interest for this study include: (1) self-reported 7-day abstinence, determined by the question in the end-of-study survey: "Have you used any e-cigarettes, even a puff or pinch, in the last 7 days?" [61]; (2) changes in nicotine dependence, measured by the Penn State E-Cigarette Dependence Index at baseline and end-of-study; and (3) changes in media literacy, assessed using the Vaping Media Literacy Scale [30] at baseline and end-of-study.

Data Analysis Plan

Quantitative Analysis

Descriptive statistics will be used to summarize participants' sociodemographic characteristics, e-cigarette use history, exposure to tobacco marketing and its influence, social support, and self-efficacy at baseline. Bivariate analyses, using either the Chi-squared test for categorical variables or the ANOVA test for continuous variables, will be conducted to identify differences in sociodemographic characteristics and other vaping-related variables at baseline across the study groups.

We will provide a descriptive summary of feasibility outcomes, including the rate of recruitment, reach, engagement, and retention. In addition, we will assume that all covariate data are missing at random, and this assumption will be tested by comparing the missing data patterns with sociodemographic characteristics in the bivariate analyses.

Chi-squared tests will be used to determine differences in proportions of participants with negative saliva test results at the end of the study as well as each remote check-in. Missing end-of-study abstinence outcomes will be coded as vaping (not abstinent) [27]. Similarly, differences in the proportion of participants who self-reported 7-day abstinence across study groups will be evaluated using the Chi-squared test, while the ANOVA test will be used to assess changes in nicotine dependence index and media literacy scores.

Nonparametric methods (eg, Fisher exact test when the sample size is less than 5 in a category or the Kruskal-Wallis test) will be applied when appropriate. All quantitative analyses will be

conducted in SAS (version 9.4; SAS Institute Inc) with a 2-tailed significance level <.05 if applicable.

Qualitative Analysis

Using a hybrid deductive and inductive qualitative approach, we will analyze data obtained from semistructured interviews to explore the facilitators and barriers to participation and engagement in vaping cessation programs. All interviews will be recorded and transcribed verbatim. Subsequently, 2 trained research staff members will independently code the transcripts into reduced meaning units (sentences or phases with singular meaning). Intercoder reliability will be assessed using Cohen κ, with a threshold of ≥.80. All qualitative data analyses will be conducted using NVivo 14 (Lumivero) or Microsoft Excel.

Ethical Considerations

The study protocol was approved by the institutional review board (0596-22-EP) at the University of Nebraska Medical Center and was registered on ClinicalTrials.gov (NCT05586308).

Informed Consent

Approximately 10 days before the baseline visit, eligible individuals scheduled for the in-person visit will receive an email containing an initial packet with the informed consent form, a letter with instructions for their first visit, and contact information for any questions. During the baseline visit, trained research staff members or study investigators will verbally review the informed consent with participants, covering the data collection procedure and plans for protecting participants and their privacy (ie, data deidentification), address any questions, and obtain written informed consent before proceeding with the baseline assessment.

For participants who opt to provide a urine sample during the baseline visit, verbal consent will be obtained by the research staff members before the sample collection. Participants will be guided through the recommended procedures for urine sample collection according to best practices.

Compensation

All study participants will receive a US $25 gift card each for completing baseline and end-of-study visits. Participants who opt to provide a urine sample will receive an additional US $10 at both baseline and end-of-study visits. As a result, participants in the Text Message or Media Literacy groups can earn up to US $70 in total compensation, while those in the Financial Incentive or Combined groups may earn up to US $140, including additional financial rewards contingent on the submission of 4 saliva samples during remote check-ins or end-of-study visit.

Results

Recruitment for the study commenced in December 2023 and concluded in August 2024. A total of 40 participants were randomized into the following groups: 9 for Text Message, 11 for Media Literacy, 10 for Financial Incentive, and 10 for the Combined group. The final assessment was completed in November 2024, and analyses are currently ongoing.

Discussion

Principal Findings

This study is one of the few to assess the feasibility and potential effects of different vaping cessation program combinations in helping young adults quit vaping. We anticipate that the addition of either media literacy or financial incentives will lead to better preliminary abstinence outcomes (ie, more participants quit vaping) by the end of the study, compared with text message support alone.

Unlike other behavioral trials for vaping cessation, which often use a “doing nothing” approach (ie, assessment-only) for the control condition [28,50], we aim to enhance vaping abstinence outcomes by examining the potential additive effects of various interventions on top of an evidence-based program. This approach accounts for participants’ expectation of receiving some levels of interventions when taking part in research studies [28].

There are currently few published studies on behavioral interventions for young adult vaping cessation [26,27,29]. As of the time of writing, 9 other clinical trial protocols are actively recruiting participants to evaluate behavioral vaping cessation interventions among youth (n=3), young adults (n=4), or a mixed youth and young adult population (n=1). These trials have target sample sizes ranging from 30 to 1715 participants, as listed in their registration records on ClinicalTrials.gov. Given the persistently high prevalence of e-cigarette use among young adults, it is crucial to identify effective cessation programs and the supplementary components that may enhance their success. The study findings will be disseminated through peer-reviewed manuscript publications and presentations at national conferences, as well as shared with relevant stakeholders and communities.

Limitations

This study has several limitations that warrant acknowledgment. First, the exclusion of individuals without access to internet services may inadvertently overlook those most in need of cessation assistance, particularly those of low socioeconomic status or residing in remote areas. However, studies have indicated that approximately 95% of American adults have internet access and 90% own smartphones [62], suggesting that the benefits of using technology-assisted behavioral interventions likely outweigh the drawbacks of this exclusion criterion. Second, our use of a commercially available saliva cotinine test kit, which provides binary positive or negative results, to verify abstinence status may not fully capture the extent to which cotinine levels have fluctuated as a result of cessation efforts. Nonetheless, the saliva test offers cost-efficiency compared with urine testing and may serve as a useful monitoring tool for follow-up assessments during the intervention period. Third, although we apply a population health management approach to identify potential participants from an EHR database, it is likely that we are capturing only individuals who receive health care within a specific system rather than from a broader regional population. In addition, due to institutional policy, we are limited to including only those individuals who have opted in for research participation, which

may introduce selection bias, as these individuals may be less representative of the broader target population [63]. Furthermore, concerns exist regarding the reliability of using vaping or smoking status as a filter to identify potential participants from the EHR database. To address this, we have incorporated an additional step in the recruitment process, requiring potential participants to complete a screening survey to confirm their eligibility before scheduling the baseline assessment. Finally, while our study targets young adults aged 19-29 years, the text message program (This is Quitting) is tailored for individuals aged 18-24 years. We believe that individuals within the broader age range can still benefit from the support program. To accommodate this, participants aged 25-29 years in the trial will be instructed to adjust their age when registering for the text message program during the baseline visit.

Conclusion

In summary, the findings from this trial will aid in refining the study design, particularly regarding vaping program components, and in planning program implementation. In addition, the results may help identify or develop strategies to enhance participant reach and program uptake among young adult populations.

Acknowledgments

We would like to acknowledge Ms Hayley Jurek and Deb Meyer at the University of Nebraska Medical Center Office of the Vice Chancellor for Research, who have been instrumental in participant recruitment of the pilot trial.

Abstract

Background: Virtual reality (VR) has strong potential to enhance the effectiveness of telemental health care (TMH) by providing accessible, personalized treatment from home. While there is ample research supporting VR for in-person treatment, there is only preliminary data on the efficacy of telemedicine-based VR. Furthermore, the majority of VR apps used in therapy are not designed for mental health care. VR has the potential to enhance TMH through innovative technology solutions designed specifically for the enhancement of remotely delivered evidence-based practices. This feasibility randomized controlled efficacy trial aims to fill both of these gaps by piloting a novel telemedicine-based VR app (Doxy.me VR) equipped with animal phobia exposure stimuli.

Objective: This is a feasibility randomized controlled efficacy trial comparing exposure therapy via a telemedicine-based VR clinic versus standard TMH with adults with an intense fear of dogs, snakes, or spiders. The primary objective is to assess the feasibility of a fully powered trial. The secondary objective is to conduct a preliminary examination of clinical outcomes (eg, specific phobia symptoms).

Methods: This single-site trial will enroll a minimum of 30 and a maximum of 60 adults with self-reported fear of dogs, snakes, or spiders. Potential participants will be recruited through clinical trial and research recruitment websites and posting flyers. All self-report assessments and homework will be partially automated using REDCap (Research Electronic Data Capture; Vanderbilt University) forms and surveys, but the baseline assessment of phobia symptoms and exposure intervention will be administered by the study therapist.

Results: The feasibility of the proposed trial methodology will be assessed using enrollment, retention, assessment completion, and treatment protocol fidelity benchmarks. Between-group differences in specific phobia, anxiety, and depression symptoms while covarying for pretreatment scores, will be conducted using repeated measures ANOVA along with differences in therapeutic alliance and presence. Data obtained from these analyses will inform power analyses for a fully powered efficacy trial. In total, 54 participants were randomized between October 25, 2023, and July 26, 2024 (Doxy.me VR n=28 and TMH n=26). Data analysis will be completed and submitted by the end of the second quarter of 2025.

Conclusions: This feasibility randomized controlled trial comparing Doxy.me VR versus TMH aims to enhance the delivery of evidence-based treatments via telemedicine and reduce barriers to remotely delivered exposure therapy. This feasibility trial will be followed by a fully powered efficacy trial on telemedicine-based VR for animal phobias.

Introduction

Background

Telemental health care (TMH) has revolutionized mental health services by providing accessible, personalized treatment from the comfort and privacy of home [1,2]. TMH is equally to more effective than in-person care, with patients generally reporting higher satisfaction and reduced costs [3-11]. Furthermore, TMH alleviates sociocultural (eg, stigma) and geographic (eg, transportation) barriers to mental health care [12-14]. TMH increased from 41.8% to 62.8% of all telehealth services during 2022, surpassing all other forms of digital clinical care [15]. This trend suggests that clients view TMH as an appropriate substitute for in-person care. As TMH services continue to evolve, there will be a growing need for innovative solutions to enhance the effectiveness of remote care [1,16,17].

Virtual reality (VR) is a promising avenue for advancing TMH. By leveraging immersive simulations, VR can recreate stressors—both physical and psychological—in a safe, controlled environment, which can enhance the effectiveness of remotely delivered evidence-based treatments [18-21]. VR improves treatment compliance and patient retention by offering engaging content for in- and between-session mental health exercises [22]. There is abundant support for on-site VR mental health therapy [23,24]; however, evidence for telemedicine-based VR mental health is limited to a few studies of preliminary efficacy [25-27]. VR has strong potential to drive innovations in TMH [28,29].

The customizable simulations of VR can create new opportunities to personalize TMH. For example, exposure therapy is a gold standard treatment for phobias and other anxiety-related mental health disorders that is efficient and produces durable effects [30,31]. By exposing an individual to fear-related stimuli (eg, a dog) in a controlled setting (eg, the therapist's office), anxiety reduces, and the fear response diminishes over prolonged and repeated exposure (eg, the individual is no longer fearful around dogs). One approach to conducting gradual exposure includes using multimedia stimuli (eg, screen-shared photos or videos), but it can be challenging to standardize exposure formats and assess client affect over conventional telemedicine [32,33]. Another approach is exposing patients to their fears using VR. VR-based exposure therapy (VRET) is a safe, accessible, and engaging alternative to in vivo exposure therapy that can be less stressful and more conducive to treatment success [34-37]. However, most VRET research to date has been conducted in-person, requiring that patients travel to and complete therapy in a clinician's office [38]. Delivering VRET over telemedicine may provide patients with highly engaging and immersive treatment with greater accessibility [39]. Telemedicine-based VR may also address lingering barriers to TMH by expanding the experience of therapeutic alliance and presence. Therapeutic alliance, or working alliance, refers to the extent to which a patient and therapist experience a collaborative and trusting relationship [40,41] and is among the strongest predictors of outcomes in mental health care [42,43]. Presence, also referred to as telepresence, is the extent to which places, activities, and other individuals feel real in a digital environment (eg, VR and videoconferencing) [44].

To explore the potential of telemedicine-based VR therapy, we conducted in-depth interviews with 18 practicing TMH therapists who had delivered exposure therapy via conventional telemedicine [45]. Therapists wanted VR features to build rapport with their patients and the ability to customize VR components for individual patient needs. Therapists needed clinical evidence supporting tele-VR, low costs to adopt VR into their TMH practice, and information on possible side effects for patients. We then surveyed 176 practicing TMH therapists about their perspectives on telemedicine-based VR. We asked therapists to rate the relative importance of tele-VR simulations, features, and implementation factors. Therapists strongly favored tele-VR simulations related to social anxiety, flying, driving, and animals. Therapists rated between-session VR exercises and immersive cooperative activities as some of their most valued tele-VR features. Therapists' highest-rated factors for implementing telemedicine-based VR were HIPAA (Health Insurance Portability and Accountability Act)-compliant, followed by affordability, insurance coverage, and accessibility [46].

Using insights obtained from these studies, we developed Doxy.me VR—an innovative app developed specifically to facilitate immersive TMH. We developed Doxy.me VR with the frequent and direct involvement of key stakeholders. Doxy.me VR is designed for a therapist to meet with a client remotely in a private, comfortable VR clinic that looks and feels like a therapist's office (refer to Figure 1 for screenshots of the clinic). To join the VR session, the therapist provides their unique, persistent 4-digit room code to their client, who enters the code to check in. Once the therapist admits the client, they can interact by speaking and gesturing with each other in immersive VR. Therapists can use a menu to spawn animals such as dogs, snakes, and spiders for use in treating specific phobias. Multiple exemplars are available for each type of animal in varying sizes. For example, there are small dogs (eg, Chihuahua, Corgi, and Jack Russell Terrier), medium dogs (eg, Golden Retriever, Shiba Inu, and Pit Bull), and large dogs (eg, German Shepherd, Doberman, and Husky). Each animal is animated with 4 behavior states, that is, idle (ie, no movement), calm (ie, small, slow movements in a relaxed posture), active

(ie, fast, frequent movements in a playful posture), and aggressive (ie, fast, attacking movements in a defensive posture). Each behavior state also includes corresponding audio such as a calm dog breathing lightly, an active dog panting and barking playfully, and an aggressive dog snarling and barking loudly. Therapists can select, rotate, and move these animals around the room before making them visible to clients. Once therapists make the animal visible, they can continue to move and rotate the animal or remove the animal entirely. Clients cannot directly manipulate objects; however, clients gain access to all the control features while engaging with Doxy.me VR's homework mode, which is used for between-session practice.

Figure 1. Screenshots from Doxy.me VR. Virtual reality clinic space (top left); client admission menu (top right); phobia stimulus menu (bottom left); and therapist and client interacting with phobic stimulus in virtual reality (lower right).

This Study

We present the protocol for a feasibility randomized controlled efficacy trial comparing exposure therapy delivered via Doxy.me VR versus standard TMH to adults with an intense fear of dogs, snakes, or spiders. The primary aim of this study is to assess the feasibility of and refine our study methodology in preparation for a large, fully powered randomized controlled efficacy trial. The secondary aim is to conduct a preliminary examination of clinical outcomes, including between-group differences in specific phobia symptoms, therapeutic alliance, and presence.

Methods

Enrollment and Randomization

This study will use a feasibility randomized controlled efficacy trial design. This single-site trial will enroll a maximum of 60 adults with self-reported fear of dogs, snakes, or spiders with the goal of completing treatment with 30 adults. Participants will be randomly assigned using the REDCap (Research Electronic Data Capture; Vanderbilt University) [47-49]. Randomization Module on a 1:1 allocation ratio to receive 12 weekly sessions of exposure therapy over the course of three months delivered via standard TMH (n=15) versus Doxy.me VR (n=15). Participants randomized to the Doxy.me group will be provided with Meta Quest 2 VR headsets preloaded with the Doxy.me VR app, to be returned to the study team following completion of the study. All therapy sessions will be conducted via remote videoconferencing, with the Doxy.me VR group transitioning to the Doxy.me VR clinic for the exposure exercise portion of the session, and the standard TMH group using multimedia (ie, photos and videos) shared by the study therapist during video calls. Participants randomized to Doxy.me VR received a Meta Quest 2 headset via mail with the VR clinic already downloaded and were provided a clinic code by their therapist at the beginning of each session.

Study Intervention

This study will follow the treatment protocol developed specifically for VRET by Bouchard et al [50], Côté and Bouchard [51], Michaliszyn et al [52], and St-Jacques et al [53]. Following the baseline assessment session, treatment consists of 12, ≤60-minute therapy sessions, including 1 psychoeducation and treatment planning session (session 1), 10 exposure sessions (sessions 2-11), and 1 relapse prevention session (session 12). During the first therapy session, patients learn about the principles of cognitive behavioral therapy, the etiology of anxiety and specific phobias, and procedures for exposure. They then complete a fear hierarchy (ie, a list of situations ranked from least to most anxiety-provoking) with therapist guidance. Fear hierarchies include a text-based list of various VR situations

or multimedia situations (ie, static and active states of different types of feared animals) and "in vivo" or live situations (eg, petting a dog and touching a snake at a pet store). Therapy sessions 2-11 begin with a review of homework assigned during the previous week's session, followed by an approximately 35-minute virtual exposure session. Patients report their anxiety level using a 1- to 100-point scale at a 5-minute interval throughout the exposure and remain in the exposure until their self-reported anxiety reaches a 50% reduction from their peak anxiety rating from baseline following the introduction of the stimulus or 35 minutes elapses. That is, participants will spend a maximum of 35 minutes in the exposure and if they have reached a 50% reduction or greater from their peak anxiety rating before the 35 minutes is over, they will move on to the next exposure. Following the exposure, the therapist and patient process thoughts and feelings related to the exposure, reframe appraisals of their feared stimuli through cognitive restructuring, and practice box breathing. The Doxy.me VR group will conduct their in-session exposures in the VR clinic and the TMH group will conduct their in-session exposures using multimedia on the Doxy.me platform by screen-sharing videos and photos. Once patients have progressed through all VR and multimedia situations in their hierarchy and are ready to complete their first in vivo exposure between therapy sessions for homework, weekly therapy sessions will be devoted to processing and planning between-session in vivo exposures.

Homework

All therapy sessions will include the assignment of homework, including reading an informational handout after the psychoeducation and treatment planning session (session 1) and exposure therapy assignments after therapy sessions 2-11. Daily exposure-based homework assignments will require participants to practice exposure exercises similar to those completed during that week's therapy session (ie, using VR or multimedia stimuli) for a minimum of 30 minutes. When the patient states that they are ready, these will include in vivo exposure exercises planned during the therapy session. Participants will receive text or email reminders with links to REDCap surveys with instructions for the homework assignment and the situation to be used in the exposure exercise. The survey will also ask participants to report the date and time of the exposure, their baseline anxiety rating, their peak anxiety level during the exposure, and their anxiety level following completion of the exposure exercise.

Recruitment Strategy

Potential participants will be recruited through Clinical Connection [54], Research Match (retrieved from researchmatch website [55]), Facebook (Meta [56]) advertisements, and flyers distributed on the University of South Florida campus and off-campus community centers. Potential participants will be provided with a URL or QR code directing them to an online prebaseline screening questionnaire administered via REDCap. Those meeting preliminary eligibility criteria will then schedule an initial consent and baseline assessment visit via Microsoft Bookings with text or email reminders 24 hours and 1 hour before the scheduled visit time.

Eligibility Criteria

Eligible participants will (1) be ≥18 years old; (2) have a self-reported fear of dogs, snakes, or spiders; (3) have subthreshold or present specific phobia symptoms as determined by the study therapist via administration of the Diagnostic Assessment Research Tool (DART) Specific Phobia Module [57]; (4) have access to the internet and a computer or smartphone with videoconferencing capabilities; and (5) plan to reside in the state of Florida for the duration of the study.

An individual who endorses any of the following criteria will be excluded from participation in the study: (1) participation in ongoing mental health therapy from a nonstudy therapist; (2) changes to psychotropic medication use within 6 weeks preceding enrollment in the trial; (3) active suicidal or homicidal intent or plan as determined by the study therapist via the DART Risk Assessment Module [57]; (4) active auditory, visual, or tactile hallucinations via the DART Psychosis Module screening question; or (5) a diagnosis of photosensitive epilepsy by a medical doctor or a history of experiencing seizures caused by photosensitivity.

Criteria for Withdrawing Participants

Anticipated circumstances under which participants will be withdrawn without their consent include (1) new participation in mental health therapy from a nonstudy therapist; (2) changes to psychotropic medication use; (3) active suicidal or homicidal intent or plan; (4) onset of auditory, visual, or tactile hallucinations; (5) onset of photosensitive epilepsy or seizures; and (6) moving out of the State of Florida during the study period.

If participants completely withdraw or are administratively withdrawn from the study, staff will attempt to provide them with a referral to a therapist in their area. If participants partially withdraw from the research, study staff will attempt to administer mid- and posttreatment assessments. Participants will be given the option to completely withdraw from the study, including withdrawing previously collected data.

Criteria for Wait-Listing Participants

If potential participants do not meet eligibility criteria due to participating in ongoing mental health therapy from a nonstudy therapist or recent changes to psychotropic medication use within 6 weeks preceding enrollment in the trial, they will be presented with a message on the prescreening survey inviting them to revisit the prescreening questionnaire at a later date if and when those conditions no longer apply.

Consent and Baseline Assessments

The consent and baseline assessment visit will be conducted via videoconferencing platform and will not be audio or video-recorded. During this visit, study staff will (1) confirm the potential participant's responses on the online prescreening questionnaire, (2) provide detailed information about the study and obtain informed consent, (3) assist participants in completing baseline questionnaires via REDCap survey, (4) administer the Specific Phobia and Risk Assessment modules of the DART, and (5) make a final determination on the participant's eligibility. Eligible participants will then be

randomized using the REDCap Randomization Module and scheduled for their first treatment visit. Neither participants nor study staff will be blinded to the comparator of interest or their group assignment.

Assessment Strategy and Measures

Overview

All assessments were chosen considering several factors including (1) sound psychometric properties, (2) ease of administration, (3) past use in similar clinical trials, and (4) brevity. All assessments will be facilitated remotely by the study therapist and will occur at baseline, each session, midtreatment (ie, after completion of 6 therapy sessions, up to 6 weeks post baseline), and 12 weeks post baseline. Self-report questionnaires will be completed by patients via REDCap survey with the study therapist present to answer any questions. Structured diagnostic interviews will be administered by study therapists and recorded in REDCap.

Specific Phobia Symptoms and Severity

The DART [57] is a modular semistructured interview corresponding with the *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders* [Fifth Edition]) [58]. Study therapists will administer the DART Specific Phobia Module, which provides designations of absent, subthreshold, and present. While the DART is a new tool, initial validation indicates excellent construct validity, discriminant validity, and convergent validity across modules [57,59].

The Severity Measure for Specific Phobias (SMSP) for adults [60] is a 10-item self-report questionnaire assessing the severity of specific phobia symptoms as they relate to the respondent's feared stimulus. Total scores range from 0 to 4 with higher scores indicating higher phobia severity. The SMSP has excellent internal consistency, criterion, and discriminant validity [61].

Other Mental Health Symptoms

Suicide and Homicide Risk

The DART-Risk Assessment Module [57] will be administered by study therapists to assess risk for suicidal and homicidal ideation, intention, and plans and guides the formation of safety plans where warranted.

Generalized Anxiety

The Generalized Anxiety Disorder-7 Scale (GAD-7) [62] is a 7-item self-report measure of anxiety symptom severity. Scores range from 0 to 15 with higher scores indicating higher anxiety severity. The GAD-7 is widely used and has demonstrated excellent internal consistency reliability and good convergent validity [63].

Depression

The Patient Health Questionnaire-8 (PHQ-8) [64] is an 8-item self-report measure of depression symptom severity. Scores range from 0 to 27 with higher scores indicating higher depression severity. The PHQ-8 has demonstrated excellent internal consistency reliability, good convergent validity, and specificity for depression diagnosis [65].

Treatment-Related Factors

Working Alliance

The Working Alliance Inventory [66] is a 10-item client-rated measure of therapeutic alliance. Total scores range from 1 to 5 with higher scores indicating a better therapeutic alliance. The WAI-SR has demonstrated excellent internal consistency, reliability, and good convergent validity [67].

Presence

The Single Item Presence Questionnaire (SIPQ) [68] is a 1-item self-reported measure of telepresence. Respondents are asked, "To what extent did you feel present in the environment, as if you were really there?" and provide ratings on a scale of 0 "not at all present" to 10 "totally present." The SIPQ has demonstrated good to excellent content, face validity, test-retest, convergent and divergent validity, and sensitivity [68].

Cybersickness

The Cybersickness in Virtual Reality Questionnaire (CSQ-VR) [69] is an 8-item measure of nausea, vestibular, and oculomotor cybersickness experienced in VR. Scores range from 6 to 27 with higher scores indicating higher levels of cybersickness. The CSQ-VR has demonstrated excellent internal consistency and convergent validity [70].

Client Satisfaction With Treatment

The Client Satisfaction Questionnaire-8 (CSQ-8) [71] is an 8-item client-rated measure satisfaction with treatment. Scores range from 8 to 32 with higher scores indicating higher satisfaction. The CSQ-8 has demonstrated good structural validity and internal reliability and is correlated with clinical outcomes and posttreatment functioning [72].

System Usability

The System Usability Scale (SUS) [73] is a 10-item self-report measure of the usability of a particular software system, platform, or app. Scores range from 0 to 100 with higher scores indicating better usability. The SUS has demonstrated good internal consistency reliability and is a useful tool for comparing system usability between 2 and more platforms.

Fidelity to the Treatment Protocol

All treatment sessions will be recorded and 20% (120/600) will be rated by the supervisor (principal investigator) using a treatment fidelity checklist based on the treatment manual. Refer to Table 1 for a summary of study assessments.

Table 1. Study assessments.

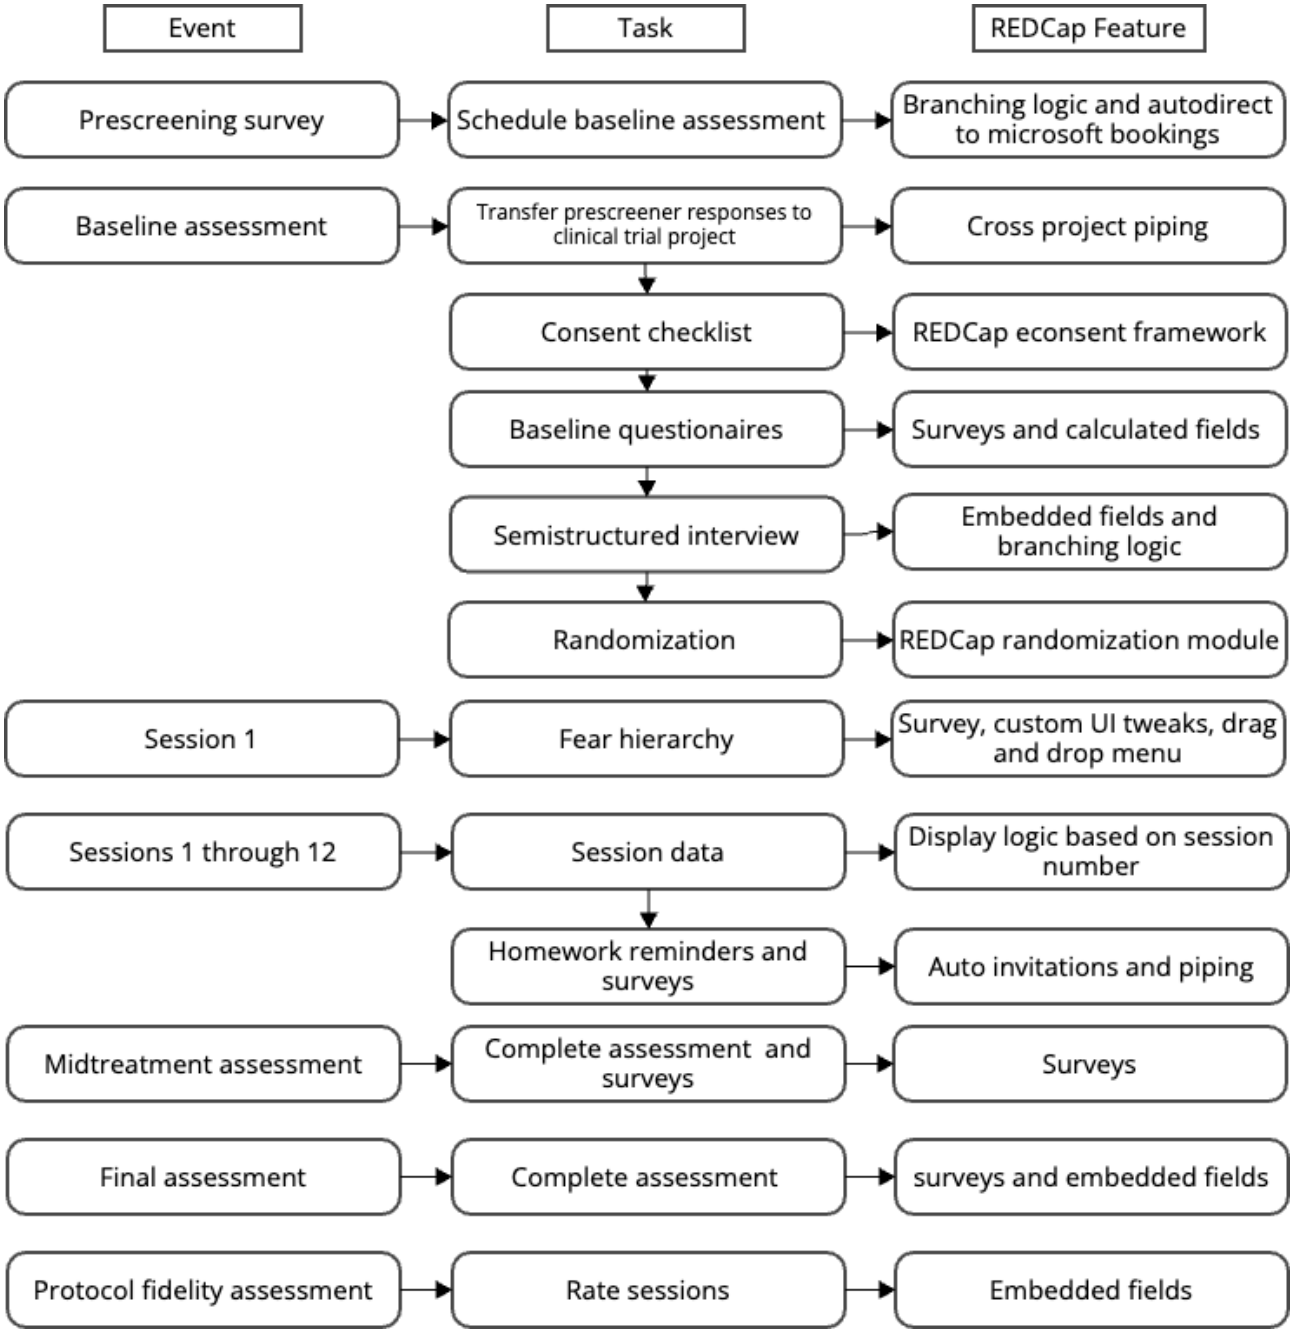
Domain	Measure	Time point				
		Pre	Baseline	Weekly	Mid	Post
Demographics	Demographics Questionnaire		✓			
Specific phobia diagnosis	Diagnostic Assessment Research Tool–Specific Phobia Module (DART-SP)		✓			✓
Specific phobia severity	Severity Measure for Specific Phobia-Adult (SMSP-A)	✓	✓		✓	✓
Risk	Diagnostic Assessment Research Tool–Risk Assessment (DART-RA)		✓			
Anxiety severity	General Anxiety Disorder-7 (GAD-7)		✓		✓	✓
Depression severity	Patient Health Questionnaire-9 (PHQ-9)		✓		✓	✓
Therapeutic alliance	Working Alliance Inventory- Short Revised (WAI-SR)				✓	✓
Presence	Single Item Presence Questionnaire (SIPQ)			✓		
Cybersickness	Cybersickness in Virtual Reality Questionnaire (CSQ-VR)			✓		
Treatment satisfaction	Client Satisfaction Questionnaire (CSQ-8)				✓	✓
Usability	System Usability Scale (SUS)				✓	✓

Partial Automation of Trial Data Collection Using REDCap

All feasibility trial data will be collected via 2 REDCap projects. The first REDCap project will include a survey to collect responses to the online prescreening questionnaire, which will include questions about basic eligibility criteria, the SMSP, and contact information. If potential participants meet the initial study eligibility criteria of the REDCap survey, they will be directed to a Microsoft Bookings page to schedule their baseline assessment, with automated reminders about the appointment 24 and 1 hours before the appointment.

The second, main REDCap project will facilitate all other data collection for the feasibility trial. Participants' online prebaseline screening questionnaire responses will be automatically transferred to the main clinical trial project using the REDCap piping function in preparation for the baseline assessment. After obtaining informed consent, supported by the REDCap e-Consent Framework feature, participants will be automatically directed to baseline questionnaire surveys, for which REDCap auto-calculates the scores. Following completion of the baseline assessment, the participant will be randomized to their respective treatment conduction using the Randomization Module. All therapy session data (ie, session number, date, time, and length), adherence checklist, clinical notes, and in-session exposure ratings will be entered into a REDCap form by the study therapist during each therapy session. Following the completion of each session, participants will receive automated survey invitations to complete homework assignments, which will be delivered on specific days during the following based on the session number, session date, and treatment condition. Weekly postsession questionnaires (ie, SIPQ and CSQ-VR) will be completed via REDCap surveys, displayed conditionally based on treatment condition (eg, the CSQ-VR will only be displayed to those in the Doxy.me VR condition). Specific REDCap automations and features used for each stage of the trial are included in Figure 2.

Figure 2. REDCap (Research Electronic Data Capture) automation and features. UI: user interface.



Ethical Considerations

The protocol was approved by the University of South Florida institutional review board (#006215). All participant data will be stored in the University of South Florida REDCap database and only study staff members have access to the REDCap project. All data exported for analysis from REDCap will be anonymized with only participant ID numbers. Participants will be compensated US $50 for completing the baseline, midtreatment assessment, and 3-month post baseline assessment at a total of US $150. Participants will be compensated using Tango e-gift cards.

Procedures to Ensure Participant Safety

Some questions asked during assessments and exposure exercises may cause participants distress, but this distress is expected to be similar to what participants would experience with routine care for specific fears or phobias. The study therapist will ensure that any questions causing distress are discussed with participants and provide them with techniques to reduce distress. A temporary increase in the severity of anxiety is expected at the beginning of exposure therapy, along with a gradual decline in severity over the course of treatment. If participants are distressed and unable to participate in the study following baseline assessments, or at the end of the study, participants feel that they need further treatment, the study therapist will provide a referral to therapists in the participants' local area. Referrals will be provided verbally to participants and the study therapist will follow up in 1 week via telephone to inquire as to the state of the referral and provide further assistance as necessary. If participants endorse suicidality or homicidality at any point during the study, we will follow the

standard operational procedures of the University of South Florida Department of Psychiatry and Behavioral Neurosciences requiring safety planning with the participant at risk and mandatory reporting responsibilities.

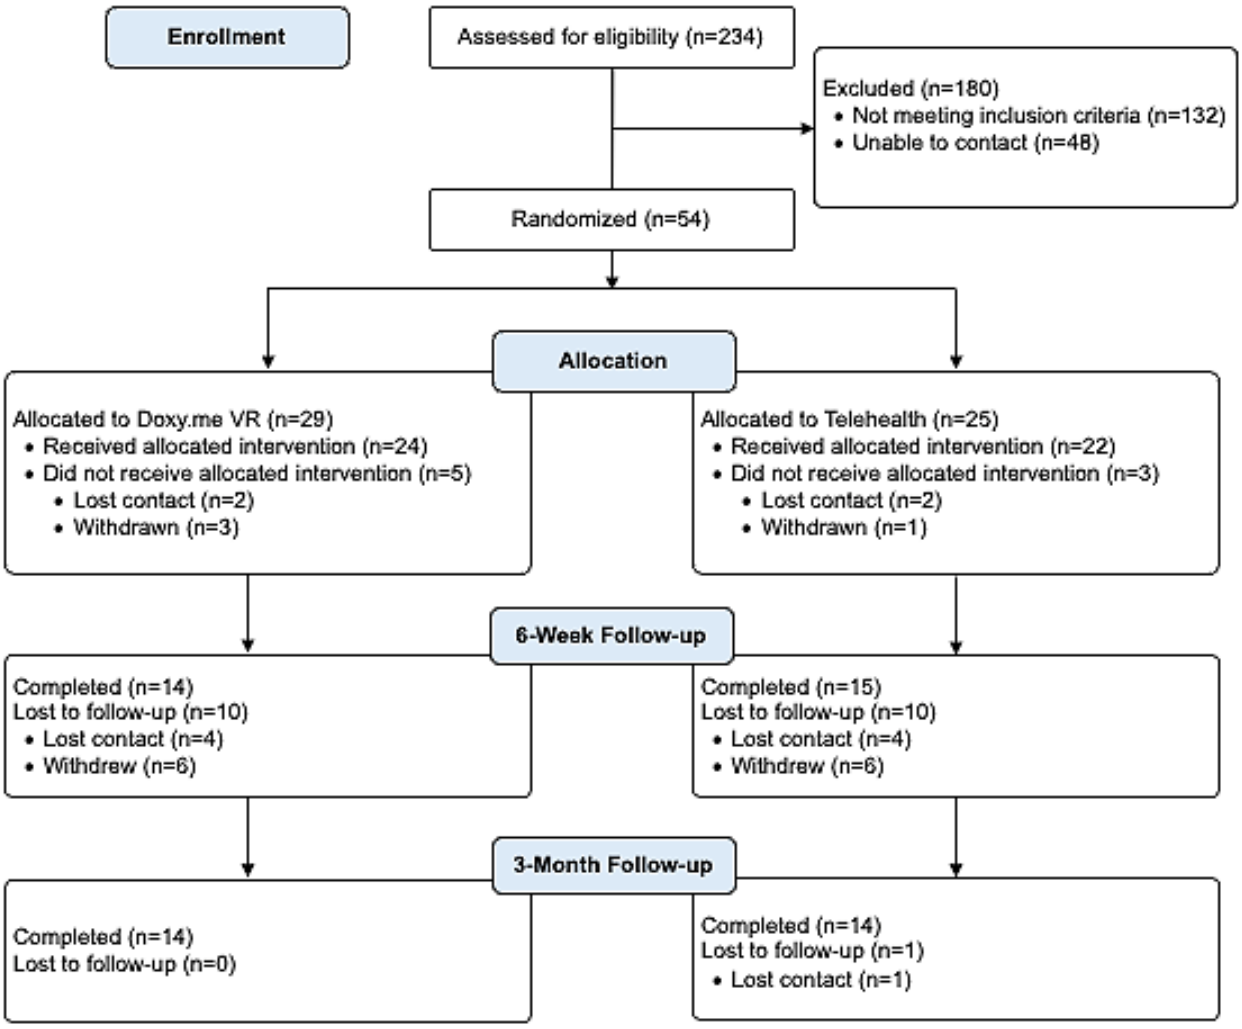
Data Analytic Plan

We will assess the feasibility of the proposed trial methodology using the following benchmarks: (1) 30 participants will be enrolled in months 1-9 of the trial, (2) ≥70% (21/30) of participants will be retained for 3-month follow-up assessments, (3) 70% (420/600) of weekly self-report assessments will be completed, and (4) treatment fidelity we will be ≥80%. The small sample size of this feasibility trial will prevent us from making conclusions about efficacy; however, a repeated measures ANOVA will be used to conduct a preliminary assessment of between-group differences in clinical outcomes while covarying for pretreatment scores. We will also conduct a preliminary examination of associations between study targets (ie, therapeutic alliance and presence) and homework adherence. Data obtained from these analyses will inform power analyses aimed at determining sample size requirements for a fully powered efficacy trial.

Results

The first participant was enrolled on October 25, 2023, and the last therapy session and 3-month post baseline assessment were completed on July 26, 2024. In total, 54 participants were randomized. Refer to Figure 3 for the CONSORT (Consolidated Standards of Reporting Trials) diagram and Multimedia Appendix 1 for the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist. Data analysis for the primary and secondary aims of the clinical trial will be completed and submitted by the end of the second quarter of 2025.

Figure 3. CONSORT diagram.



Discussion

Overview

There will be a growing need for innovative solutions to enhance the effectiveness of remote care as TMH services continue to evolve [1,16,17]. VR has tremendous potential to increase the efficacy of evidence-based practices that were originally designed for in-person treatment but are now delivered via TMH with increased regularity (eg, exposure therapy). This feasibility trial comparing exposure therapy via Doxy.me VR versus TMH for adults with an intense fear of dogs, snakes, or spiders fills an important gap in the nascent research on telemedicine-based VR exposure therapy. Using this protocol, we will assess the feasibility of our proposed study methodology in preparation for a fully powered efficacy trial. We anticipate meeting or exceeding these feasibility criteria, which will provide valuable insights into the feasibility of conducting a large-scale efficacy trial.

Principal Findings

As anticipated, we exceeded our recruitment goal of enrolling 30 or more participants in months 1-9 of the clinical trial by enrolling 54 participants during months 1-7. Data analysis will be completed and submitted by the second quarter of 2025 at which point we will report on the remaining feasibility results.

Comparison With Previous Work

Our study builds upon previous research demonstrating the efficacy of VR exposure to enhance treatment delivery. While there is significant support for in-clinic VR mental health therapy, evidence for telemedicine-based VR mental health is limited. Our study addresses this important gap by evaluating the feasibility and preliminary efficacy of exposure therapy via an innovative telemedicine-based VR clinic (ie, Doxy.me VR), thereby contributing to the nascent research on the use of VR in TMH.

Limitations

The small sample size proposed by this study limits the generalizability of our findings and prevents us from drawing conclusions about treatment efficacy. A large-scale efficacy trial will address this limitation.

Conclusions

This feasibility randomized controlled trial comparing Doxy.me VR versus TMH represents an important step toward leveraging VR technology to enhance the delivery of evidence-based treatments via telemedicine. By evaluating the feasibility and preliminary efficacy of exposure therapy via a telemedicine-based VR clinic, we will contribute a potential solution to common barriers to remotely delivered exposure therapy.

Future Directions

Future research will involve fully powered efficacy trials on telemedicine-based VR and the potential of this technology to improve treatment outcomes for mental health disorders.

Abstract

Background: A significant increase in eating disorder (ED) service waitlists has been observed in the past several years, exacerbating existing barriers to care (eg, long waitlists, scarcity of treatment centers, and positive beliefs surrounding pathology). Given that treatment delays have important clinical correlates (eg, entrenchment of ED pathology), exploring new methods of mental health service delivery for this population is of critical concern. App-based motivational interviewing (MI) delivered prior to the start of treatment has the potential to improve accessibility by simultaneously addressing structural (eg, travel costs) and individual (eg, low motivation) barriers to care. Despite the potential benefits, there remains a lack of empirically validated, ED-specific MI-based mobile apps. Evaluating the feasibility and acceptability of such interventions is a crucial first step before progressing to full-scale efficacy trials.

Objective: This multiphasic mixed methods study aims to develop and assess the feasibility and acceptability of MI-Coach: ED, a novel app designed to increase motivation among women waitlisted for ED treatment. Specifically, this study seeks to determine participant engagement levels, user satisfaction, and perceived usability of the app, as well as to explore preliminary trends in motivation and ED-related symptoms following app use.

Methods: Phase I adapted the content and interface of an existing app based on evidence-based principles (MI-Coach) for an ED population. Phase II pilot tested the app through a pre-post evaluation. Participants (n=30) aged 18 years and older were recruited from ED treatment waitlists in British Columbia, Canada. After completing baseline assessments evaluating demographic and clinical variables (eg, motivation, eating pathology, depression, and anxiety symptoms), participants were provided access to MI-Coach: ED for 1 month. Participants completed postintervention assessments and provided both quantitative and qualitative feedback on the app. Feasibility will be evaluated through the total number of participants recruited, study dropout rates, and engagement indicators (eg, modules completed) within the app. Acceptability will be assessed through self-report measures and semistructured exit interviews, which will explore user experiences, perceived benefits, and barriers to app engagement. Additionally, exploratory analyses will examine changes in motivation and ED symptoms before and after the intervention.

Results: The MI-Coach: ED app has been developed, and recruitment was initiated in November 2022 and terminated in May 2024. Results are being analyzed and will be submitted for publication in May 2025.

Conclusions: This study has the potential to transform ED service delivery and mitigate the impacts of existing treatment barriers for this population. By leveraging a digital MI-based intervention, MI-Coach: ED could serve as a scalable and accessible pretreatment tool, helping to bridge the gap between initial help-seeking and formal ED treatment. Findings from this study will inform the refinement of the intervention and recruitment strategies for future large-scale efficacy trials.

Introduction

Eating disorders (EDs) are serious, life-threatening psychological illnesses that involve disturbances surrounding body image, emotion regulation, and eating behaviors [1,2], resulting in a number of deleterious health consequences and high levels of psychiatric comorbidity [3-5]. Despite the severity of these disorders, ED populations are significantly less likely to access mental health services compared to those with other disorders [5,6]. For instance, wait times exceeding 12 months for ED-specific services have been reported in Ontario, Canada, and nonprofit organizations have observed a 2-fold increase in requests for peer-support services following the COVID-19 pandemic [7]. In this regard, several treatment barriers have been identified limiting access to ED treatments and services. As EDs require specialized forms of care, treatment centers are typically few in number, necessitating significant travel time and associated costs (eg, costs related to travel and childcare and loss of income due to sick leave), and often resulting in long waitlist durations [6]. Further, ambivalence regarding treatment is common among ED populations, with motivation for recovery often in conflict with other factors, such as engaging in ED behaviors to cope with difficult emotions or to provide a sense of control [8-10].

Unfortunately, treatment delays are associated with adverse outcomes, such as reductions in pretreatment levels of motivation and poorer long-term prognosis. Early intervention has been associated with improved treatment outcomes following discharge, longer durations between relapses, and improvements in related psychological symptoms such as depression and anxiety [11]. Recent efforts to bridge treatment barriers and improve outcomes for this population include the delivery of brief interventions such as motivational interviewing (MI) prior to the start of formal treatment. Initially developed by Miller and Rollnick [12] to address ambivalence within substance use treatment, MI is a person-centered approach that aims to strengthen the individual's intrinsic motivation to change [13]. A recent systematic review conducted by Denison-Day et al [8] found substantial support for the use of MI interventions for individuals with EDs, with a majority (74%) of the studies reviewed reporting significant and long-term improvements in motivation as a result of MI interventions compared to passive interventions, such as psychoeducation. Broadly, studies report that brief MI interventions lead to improvements in motivation, self-esteem, depressive symptoms, and positive treatment outcomes (eg, greater engagement in treatment), particularly when delivered prior to the start of formal treatment [14-16].

Despite the potential for pretreatment MI interventions to address individual treatment barriers, they are typically conducted through in-person, face-to-face sessions [8,14,16,17]. In-person interventions may not adequately address structural treatment barriers, such as costs and scarcity of treatment providers. In order to address this issue, internet and communications technology (ICT)–based interventions have been proposed as a low-cost and accessible form of delivering ED interventions [5,18-20]. Apps in particular show potential in the delivery of pretreatment MI interventions, as they are easy to use, require low effort, and become habitual over time. Further, unlike other ICT-based interventions, they have high hedonic motivation (ie, they are enjoyable to use), which increases their use and adoption [21,22]. In addition, the digital components embedded within apps (eg, modules, graphic design, and diverse multimedia content) have been shown to significantly improve adherence to interventions and reduce dropout rates [23].

Despite preliminary findings suggesting that apps may be an acceptable means of delivering ED services, there is a paucity of effective, evidence-based apps available for use [24-27]. Most publicly available app interventions are based on CBT and behavioral self-monitoring principles but demonstrate limited efficacy compared to traditional delivery methods [24,28]. However, considering the accessibility of apps and their wide adoption in various health and social contexts [29], they may be an effective mode of delivery for pretreatment MI contexts. Help-seeking individuals waiting for formal services likely do not have access to in-person treatment options, despite their urgent need for services. Further, as they have not yet started formal ED treatment, receiving a pretreatment MI intervention may significantly improve treatment outcomes. For example, such interventions may increase motivation to stay on the waitlist and adhere to treatment once services are received [30]. An app-based MI intervention thus has the potential to simultaneously address structural and individual treatment barriers. Despite the potential benefits, to date, no research has investigated the use of app-based MI pretreatment interventions for EDs.

The proposed study aims to adapt and pilot-test MI-Coach, a widely available app-based MI platform, for individuals on ED treatment waitlists. Created by Resiliens Inc, MI-Coach is an evidence-based self-help app developed in collaboration with a registered clinical psychologist. The app was adapted for use within an ED pretreatment context. Furthermore, this will be the first study to investigate whether an app-based MI pretreatment intervention improves clinical symptoms, motivation for treatment, and openness to change for individuals while they wait for ED treatment.

Methods

Hypotheses

This project is guided by the technology acceptance model (TAM), which theorizes that an ICT's acceptability is determined by its perceived ease of use and usefulness [31]. It is thus hypothesized that greater perceived usefulness and ease of use of the MI-Coach: ED app will lead to greater use and engagement with the app, and subsequently, improved treatment

outcomes. It is also hypothesized that participants will experience an improvement in their motivation to recover from an ED following use of the app. In addition, the app's acceptability and feasibility will be examined, as well as the possible impacts of other clinical variables (eg, depression, anxiety, BMI, and ED severity) on motivation to recover.

Ethical Considerations

Ethics approvals were granted by the University of British Columbia Okanagan Campus' Behavioral Research Ethics Board (H22-02046) on October 4, 2022, and by the Vancouver Coastal Health Research Institute (V22-02046) on October 10, 2023. All eligible participants provided informed consent electronically through the secure web-based platform Qualtrics prior to enrollment, after receiving detailed information about study procedures, potential risks and benefits, data confidentiality, and voluntary participation. Participants were informed of their right to withdraw from the study at any time without penalty. Participant privacy was maintained by storing data on password-protected university servers accessible only to research personnel. All identifying information was stored separately from the study data. Participants received compensation of up to CAD $40 (≈US $28.41) in the form of digital gift cards. Compensation was clearly outlined in the informed consent form and was structured to avoid influencing participation or app use.

Study Design

The current pilot test evaluation follows a naturalistic pre-post design. A pilot test framework was chosen to assess the initial feasibility and acceptability of the app and to identify any potential issues with the study design and delivery format prior to evaluating the app's efficacy at a larger scale [32]. The MI-Coach: ED app was designed to improve motivation in women-identifying people waiting for formal ED treatment and will be pilot-tested in the province of British Columbia, Canada. Qualitative and descriptive data were collected to determine the acceptability and feasibility of the MI-Coach: ED app.

Study Population

Sample Size Estimation

Given the focus of this study on the acceptability and feasibility, rather than the efficacy, of the MI-Coach: ED app, formal analytic methods were not used to estimate the prehoc sample size. In keeping with previous feasibility studies in the ED field [14,33,34] and pilot study guidelines, which suggest that modest sample sizes based on the pragmatics of recruitment are sufficient when evaluating the processes, feasibility, and preliminary acceptability of novel interventions [32,35], a sample size of 30 participants was selected, recruited while they wait for ED services and treatments in British Columbia, Canada. Additionally, it was determined that qualitative interviews would be conducted with interested participants on a rolling basis until thematic saturation is reached [36].

Participant Recruitment

ED treatment providers and clinicians located in British Columbia were contacted by email and asked to distribute study recruitment flyers providing an overview of the study, incentives, and instructions to contact the study team to indicate their interest to clients on their waitlists (Multimedia Appendix 1). To address existing barriers to ED treatment (eg, logistical challenges and clinician burnout [6,37]) and research [38], a multipronged approach to recruitment has been used in previous studies [15,39], whereby clinician-based referrals are supplemented by web-based recruitment and partnerships with peer support organizations. As such, clinician-based referrals were supplemented by web-based recruitment strategies, including postings on the National Eating Disorder Information Center website and social media, as well as partnerships with peer support organizations. Additionally, a research partnership was established with a local provincial health authority, the Vancouver Coastal Health Eating Disorders Program, which embedded the study flyer as part of an initial resource package provided to patients newly added to their waitlist. Given the findings that recruitment strategies influence sample characteristics and engagement [38], this multipronged approach aimed to maximize the accessibility of the study and diversity within the study sample.

Eligibility Criteria

Eligibility criteria were (1) being on a waitlist to receive services for an ED-specific concern and not for a separate mental disorder in British Columbia, (2) being at least 18 years of age, (3) self-identifying as a woman, (4) fluency in written and spoken English, (5) meeting the criteria for a diagnosis of a threshold or subthreshold ED (ie, BN, AN-R, AN-BP, BED, and OSFED), (6) absence of psychosis or diagnosis of a schizophrenia-spectrum disorder, and (7) absence of cognitive impairments or sensory deficits that may interfere with technology use (eg, hearing impairments and recent traumatic brain injury).

Intervention

MI-Coach is a self-help app created by Resiliens Inc [40] targeting motivation to engage in health behavior change (eg, exercising, smoking cessation, and sleep hygiene), and is widely available on both Apple and Android app stores. Developed in collaboration with a clinical psychologist and MI expert from the University of Queensland (Stan Steindl, PhD), the app features eight modules, consisting of over 35 lessons led by a registered clinical psychologist with accompanying exercises. In addition, the app includes short articles, mood and behavior assessments, mindfulness-based audio tracks, summary screens and analytics, community-based discussion groups, and the ability to communicate directly with a trained mental health professional.

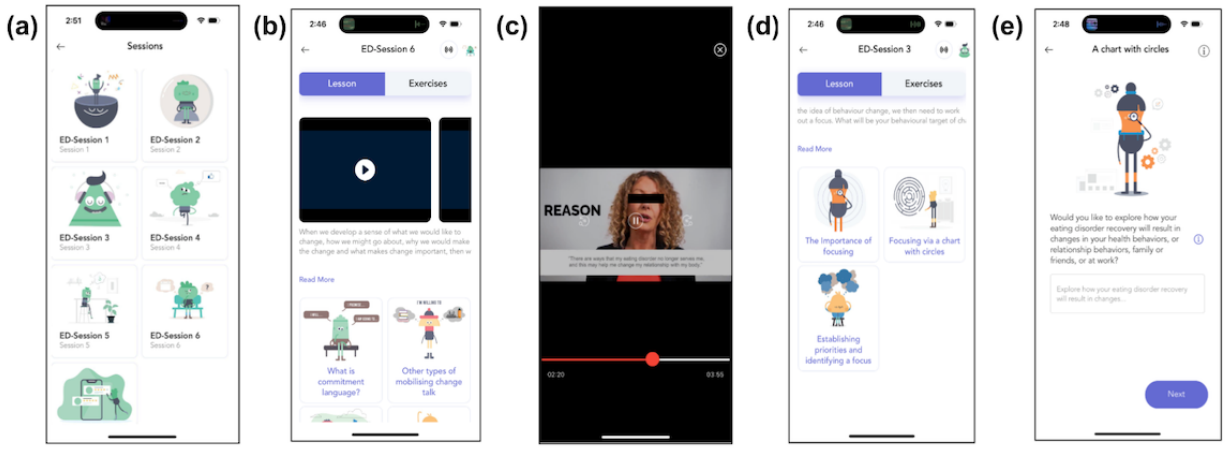
For the purposes of this study, the content of MI-Coach was tailored for an ED population. In line with best practices for developing ED-specific digital interventions [17,30,41], an in-depth review of potentially iatrogenic or triggering content in the existing app was identified. Specifically, content referring to weight loss or health-focused exercise goals was identified, which prior research suggests may inadvertently reinforce disordered eating behaviors [28,30,37,42]. Subsequently, a literature review was conducted to identify MI topics and ED behavior change goals used in previous interventions, such as exploring reasons for and against pursuing treatment, validating

the difficulties of addressing ED pathology, and identifying values and goals driving ED recovery efforts [11,17,30,41].

Following approaches outlined in previous research [15], the research team then performed iterative content analyses to remove or reframe any references misaligned with ED recovery principles (eg, shifting from weight-centric to motivation-centered goals that explore the individual's reasons for seeking treatment, and the inclusion of topics such as ambivalence and identification of goals and values relevant to recovery). The overall structure and MI principles used in the original app were retained given their demonstrated effectiveness within an ED context [8]. Throughout this process, informal stakeholder consultations were conducted with ED-specialized clinicians involved in the project, who verified the appropriateness of the revised app content. All video lessons were subsequently refilmed using the University of British Columbia Okanagan's recording studio and equipment. The new videos featured a clinical psychologist with ED treatment expertise to reduce discrepancies between the original and adapted app content (eg, clinical expertise and years of training). Examples of the MI-Coach: ED interface are provided in Figure 1.

Once the adaptation of app content was completed, a new section was built into the interface of the existing MI-Coach app by technological partners (Resiliens Inc) to house the adapted content. Several components of the base app (ie, assessments, audio tracks, analytics, discussion groups, and communication with the mental health professional) were removed to reduce the scope of the project and to protect participant confidentiality. The final adapted MI-Coach: ED app consisted of seven modules (Multimedia Appendix 2) targeting motivation to engage in ED recovery behaviors (eg, help-seeking, values exploration, and self-acceptance) covering the following topics sequentially: ambivalence and behavior change, self-acceptance and compassionate motivation, exploring possible behavior change goals, sustain and change talk, commitment language, and relapse prevention.

Figure 1. Screenshots of the MI-Coach: ED interface illustrating (a) the home screen with session modules, (b) example module content, (c) brief videos, (d) examples of exercises available per module, and (e) example exercise content. Each feature targets ED-specific barriers such as ambivalence or low treatment motivation. ED: eating disorder.



Outcomes and Measures

The primary outcomes that will be evaluated are the overall acceptability and feasibility of the MI-Coach: ED (Multimedia Appendix 3). Feasibility will be assessed through attrition rates throughout the study period, frequency of app use, and module completion. Acceptability will be assessed through qualitative and quantitative feedback from participants through semistructured interviews and self-reports. Additionally, exploratory analyses will be conducted regarding the impacts of the MI-Coach: ED app on motivation and associated clinical characteristics.

Self-reported demographic data, including gender identity, age, level of education, ethnicity, and socioeconomic status were collected using Qualtrics, a web-based and secure data collection platform. Additionally, clinical data (ie, weight and height, history of ED treatment, age of ED onset, presence of cognitive difficulties, sensory deficits, history of traumatic brain injury, other mental health comorbidities, and ED waitlist experiences) was collected. The Sick, Control, One, Fat, and Food questionnaire [43], a brief screener that identifies the presence of common ED symptoms, was used to determine eligibility prior to enrollment. Clinical characteristics (ie, eating pathology, recovery motivation, body dissatisfaction, depression, and anxiety symptoms) were evaluated through several self-report questionnaires administered at baseline and posttest, including the Eating Disorder Examination Questionnaire (EDE-Q) [44], the Readiness and Motivation for Change Questionnaire (RMQ) [45], the Body Shape Questionnaire (BSQ) [46], the Patient Health Questionnaire-9 (PHQ-9) [47], and the 7-item General Anxiety Disorder Scale (GAD-7) [48]. Additionally, technological literacy was evaluated at baseline using the Mobile Device Proficiency Questionnaire [49] and the eHealth Literacy Scale [50].

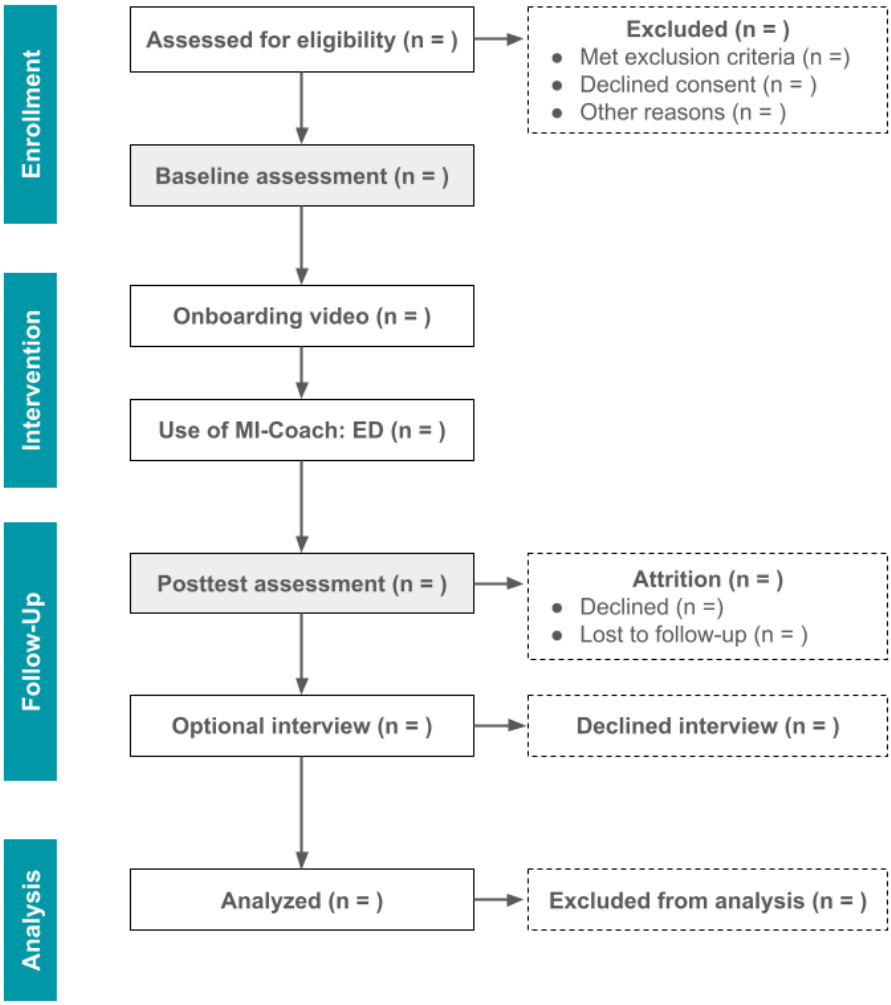
Quantitative measures of feasibility and acceptability of the MI-Coach: ED app were assessed using an adapted version of the TAM Questionnaire [31] and the user version of the Mobile App Rating Scale (uMARS) [51]. The adapted version of the TAM questionnaire includes changes to each item to better fit the research question and sample characteristics of this study (eg, "Using CHART-MASTER in my job would enable me to

accomplish tasks more quickly" was modified to "Using MI-Coach: ED allowed me to access mental health services more quickly"). An optional semistructured interview was conducted with interested participants to assess their experiences with the app and to further evaluate the feasibility and acceptability of MI-Coach: ED.

An overview of participant flow is provided in Figure 2. Participants were recruited between November 2022 and April 2024. Clinicians and administrators working in a range of ED treatment settings (eg, provincial health authorities, nonprofit charities, and private practice clinics) were contacted via email and asked to share the recruitment advertisement with clients on their waitlists. Interested participants were asked to communicate with the study team via email to enroll in the study. Once initial contact was established, a 15-minute telephone screener was conducted by the study team to assess participants' eligibility for the study and to provide additional details regarding the study. The Sick, Control, One, Fat, and Food questionnaire was used to evaluate the presence of ED symptoms. Once eligibility was established, consent (Multimedia Appendix 4) and baseline measures were collected through Qualtrics, including a demographics questionnaire, the EDE-Q, the RMQ, the PHQ-9, the GAD-7, and the BSQ. Following this, an onboarding session was conducted through a secure videoconferencing platform (ie, Zoom), during which participants were given a demonstration on downloading and using the app and provided their log-in information.

The subsequent pilot-test portion of the study consisted of a four-week period during which participants used the app in a naturalistic way. Following study completion, participants were compensated CAD $10 (≈US $7.10) for each study portion completed (ie, baseline questionnaire package, onboarding session, posttest questionnaire package, and exit interview), receiving up to CAD $40 (≈US $28.41) through the Tango Card rewards platform. To reduce the impact of possible confounds (eg, financial motivation), participants were informed that their compensation would not be impacted by their app use during the pilot test phase and that there are no minimum requirements for app use. Once the pilot test was completed, a second brief consent form (Multimedia Appendix 5) and posttest questionnaires assessing self-reported clinical features (ie, the EDE-Q, RMQ, PHQ-9, GAD-7, and BSQ) and feedback regarding the app (ie, the adapted TAM-Q and uMARS) were completed. Finally, participants were invited to participate in a videoconferencing-based exit interview to provide additional feedback on their experience with the study author. The semistructured interview guide (Multimedia Appendix 6) was used as an outline to standardize the interview process across participants [52].

Figure 2. Participant flow diagram.



Statistical Analysis

Prior to analysis, interview audio recordings will be transcribed verbatim by 2 trained research assistants and verified by the primary researcher (AH-A). Qualitative interview transcripts will be analyzed using the NVivo software package (version 12; QSR International), to assess in-depth feedback regarding MI-Coach: ED's feasibility and acceptability. A thematic content analysis will be conducted to analyze the qualitative responses from the open-ended uMARS questionnaire and semistructured interview data using Braun and Clarke's [36] framework. A bottom-up theoretical approach was used, in which the analysis was driven by the data generated through the semistructured interviews [36,53].

Additionally, quantitative analyses will be conducted using the R statistical package (version 4.2.0; R Core Team). Descriptive analyses of posttest feedback questionnaires, attrition data, and sessions completed will be used to determine the feasibility and acceptability of the MI-Coach: ED app. Means, SDs, ranges, and percentages will be calculated for all descriptive variables (ie, age, ethnicity, BMI, height, and weight), and total and mean scores will be calculated for app acceptability measures. Overall app use (ie, number of modules completed, days that the app was used, assessments and exercises completed, and logins) will be calculated using in-app data provided by Resiliens Inc.

Finally, tests of clinical significance [54] will be used to evaluate changes in clinical presentation across time points. The following categorizations will be used to identify whether change is clinically significant: reliably improved, in which there is reliable change and the clinical cutoff is no longer met; reliably deteriorated, in which there is a reliable change in the disordered direction and the individual's score falls within the clinical range; and unchanged, in which neither criteria of the Jacobson-Truax method are met [54,55]. Finally, exploratory growth curve analyses will be used to model individual participants' change trajectories across the 4-week pilot test period [56].

Results

The MI-Coach: ED app has been developed and is available for download and use. Recruitment was initiated in November 2022 and terminated in May 2024. Data analysis is currently underway, and we anticipate reporting results through peer-reviewed academic publications in May 2025.

Discussion

Anticipated Results

This study aimed to evaluate the feasibility and acceptability of MI-Coach: ED, an app designed to support motivation for ED recovery among individuals on treatment waitlists. It is anticipated that the intervention will be feasible to implement, with a high rate of participant engagement with the app, and that MI-Coach: ED would be perceived as an acceptable and useful tool for supporting motivation during the waitlist period. Prior research suggests that digital mental health interventions targeting ED populations are generally acceptable and feasible to users, particularly when they incorporate evidence-based therapeutic principles such as MI [15,28]. Additionally, app-based self-help interventions have demonstrated high engagement rates, which MI-Coach: ED was designed to include [23,27]. Furthermore, we anticipate that exploratory analyses will demonstrate preliminary improvements in motivation and ED-related symptoms following app use, given findings that brief MI-based interventions can enhance motivation for change, improve treatment engagement, and reduce ambivalence in ED populations [8,14,16,17]. As motivation is a key predictor of ED treatment outcomes [11], even small gains during the waitlist period could have meaningful clinical implications.

Conclusions

Individuals with EDs face substantial barriers to accessing appropriate care, despite their urgent need for treatment [37,57,58]. Though both MI and app-based interventions have been suggested as ways to support treatment-seeking ED patients, in isolation, these interventions may not adequately address treatment barriers. For example, in-person MI interventions may be inaccessible to individuals in rural and remote locations, and interventions currently delivered through apps have limited evidence to support their efficacy [24]. As such, this study aims to simultaneously address individual and structural treatment barriers by developing and pilot-testing an MI-based app intervention for women on waitlists for ED treatment.

Providing app-based interventions to individuals who are waiting for ED treatment has the potential to improve treatment outcomes and represents a largely barrier-free, positive-approach method of addressing the growing problem of wait times for mental health care. Although this pilot study focuses on a modest sample, existing intervention frameworks and ED-focused digital interventions demonstrate how pilot studies can be used to guide the adaptation and evaluation of novel interventions through large-scale clinical trials [15,20,28]. For example, collecting and implementing end user feedback prior to formal efficacy testing has been suggested to ensure that the final intervention is used by the targeted population [28]. Furthermore, exploratory analyses on motivation and ED-related symptoms will help identify meaningful clinical outcome measures and establish preliminary effect size estimates to guide the design and power calculations for a full-scale randomized controlled trial. Additionally, by collecting demographic and digital literacy data, this study will provide insights into the app's accessibility across diverse populations and inform potential adaptations to increase inclusivity. Future evaluations will also aim to follow participants into formal psychological treatment to assess the long-term clinical impact of pretreatment MI interventions.

Given that prior research has demonstrated that multimodal recruitment modalities can enhance sample diversity, improve engagement, and ensure the inclusion of individuals with varying levels of symptom severity in digital intervention studies [38], data collected through this pilot study will be particularly valuable in refining future participant engagement strategies. In this regard, feasibility data collected from this study (including recruitment and retention rates, participant engagement with the app, and qualitative user feedback) will directly inform refinements to MI-Coach: ED and recruitment

methods for subsequent large-scale efficacy evaluations, ensuring that the intervention is optimally structured for broader implementation. For example, future studies may continue to use a multipronged approach, such as the use of social media campaigns to supplement clinician referrals [38], and partnerships with provincial authorities may be expanded to integrate study recruitment directly into clinical workflows given their success in prior research [59]. As such, this pilot study serves as a crucial step in optimizing MI-Coach: ED for large-scale implementation and has the potential to provide tangible psychological support to its participants while contributing to the reconceptualization of ED service delivery.

Acknowledgments

This research stream is funded by both the Canadian Institutes of Health Research and the Social Sciences and Humanities Research Council as part of the Canadian Triagency funding program. Additionally, we would like to extend our gratitude toward Resiliens Inc for providing access to their app and offering technological support during the development of MI-Coach: ED. However, it is important to note that they did not directly fund or provide monetary incentives to the research team for this line of research.

Authors' Contributions

AH-A and ML are the primary authors responsible for the development of the underlying research, and all named authors contributed to the drafting of the manuscript.

Abstract

Background: A strong association exists between sleep duration and glycemic control in patients with type 2 diabetes (T2D), yet convincing evidence of a causal link remains lacking. Improving sleep is increasingly emphasized in clinical T2D treatment guidance, highlighting the need for effective, scalable sleep interventions that can affordably serve large populations through mobile health (mHealth).

Objective: This study aims to pilot an intervention that extends sleep duration by modifying bedtime behavior, assessing its efficacy among short-sleeping (≤6 hours per night) patients with T2D, and establishing robust evidence that extending sleep improves glycemic control.

Methods: This randomized, single-blinded, multicenter study targets 70 patients with T2D from 9 institutions in Japan over a 12-week intervention period. The sleep extension intervention, BedTime, is developed using the Theory of Planned Behavior (TPB) and focuses on TPB's constructs of perceived and actual behavioral control (ABC). The pilot intervention combines wearable actigraphy devices with SMS text messaging managed by human operators. Both the intervention and control groups will use an actigraphy device to record bedtime, sleep duration, and step count, while time in bed (TIB) will be assessed via sleep

diaries. In addition, the intervention group will receive weekly bedtime goals, daily feedback on their bedtime performance relative to those goals, identify personal barriers to an earlier bedtime, and select strategies to overcome these barriers. The 12-week intervention period will be followed by a 12-week observational period to assess the sustainability of the intervention's effects. The primary outcome is the between-group difference in the change in hemoglobin A_{1c} (HbA_{1c}) at 12 weeks. Secondary outcomes include other health measures, sleep metrics (bedtime, TIB, sleep duration, total sleep time, and sleep quality), behavioral changes, and assessments of the intervention's usability. The trial commenced on February 8, 2024, and is expected to conclude in February 2025.

Results: Patient recruitment ended on August 29, 2024, with 70 participants enrolled. The intervention period concluded on December 6, 2024, and the observation period ended on February 26, 2025, with 70 participants completing the observation period. The data analysis is currently underway, and results are expected to be published in July 2025.

Conclusions: This trial will provide important evidence on the causal link between increased sleep duration and improved glycemic control in short-sleeping patients with T2D. It will also evaluate the efficacy of our bedtime behavior change intervention in extending sleep duration, initially piloted with human operators, with the goal of future implementation via an mHealth smartphone app. If proven effective, this intervention could be a key step toward integrating sleep-focused mHealth into the standard treatment for patients with T2D in Japan.

Introduction

Worldwide, approximately 537 million people aged 20-79 years have diabetes [1]. Diabetes is a serious public health concern, significantly impacting health care expenditures and human life, causing 4.2 million deaths annually [2,3]. Type 2 diabetes (T2D) is difficult to cure once it develops and, if left untreated, can lead to complications such as cardiovascular disease and microvascular damage [4].

T2D treatment guidelines include both pharmacological and lifestyle modification elements. Traditionally, lifestyle modifications have focused on diet and exercise, but recently, improving sleep in patients with T2D has gained prominence [5,6]. Some patients with T2D suffer from sleep disorders, including obstructive sleep apnea, restless leg syndrome, and insomnia, for which treating the underlying disorder is the appropriate approach [7]. Sleep quality is associated with T2D risk [8], and interventions to improve sleep quality have shown effectiveness [9]. Many patients with T2D do not get sufficient sleep, experiencing what is termed *short sleep*. Definitions of short sleep vary across studies, ranging from 6 or fewer hours per night to less than 4.5 hours per night [10]. This issue is widespread, with data indicating that 39.4% of patients with T2D in Japan sleep fewer than 6.4 hours per night [11].

There is strong evidence that short sleep is associated with an increased risk of T2D and poorer glycemic control. In Japanese patients with T2D, short sleep is linked to higher hemoglobin A_{1c} (HbA_{1c}) levels [11], with a meta-analysis indicating a 0.23% difference in HbA_{1c} due to short sleep [12]. Prospective studies have also shown an increased risk of T2D associated with short sleep [8]. Plausible biological mechanisms support these findings, as sleep extension has been shown to reduce energy intake [13], while sleep restriction worsens insulin sensitivity [14].

Surprisingly, there is a lack of strong evidence for causality—specifically, increasing sleep duration in short-sleeping patients with T2D without sleep disorders leads to improvements in HbA_{1c} levels. Recent meta-analyses [15,16] found limited and conflicting evidence on the effect of sleep interventions on glycemic control. Some studies have investigated interventions for patients with T2D with insomnia [17,18]. One study examined an educational intervention for patients with T2D, including those with short sleep, but results from a published abstract [19] are unclear, and no full paper has been published. Two related studies used cognitive behavioral therapy to improve HbA_{1c} by enhancing sleep quality rather than duration [20,21]. Overall, strong evidence is lacking to support the idea that increasing sleep duration in short-sleeping patients with T2D without sleep disorders leads to improved HbA_{1c} levels.

Numerous studies have successfully increased sleep duration in various populations. A recent meta-analysis of 42 studies found that extending time in bed (TIB) has the greatest potential to modify sleep, with direct interventions (ie, scheduling a longer period in bed) resulting in an average increase of 1 hour and 23 minutes in sleep duration [22].

Mobile health (mHealth) interventions, such as mobile phone apps supporting self-management, have been shown to be effective in increasing physical activity, reducing body weight [23,24], and improving glycemic control [25,26]. However, to our knowledge, no mHealth apps have been designed specifically to improve sleep duration in short-sleeping patients with T2D without sleep disorders. Personalization of intervention components has been shown to enhance patient motivation and engagement with the app [27]. Several studies

have found that tailored interventions are more effective at changing health behaviors than nontailored ones [28,29]. Moreover, interventions based on behavior change theory have been shown to be more effective than those lacking a theoretical foundation [30], with those based on the Theory of Planned Behavior (TPB) being particularly effective [31]. TPB emphasizes intention and ABC as key determinants of behavior, with perceived behavioral control (PBC)—similar or identical to Bandura's self-efficacy—playing a central role in shaping intention [32,33].

To address the lack of evidence on whether improvements in sleep duration lead to better glycemic control, we developed a pilot study of a personalized mHealth intervention, BedTime, designed to increase sleep duration and assess its impact on glycemic control in short-sleeping patients with T2D. The intervention is based on the TPB framework to promote behavior change toward earlier bedtimes. This trial aims to evaluate the efficacy of the BedTime approach in a 12-week, single-blind, randomized controlled pilot trial. The specific research objectives and hypotheses are as follows:

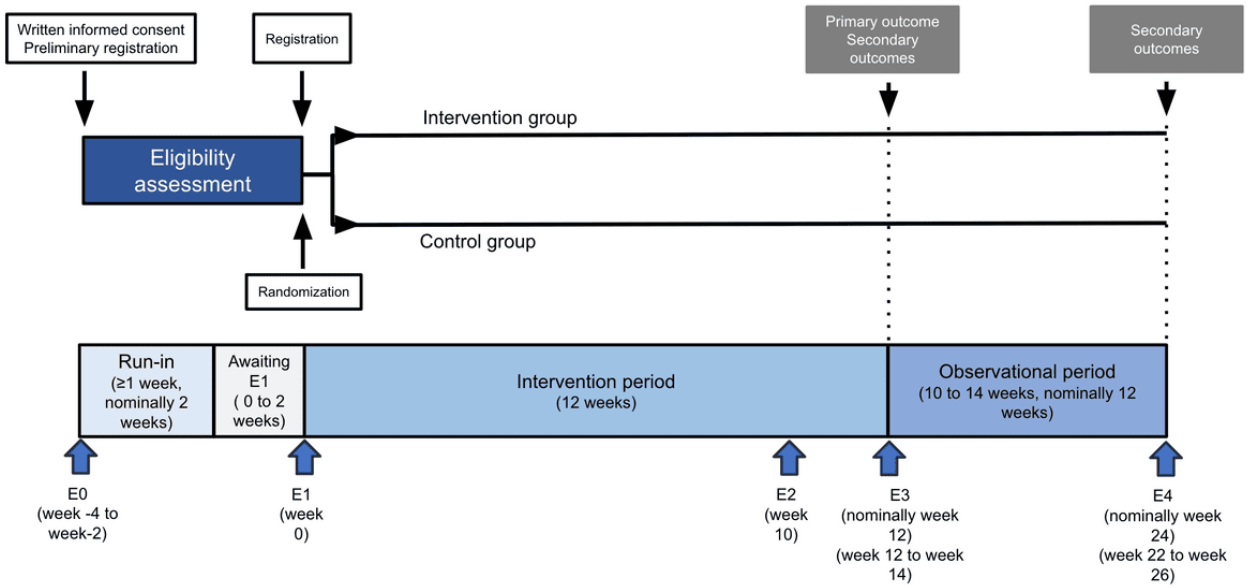
- Objective 1: To evaluate the efficacy of the BedTime approach in shifting patients to an earlier bedtime, as measured by daily bedtime reporting, and increasing sleep duration, as measured by daily actigraphy.
- We hypothesize that, by the end of the intervention, the intervention group will show statistically significant changes in bedtime and sleep duration compared with the control group.
- Objective 2: To evaluate the efficacy of the BedTime approach in reducing HbA_{1c} levels.
- We hypothesize that, by the end of the intervention, the intervention group will show a statistically significant reduction in HbA_{1c} levels compared with the control group.

Methods

Study Overview

This single-blinded, multicenter pilot study is a 2-arm randomized controlled trial designed to evaluate the efficacy of the BedTime mHealth intervention in promoting earlier bedtime behavior and increasing sleep duration among short-sleeping patients with T2D. The trial will be conducted and reported in accordance with CONSORT (Consolidated Standards of Reporting Trails) guidelines. As outlined in Figure 1, the study begins with recruitment (E0), followed by a baseline measurement period (nominally 2 weeks, but at least 7 days), and then randomized assignment to intervention and control groups (E1). Patients in the intervention group will record their daily bedtime, sleep duration, and step count using an actigraphy device, with TIB assessed via sleep diaries. They will receive weekly bedtime goals, daily feedback on their bedtime performance relative to these goals, and guidance to identify personal barriers to an earlier bedtime along with strategies to overcome them. The control group will also record daily bedtime, sleep duration, and step count using an actigraphy device, with TIB assessed via sleep diaries, but they will receive no feedback and will not be assigned goals. During week 10 of the intervention period (E2), the intervention group will complete a TPB questionnaire. The intervention will last for 12 weeks, followed by end-of-intervention assessments of the primary and secondary outcomes (E3). After the intervention period, there will be an observation phase, nominally 12 weeks in length, but its duration will depend on the date of the final visit (E4), which may occur between 10 and 14 weeks after the intervention ends. The study will be conducted over 1 year, from February 8, 2024, to January 22, 2025.

Figure 1. Overview of the study timeline.



Intervention Design

Some features of the intervention are shared by both the control and intervention groups, while others are unique to the intervention group (Table 1). This mHealth intervention incorporates a physical activity monitoring system (iAide2; Tokai) and a researcher-designed paper diary for patients in both groups. The iAide2 measures activity intensity levels, skin

temperature, and pulse rate [34,35] to assess step count and sleep, providing minute-by-minute wake/sleep assessments [36,37]. Additionally, the iAide2 enables timely behavioral feedback via a wirelessly connected Event button and near-real-time data access for researchers through an administrative screen. During the 12-week intervention period, patients in both the control and intervention groups wear the iAide2 device at all times except when bathing and press its Event button at bedtime each day. Patients record their bedtime and risetime daily in the paper diary. For the intervention group, the diary includes additional pages implementing specific aspects of the intervention. Bedtime is defined as the time when a patient begins trying to sleep, and risetime as the time when they stop trying to sleep. Diary entries are used to calculate TIB, the duration between bedtime and risetime. The intervention is designed to encourage an earlier bedtime, with the expectation that this will extend TIB and thereby increase sleep duration (ie, the portion of the TIB interval during which the patient is asleep).

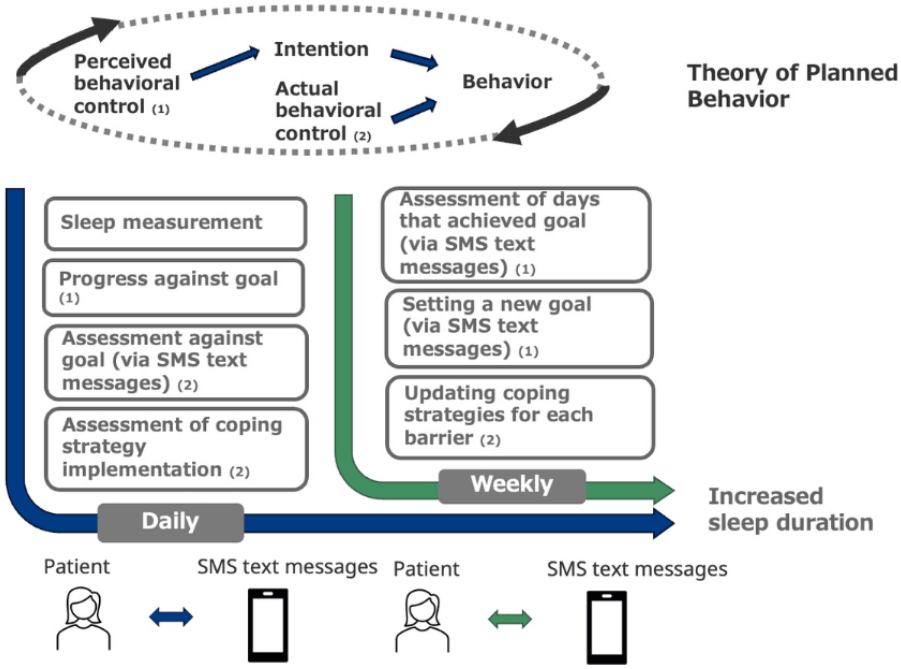
Table 1. Intervention features for the intervention and control groups.

Features	Intervention group	Control group
iAide2		
Press the Event button to send bedtime	Yes	Yes
Measure daily sleep and steps (without providing this information to patients)	Yes	Yes
Diary		
Enter bedtime and risetime	Yes	Yes
Define barriers and coping strategies and report the number of coping strategies implemented	Yes	No
TPB[a] questionnaire at E2	Yes	No
SMS text message		
Diary reminder	Yes	Yes
Low battery message	Yes	Yes
Daily feedback and target bedtime	Yes	No
Request for a reply message when patients forget to press the Event button	Yes	No
Surveys and questionnaires		
Screening at E0	Yes	Yes
Sleep and Transtheoretical Model Questionnaire at E0, E3, and E4	Yes	Yes
Feedback survey	Yes	No
TPB questionnaires at E1	Yes	No
Ask if taking any medication that may affect one's sleep at E0, E1, E3, and E4	Yes	Yes
Obtain information about medications, including type 2 diabetes treatments and other drugs, either by asking the patients or by checking their medical records at E0, E1, E3, and E4	Yes	Yes
Measure height at E0, and measure weight and blood pressure at E0, E1, E3, and E4	Yes	Yes
Ask about any adverse events or malfunction in iAide2 at E1, E3, and E4	Yes	Yes
TPB questionnaires at E3 and E4	Yes	Yes

[a]TPB: Theory of Planned Behavior.

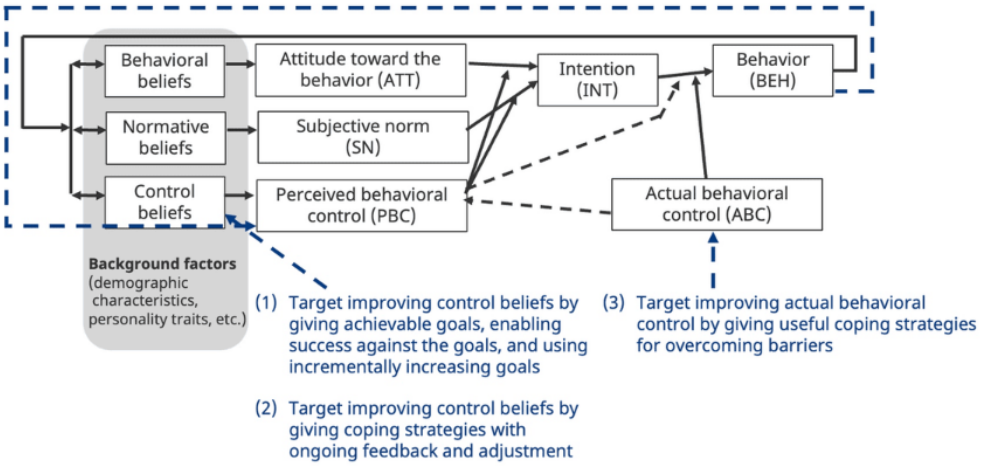
For the intervention group, daily and weekly messaging will deliver a TPB-based intervention targeting PBC and ABC (Figure 2). A researcher or clinical research coordinator (CRC), under the supervision of the researcher, will establish a baseline bedtime and set an initial goal for an earlier bedtime. They will also assist patients in identifying barriers to an earlier bedtime and developing coping strategies. Intervention group patients will receive a daily SMS text message assessment of their performance relative to their target bedtime and will record whether they implemented their coping strategies each day. They will also receive weekly assessments of their progress toward the goal, along with an updated target bedtime, via weekly SMS text messages. Additionally, they will determine coping strategies for the upcoming week.

Figure 2. BedTime's process for implementing Theory of Planned Behavior–based personalization.



The intervention is based on the TPB framework (Figure 3) [32,33]. According to TPB, behavior is driven by an individual's intention to perform the behavior and their ABC, or ability to do so. A behavior is more likely to occur when both intention and actual ability are high. Intention itself is influenced by 3 factors: personal attitude toward the behavior, subjective norms or the perceived expectations of important others, and PBC, which reflects one's confidence in their ability to perform the behavior. Each of these 3 drivers of intention (attitude toward the behavior, subjective norms, and PBC) is, in turn, influenced by the person's beliefs about them. The stronger the positive behavioral, normative, and control beliefs, the more likely an individual is to intend to perform the behavior. Actually carrying out the behavior depends on both intention and ABC. As ABC is difficult to measure, researchers generally use PBC as a proxy for ABC in predicting behavior [32,38].

Figure 3. Theory of Planned Behavior applied to the BedTime intervention.



The BedTime intervention is designed to influence PBC by modifying control beliefs. The primary strategy for improving control beliefs—and thus PBC—is to set achievable goals, enabling patients to experience success and build positive self-mastery. We implement progressively challenging but attainable goals using a simple algorithm based on our prior work [39]. This algorithm adjusts the suggested target bedtime each week based on the number of days the user met their goal in the previous week. Adjustments include increases of 5, 10, or 15 minutes and decreases of 5 or 10 minutes, depending on past target bedtime achievement levels.

The secondary mechanism for improving control beliefs involves daily self-reflection on barriers and coping strategies, reinforcing patients' sense of control over their behavior. These mechanisms align with those used to enhance self-efficacy in social cognitive theory [32]. Beyond influencing PBC, the barrier and coping strategy intervention may also improve ABC by providing useful coping strategies. However, its impact on ABC is expected to

be minor, as the suggested strategies may not be entirely novel or groundbreaking for patients. Each week, participants select or write down 1-3 barriers to achieving their target bedtime and propose a coping strategy for each (Table 2). Participants can select coping strategies from a literature-based list of solutions to common barriers to early bedtime [40-60] or describe their own. At the end of each day, they use the diary to report the number of coping strategies they implemented.

Table 2. Example of personalized coping planning strategy (with English translation).

Japanese		English translation	
Barriers	Coping strategies	Barriers	Coping strategies
遅い時間に夕食を食べて、まだやるべきことがある	就寝時刻の少なくとも2時間前に夕食を終える	I eat dinner late and still have things to do.	Finish dinner at least 2 hours before bedtime.
遅い時間にお風呂に入って、まだやるべきことがある	寝る1～2時間前にぬるめのお風呂に入る	I take a bath late and still have things to do.	Take a lukewarm bath 1-2 hours before going to bed.
就寝前にやるべき仕事がある	もっと睡眠をとるようにという医師の指示を上司に伝え、終業時間を早めるよう交渉する	I have work to do before bed	Tell your boss about your doctor's orders to get more sleep and negotiate an earlier finish time.
仕事から帰ってくるのが遅いため、まだやるべきことがある	もっと睡眠をとるようにという医師の指示を上司に伝え、終業時間を早めるよう交渉する	I'm late coming home from work, so I still have things to do.	Tell your boss about your doctor's orders to get more sleep and negotiate an earlier finish time.
家事など、まだ手をつけていないことがある	就寝1時間前を空けるようにスケジュールを組み立てる	There are things I haven't gotten around to yet, such as housework.	Plan your schedule so that you leave an hour before bedtime.
N/A[a]	やることのリストを作成し、就寝時ではなく翌日にそれをすることに専念する	N/A	Make a to-do list and commit to doing it the next day instead of at bedtime.
N/A	より多くの睡眠をとるようにという医師の指示に基づいて、他の人の助けを借りて家事をする	N/A	Do housework with the help of others based on your doctor's instructions to get more sleep
就寝時に高血糖または低血糖を管理する必要がある	必要な食事療法や投薬治療が就寝時刻までに完了するように、就寝時刻の 30 分～60 分前に血糖値を測定する	I need to manage hyperglycemia or hypoglycemia at bedtime	Measure your blood sugar 30-60 minutes before bedtime to ensure that any necessary dietary or medication therapy is completed by bedtime.
もう少し「自分」の時間が必要だ	「自分」の時間として、日中に10分間の休憩をいくつか取り入れる	I need a little more "me" time.	Incorporate several 10-minute breaks during the day for "me" time.

[a]N/A: not applicable.

The intervention provides daily individualized feedback via an SMS text message (Table 3). These messages, typically sent between 12 PM and 6 PM, inform the patient whether they went to bed earlier or later than their target bedtime the previous night, using an encouraging tone. This timing ensures that participants receive feedback well before their usual bedtime, allowing them sufficient time to adjust their nightly activities accordingly. The exact delivery time of the SMS text messages varies slightly due to the manual nature of the sending process.

At the end of each week, the intervention provides feedback via an SMS text message reporting the number of days the goal was achieved.

Table 3. Example of daily feedback (with English translation).

Situation	SMS text message	English translation
Last night, bedtime was earlier than the target bedtime which is 10 minutes earlier than the baseline bedtime.	昨夜は、「少なくとも10分早く就寝する」という目標を達成できました。よく頑張りました! 健康を改善するための行動ができています！	Last night you achieved your goal of going to bed at least 10 minutes earlier. Great job! You're taking action to improve your health!
Last night, bedtime was 15 minutes later than the goal bedtime of 30 minutes earlier than the baseline bedtime.	昨夜は15分遅く就寝しましたね。「30分早く就寝する」という目標には達しませんでしたが、今夜は目標就寝時刻の達成に向けてがんばりましょう。 あなたならできます！ お選びになった対処方法を確認して、今夜の就寝時刻を考えてください。 早く寝ると健康増進につながります！	You went to bed 15 minutes later than your goal last night. You didn't reach your goal of going to bed 30 minutes earlier than your baseline bedtime. Try your best to reach your target bedtime tonight. You can do it! Review your chosen coping strategy and think about your bedtime tonight. Sleeping early will improve your health!

Patient Recruitment

Patients will be recruited from 9 medical institutions in Japan (Textbox 1). Attending physicians will conduct recruitment during patients' regular outpatient consultations. The recruitment period will run from February 8, 2024, to July 30, 2024.

Textbox 1. Participating institutions: 11 medical centers in Japan.

- The University of Tokyo Hospital
- Mitsui Memorial Hospital
- Meiji Yasuda Life Insurance Company Tokyo Hospital
- Kobe University Hospital
- Akita University Hospital
- Tokai University Hospital
- Okayama Saiseikai General Hospital
- Sawaki Internal Medicine and Diabetes Clinic
- Yokota Medical Clinic
- Aikawa Comprehensive Internal Medicine Clinic
- Yokohama Rosai Hospital

To detect a 0.3% difference in the primary outcome (change in HbA_{1c}), assuming an SD of 0.41% (the average observed in 2 prior studies [17,61]), and to achieve a 2-sided significance level of .05 with 80% statistical power, the minimum required sample size is 31 patients per group. Considering an estimated dropout rate of approximately 10%, we aim to recruit a total of 70 patients (35 in the intervention group and 35 in the control group).

All participants will receive a comprehensive written and verbal explanation before providing written informed consent. Eligibility screening will be conducted only after consent is obtained. If any findings related to efficacy or safety arise during the trial that may impact patient consent, we will promptly disclose this information to participants and obtain renewed consent.

We will use survey instruments as part of the inclusion and exclusion criteria (Textbox 2). To recruit patients who are both likely to benefit and capable of participating, we will include only those meeting all inclusion criteria (Textbox 3) while ensuring they do not meet any exclusion criteria (Textbox 4), following the methods of a prior study [62]. We anticipate a roughly equal sex distribution and an average participant age in the late 50s. Women undergoing menopausal transition will be included if they meet the study's criteria.

We will use a Transtheoretical Model (TTM) questionnaire to categorize participants into the contemplation stage (willing to change health behavior within the next 6 months), preparation stage (willing to change health behavior within the next month), or action stage (has already made modifications to health behavior) [63]. In our previous study, patients in the contemplation and preparation stages were more likely to prefer smartphone-based self-management tools than those in the precontemplation stage [64]. Therefore, we will target patients in the contemplation, preparation, or action stage of increasing their sleep duration by 1 hour per day.

Textbox 2. Screening surveys.

- STOP-J (Snoring, Tiredness, Observed Apnea, High Blood Pressure Screen, Japanese version): screening for obstructive sleep apnea [65]
- ISI-J (Insomnia Severity Index, Japanese version): screening for insomnia [66]
- IRLSQ-J version 2.2 (International Restless Legs Syndrome Study Group Rating Scale, Japanese version): screening for restless legs syndrome [67]
- AUDIT-C-J (Alcohol Use Disorders Identification Test—Consumption, Japanese version): screening for alcohol use disorder [68,69]
- PHQ-8-J (Patient Health Questionnaire-8, Japanese version): screening for major depression [70,71]
- TTM (Transtheoretical Model) Sleep Questionnaire: assess the TTM stage [63] relative to sleeping 7 or more hours nightly

Textbox 3. Study inclusion criteria (selecting patients who are likely to benefit from the intervention and are likely to be capable of participating).

At the time of consent acquisition (E0)

- Diagnosed with type 2 diabetes and attending the hospital/clinic
- Hemoglobin A_{1c} (HbA_{1c}) is 7.5% or higher at the time of obtaining consent
- A patient with short sleep (self-reports an average sleep duration in the prior month of 6 or fewer hours)
- In the contemplation, preparation, or action stage of the Transtheoretical Model (TTM) for the action of sleeping 7 hours or more per day
- Willing and able to wear a wristband-type measuring device on the nondominant wrist during the research period
- Has and uses a mobile phone capable of sending and receiving SMS text messages
- Able to attend consultations at designated times during the research period
- 18 years or older
- Fluent in spoken and written Japanese
- Does not have impaired cognitive function as determined by the investigator or subinvestigator
- Can undergo sleep treatment, as determined by the investigator or subinvestigator
- Fully informed about participation in this study, and has given free and voluntary written consent based on a thorough understanding of the study

Textbox 4. Exclusion criteria, focusing on patients who may not be able to participate safely or whose participation may interfere with the effectiveness of the study.

1. Exclusion criteria at the time of consent acquisition (E0)
    - BMI is greater than 35.0 kg/m^2
    - Age is 76 years or older
    - A shift worker or someone who occasionally deviates from a single main sleep period at night
    - A caregiver (of a child or adult) who needs to wake up during the night
    - At high risk of obstructive sleep apnea (STOP-J [Snoring, Tiredness, Observed Apnea, High Blood Pressure Screen, Japanese version] score of 3 or higher)
    - At high risk of insomnia (ISI [Insomnia Severity Index, Japanese version] score of 15 or higher)
    - Possibility of restless legs syndrome (IRLSQ-J [International Restless Legs Syndrome Study Group Rating Scale, Japanese version] score of 1 or higher)
    - High possibility of depression (PHQ-8 [8-item Patient Health Questionnaire] score of 10 or higher)
    - Taking medications that affect sleep
    - Changed type 2 diabetes medication within the past 8 weeks
    - Currently participating in another clinical research program
    - A heavy user of alcohol (AUDIT-C-J [Alcohol Use Disorders Identification Test—Consumption, Japanese version] score of 4 or higher for females, and 6 or higher for males)
    - Has severe chronic pain (due to cancer, etc)
    - Has a diagnosed clinical sleep disorder
    - Has an uncontrolled psychiatric disorder
    - Pregnant at the time of consent acquisition
    - Any other reason why the patient is classified as unfit for participation by the investigator or subinvestigator
2. Exclusion criteria before allocation (E1)
    - Recorded both bedtime and risetime in a diary for fewer than 7 days during the trial period
    - Recorded the Event button of the iAide2 fewer than 7 days during the trial period
    - Recorded fewer than 7 days of valid iAide2 data showing sleep duration, as judged by the investigator or subinvestigator

We will provisionally register patients who meet the eligibility criteria at E0. At this stage, each participant will receive an actigraph (iAide2) and will be instructed to wear it 24 hours a day, except when bathing, to press the Event button at bedtime, and to record their bedtimes and risetimes in the diary. Patients who fail to press the Event button for 7 or more days or fail to complete the diary for 7 or more days during the run-in period will be excluded to ensure adequate participation. Data collected during the run-in period will be used to confirm eligibility and establish baseline sleep and step counts. We will randomize eligible participants in a 1:1 ratio to either the intervention or control group using covariate-adaptive randomization by minimization to ensure balance across age (<65 and ≥65 years), sex, HbA_{1c} (<8.5% and ≥8.5%), and institution [72]. Random allocation will be conducted via the Internet Data and Information Center for Medical Research cloud, provided by the University Hospital Medical Information Network, an internet-based central randomization system. A research co-investigator will access the University Hospital Medical Information Network Internet Data and Information Center for Medical Research cloud and input the required baseline information. The system will then securely generate the allocation result immediately before assigning each participant to a group. This process ensures that researchers cannot access or predict allocation results in advance, minimizing potential bias.

Intervention Process

The study (Table 4) consists of 5 events (E0-E4), a 2-week run-in period, a 12-week intervention period, and a 12-week observation period. Initial measurements will be taken at event E0. Questionnaires will be used to assess sleep behavior and gather patient feedback (Textbox 5).

Following randomization, the intervention begins. Before explaining the intervention, the researcher or CRC will administer the TPB Sleep Questionnaire and the Sleep-Related Behavior (SRB) Questionnaire to the intervention group. The researcher or CRC will then provide a diary customized for the intervention group. To establish a baseline bedtime, the researcher or CRC will average bedtimes recorded during the run-in period, considering any exclusions due to unusual circumstances in consultation with the patient. Patients will be informed that their ultimate goal is to shift their bedtime 1 hour earlier than the baseline, with an initial target of going to bed 10 minutes earlier during the first week. The researcher or CRC will help patients identify barriers preventing them from going to bed early and assist them in selecting up to 3 coping strategies tailored to these barriers for the first week. During this process, the researcher or CRC will facilitate discussions using the list in the diary as a reference. Patients may either choose strategies from the list or write their own in the diary. For the control group, the researcher or CRC will provide a diary similar to the one used during the run-in period but covering 12 weeks. Control group patients will be instructed to continue recording their bedtime and risetime as they did during the run-in period. The intervention period lasts 12 weeks, from E1 to E3. We will send reminder SMS text messages to both groups at the end of weeks 1 and 10 to encourage diary use. All equipment, including the diary, will be collected at E3 before the follow-up observation period begins.

For the intervention group, we will provide both daily and weekly feedback. Researchers will monitor the receipt of the Event time, and if it is missing, they will send a reminder asking the patient to report their bedtime via an SMS text message. If no bedtime is reported through either the Event record or SMS text message, the night will be considered a failure to achieve the target bedtime. At E2, 10 weeks after E1, we will send a reminder for participants to complete the TPB Sleep Questionnaire in the diary.

During the study, we will not restrict the use of supplements or drinks that may affect blood glucose and blood pressure. In both the intervention and control groups, T2D treatment—including oral T2D medications, insulin, glucagon-like peptide 1 receptor agonists, and medication dosage—may be adjusted at the discretion of the attending physician. We will collect information on T2D-related medication and medications affecting sleep at E1, E3, and E4.

Discontinuation is defined as a patient expressing a decision to withdraw or failing to record data for a continuous period of 7 or more days. If a participant discontinues during the intervention period, we will attempt to collect E3 measurement items. If discontinuation occurs during the observation period, we will attempt to collect E4 measurement items.

Table 4. Study events—1 measurement period and 4 visits spanning approximately 26 weeks.

Event	Focus	Time	Key activities
E0	Physical baseline assessments and initial registration	Enrollment: ≥7 days before the beginning of the intervention	• Collect consent • Collect demographic information: age, sex, date of type 2 diabetes diagnosis, smoking and drinking habits, macrovascular disease, diabetic retinopathy, periodontal disease, tinea pedis, diabetic neuropathy, and other medical history • Collect physical data: hemoglobin levels, albumin, uric acid, blood urea nitrogen, estimated glomerular filtration rate, creatinine, fasting blood glucose, HbA_{1c}[a], low-density lipoprotein cholesterol, high-density lipoprotein cholesterol, triglycerides, urine specific gravity, urinary protein, urine albumin-to-creatinine ratio, height, body weight, and blood pressure measurements • Collect medication status • Conduct screening surveys (STOP-J[b], ISI-J[c], IRLSQ-J version 2.2[d], AUDIT-C-J[e], PHQ-8-J[f], and TTM[g] Sleep Questionnaire) • Conduct PSQI-J[h] survey • Distribute actigraph (iAide2) and run-in period diary
Run-in	Baseline	From E0 for 2 weeks	• Patients record daily bedtime and risetime, with automated (blinded) measurements of sleep parameters and step count
E1	Registration, allocation, and beginning of the intervention	Beginning of the intervention	• Verify that run-in diary and iAide recording do not cause exclusion • Finalize registration and allocation • Collect medication status • Intervention only: conduct surveys (TPB[i] Questionnaire, SRB[j] Questionnaire) • Distribute the intervention diary or the control group diary • Check for malfunctions or adverse events during run-in
Intervention period	Ongoing measurement	From E1 for 12 weeks	• Patients record daily bedtime and risetime, with automated (blinded) measurements of sleep parameters and step count • Intervention only: daily feedback, weekly self-set barriers and coping strategies via diary, weekly personalized target bedtime setting via SMS text messages
E2	Ongoing measurement	End of 10 weeks from E1	• Intervention only: conduct TPB Questionnaire via diary
E3	End of the intervention	End of 12 weeks from E1	• Collect physical data: hemoglobin levels, albumin, uric acid, blood urea nitrogen, estimated glomerular filtration rate, creatinine, fasting blood glucose, HbA_{1c}, low-density lipoprotein cholesterol, high-density lipoprotein cholesterol, triglycerides, urine specific gravity, urinary protein, urine albumin-to-creatinine ratio, body weight, and blood pressure measurements • Collect medication status • Conduct surveys (TTM Sleep Questionnaire, TPB Questionnaire, SRB Questionnaire, PSQI-J) • Intervention group: conduct survey (feedback survey) • Collect actigraph (iAide2) and intervention period diary • Check for malfunctions or adverse events
E4	End of follow-up	End of 24 weeks from E1	• Collect physical data: hemoglobin levels, albumin, uric acid, blood urea nitrogen, estimated glomerular filtration rate, creatinine, fasting blood glucose, HbA_{1c}, low-density lipoprotein cholesterol, high-density lipoprotein cholesterol, triglycerides, urine specific gravity, urinary protein, urine albumin-to-creatinine ratio, body weight, and blood pressure measurements • Collect medication status • Conduct surveys (TTM Sleep Questionnaire, TPB Questionnaire, SRB Questionnaire, PSQI-J)

[a]HbA_{1c}: hemoglobin A_{1c}.

[j]SRB: Sleep-Related Behavior.

Textbox 5. Assessment questionnaires and surveys.

- TPB (Theory of Planned Behavior) Sleep Questionnaire: assess individual components of TPB [32,33] relative to implementing an earlier bedtime
- SRB (Sleep-Related Behavior) Questionnaire: self-assessment of sleep over the past 2 weeks
- PSQI-J (Pittsburgh Sleep Quality Index, Japanese version): assess sleep quantity and quality [73,74]
- Feedback survey: collect feedback on the intervention

Monitoring, Quality Control, and Data Management

An auditor, independent of the departments involved in the trial, including those responsible for monitoring, will inspect the medical institution and other facilities to ensure the trial is conducted appropriately.

Ethical Approval

This trial will be conducted in compliance with the Declaration of Helsinki, the Pharmaceutical and Medical Device Act, the Ministerial Ordinance on Good Clinical Practice for Medical Devices, and all other relevant guidelines (jRCT1030230650). The study was approved by the Institutional Review Board of the University of Tokyo School of Medicine (approval number 2023336NI). We will obtain written informed consent from all study participants, and all patient data will be pseudonymized. Patients will receive compensation of JPY 30,000 (approximately US $200) at the end of E4.

The participant information materials and informed consent form are available from the corresponding author (KW) upon request. Any amendments to the protocol will be submitted for review and approval by the institutional review board. Study findings will be disseminated through peer-reviewed publications and conference presentations.

Outcome Measures

Primary Outcome

The primary outcome of this study is the between-group difference in the change in HbA_{1c} from baseline (E0) to either the end of the intervention period at week 12 (E3) or, for patients who discontinue before E3, the point of discontinuation. A reduction of 0.3 percentage points in HbA_{1c} is considered clinically significant [75,76].

Secondary Outcomes

Secondary outcomes (Table 5) include health measures, bedtime and sleep measurements, other behavior change assessments, and evaluations of actigraph and diary usage. We will also assess safety outcomes, including hypertension requiring medical assistance (evaluated from system records), subjective hypoglycemia, lower back pain, and pain in the lower extremities (tarsus, thighs, knees, calves, shins, ankles, and feet), as well as any other adverse events (all assessed through patient interviews).

Table 5. Secondary outcomes investigated in the study.

Measurements	Outcomes
Differences in changes	• Hemoglobin A_{1c} (%) (only after the end of the observation period)[a] • Weight (kg)[a] • BMI (kg/m^2)[a] • Systolic blood pressure/diastolic blood pressure (mmHg)[a] • Estimated glomerular filtration rate (mL/min/1.73 m2)[a] • Fasting blood sugar (mg/dL)[a] • Low-density lipoprotein cholesterol (mg/dL)[a] • High-density lipoprotein cholesterol (mg/dL)[a] • Neutral fat (mg/dL)[a] • Urine albumin-to-creatinine ratio (mg/gCr)[a] • PSQI-J[a,b]
Differences in the measured values	• Survey on past bedtimes[a]
Difference in proportions	• Behavior change questionnaire[a]
Observed data	• Elements of the bedtime questionnaire: attitude, subjective norms, perceived behavioral control, intention[c] • Sleep time calculated from iAide2's sleep data and diary data[d] • Time in bed calculated from bedtime and wake-up time recorded in the diary for each period[d] • Bedtime recorded in the diary for each period and bedtime sent from iAide[d] • Steps recorded by iAide2[d] • Achievement rate of target bedtime[e] • Number of barriers and coping strategies set and implemented in the diary for the intervention period[e] • Percentage of use of each drug[f] • Percentage of new additions for each drug since consent was obtained[g] • Changes in antidiabetic drugs since consent was obtained (strengthened, unchanged, or attenuated)[g]

[a]Evaluate the differences after the end of the intervention period (at 12 weeks) and after the end of the observation period (at 24 weeks) from the time of consent acquisition.

[b]PSQI-J: Pittsburgh Sleep Quality Index, Japanese version.

[c]Evaluate the differences in the measured values for the following items at 10 weeks and after the end of the observation period (24 weeks).

[d]Evaluate the differences in the average change from the trial period in the 2 weeks before the end of the intervention period.

[e]Evaluate the rates weekly during the intervention period, for the intervention group.

[f]Evaluate the differences in percentages at the time of consent acquisition, at the time of actual registration, after the end of the intervention period, and after the end of the observation period.

[g]Evaluate the difference in proportions after the intervention period and after the observation period.

Statistical Analysis

In this study, we define 3 analysis populations: the full analysis set (FAS), the per-protocol set (PPS), and the safety analysis set (SAS). The FAS includes all patients for whom the primary outcome was obtained. Following the intention-to-treat principle, we will analyze data based on the assigned group in the FAS analysis. The PPS consists of the FAS population, excluding patients who violated eligibility criteria after randomization, had 7 or more contiguous days of nonuse of the iAide2, or took medications affecting sleep. The SAS includes all patients who used the iAide2 at least once after randomization. In the safety analysis using the SAS, we will analyze data based on the intervention actually used by patients, regardless of allocation. The FAS will serve as the primary analysis population, while the PPS will provide supportive results. All safety analyses will be conducted using the SAS.

Patient characteristics will be presented as mean, SD, minimum, 25th percentile, median, 75th percentile, and maximum for continuous variables, and as frequency and proportion for categorical variables.

In the primary analysis, we will compare the change in HbA_{1c} from baseline (E0) to week 12 (E3; or the point of discontinuation, if earlier) between groups using analysis of covariance, with baseline HbA_{1c} (ie, HbA_{1c} at E0) included as a covariate in the FAS. For participants who discontinue the study, the most recent HbA_{1c} measurement before E3 will be used.

We will also conduct 2 subgroup analyses: one based on baseline HbA_{1c} at E0 (<8.5% or ≥8.5%) and the other based on age at initial registration (E0; <65 or ≥65 years). Subgroup analyses of the primary outcome will be performed in each analysis set to assess whether the efficacy of BedTime is consistent across these subgroups.

In the secondary analysis, changes in HbA_{1c} at week 12 (E3) and week 24 (E4) will be analyzed using the same approach as in the primary analysis. The proportion of patients with HbA_{1c} below 7% at E3 and E4 (or at the point of discontinuation, if earlier) will be compared between groups using the Fisher exact test. Changes from baseline in step counts, various laboratory test values, and questionnaire scores at E3 and E4 (or at the point of discontinuation, if earlier) will also be analyzed as key endpoints. Changes in T2D medications, categorized as weakened, unchanged, or strengthened, will be compared between groups using the Cochran-Mantel-Haenszel test. The proportion of newly added medications will be compared between groups using the Fisher exact test. A paired (2-sample) *t* test will be used for within-group comparisons of changes in TPB Questionnaire measurements over weeks 0 (E1), 10 (E2), 12 (E3), and 24 (E4). Changes in TPB Questionnaire and SRB Questionnaire measurements between week 12 (E3) and week 24 (E4) will be compared using a *t* test. A paired *t* test will also be used for within-group comparisons from week 0 (E1) to week 12 (E3) for goal achievement rate, goal increment rate, goal reduction rate, average number of coping strategies implemented per day, and the number of identified barriers.

As an exploratory analysis, we will use linear regression to examine the relationship between the average number of coping strategies implemented per day and improvement in HbA_{1c} within the intervention group. The model will include the average number of coping strategies implemented per day and baseline HbA_{1c} as explanatory variables, with the change in HbA_{1c} as the response variable. Changes from baseline to week 12 (E3) and week 24 (E4) (or the point of discontinuation, if earlier) will be assessed.

We will perform a statistical analysis of safety outcomes by calculating the frequency, number of cases, and percentage of individuals experiencing adverse events during the trial, intervention, and observation periods. For the intervention and observation periods, data will be compiled separately for each group, and the percentages will be compared between groups using the Fisher exact test.

Results

Recruitment began on February 8, 2024, and ended on August 29, 2024. The intervention period concluded on December 6, 2024, and the observation period ended on February 26, 2025, with 70 participants completing the observation period (Figure 4). The analysis is currently underway, and we anticipate publishing the results in July 2025. Before commencing analysis, we will conduct a thorough review of all collected data and data entry.

Discussion

We designed this study based on the foundational concept that it is a behavioral change intervention, despite measuring medical outcomes. The intervention is grounded in a specific theory of behavioral change (TPB) to provide a structured framework, ensure clarity on intervention targets, and maintain focus, avoiding a scattershot approach. We identified a specific, actionable target behavior—going to bed earlier—and developed a measurement and feedback system centered on this behavior. This focused approach provides clarity for both researchers and patients. By maintaining this focus, we can determine whether the intervention effectively changes sleep behavior while also evaluating its impact on sleep patterns and, ultimately, health outcomes. Demonstrating that a behavioral intervention improves HbA_{1c} is not enough, we need to understand the intermediate steps, particularly the behavioral response, to refine the intervention by enhancing effective components and eliminating ineffective ones. This study is designed to generate evidence on these intermediate stages.

Our study utilizes objectively measured data for all primary outcomes and many secondary outcomes. The intervention leverages wireless technology, enabling automatic synchronization of sleep and step count data to the server. These simple, passive features facilitate easy-to-use objective measurements, particularly for older patients.

Participants will be blinded to group assignments to minimize social desirability bias. To achieve this, they will not be informed that the study involves random assignment to 2 groups or that the intervention specifically targets advancing bedtime. Instead, patients will be told that the study examines the relationship between self-management of lifestyle habits (including exercise and sleep) and blood glucose control in individuals with T2D. They will also be informed that various lifestyle factors, including sleep, will be monitored. This approach minimizes the risk of unblinding in the control group by preventing participants from identifying the absence of an intervention. We believe that maintaining blinding offers significant scientific benefits by reducing potential bias and enhancing the validity of the study findings.

We selected the HbA_{1c} level as our primary outcome, as it is recognized as a global standard for assessing glycemic control and an appropriate indicator of T2D treatment effectiveness [77]. According to the Japan Diabetes Society's treatment guidelines, patients with T2D should aim to lower their HbA_{1c} level below 7% to prevent complications [78]. Therefore, in addition to analyzing absolute changes in HbA_{1c} levels, we examined the proportion of patients achieving an HbA_{1c} level below 7%. We acknowledge that T2D duration may influence the primary outcome. Although our recruitment process does not explicitly stratify participants by disease duration, this information is collected at registration and will be incorporated into the analysis to account for its potential impact on study outcomes.

In this study, we have chosen a "formidable" control [79], using the same devices as the intervention group. As an initial proof-of-concept study, our goal is to determine whether our specific behavior change intervention is more effective than simply having patients record their bedtime and risetime. Evidence suggests that providing patients with a pedometer can increase their activity levels [80], raising concerns that bedtime and risetime recording in the control group may similarly trigger behavioral changes, potentially making it more challenging to demonstrate the intervention's superiority statistically. By providing the control group with a diary but withholding the intervention functionality, we have designed the study to offer strong evidence of the intervention's effectiveness—should it indeed be effective.

Many behavior interventions demonstrate solid short-term gains that later fade [39]. This study includes a 12-week observation period following the intervention to assess whether the benefits persist or diminish. Behavior change maintenance is theorized to result from active, ongoing self-regulation, with habit formation emerging after a period of successfully regulating a new behavior [81]. Our goal is to foster sustainable behavior change, ensuring that the new pattern becomes an enduring habit.

A key aspect of our approach is providing patients with a strong introduction to the mechanics of the intervention. Given their busy lives, we strive to make participation clear and manageable. By offering thorough training and ensuring that all intervention messaging remains simple and focused, we maximize the likelihood that patients will engage with the tools as intended.

Another key aspect of our approach is prioritizing the needs of the patients the intervention is designed to serve. Rather than adopting a one-size-fits-all approach, we tailored the intervention for a specific target population, ensuring it aligns with their needs and preferences. Our previous study [39] highlighted the importance of considering cultural background and patient preferences in intervention design. Additionally, we recognize that socioeconomic background may influence sleep patterns. While our recruitment strategy does not explicitly target specific socioeconomic groups, the participating institutions serve patient populations whose demographics are representative of the general community.

Another key aspect of our approach is applying the intervention only to patients who are already motivated to change their behavior. We use the TTM stage as a filter, an approach that has proven highly effective in previous research [39,63]. Our intervention is specifically designed for highly motivated patients who need support in implementing their desired behavior changes, whereas low-motivation patients require a different intervention focused on enhancing motivation. Notably, a large proportion of patients with T2D in Japan exhibit high motivation, with one study indicating that 92% are in the contemplation-through-action stages of TTM for dietary behavior change [82]. There is a substantial pool of patients who could benefit from this targeted intervention. As a multicenter randomized controlled trial, this study enhances the generalizability of our findings to patients with T2D across Japan. Moreover, our techniques are broadly applicable, and there is strong reason to believe that these methods could be

adapted to increase sleep duration for patients with other conditions and in diverse health care settings worldwide.

This study has several limitations. The findings may be specific to the population studied and may not fully generalize to other groups. Our participants are likely to be older individuals of Japanese ethnicity, and differences in lifestyle and T2D pathophysiology between Japanese and other populations may limit broader applicability. Additionally, the study includes only patients capable of using mobile phones, introducing potential biases related to digital literacy. Furthermore, our baseline sleep measurements rely on actigraphy and sleep diaries provided to participants, which may overestimate true prestudy sleep levels. This effect is mitigated by the 2-arm design and the duration of our trial. However, it may lead to an underestimation of increases in sleep duration, potentially resulting in an overestimation of the per-hour-of-sleep impact on health outcomes.

This trial will provide important evidence on the efficacy of a TPB-based mHealth intervention in improving sleep duration and glycemic control in patients with T2D. If the intervention is proven effective and safe, this study could serve as a key step toward integrating mHealth into standard T2D treatment in Japan.

Abstract

Background: Mental health needs in the community surged during the pandemic, with concerning reports of increased negative mood symptoms among youth. At the same time, preventive psychoeducational interventions were insufficient within frontline youth mental health services in Hong Kong, and research specifically addressing youth loneliness remained limited on an international scale. Given the association between loneliness and other mental health symptoms, psychoeducational programs that empower adolescents to cope with emotions may help address both the research gap and local demand. As such, Tuned In, a previously validated intervention program originally developed in Australia, was introduced to the local context. Cultural adaptations and an added focus on loneliness were incorporated into the project to enhance its acceptability and test its effectiveness.

Objective: This study aims to evaluate an adapted version of the Tuned In music-based psychoeducation program, designed to reduce loneliness, depression, and anxiety symptoms among young people in Hong Kong by enhancing their emotion regulation skills.

Methods: Participants aged 16-19 years will be randomly assigned to either the experimental or control group. The experimental group will receive an online, group-based psychoeducation program focused on emotion recognition and management, delivered weekly over 4 consecutive weeks. The intervention is grounded in Russell's emotion circumplex model and music psychology, and program content included: The 2D model and characteristics of emotions from different quadrants (session 1); happiness and loneliness (session 2); high-arousal and negative-valence emotions, for example, stress and anxiety (sessions 3); and anxiety, perfectionism, and a celebration of achievement (session 4). Both therapist- and participant-selected music will be used in the intervention to provide a rich repertoire for group discussion, psychoeducation, reflection, and the practice of social skills. The main outcome measures will be assessed using the Emotion Regulation Questionnaire, the Difficulties in Emotion Regulation Scale, the Depression Anxiety Stress Scale, and the De Jong Gierveld Loneliness Scale. Feedback on the project arrangement will be gathered through qualitative input. A mixed methods analysis will be conducted following data collection.

Results: The project was successfully funded in February 2023 by the Health and Medical Research Fund in Hong Kong and commenced in August 2023. As of September 16, 2024, a total of 316 completed questionnaires had been received through Qualtrics for screening purposes, with 89 participants deemed eligible for the program. The project is scheduled to conclude in August 2025, with results to be published thereafter.

Conclusions: Participants are expected to show improvements in emotion regulation, along with reductions in mood symptoms and loneliness, following the intervention.

Introduction

Significance of Study

Youth mental health is a significant concern in Hong Kong. Studies have reported that the prevalence of depression and anxiety among adolescents is approximately 11.3% locally [1]. Loneliness is also widespread among young people in Hong Kong, occurring at a higher rate than that reported for their counterparts in North America [2]. Around 39% of young people in Hong Kong reported feeling lonely—an increase of 55% from 2012 to 2018 [3]. Furthermore, the prevalence of loneliness rose to 47% among adolescents and young adults in 2020 due to the pandemic [4]. A recent survey found that loneliness was associated with symptoms of depression, anxiety, and stress, even after controlling for demographic factors and views on the COVID-19 pandemic [2]. These negative emotional states have also been shown to be linked to other issues, such as substance use [5]. The connection between negative experiences, low mood, and substance use problems may be partly explained by a lack of emotion regulation skills. Emotion regulation involves the ability to manage emotions within a social context, which includes expressing emotions appropriately and with suitable intensity [6]. The Transdiagnostic Emotion Vulnerabilities Model proposes that emotional vulnerability is a core transdiagnostic factor underlying major depression, anxiety, and tobacco smoking [7]. In particular, young people may believe that unhealthy coping mechanisms, such as smoking, help them to relax. Because of this pairing of mental distress and poor health habits, they are likely to engage in—or continue—smoking during times of distress [5]. By contrast, a meta-analysis by Schafer et al [8] found that healthy coping during distress was associated with reduced depressive and anxious symptoms (r ranging from –0.29 to –0.50) among adolescents and young adults.

Given the significant role that emotion regulation plays in promoting youth mental health, it is desirable for preventative interventions to equip young people with age-appropriate, healthy coping strategies that serve as protective factors against long-term emotional difficulties, health problems, addiction, or substance abuse. Unfortunately, few such interventions have been validated by research in Hong Kong [9]. The proposed pilot trial will evaluate the effectiveness of a music-based prevention program in reducing mood problems among young people by enhancing their emotion regulation skills. This project is supported by a seed grant to conduct a small-scale trial in preparation for future large-scale research.

To evaluate the validity and effectiveness of the project in the Hong Kong context, the following hypotheses will be tested:

- The emotion regulation skills of adolescents and young adults will be enhanced following participation in the music-based program (primary outcome).
- The depression and anxiety symptoms of adolescents and young adults will be reduced following participation in the music-based program (secondary outcome).
- The sense of loneliness experienced by adolescents and young adults will be reduced following participation in the music-based program (secondary outcome).

Definition of Terms of Music Interventions

Music, defined by The New Penguin English Dictionary as “any vocal, instrumental or mechanical sounds that have rhythm, melody or harmony” [10], can influence emotions in many ways. As such, music is often perceived as the language of emotion [11]. Distinct from the term song, which refers to a short composition combining both words and music, music is considered a hypernym of song. In other words, music is a broader term that encompasses a range of activities—from listening to background music to engaging in composition and improvisation [12]—whereas song specifically refers to music with lyrics that can be sung [13]. This broader definition of music is adopted by music therapists to allow greater flexibility in the use of music or sound during interventions, enabling them to meet clients where they are in the present moment [14].

Music interventions are broadly classified into 2 types: active and receptive [15]. In active interventions, clients participate in the process of music production. By contrast, receptive interventions involve clients receiving the music experience, with listening focused on the intellectual, emotional, or other aspects of the music [15,16]. Previous studies on group music interventions for young people have not found significant differences in treatment outcomes between the 2 approaches [17].

Music and Emotions

The activation of the limbic system—responsible for processing emotions—when the ears perceive music provides a biological foundation for music’s influence on emotions [18]. The emotions experienced by listeners result from an interplay of multiple factors, including elements of the music itself, the performance, and the surrounding environment. For example, structural features of music such as tempo and melody are known to influence emotional responses. It is widely accepted that tempo can directly affect the pleasantness of emotions and that melodies tend to be higher in pitch in happy music compared with sad music [19]. In addition to musical structural features, song lyrics are often used as a springboard for discussing life events that evoke emotions during interventions [16]. Lyrics play a vital role in eliciting emotions, particularly sadness [20].

Previous research has also found that engaging with self-selected music can foster a sense of connectedness [21].

Music Interventions, Youth Emotion Regulation, and Tuned In

Listening to music is an effective emotion regulation strategy [22-24], and existing literature supports its use in reducing symptoms of depression and anxiety. One study examining the use of online group music therapy to manage anxiety and stress among university students confirmed the effectiveness of this type of intervention [17].

Tuned In, a preventative program developed by 1 of the coinvestigators to address mild to moderate levels of psychological distress, has demonstrated positive psychological outcomes in both adolescents [25,26] and young adults in Australia [6]. A related intervention, Smoke into Sound, was found to be more effective in reducing cigarette cravings than the gold standard of cognitive behavioral therapy delivered via telephone, as shown in a randomized controlled trial (RCT) [27].

During the COVID-19 pandemic, young adults rated listening to music as the most effective coping mechanism [24]. The Tuned In program is based on Russell's [28] circumplex model of emotion, which categorizes emotions along 2 dimensions: valence and arousal. The theoretical foundation linking music and emotion in the Tuned In program draws from this 2D model [28,29], in which emotions are positioned along an arousal axis (ranging from high to low energy) and a valence axis (ranging from pleasant to unpleasant). It also incorporates the BRECVEMA (brain stem reflexes, rhythmic entrainment, evaluative conditioning, contagion [emotional contagion], visual imagery, episodic memory, musical expectancy, and aesthetic judgment) theory of music and emotion [30], which identifies mechanisms such as lyrical meaning, personal memories associated with music, and imagery evoked by music as key factors influencing emotional responses to listening. Although not explicitly stated in the program materials, this theoretical background is embedded in the content and activities—such as lyric analysis and imagery drawing tasks conducted while listening to music.

Through psychoeducation and experiential activities designed to explore and make meaning of emotions—such as locating emotions in the body, lyric analysis, drawing imagery while listening to music, and group discussions—participants in the program first learn to categorize their emotions in terms of intensity (ie, arousal level) and positivity (ie, valence). They then reflect on and develop a personalized list of songs they relate to, using these songs to increase or decrease the intensity and positivity of their emotions. In other words, participants practice monitoring their emotional states and using music to help modify how they feel.

In addition, music can enhance social connectedness—and potentially foster actual social connections—when shared with others [12]. Therefore, music serves as a universal and comprehensive tool for promoting emotion regulation and reducing feelings of loneliness, as well as depressive and anxious symptoms [24,25,31-33]. Furthermore, emerging local evidence supports the positive role of music listening as a promising strategy for enhancing mental health among adolescents in Hong Kong. In a large-scale cross-sectional survey, Leung and Cheung [34] found that music listening contributed to psychological well-being among young people by enhancing emotional awareness.

Music Interventions, Youth Loneliness, and Tuned In

In addition to depression and anxiety, loneliness is a socioemotional state that has attracted increasing research attention [35]. In 2019, 22% of young Chinese people reported experiencing feelings of loneliness [36]. Recent data also suggest that loneliness is associated with poor health habits—such as smoking—among young Chinese individuals [36].

Although lonely young people may have friends and families, everyday interactions often provide limited opportunities for deep connection and personal sharing within a trusting environment for this age group [37]. This is echoed by recent research findings showing that 76% of lonely adolescents and young adults feel they are not well understood by others—a situation that could potentially be addressed through the empathic effects of music [21,31].

Feelings of empathy or being understood can arise not only through human interactions but also through listening to comforting music, suggesting a promising mechanism for reducing loneliness in young people [21]. Schafer and colleagues [21] found that listening to self-selected music improved participants' self-reported mood following a sad mood induction, regardless of the type of music chosen. They proposed that self-selected (ie, familiar) music acts as a surrogate listener, helping individuals feel that their emotions are being "heard," thereby providing a comforting effect. These soothing effects of music could be leveraged to address a key issue underlying loneliness among young people.

However, there is limited research on interventions aimed at reducing loneliness among young people in Hong Kong. This scarcity is also evident in the broader literature. A recent meta-analysis and systematic review found that certain group-based psychological interventions can be effective in reducing loneliness [38,39].

One psychoeducation group intervention found no significant decrease in loneliness at follow-up [40], while other interventions—such as online dancing and various psychoeducation-based group programs—reported reductions in loneliness [41-43]. These mixed results highlight the need for more promising and effective programs to reduce loneliness, both locally and within the broader research literature.

Nevertheless, there is preliminary evidence that the Tuned In program has positive effects in reducing loneliness among young people. Coinvestigator GD and her team (email communication, February 18, 2025) completed a study applying the original program in a passive control design with 35 English-fluent international students in Australia. They found a significant interaction between time and condition, resulting in a reduction in self-reported loneliness among participants—with a moderate effect size (η^2_p=0.12)—compared with the waitlist group. This

overall positive effect is attributed to the synergy of the program's core components: psychoeducation, group work, and music. Each serves as an essential therapeutic element, and together they form the comprehensive Tuned In intervention.

Undeniably, adopting an active control would be more ideal. However, due to limited resources and the need to maintain fidelity to the original program, a waitlist control design was chosen for practical reasons. The primary aim of this study is to examine whether this combination of elements can produce desirable outcomes in the Hong Kong context. Investigating the specific role and contribution of each component, as well as comparing the effectiveness of this combination with other types of interventions, represents a valuable direction for future research.

Theoretical Framework for Tuned In

The Tuned In program was developed as an alternative to cognitive behavioral therapy and is grounded in emotion theory and music psychology research on the links between music listening and emotional responses [25-27]. The 4 sessions primarily aim to not only address negative emotions—such as depression, loneliness, anxiety, and anger—but also explore ways to enhance positive emotions or states such as motivation, happiness, and calmness. Each session begins with the facilitator describing the components and functions of emotions (eg, physiological responses and common thoughts), followed by participant sharing and group discussion about songs they currently listen to—or could listen to—that elicit or help regulate those emotions.

As engagement in music does not require participants to have prior knowledge or skills in music [17], a receptive intervention has been chosen for the current project. According to Juslin's BRECVEMA model [30], the meaning of lyrics is one of several mechanisms that link music listening with emotional responses. The model identifies multiple pathways through which a musical event can influence emotions, including brain stem reflex, rhythmic entrainment, evaluative conditioning, emotional contagion, visual imagery, episodic memory, musical expectancy, and aesthetic judgment [30].

Although some experimental evidence suggests that melody has a stronger influence than lyrics on emotional responses to music [44], this effect is highly individualized—some people focus more on melody, while others are more affected by lyrics. Therefore, both instrumental music and songs will be used in this project. In alignment with both the original program and guidelines for receptive music interventions, instrumental music may be used for imaginal and somatic listening, with the flexibility to adjust based on participants' emotional states and feedback. Songs, by contrast, will be used for lyric discussions. Given that the current project is psychoeducational, with music serving as a tool for relationship building and emotional regulation, the inclusion of both songs and instrumental music allows for greater acceptance of diverse musical styles and gives participants the freedom to share and appreciate various kinds of music. Discussions about song components (eg, lyrics) can also deepen participants' understanding of the physiological and cognitive aspects of different emotions. The intention is that, by the end of the program, participants will be able to assess their emotional valence and arousal, and they will have a personalized playlist they can use to enhance or regulate their emotional states. In other words, they will be "tuned in" to their emotions.

Building on the existing evidence, the proposed study aims to establish an effective music-based program to enhance emotion regulation skills among young people in Hong Kong. This approach complements current practices in the region, which often focus on areas such as self-esteem, resilience, social competence, problem-solving, and communication [1,9]. Notably, the proposed study introduces a new session targeting "loneliness"—an addition to the original Tuned In program implemented in Australia [6]. This new component directly addresses the rising prevalence of loneliness among adolescents in Hong Kong [3,4].

The program will be facilitated by a registered music therapist and a research assistant, both under the supervision of the primary investigator. The research assistant will receive training from the coinvestigator and original developer of Tuned In before delivering the groups, along with ongoing supervision from her. This arrangement ensures the standardized delivery of both the music-based activities and the psychoeducational content. Because of previous COVID-19–related restrictions, the program was initially proposed to be conducted online. However, with the loosening of COVID-19 restrictions, the study has incorporated an introductory session where participants can meet each other and the facilitator in person. This session is intended to build rapport and foster a sense of group identity, which is expected to enhance engagement during the subsequent online group sessions while preserving the flexibility of the program format [45,46].

Aims and Objectives

The ultimate aim of this study is to test and validate a music-based program designed to improve emotion regulation among adolescents and young adults in Hong Kong, with the broader goal of reducing symptoms of depression, anxiety, and loneliness.

The objective of the proposed project is to evaluate the effects of a music-based program on young people in Hong Kong. The hypotheses to be tested are listed below.

The primary outcome is as follows:

- The emotion regulation skills of adolescents and young adults will be enhanced following participation in the music-based program.

The secondary outcomes are as follows:

- Symptoms of depression and anxiety among adolescents and young adults will be reduced following the program.
- Feelings of loneliness among adolescents and young adults will be reduced following the program.

Methods

Ethical Considerations

Ethical approval for the study was obtained from The University of Hong Kong (approval number EA230395) and The Hong

Kong Polytechnic University (approval number HSEARS20221024004). Ethical approval was either exempted or not required by other participating universities for the distribution of advertisement materials.

In adherence to the ethical regulations of the university, signed active parental consent will be obtained for participants under the age of 18 years. All participants are required to sign a physical consent form before participating in the intervention. Participation is entirely voluntary, and all participants have the right to withdraw from the project at any time without any negative consequences.

Study Design

The study adopts a waitlist RCT design. Participants are randomly assigned to either the intervention group, who will receive the program immediately, or the waitlist control group, who will receive the intervention after a 4-week waiting period. The main assessment time points are pre- and postintervention for the intervention group, and baseline and postwaiting period for the control group. Additionally, the control group will be invited to complete an optional postintervention survey following their participation, which will be used for secondary data analysis. The postintervention surveys for both groups will contain identical items to ensure comparability. It is also planned that all participants who complete the intervention will be invited to take part in an optional qualitative interview to gain deeper insights into their experiences using the strategies taught in the program.

Given the project's strong emphasis on psychoeducation, participants' application of the strategies taught serves as an indicator of the program's acceptability. Qualitative inquiry offers valuable insights into the extent to which participants have internalized and consolidated the healthy coping strategies introduced during the intervention. This approach enables exploratory interpretations of the project's outcomes and helps uncover the nuanced, individualized experiences of participants. Therefore, qualitative research is considered appropriate to capture the subjective and personal dimensions of the intervention's impact.

Online delivery was chosen in response to the prevailing pandemic conditions at the time. This decision not only aligned with the original program design but also helped overcome geographical barriers. By eliminating distance as a constraint, the online format significantly enhanced the accessibility of the program. While this mode of delivery presented challenges—such as difficulty in maintaining participants' attention and limited nonverbal communication—it also expanded the potential of digital platforms to support mental health through digital expressive arts and peer support [47]. Moreover, the web-based design increased the mobility and flexibility of the intervention [48]. Previous studies have shown that online group interventions can be effective in reducing mental health symptoms such as depression [43,48], and Draper and Dingle [49] found that virtual groups were effective in addressing psychological needs.

Material and Personnel Preparation

The group sessions are cofacilitated by 2 individuals: a research assistant with a background in a mental health–related discipline and a registered music therapist. The research assistant takes the lead in delivering the psychoeducational content, while the music therapist facilitates the musical experiential activities and supports group discussions. Both facilitators employ techniques such as encouraging participants to be "good group members" to manage group dynamics effectively. For instance, during ice-breaking activities or group discussions led by the research assistant, the music therapist may participate as though they are a group member. This approach helps to foster rapport and strengthen the connection between the facilitators and participants. The same roles and techniques also apply to the research assistant during music activities. Additionally, the research assistant serves as the main point of contact for participants and is responsible for participant follow-up and distribution of reimbursement. The follow-up, limited to the scope of the project, includes administrative liaison (eg, responding to participant inquiries, delivering materials, arranging logistics) and crisis intervention. Crisis intervention involves providing appropriate community crisis support resources and information and making an informed decision regarding the participant's eligibility to continue with the group intervention.

To enhance project fidelity, the English manual from the original program was revised and translated into Chinese. The music selections from the original program were also adapted by the music therapist to better suit the local context. The incorporated music in this project is intended to produce equivalent therapeutic effects while maintaining consistency in music type with the original selections. For instance, Shawn Mendes' *A Little Too Much* [50] from the original program was replaced with Eason Chan's *Today* [51], which is more culturally relevant and relatable for local youth.

The manuals will be printed and distributed to participants and facilitators before the sessions. In cases where distributing hard copies is not feasible, an electronic version will be provided instead. To enhance readability and engagement during session presentations, PowerPoint (Microsoft Corporation) slides aligned with the manual content will also be used.

A session checklist outlining the key components of each session was prepared for facilitators to log the completion of intervention activities. These entries serve as records to support program fidelity and ensure consistency across sessions.

Recruitment

The recruitment process began in August 2023 and will continue until August 2025. Various strategies have been implemented to improve the accessibility of project information across all regions of Hong Kong.

Three main recruitment channels have been used:

- Social Media Platforms: project posters, welcome messages, and links to detailed information were posted on Instagram (Meta Platforms, Inc.), Facebook (Meta Platforms, Inc.), and Social Career (Social Career Limited), which are widely

used by local youth. Additionally, project details were published on the university website to reach the general public.

- Existing Partnership Networks: Information about the project was shared with 3 local universities, a local integrated children and youth services center, and several secondary schools that either have existing collaborations with the principal investigator (YC) or have expressed partnership interest. These institutions helped disseminate project details to their students or service users (eg, the ELCHK Lutheran Academy).
- Exploratory cold calls and emails: The research assistant reached out to additional secondary schools and integrated children and youth services centers via phone and email. These contacts were selected based on alignment between their service targets, institutional missions, and the goals of the project. Project information and partnership invitations were conveyed either verbally or in writing.

Randomization and Blinding

Participants will be randomly assigned to either the intervention or waitlist control group using a computer-generated randomization procedure. The Random Allocation Software developed by Dr. Mahmood Saghaei [52] will be used to facilitate this process. Block randomization will be implemented to ensure balanced group sizes, with a maximum of 8 participants per group. Randomization will be carried out by an independent researcher who is not part of the current research team or is listed as an author. The principal investigator remains blinded to group assignments to maintain objectivity and reduce potential bias. Outcome measures are managed by a separate research assistant who is not involved in the delivery of the intervention, ensuring independence and reducing potential bias. Once a sufficient number of eligible participants have been recruited, randomization will be conducted, typically 2 weeks before the intervention start date. Participants will then be informed of their group allocation, along with the schedule of their assigned group sessions, by the designated research assistant. In alignment with the ongoing recruitment process and rolling admission, the intervention will be delivered to participants as they are randomized and assigned to groups.

Participants

The target population for this study comprises post–high school students and adolescents aged 16-19 years. This age range aligns with international guidelines, such as those from the World Health Organization, which defines adolescence as ranging from 10 to 19 years, and the United Nations, which considers individuals aged 15-24 years as adolescents and young adults. Recruitment materials for the project will be disseminated to students in their final year of high school as well as recent graduates who maintain connections with their schools. Young adults, primarily those in their first year of undergraduate studies (typically aged 17-19 years in the Hong Kong context), will be recruited through posters displayed on university campuses and word-of-mouth referrals. A snowball sampling method will also be used to expand participant recruitment. Consistent with the approach used by Dingle and Fay [6], this study will include youth who self-report experiencing symptoms of low mood, anxiety, or loneliness.

Inclusion criteria for participation are (1) self-reported difficulties with low mood, anxiety, or loneliness; and (2) a score of 3 or above on the 12-item General Health Questionnaire (GHQ-12), indicating the presence of psychological distress. Exclusion criteria are the presence of severe mental health symptoms, such as self-harm or suicidal ideation, as the Tuned In program has not yet been trialed with individuals experiencing more acute mental health conditions.

Interested participants who do not meet the inclusion criteria will be provided with an information sheet about community counseling services. Eligible participants who confirm their enrollment will be randomized.

Sample Size Calculation

Dingle and Fay [6] found a medium effect size (η^2_p=0.076) for improved emotion regulation after the music intervention with young adults, compared with the control group. Based on this medium effect size, at least 98 participants are needed to detect a significant group × time interaction effect (P<.05). However, based on previous trials, some dropout is expected after the intervention has commenced. The estimated attrition rate is 15%. Besides, considering that partnerships with middle schools have only recently begun to develop, while many university students have already expressed interest in committing to the project, we expect to recruit more university participants. Therefore, we aim to recruit over 100 participants for the randomization stage, including around 50 adolescents and 65 young adults, to account for possible dropouts before the intervention begins.

Contingency Plan

Based on prior trials of Tuned In, we expect a high retention rate among youth [6]. However, some attrition may occur among adolescents [25]. Even with that attrition rate, we anticipate retaining at least 30 adolescents at the postintervention stage, providing sufficient data from this pilot study to inform future large-scale trials. In the event of significant challenges in recruiting adolescents, our backup plan is to recruit additional youth from the university community for this trial.

Because of the online mode of intervention, the study design minimizes potential disruptions arising from any local changes in the COVID-19 pandemic situation. If difficulties or delays in participant recruitment arise, we will place advertisements on social media as an additional recruitment channel.

Considering the risk of potential emotional disturbances, a page listing several 24-hour community crisis support hotlines has been incorporated into the manual to provide participants in need with an additional channel to external resources. Alongside the distribution of these resources, the research assistant will also give instructions on how to use them during the group contracting phase and explicitly encourage participants to seek help and notify the research assistant immediately if they experience emotional distress during the session.

In situations where psychological distress is identified either by a facilitator or self-reported by a participant, the research assistant will separate the individual from the rest of the group, while the music therapist continues to lead the remaining activities. The research assistant will provide immediate emotional support and conduct a timely risk assessment, and the principal investigator will be informed of the situation. Based on the participant's condition, appropriate referrals will be made as necessary.

The research assistant will follow up with individuals who disclose intentions or actions related to self-harm, suicide, harm to others, or breaches of the law, and will discuss with them the appropriateness of continuing in the project or the available options for discontinuation.

Description of the Intervention

The project consists of 5 weekly sessions: 1 introductory (preassessment) session followed by 4 psychoeducational sessions. Each session lasts approximately 60-90 minutes.

In the introduction session, participants sign the informed consent forms after being informed about the program's content and expectations by the main group facilitator (ie, the research assistant). For participants under 18 years of age, parental consent will also be obtained during the session. Following the signing of consent, the baseline survey will be distributed and collected. Participants' demographic information will be gathered through the survey. This includes, but is not limited to, age, gender, education level, household income, region of residence, living arrangement, and employment status.

Each week, participants will receive WhatsApp (Meta Platforms, Inc.) text message reminders about upcoming sessions and other important announcements.

The psychoeducational sessions differ in theme but follow a similar structure. Session 1 focuses on emotions located in various quadrants of the 2D model, such as high-arousal and negative-valence emotions. Session 2 explores happiness and loneliness, with the new component of loneliness added to this session. Sessions 3 and 4 address high-arousal emotions, such as stress and anxiety. An example session plan is provided in Multimedia Appendix 1 for reference (Table 1).

Table 1. Summary of session content.

Session	Content
Session 1	Emotions located in various quadrants of the 2D model, such as high-arousal and negative-valence emotions
Session 2	Happiness and loneliness
Session 3	High-arousal and negative-valence emotions, such as stress and anxiety
Session 4	High-arousal emotions, such as perfectionism and anxiety (continue) and achievement

For the new loneliness component, in addition to discussing songs that evoke a sense of receiving empathy, psychoeducation will be provided on the positive effects of music sharing in building and strengthening emotional bonds in relationships [12]. The group sessions will offer a safe and pleasant environment where participants can talk about music, using this topic as a channel to foster new connections with fellow group members. In session 2, participants will be guided to discuss how they can apply this skill outside of the program to strengthen existing relationships and build new connections.

Participants are also expected to select music for themselves during the group sessions. These self-selected songs serve to evoke the target emotions for each session and support group discussions and experiential psychoeducation—specifically, increasing awareness of the bodily or physiological changes that accompany each emotion as elicited by music. As music appreciation is used as a tool to support psychoeducation about emotions, rather than being a goal in itself (ie, the program is not intended to enhance musical understanding), we believe that participant-selected songs are more appropriate than those prescribed or suggested by the program facilitators. This is also in line with literature supporting the benefits of using self-selected and familiar music [21]. As such, participants' sharing of their self-selected music is incorporated as a core element in the sessions. The music submitted by participants spans a wide range of styles, reflecting their individual tastes, and includes Cantonese pop songs, classical music, movie soundtracks, and more.

Each session begins with a music check-in led by the music therapist, followed by participants listening to their self-selected music. This music listening and sharing segment takes approximately 15-20 minutes. Once the target emotions are evoked, the research assistant provides psychoeducation on the theme emotion and facilitates a group discussion on coping strategies. Around 10-15 minutes are allocated for this group discussion. Next, the music therapist guides participants through a core music activity designed to support reflection and reconnection with the theme emotion. Selected music activities include body scan, drawing, and lyric analysis. Each activity takes approximately 15 minutes. Each theme emotion is paired with its own specific psychoeducational content and corresponding music activity. The session concludes with a summary and debriefing provided to participants.

By the end of the last session, participants will be invited to complete the postquestionnaire. Individuals who complete both the prequestionnaire and postquestionnaire will receive a reimbursement of HK $200 (US $25.77) in cash. Reimbursement will be provided in person, and participants will be required to sign a receipt for record-keeping purposes. The intervention for the control group will be delivered after the final session of the experimental group and upon completion of the postquestionnaire by its participants. A flowchart outlining the project has been included in Multimedia Appendix 2.

Outcome Measures

Overview

The following measures of emotion regulation (primary outcome), mood symptoms (secondary outcome), and loneliness (secondary outcome) will be administered pre- and postintervention via Qualtrics (Silver Lake Technology Management, L.L.C.).

Primary Outcome: Emotion Regulation

- The Emotion Regulation Questionnaire is a widely used measure with subscales assessing 2 styles of emotion regulation: cognitive reappraisal and expressive suppression. It has been translated and validated for use in Hong Kong (Cronbach α=0.80-0.83) [53]. A child and adolescent version of the scale has also been translated into Chinese [54]. Given that the primary focus of the Tuned In program is to encourage the outward expression of emotion through music, it is anticipated that changes will be observed in expressive suppression scores, but not necessarily in cognitive reappraisal scores, following the program.
- The Difficulties in Emotion Regulation Scale (DERS) is a more comprehensive measure that assesses emotional awareness, emotional acceptance, impulse control, and emotion regulation strategies among both adolescents and adults. This scale has also been validated for use with Chinese participants (Cronbach α=0.68-0.89) [55]. Given its comprehensive nature, the DERS is considered the primary outcome measure in this study.
- To measure confidence in managing emotions, items from the program evaluation tool used by Dingle and Carter [27], which explicitly asks participants to rate their self-confidence in managing both positive and negative emotions, will also be included.

Secondary Outcomes: Mood Symptoms And Loneliness

- The 21-item Depression Anxiety Stress Scale (DASS-21), which has been used with Chinese participants [56], will be used to measure mood symptoms. Recent research has demonstrated the scale's validity for assessing emotional distress among young people in Hong Kong [57].
- The Hong Kong version of the 6-item De Jong Gierveld Loneliness Scale (Cronbach α=0.76) [58] will be used to assess loneliness.

Additional Measure

We will use the Music USE (MUSE) Questionnaire [59] to assess each participant's typical music listening habits, including whether they play a musical instrument and if they have received formal musical training. This scale was successfully used in a study involving 1318 adolescents in Hong Kong [34], making it a valuable tool for describing participants' engagement with music.

For demographic information such as gender and socioeconomic status collected in the survey, tests will also be conducted across the 2 conditions to examine whether the results differ.

The effect of the intervention on reducing anhedonia will also be explored using the Chinese version of the Snaith-Hamilton Pleasure Scale [60]. Data collected from this scale will be used for future outcome analysis.

The Tuned In program's acceptability among Hong Kong adolescents will be examined using a combination of quantitative and qualitative approaches. Satisfaction ratings will be collected from participants using a 7-point Likert scale. With "strongly disagree" at 1 point and "strongly agree" at 7 points, the ratings will capture the extent to which participants agree with the positive statements. The questions will address the perceived usefulness of the program, the level of interest in the program, the likelihood of recommending the program to other adolescents, and the likelihood of continuing to use music as an emotion regulation strategy in the future [25]. The aforementioned areas of investigation regarding the project's acceptability are framed into 4 separate rating questions, all of which are included in the postintervention survey. The quantitative questions are provided in Multimedia Appendix 3.

In addition, we will include open-ended qualitative questions to gather feedback from participants on their experiences with the program and to collect suggestions for improvements for a future RCT. Written responses are expected from participants. As feasibility indicators, we will also record the recruitment rate and dropout rate for this trial. The qualitative questions are incorporated into the postintervention survey, to be completed by participants at the end of the final session.

To explore participants' continued use of music for emotion regulation after the program, invitations to qualitative interviews will be sent at the 1-month follow-up. All participants who received the intervention will be invited. Open-ended and probing questions will be used to gather descriptive data on participants' views of the program and their music listening habits. Data saturation is expected to be reached by the conclusion of the project. Please refer to Multimedia Appendix 3 for the interview and postintervention survey questions.

Data Analysis

For the main outcome evaluation measures, mixed measures ANOVAs will be performed. The between-participants factor is group (intervention vs control), and the within-participants factor is time (pre- vs postintervention). Before the main analyses, independent samples *t* tests (2-tailed, paired) will be conducted on the baseline demographic variables to identify any significant differences between the 2 groups. Any variables that show statistically significant differences will be included as covariates in the subsequent main analyses. It is expected that the treatment group will demonstrate improved emotion regulation and reduced mood symptoms and loneliness following the music intervention, compared with the control group. A medium effect size is anticipated for the significant group × time interaction effect.

All verbal and written feedback will be analyzed using thematic analysis [61]. The qualitative analysis software NVivo (QSR International) will be used to assist with the process. Content analysis will be conducted following the transcription and coding of the data.

Results

The successful funding outcome of this project was announced in February 2023. Participant recruitment began in January 2024, and as of September 16, 2024, a total of 316 responses had been received through Qualtrics. Upon submission of the questionnaire, all participants are promptly notified of its receipt. Those deemed eligible receive a basic information sheet, while individuals who are ineligible are provided with a list of supporting resources. Of the responses received, 89 participants were considered eligible for the program. The project is scheduled to conclude in August 2025, with results to be published thereafter.

Discussion

Expected Findings

This proposal focuses on examining the short-term impact of a music-based emotion regulation program for young people in Hong Kong. For this trial, we expect the intervention group to demonstrate improved emotion regulation and reduced mood symptoms and loneliness after completing the Tuned In program, compared with the control group. This expectation is based on previous successful trials of Tuned In conducted in Australia [27]. Furthermore, in line with the Transdiagnostic Emotion Vulnerabilities Model, enhanced emotion regulation may help alleviate a range of mood-related issues [7].

Qualitatively, we expect that participants will describe their reduced loneliness and enhanced mental well-being as being directly and indirectly related to music. For example, they may resonate with the music and experience a sense of being understood [12]. We also anticipate that participants will appreciate the use of self-selected music throughout the program [21]. In the future, we plan to conduct longitudinal studies to examine the medium- to long-term impacts of the intervention.

Strengths

The study demonstrates notable strengths, including the involvement of 2 cofacilitators—a registered music therapist and a trained research assistant with a mental health background—ensuring both clinical expertise and research rigor in program delivery. Additionally, the inclusion of a new session component specifically targeting “loneliness” enhances the intervention by building upon and extending the established “Tuned In” program previously conducted in Australia, thereby addressing an important psychosocial issue with a tailored and evidence-informed approach.

Limitations

As this study is a pilot RCT, the primary focus is on assessing the feasibility and effectiveness of the intervention. The long-term effects can be explored in future, larger-scale trials. It is acknowledged that the outcome measures used are self-reported. This method was chosen to capture participants’ subjective experiences and perceptions. Additionally, the study does not account for individual differences that may influence outcomes. Factors such as the impact of life events or levels of alexithymia may potentially influence the outcomes of the program and should be taken into account in future research. Subsequent studies could incorporate additional forms of assessment, such as physiological measures or reports from family members, to provide a more comprehensive and corroborated evaluation.

As coping through emotions mediates the relationship between resilience and youth well-being [62], equipping young people with adaptive strategies to manage stress and difficult emotions helps consolidate learning and builds greater internal resources and capacity. This, in turn, positively influences both their short- and long-term mental health. Healthy coping also acts as a protective factor for their future emotional well-being.

Although this project does not investigate the medium- to long-term effects of the intervention on youth mental health due to resource constraints, future research could adopt a longitudinal perspective to explore the factors that help sustain the positive outcomes. Future studies could also incorporate an active control design and examine the individual contribution of each component to the overall effectiveness of the program.

Conclusions

This project aims to examine the short-term effects of a music-based emotion regulation program for young people in Hong Kong. We expect positive outcomes from this trial, and the preliminary results will inform the planning of future studies to better understand the underlying mechanisms and longer-term impacts.

From a practical perspective, the project will provide valuable insights into the use of music and psychoeducation in youth mental health work in Hong Kong. From a research and theoretical perspective, it may offer evidence regarding the effectiveness of combining music, psychoeducation, and group work in improving youth mental health. Building on the current project, future studies are encouraged to explore innovative ways to enhance the cost-effectiveness, outcome magnitude, reliability, and sustainability of the intervention.

Acknowledgments

This project is funded by the Health and Medical Research Fund, Health Bureau, The Government of the Hong Kong Special Administrative Region (reference number 10211636), and the Seed Fund for Basic Research for New Staff from the University of Hong Kong. DHKS is supported by internal funding from The Hong Kong Polytechnic University.

Authors' Contributions

YC designed the study, contributed to the intervention design, and was responsible for funding acquisition. DTLS and DHKS contributed to the program evaluation and participant recruitment planning. RT and GD contributed to the intervention design

and program evaluation planning. YC and DCWL drafted earlier versions of the paper. YS contributed to paper revisions. All authors reviewed and edited the final manuscript before submission.

Abstract

Background: Standard lifestyle interventions have shown limited efficacy in preventing type 2 diabetes among individuals with isolated impaired fasting glucose (i-IFG). Hence, tailored intervention approaches are necessary for this high-risk group.

Objective: This study aims to (1) assess the feasibility of conducting a high-intensity interval training (HIIT) study and the intervention acceptability among individuals with i-IFG, and (2) investigate the preliminary efficacy of HIIT in reducing fasting plasma glucose levels and addressing the underlying pathophysiology of i-IFG.

Methods: This study is a 1:1 proof-of-concept randomized controlled trial involving 34 physically inactive individuals (aged 35-65 years) who are overweight or obese and have i-IFG. Individuals will undergo a 3-step screening procedure to determine their eligibility: step 1 involves obtaining clinical information from electronic health records, step 2 consists of completing questionnaires, and step 3 includes blood tests. All participants will be fitted with continuous glucose monitoring devices for approximately 80 days, including 10 days prior to the intervention, the 8-week intervention period, and 10 days following the

intervention. Intervention participants will engage in supervised HIIT sessions using stationary "spin" cycle ergometers in groups of 5 or fewer. The intervention will take place 3 times a week for 8 weeks at the Aerobic Exercise Laboratory in the Rehabilitation Hospital at Emory University. Control participants will be instructed to refrain from engaging in intense physical activities during the study period. All participants will receive instructions to maintain a eucaloric diet throughout the study. Baseline and 8-week assessments will include measurements of weight, blood pressure, body composition, waist and hip circumferences, as well as levels of fasting plasma glucose, 2-hour plasma glucose, and fasting insulin. Primary outcomes include feasibility parameters, intervention acceptability, and participants' experiences, perceptions, and satisfaction with the HIIT intervention, as well as facilitators and barriers to participation. Secondary outcomes comprise between-group differences in changes in clinical measures and continuous glucose monitoring metrics from baseline to 8 weeks. Quantitative data analysis will include descriptive statistics, correlation, and regression analyses. Qualitative data will be analyzed using framework-driven and thematic analyses.

Results: Recruitment for the study is scheduled to begin in February 2025, with follow-up expected to be completed by the end of September 2025. We plan to publish the study findings by the end of 2025.

Conclusions: The study findings are expected to guide the design and execution of an adequately powered randomized controlled trial for evaluating HIIT efficacy in preventing type 2 diabetes among individuals with i-IFG.

Introduction

The prevalence of type 2 diabetes is increasing globally [1-3], driven predominantly by a rising number of individuals with prediabetes [2]. Globally, an estimated 860 million (8.4%) adults are living with prediabetes, a condition that increases the risk of developing type 2 diabetes [2], micro- and macrovascular complications, and mortality [4].

Prediabetes is not a singular entity but rather a heterogeneous group of metabolic defects that often precede type 2 diabetes [5-7]. Prediabetes phenotypes include isolated impaired fasting glucose (i-IFG), isolated impaired glucose tolerance (i-IGT), and IFG + IGT. Each prediabetes phenotype exhibits distinct pathophysiological abnormalities [5-7]. i-IFG is marked by impaired early-phase insulin secretion and hepatic insulin resistance. Conversely, i-IGT involves impairments in both early- and late-phase insulin secretion and skeletal muscle insulin resistance [5,7]. IFG + IGT presents a combination of defects observed in both i-IFG and i-IGT [5,7]. i-IFG accounts for a substantial portion of the global prediabetes population, ranging from 43.9% to 58% among Caucasian individuals and 29.2% to 48.1% among Asian individuals, depending on the diagnostic criteria [8]. Individuals with i-IFG exhibit a 4 to 5.5 times higher rate of progression to type 2 diabetes, depending on the diagnostic criteria, compared to those with normoglycemia [9].

Individuals with prediabetes are typically advised to adopt standard lifestyle interventions that emphasize improving diet quality with a modest calorie restriction and increasing moderate-intensity physical activity to reduce the risk of developing type 2 diabetes [10,11]. However, recent research highlights the varied effectiveness of these interventions among different prediabetes phenotypes. While these approaches prove highly effective for individuals with i-IGT and IFG plus IGT, their efficacy is notably limited for those with i-IFG [6,12,13]. Thus, there arises a necessity for alternative lifestyle intervention strategies tailored specifically to individuals with i-IFG.

One of the promising approaches is high-intensity interval training (HIIT), recognized as a time-efficient exercise option with significant benefits for metabolic health [14]. HIIT entails alternating short bursts of high-intensity exercise with periods of less active or passive recovery [15]. It is noteworthy that HIIT represents a more intensive exercise regimen compared to the current physical activity recommendations for individuals with prediabetes [10,11].

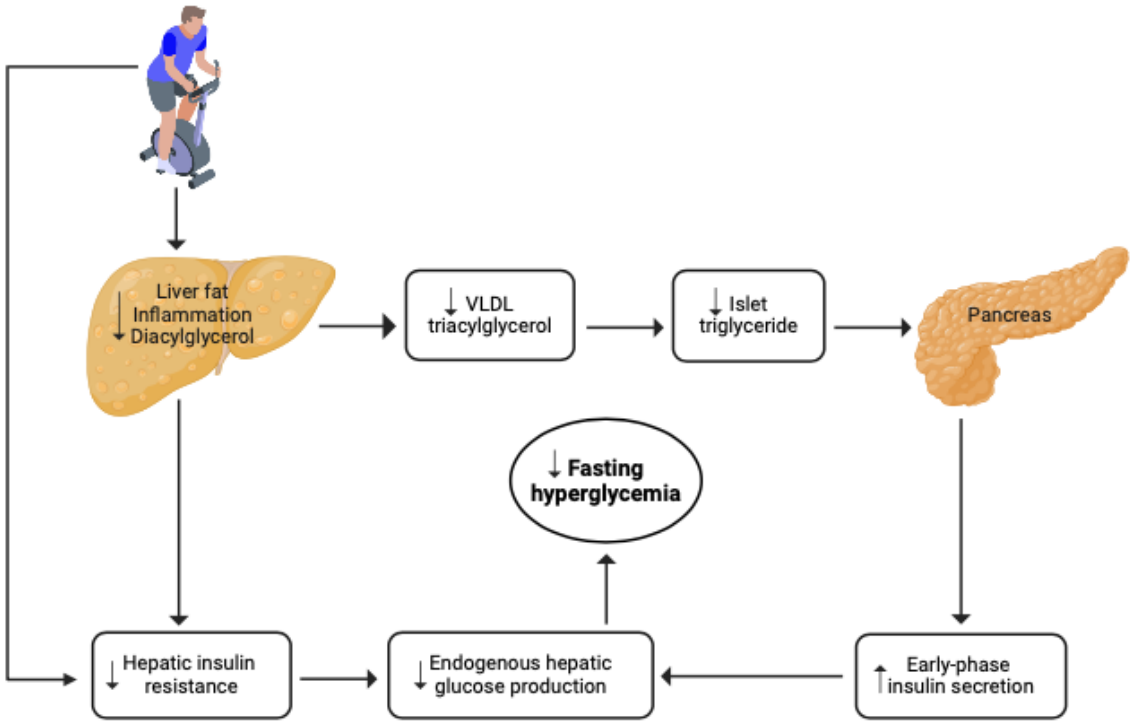
HIIT has been shown to effectively reduce hepatic insulin resistance and improve early-phase insulin secretion in individuals with type 2 diabetes [16-20], leading to significant reductions in fasting plasma glucose (FPG) levels [17,21-25]. Given that i-IFG shares these same pathophysiological defects [5-7], it is reasonable to hypothesize that HIIT could also be effective in individuals with i-IFG, as depicted in Figure 1. However, this hypothesis has yet to be tested in a randomized controlled trial (RCT). This is a critical investigation, as reducing fasting hyperglycemia is key to preventing the progression of type 2 diabetes in those with i-IFG [6,26]. To inform the design and implementation of this RCT, we propose conducting a proof-of-concept study among individuals with i-IFG, with the following objectives.

- Primary objectives (feasibility and acceptability): (1) assess the feasibility of recruiting and retaining participants and executing study procedures; (2) examine the feasibility, acceptability, and appropriateness of the HIIT intervention for participants; and (3) investigate participants' experiences, perceptions, and satisfaction with the HIIT

intervention, and identify facilitators and barriers to participation.

- Secondary objective (preliminary efficacy): Investigate the preliminary efficacy of HIIT in reducing FPG levels and addressing the underlying pathophysiology of i-IFG.

Figure 1. Potential pathways through which high-intensity interval training sessions may address the pathophysiological abnormalities and fasting hyperglycemia in individuals with isolated impaired fasting glucose. VLDL: very low-density lipoprotein.

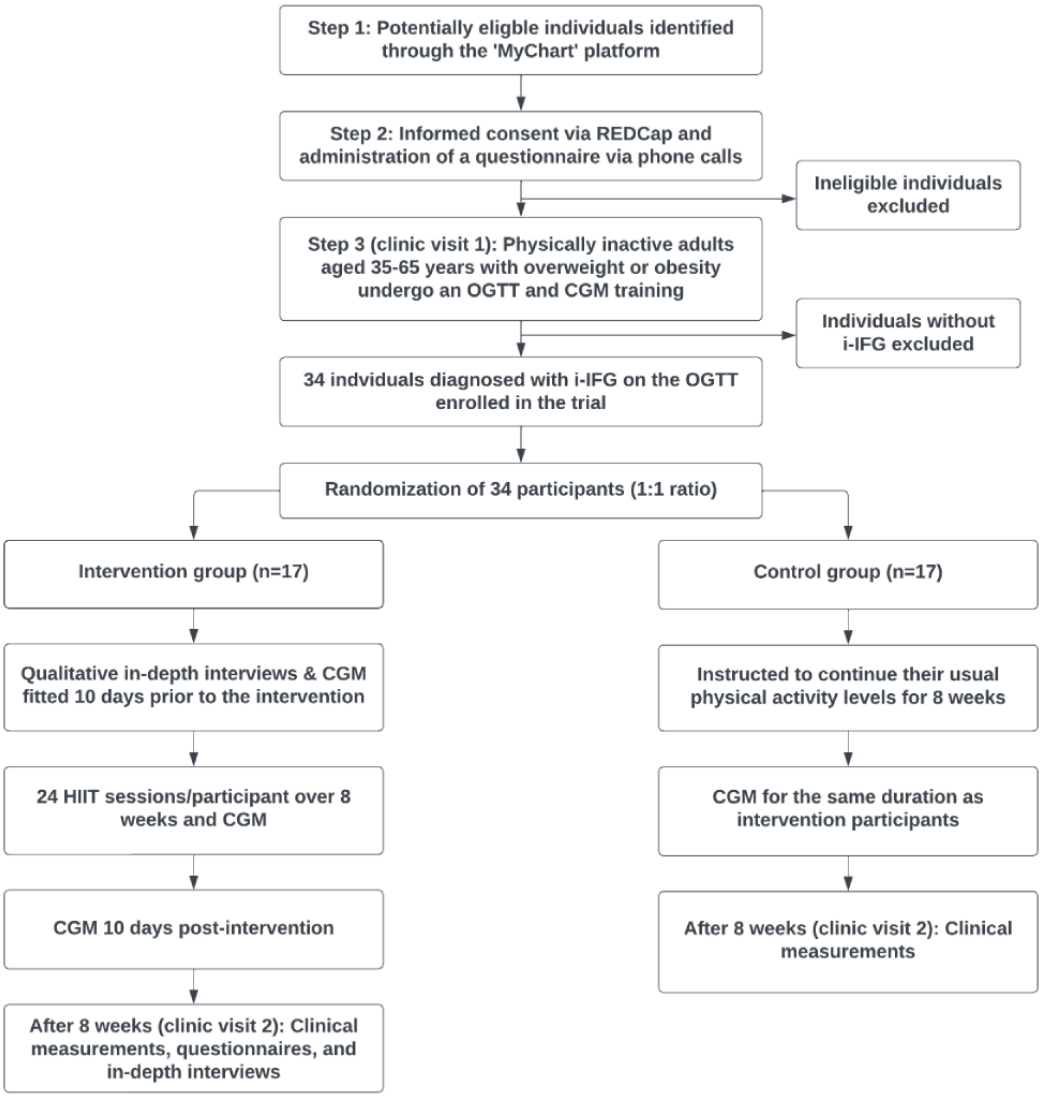


Methods

Study Design, Study Setting, and Participants

The study will be reported in accordance with the CONSORT (Consolidated Standards of Reporting Trials) guidelines for randomized pilot and feasibility trials [27]. This is a "proof-of-concept" 1:1 parallel-group RCT involving 34 physically inactive individuals aged 35-65 years who are overweight or obese and have i-IFG. Figure 2 presents the study's CONSORT diagram. The Georgia Clinical Research Center (GCRC) at Emory University Hospital will serve as the site for participant recruitment and conducting study procedures. A highly trained and experienced study coordinator will recruit participants through a comprehensive 3-step screening procedure.

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) flow diagram. CGM: continuous glucose monitoring; HIIT: high-intensity interval training; i-IFG: isolated impaired fasting glucose; OGTT: oral glucose tolerance test; REDCap: Research Electronic Data Capture.



Step 1: Screening (via Electronic Health Records)

Potential participants will be identified using Emory's electronic health care records system, known as "MyChart." Queries within this database will target individuals aged 35-65 years with a BMI≥25 kg/m^2 (≥23 kg/m^2 if Asian descent) [28], who have been diagnosed with prediabetes (hemoglobin A_{1c} [HbA_{1c}] 5.7%-6.4%) [29] within the last 12 months, have no diagnosis of diabetes (FPG≥126 mg/dL or 2-hour plasma glucose ≥200 mg/dL or HbA_{1c}≥6.5% or currently taking antidiabetic drugs) [29], not currently taking weight-loss medications, not currently taking drugs known to influence glucose tolerance (steroids and antipsychotics), not currently taking beta-blockers and calcium channel blockers (individuals taking these drugs will not reach heart rate (HR) targets for the HIIT sessions), did not undergo bariatric surgery, no anemia (anemia may limit the exercising capacity), and have no chronic illnesses (cardiovascular disease, stroke, cancers, chronic respiratory diseases, and mental health disorders). Individuals meeting these criteria will receive an invitation through the MyChart platform to participate in the second screening step.

Step 2: Screening (via Phone Calls)

Those expressing interest in participating in the study through MyChart will be contacted via phone. During these calls, individuals will receive a comprehensive explanation of the study and have any questions addressed. They will then be asked to sign an electronic consent form via Emory's REDCap (Research Electronic Data Capture; Vanderbilt University) platform [30]. Following consent, potential participants will complete a questionnaire to assess their eligibility for step 3 screening based on the following criteria.

- Physically inactive (less than 150 minutes per week of moderate-intensity physical activity, less than 75 minutes per week of vigorous-intensity physical activity, and <600 metabolic equivalent task–minutes per week) [31] assessed by the International Physical Activity Questionnaire (IPAQ) [32].
- Available to participate in the HIIT group sessions.
- No history of smoking (smoking is associated with reduced insulin secretion and increased insulin resistance) [33].
- Not enrolled in weight loss programs in the past 6 months.

- Not enrolled in any regular exercise programs in the past 6 months.
- Not currently following a specific diet (eg, ketogenic and Mediterranean).
- No plans to undergo bariatric surgery during the study period.
- No plans to relocate outside the study area during the study period.
- Not pregnant.
- Not breastfeeding.

Step 3: Screening (via In-Person Clinic Visits)

Individuals meeting the step 2 criteria will be invited to visit the GCRC at Emory University Hospital after fasting overnight for a minimum of 8 hours [29]. During the visit, participants will complete standard questionnaires to collect sociodemographic information (education, occupation, and marital status) [34,35] and details on alcohol consumption [34,35] and dietary intake [36]. Additionally, physical measurements will be conducted using standardized instruments in accordance with the World Health Organization's STEPwise approach to noncommunicable disease risk factor surveillance (STEPS) protocol [37]. Following these assessments, individuals will undergo an oral glucose tolerance test (OGTT) and provide blood samples for insulin. Individuals diagnosed with i-IFG, defined by the American Diabetes Association criteria as FPG between 100-125 mg/dL and 2-hour plasma glucose<140 mg/dL [29], will be deemed eligible to participate in the study. Individuals without i-IFG will be excluded from further participation in the study. They will receive a summary report of their test results and general healthy lifestyle advice and will be referred to their general practitioner if they have IGT or undiagnosed diabetes for further management.

Randomization and Blinding

Participants will be equally randomized into either the intervention or control group after completing baseline assessments and being found eligible, using a computer-generated randomization sequence by a statistician not involved in the trial. Given the nature of the study, only specific personnel such as nursing staff, laboratory personnel, and the data analyst will be blinded to participant allocation to the study groups. Participants, the study coordinator, the HIIT intervention instructor, and the principal investigator will not be blinded to participation allocation.

Intervention

Following the recommendation of the American College of Sports Medicine [38], participants in the intervention group will be required to obtain medical clearance from their general practitioner before starting the HIIT sessions. These sessions, led by a qualified exercise physiologist (the instructor) and adhering to standard protocols [39,40], will take place in the Aerobic Exercise Laboratory at Emory University's Rehabilitation Hospital. Using "spin cycle ergometers" (Schwinn), sessions will be conducted in small groups of 5 or fewer participants at specified times on Mondays, Wednesdays, and Fridays, spanning 8 weeks. Each participant will undergo a maximum of 24 HIIT sessions. Each session will consist of a 5-minute warm-up, followed by an interval-based workout phase with steady up-tempo cadences, sprints, climbs, and interspersed recovery periods. A 5-minute cooldown will conclude each session. The workout sessions will initially last 20 minutes and will progressively increase in time based on participants' tolerance and instructor recommendations. Each session will include "active rest" periods where resistance is reduced to lower HR, alternating with high-intensity intervals featuring sprints or climbs to elevate HR. The duration of active rest versus high-intensity intervals will be adjusted according to individual responses and target HR. To monitor and maintain intensity within the target HR range, participants will wear Polar H10 chest strap HR sensors [41]. The target HR will be calculated using the Karvonen method [42]. Exercise intensity will begin at 75% of the estimated maximum HR reserve (HRR) and will increase by 5% every week, as tolerated or deemed necessary by the instructor, over the 8-week intervention period. During the workout phase, the target HRR reserve will be maintained by averaging increases and decreases in intensity or HR with a target to maintain within a 10% offset from the HRR goal [39,40]. Participants will need to adhere to within-session HR targets at an 80% rate (or greater) for a session to be counted as attended and participants will need to attend 19 out of 24 sessions to be included as a "completer" in the final data analysis. To date, our interventions have yielded a within-session adherence rate to the prescribed intervention of 91% (as measured by HR) and a retention rate of 85% [40,43-45]. Participants' weight and body composition will be measured weekly.

To ensure high compliance in session attendance, the instructor will hold weekly one-on-one meetings with participants to provide personalized feedback and encouragement. Participants' HR data will also be reviewed during these meetings. Additionally, the study coordinator will remind participants of their scheduled sessions 1 day in advance through phone calls or texts. Attendance in sessions will be closely monitored, and records of attended exercise sessions will be maintained. Participants who miss sessions will be contacted via phone calls to encourage attendance.

Any adverse events occurring during or after HIIT sessions will be documented, with medical advice sought if necessary. Both intervention and control participants will receive instructions to maintain a eucaloric diet throughout the study. Dietary adherence will be monitored biweekly by a registered dietitian using the Automated Self-Administered 24-Hour Dietary Assessment Tool (National Cancer Institute) [36]. This tool will be administered via phone calls 3 times a week, covering 2 weekdays and 1 weekend day. Additionally, control participants will be instructed to refrain from engaging in intense physical activities during the study period. Physical activity adherence will be assessed biweekly using the short form of IPAQ, also administered via phone calls [32].

Procedures

The details about the measurements, study tools, and timelines are outlined in Table 1.

[a]REDCap: Research Electronic Data Capture.

[b]WHO STEPS: World Health Organization STEPwise approach to noncommunicable disease risk factor surveillance.

[c]NHANES: National Health and Nutrition Examination Survey.

[d]x: the particular variable will not be collected during that particular timepoint.

[e]Inclusion criteria: aged 35-65 years, overweight or obese (body mass index ≥25 kg/m² [≥23 kg/m² if Asian descent]), physically inactive (less than 150 minutes per week of moderate-intensity physical activity and less than 75 minutes per week of vigorous-intensity physical activity and <600 metabolic equivalent task–minutes per week), and a diagnosis of isolated impaired fasting glucose (fasting plasma glucose 100-125 mg/dL and 2-hour plasma glucose<140 mg/dL). Exclusion criteria: diagnosis of diabetes, diagnosis of other chronic illnesses (eg, cardiovascular disease, stroke), current smoker, history of anemia, currently enrolled in weight loss programs, currently enrolled in any regular exercise programs, currently following a specific diet (eg, ketogenic diet, Mediterranean diet), currently taking weight-loss medications or drugs known to influence glucose tolerance (steroids and antipsychotics), currently taking beta-blockers or calcium channel blockers, underwent bariatric surgery or plans to undergo the surgery during the study period, plans to relocate outside the study area during the study period, pregnant, or breastfeeding.

[f]IPAQ: International Physical Activity Questionnaire.

[g]ASA24: Automated Self-Administered 24-Hour Dietary Assessment Tool.

[h]Dietary habits will be assessed biweekly throughout the study duration.

[i]Physical activity of control participants will be assessed biweekly throughout the study duration.

[j]BP: blood pressure.

[k]OGTT: oral glucose tolerance test.

[l]All participants will be fitted with the continuous glucose monitoring device 10 days before the intervention, and they will be trained to replace the device every 10 days until 10 days post intervention.

Study Feasibility

Table 2 shows the study feasibility metrics. Continuous data collection on feasibility parameters, such as response rate, screening yield, enrollment rate, time to enrollment, intervention compliance, resource use (cost and staff time), and retention rate, will be conducted throughout the study.

Table 2. Study feasibility metrics.

Parameters	Calculations
Response rate	• Number of individuals responded to the invitation/number of individuals invited
Screening yield	• Number of individuals diagnosed with i-IFGa/number of individuals screened
Enrollment rate	• Number of individuals enrolled/number of individuals diagnosed with i-IFG
Time to enrollment	• Average time taken from sending the invitation to enrolling one participant in the trial
Intervention compliance	• Number of HIITb sessions attended/Total number of HIIT sessions
Resource use	• Program costs: Includes screening cost, cost of procedures, intervention cost, participant incentives, and other costs. • Staff time: Time spent screening and recruiting participants, time spent delivering the intervention, time spent making phone calls to participants, time spent implementing the study procedures, and time spent on baseline and follow-up assessments.
Retention rate	• Number of participants attended follow-up visits/number of participants enrolled

[a]i-IFG: isolated impaired fasting glucose.

[b]HIIT: high-intensity interval training.

Intervention, Feasibility, Acceptability, and Appropriateness

The Feasibility of Intervention Measure (FIM) will evaluate the feasibility of the intervention, encompassing questions regarding its implementability, possibility, doability, and ease of use [46]. The acceptability of the intervention will be assessed through the Theoretical Framework of Acceptability (TFA) questionnaire, which explores affective attitude, burden, ethicality, perceived effectiveness, intervention coherence, self-efficacy, opportunity costs, and general acceptability [47]. The Intervention Appropriate Measure (IAM) will evaluate the appropriateness of the intervention, including questions about its fittingness, suitability, applicability, and alignment with participants' needs [46]. Responses to the questions in all 3 questionnaires will be recorded on a Likert scale of 1 to 5. The mean total score for each of these scales will be calculated by combining the individual Likert points of each scale. Higher scores on the FIM, TFA, and IAM scales indicate greater feasibility, acceptability, and appropriateness, respectively, among participants.

Continuous Glucose Monitoring

By providing 288 glucose measurements per day throughout the 8-week intervention and 10-day follow-up, continuous glucose monitoring (CGM) can track the dynamic changes in fasting glucose levels induced by HIIT [48]. This can help identify when the effects of HIIT on fasting glucose levels become evident and whether these effects are sustained after the intervention, which may not be captured by a single blood glucose measurement taken after 8 weeks. All participants, regardless of their assigned treatment, will be fitted with a CGM device on their abdominal area upon enrollment. The CGM device, Dexcom G6 Pro CGM system (DexCom, Inc), will be used in blinded mode to minimize bias and ensure that it does not influence the study outcomes. Participants will be instructed to eat their last meal by 10 PM daily after the CGM fitting. They will wear CGM devices for approximately 80 days, including 10 days prior to the intervention, the 8-week intervention period, and 10 days following the intervention. Participants will be trained on how to replace the device every 10 days, using the instructions provided in the manual [49], during the first study visit. The adequacy of CGM data will be evaluated using the following criteria: a minimum of 80% of the potential 288

glucose values per day should be present for any 7 consecutive days, commencing from the day following sensor insertion [50].

Clinical Measures

Data on health behaviors, physical measurements, and biochemical measurements will be collected at both baseline and 8 weeks.

Health Behaviors

Physical activity levels will be assessed using the short form of IPAQ [32] and dietary intake with the Automated Self-Administered 24-Hour Dietary Assessment Tool questionnaire [36]. Data on smoking and alcohol use will be obtained using questions adapted from the WHO STEPS [34] and the National Health and Nutrition Examination Survey questionnaires [35].

Physical Measures

Physical measurements will be taken following standard protocols [37,51]. Height will be measured using a stadiometer (Welch Ally—Scale-Tronix) with an accuracy of 0.1 cm. Weight will be assessed using a digital weighing scale (Welch Ally—Scale-Tronix) with precision to the nearest 0.1 kg. Waist and hip circumferences will be measured using an inelastic measuring tape (BaumGartens) with a precision of 0.1 cm. Blood pressure will be measured using the DINAMAP automatic blood pressure apparatus (GE HealthCare). Body composition measures, including fat mass, muscle mass, fat-free mass, visceral adipose tissue mass, and fat percent, will be obtained using the bioimpedance analysis.

Biochemical Measures

Participants will undergo an OGTT following standard protocols [52,53]. The test will be conducted after an overnight fast of at least 10 hours, with the session scheduled between 7 and 9 AM. Venous blood samples will be collected at 0, 30, and 120 minutes after ingesting a 75-g oral glucose load dissolved in 250-300 mL of water, consumed over 5 minutes. Additionally, blood samples for insulin will be obtained at 0 and 30 minutes after glucose load ingestion. Blood samples will be processed and analyzed at the Emory Medical Laboratory (EML). EML is a fully accredited and licensed clinical laboratory, actively participating in the College of American Pathologists Laboratory Accreditation Program. Additionally, it holds Clinical Laboratory Improvement Amendments certification through the Centers for Medicare and Medicaid Services. EML is also duly licensed by the state of Georgia. Glucose levels will be assessed through enzymatic assays and insulin levels via immunoassays based on the EML protocol [53]. All these analyses will use kits provided by Beckman Coulter Inc and will be performed on a Beckman Coulter analyzer.

Indices of ß Cell Function and Insulin Resistance

Table 3 provides details on the indices of ß Cell function and insulin resistance derived from glucose and insulin levels. Early-phase insulin secretion will be assessed using the insulinogenic index [54], while total ß cell function with be evaluated with the oral disposition index [55] and homeostatic model assessment of ß cell function [56]. Whole-body insulin resistance will be determined using the Matsuda index [57] and homeostatic model assessment of insulin resistance [56], while tissue-specific insulin resistance will be assessed with the hepatic insulin resistance index [58] and muscle insulin sensitivity index [58].

Table 3. Indices of ß-cell function and insulin resistance.

ß cell function or IR[a] and components	Indices	Formula
ß cell function		
Early-phase insulin secretion:	IGI[b] [54]	$(I_{30}^{c}–I_0^{d})/(G_{30}^{e}–G_0^{f})$
ß cell function	DI_O^{g} [55]	$([I_{0\text{-}30}/ G_{0\text{-}30}]\times[1/I_0])$ • I0 in µU/l • G0 in mmol/l
ß cell function	HOMA-B[h] [56]	$(20\times I_0)/(G_0–3.5)$ • I0 in µU/l • G0 in mmol/l
Insulin resistance		
Whole-body insulin sensitivity	Matsuda index [57]	$10{,}000 /\sqrt{((G_0\times I_0)\times(G_{mean}^{i}\times I_{mean}^{j}))}$
Insulin resistance	HOMA-IR[k] [56]	$(I_0\times G_0)/22.5$ • I0 in µU/L • G0 in mmol/l
Hepatic insulin resistance	HIRI[l] [58]	$(G_0–G_{30}[AUC^{m}]\times I_{0\text{-}30}[AUC])$ • G0 in mg/dl • I0 in µU/ml
Muscle insulin resistance	MISI[n] [58]	$(dG/dt^{o})/\bar{I}^{p}$

[a]IR: insulin resistance.

[b]IGI: insulinogenic index.

[c]I_{30}: mean insulin at 30 minutes during the oral glucose tolerance test.

[d]I_0: mean insulin at 0 minutes during the oral glucose tolerance test.

[e]G_{30}: mean glucose at 30 minutes during the oral glucose tolerance test.

[f]G_0: mean glucose at 0 minutes during the oral glucose tolerance test.

[g]DI_O: oral disposition index.

[h]HOMA-B: homeostatic model assessment of ß cell function.

[i]G_{mean}: mean glucose during the 2-hour oral glucose tolerance test.

[j]I_{mean}: mean insulin during the 2-hour oral glucose tolerance test.

[k]HOMA-IR: homeostatic model assessment of insulin resistance.

[l]HIRI: hepatic insulin resistance index.

[m]AUC: area under the curve during the first 30 minutes of the oral glucose tolerance test.

[n]MISI: muscle insulin sensitivity index.

[o]dG/dt: slope of the regression line from the peak of the plasma glucose curve to its nadir (mmol/L/min).

[p]$\bar{I}$: mean insulin concentration over the 2-hour duration of the oral glucose tolerance test (pmol/L).

Qualitative Research

Participants assigned to the intervention group will be invited to take part in in-depth interviews both before and after the HIIT intervention. Trained interviewers will administer these interviews either in person during scheduled study visits or via Zoom within 1 week of the visits if participants are unable to attend in person. The interviews will be guided by interview guides specifically developed for the study and piloted with members of the study team. Preintervention interviews will delve into participants' prediabetes history, physical activity and dietary habits, perceptions of body size and image, as well as their comfort levels, perceived difficulty, confidence, and expectations regarding the HIIT intervention. Post-intervention interviews will focus on participants' experiences with the intervention. Every effort will be made to interview both dropouts and active participants to ensure a comprehensive understanding of program acceptability and to identify barriers and facilitators to adherence. All interviews will be audio recorded, transcribed verbatim, and deidentified for analysis.

Outcomes

Primary Outcomes

- Quantitative measures: (1) feasibility metrics and (2) mean FIM, TFA, and IAM scores.

Qualitative measures: participants' experiences, perceptions, and satisfaction with the HIIT intervention, and facilitators and barriers to participation.

Secondary Outcomes

- Between-group differences in changes in the following parameters from baseline to 8 weeks: (1) mean FPG and insulin levels, (2) indices of β cell function and insulin resistance, and (3) weight, body composition, waist and hip circumferences, and blood pressure.
- CGM metrics: (1) between-group differences in the proportion of time and mean time spent in nocturnal (12 to 6 AM) [50] normoglycemia (60 to <100 mg/dL) during the 8-week intervention period and the 10 days following the intervention, and (2) within-participant differences in the proportion of time and mean time spent in nocturnal (12 and 6 AM) normoglycemia (60 to <100 mg/dL) between exercise and non-exercise days during the 8-week intervention period.

Data Management

The study coordinator will enter questionnaire data, as well as physical and biochemical measurements directly into Emory University's REDCap database [30]. This database will feature validation checks to ensure data accuracy, along with skip patterns facilitated by branching logic functions. The principal investigator (ST) will constantly review the data for any errors, promptly flagging any errors for correction by the study coordinator. Upon completion of data entry and cleaning, a master copy of the data set will be generated and securely stored within the REDCap database. CGM raw data (in CSV file format per participant) will be downloaded from the DexCom Clarity software and uploaded to REDCap. Access to these datasets will be limited to the study coordinator and the principal investigator for confidentiality and data security purposes.

Sample Size Calculation

Assuming a Cohen *d* of 0.3 to <0.7 (medium standardized effect size) [25,59] for FPG in the planned main trial, with an alpha of 5% and a power of 90%, a sample size of 15 participants per treatment group is deemed necessary for this pilot study. Factoring in a 10% loss to follow-up in each group, the total sample size was estimated to be 34 participants (17 per group).

Statistical Analysis

Quantitative Research

Objective 1

Continuous variables will be summarized using either mean (SD) or median (IQR), depending on their distribution, which will be visually assessed through histograms. Categorical variables will be presented as counts (n) and percentages (%).

Objective 2

The analyses will adhere to the "intention-to-treat" principle. Between-group differences in changes in continuous variables from baseline to 8 weeks will be analyzed using mixed-effects linear regression models, while categorical variables will be assessed with log-binomial models. Skewed variables will be log-transformed prior to analysis. Fixed effects will include the study group (intervention vs control), timepoint (follow-up vs baseline), and the interaction between the study group and timepoint. Random effects will be specified for participants to account for the correlation between repeated measurements on the same individual. The *P* value for the study group-by-timepoint interaction will be used to evaluate the difference in changes between the study groups. The correlation between changes in fasting glucose levels and the indices from baseline to 8 weeks will be assessed using either Pearson or Spearman correlation coefficients, depending on the nature of the data distribution. Mixed-effects linear regression models will be used to compare CGM metrics between study groups, adjusting for baseline values. These models will also examine within-participant differences in CGM metrics between exercise and non-exercise days. Statistical significance will be considered with a 2-sided *P* value<.05 with no adjustments for the multiplicity of comparisons. All analyses will be conducted using Stata (version 18.0; StataCorp LLC).

Qualitative Research

In-depth interviews will be conducted with intervention group participants and dropouts. All interviews will be audio recorded and transcribed verbatim for analysis. The qualitative analysis plan involves 2 main components: a framework-driven analysis of intervention acceptability data and a thematic analysis focusing on participant expectations, experiences, barriers, and facilitators in undergoing the HIIT intervention. For the framework-driven analysis, a deductive codebook containing the TFA dimensions will be applied to both baseline and postintervention interview data. This approach aims to provide a comprehensive and longitudinal understanding of HIIT acceptability among program users, comparing results across timepoints and between those who remained in the program and study dropouts. Additionally, an inductive approach will be used to create a codebook of inductive codes around other aspects of acceptability, program barriers, facilitators, experiences, and sustainability through a close reading of the transcripts. Once the data is coded, thick descriptions of individual codes will be developed, including structured comparisons such as between baseline and postintervention interviews, program adherents and dropouts, men and women, and older and younger participants. These comparisons will guide data reporting and program adaptation for further trials, providing insights into the diverse experiences and perspectives of participants.

Challenges and Mitigation Strategies

The potential challenges that could be encountered at various stages of the study and the corresponding mitigation strategies are outlined in Table 4.

Table 4. Potential challenges and proposed mitigation strategies.

Study stage	Challenges	Mitigation strategies
Identifying potential participants	Insufficient number of potentially eligible individuals	• We will use physician referrals as an additional recruitment strategy.
Screening	Low yield of screening	• The 3-step screening procedure was carefully designed, drawing upon insights from our previous research and existing literature, to target individuals who are likely to have i-IFG[a].
Intervention	Low HIIT[b] compliance	• The study coordinator will remind participants of their scheduled exercise sessions through phone calls. Additionally, the coordinator will regularly review the attendance log, providing motivation and support to participants with low attendance levels. • The exercise instructor will hold weekly one-on-one meetings with participants to review their progress and provide motivation, specifically targeting those with low attendance levels.
Procedures	Periodic data gaps with CGM[c] whenever the receiver is located more than 5 feet	• The CGM data will be assessed for adequacy based on the following criteria: Data points must be present for at least 80% of the possible 288 glucose values per day for any 7 consecutive days, starting on the day after sensor insertion.
Follow-up	Low retention rate	• Compensation for time and parking: (1) participants will receive a US $50 gift card upon completion of the study and (2) parking fees at study sites will be covered. • Building rapport: study staff will create a warm and supportive environment during study visits, fostering a sense of trust and comfort. • Ongoing support: the study coordinator will provide continuous support through regular phone calls. This proactive approach ensures that participants feel connected to the study outside of scheduled visits. The study coordinator will address any concerns, answer queries, and offer encouragement, reinforcing a sense of partnership between participants and the research team.

[a]i-IFG: isolated impaired fasting glucose.

[b]HIIT: high-intensity interval training.

[c]CGM: continuous glucose monitoring.

Ethical Considerations

The study protocol was approved by the institutional review board of Emory University, Atlanta, USA (MOD001-STUDY00005855). All participants will provide written informed consent prior to study participation. Participant identifiers will be kept strictly confidential in a secure REDCap database, accessible only by the principal investigator and study coordinator. Data will be deidentified before analysis. Participants will receive a US $50 gift card as compensation for their participation.

Results

Table 5 shows the study timeline. Recruitment for the study is scheduled to begin in February 2025, with follow-up expected to be completed by the end of September 2025. We plan to publish the study findings by the end of 2025.

[e]HIIT: high-intensity interval training.

Discussion

Expected Findings

This proof-of-concept study will generate data on the feasibility and acceptability of the HIIT intervention, as well as participants' experiences and satisfaction levels. Additionally, the study will offer preliminary estimates on the efficacy of HIIT in reducing FPG levels and addressing the pathophysiology of i-IFG.

Strengths and Limitations

To our knowledge, this study will be the first to assess the feasibility and acceptability of a HIIT intervention exclusively among individuals with i-IFG. Additionally, we adhered to the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) statement [60] when reporting the details of this study protocol. However, there are some limitations. We will assess the pathophysiological abnormalities in i-IFG using indices derived from the OGTT and fasting insulin levels instead of gold-standard methods like the intravenous glucose tolerance test and glycemic clamps [61-63]. However, these indices have demonstrated strong correlations with estimates obtained from the gold-standard methods [61-63]. Additionally, our reliance on a single OGTT may be subject to day-to-day variability in glucose tolerance status. Nevertheless, strict adherence to standardized protocols for conducting the OGTT [52,53] should help minimize this variability to a significant extent.

Conclusions

The results of this study are expected to guide the design and implementation of an RCT to assess the efficacy of HIIT intervention in reducing diabetes incidence and achieving remission in individuals with i-IFG.

Acknowledgments

This study was supported by the Georgia CTSA's Pilot Program, funded by the Robert W Woodruff Health Science Center at Emory University and the National Center for Advancing Translational Sciences of the National Institutes of Health (NIH; award UL1TR002378). The qualitative research component of the study was supported by the National Institute of Diabetes and Digestive and Kidney Diseases of the NIH (award P30DK111024). ST was partially supported by a grant (75D30120P0742) from the Centers for Disease Control and Prevention, Atlanta. RB was partly funded by the NIHR Applied Research Collaboration West Midlands. The content is solely the responsibility of the authors and does not necessarily represent the official views of the Robert W Woodruff Health Science Center or the NIH. The funder had no role in the conceptualization, design, data collection, analysis, decision to publish, or preparation of the manuscript.

Authors' Contributions

ST, LS, FL, MLMS, MDS, FJP, and JRN conceived the idea; ST received funding; ST, TRZ, MBW, LS, FL, MLMS, MDS, FJP, and JRN designed the study methodology; ST wrote the first draft of the manuscript; TRZ, MBW, LS, FL, MLMS, MDS, AV, RB, FEF, MP, SK, RJT, JES, FJP, and JRN reviewed the manuscript draft and provided critical comments. All authors have read and agreed to the published version of the manuscript.

Conflicts of Interest

FP received research support from Dexcom, Ideal Medical Technologies, Tandem Diabetes Care, and Novo Nordisk, and consulting fees from Dexcom and Insulet (paid to his institution). None of these entities were involved in the development of this manuscript, and none had editorial oversight.

Abstract

Background: There are limited therapies approved for the treatment of aggression and agitation in patients with dementia. While antipsychotics and benzodiazepines are commonly used, these medications have been associated with significant side effects and US Food and Drug Administration (FDA) boxed warnings. Weighted blankets have been associated with decreased anxiety and improved sleep. Weighted blankets are potentially a nonpharmacologic option to reduce agitation in hospitalized patients with dementia.

Objective: The aim of this study is to investigate the effect of weighted blankets on aggression and agitation in hospitalized patients with dementia.

Methods: A pilot study will be conducted on a total of 30 hospitalized patients with a documented clinical diagnosis of dementia and ongoing agitated behaviors admitted to a medicine or psychiatry service. Patients will be randomly allocated to receive either a weighted blanket for 3 nights or continued usual care. The primary outcome is the change in the observational version of the Cohen-Mansfield Agitation Inventory (CMAI-O) over the course of the 3-night study period. The secondary outcomes are changes in Edmonton Symptom Assessment System Revised (ESAS-r) and Clinical Global Impression (CGI) scores, hours of sleep, use of antipsychotics and benzodiazepines, and incidence of delirium. Identical study assessments will be completed for both the usual care and the weighted blanket study groups. At 5 study time points (baseline, postnight 1, postnight 2, postnight 3, and a final assessment 48-72 h after the last use of the weighted blanket), patients will be assessed with the CMAI-O, ESAS-r, and CGI tools. All assessments will be completed by the bedside nurse or patient care assistant caring for the patient each day. Within 2 to 4 weeks post discharge from the hospital, study coordinators will contact the patient's legally authorized representative (LAR) to assess for continued use of the weighted blanket.

Results: Enrollment of participants began on April 23, 2023. As of November 2024, a total of 24 participants have been enrolled in the study. Baseline characteristics of enrolled participants will be analyzed and reported upon completion of enrollment. We anticipate completing data collection by March 2026.

Conclusions: The study will determine the effect of weighted blankets on agitation in hospitalized patients with dementia. Insights into the effect of weighted blankets on sleep will also be gained. The results of this study will be relevant in the setting of increasing numbers of older adults with dementia exhibiting agitation, leading to increased hospitalizations, caregiver burden, and health care costs.

KEYWORDS

dementia; hospitalized dementia patients; agitation; aggression; behaviors; sleep; weighted blankets; nonpharmacologic strategy; pilot study; inpatients; occupational therapy

Introduction

Background

Many patients with dementia develop neuropsychiatric symptoms and somewhere between 40% and 76% of patients demonstrate agitation and aggression [1,2]. Agitated behaviors are often disruptive and difficult to manage, and are associated with increased caregiver burden and burnout, increased hospitalizations, and elevated health care costs [1,3]. Agitation includes a range of behaviors, including restlessness, pacing, physical aggression, and verbal agitation [4].

Nonpharmacologic strategies are the first line in the prevention and treatment of neuropsychiatric symptoms of dementia, including agitation. Limited pharmacologic options exist in this setting. In fact, no pharmacologic therapies were approved by the Food and Drug Administration (FDA) for this indication until the recent approval of the atypical antipsychotic brexpiprazole for the treatment of agitation associated with dementia due to Alzheimer disease [5]. Other antipsychotics are commonly used, particularly in emergency and acute care settings when agitated or aggressive behaviors threaten either patient or caregiver [6]. These medications, however, are associated with significant serious long- and short-term side effects including akathisia and restlessness [7], and carry an FDA-boxed warning for increased risk of mortality [8]. The 2016 American Psychiatric Association practice guidelines recommend that antipsychotic medications be reserved for severe, dangerous, or significantly distressing symptoms and used at the lowest effective dose due to concern for side effects [9]. The management of agitated and aggressive symptoms without primary reliance on antipsychotics remains a challenge. Benzodiazepines are typically avoided due to the risk of cognitive impairment, falls, and respiratory depression [10].

Weighted blankets are filled with plastic pellets or beads and are commercially available in weights ranging from 5 to 30 pounds. Weighted blankets have been used in occupational therapy as a form of noninvasive deep-pressure stimulation, which appears to increase parasympathetic arousal and decrease anxiety [11-13]. Weighted blankets have been studied in patients with psychiatric diagnoses in both the inpatient and outpatient settings, and they appear to be associated with decreased anxiety and improved sleep [14,15]. Weighted blankets have also been associated with improved chronic pain and reduced anger scores [16,17]. Currently, however, there are no studies investigating the use of weighted blankets to address agitation in hospitalized patients with dementia.

Objectives

The aim of this study is to investigate the effect of weighted blankets on aggression and agitation in hospitalized patients with dementia. We hypothesize that compared to controls, patients with agitation in the setting of dementia will show reduced agitation, reduced anxiety, and potentially improved sleep while hospitalized when provided with a weighted blanket.

Methods

Design and Randomization

To address this question, we designed a pilot study (ClinicalTrials.gov NCT03643991) with 1:1 randomization of hospitalized patients with dementia and evidence of agitated behaviors to receive either a weighted blanket for 3 nights or continued usual care.

Study Population and Recruitment

Patients will be recruited from a single large tertiary care hospital. Participants are eligible for inclusion if they are 60 years or older, have a documented clinical diagnosis of dementia, and are currently admitted to either a medicine or psychiatry primary service. All participants are required to have ongoing agitated behaviors at the time of enrollment as demonstrated by an elevated CMAI-O with a score of 2, 3, or 4 on at least one aggression-related item (items 1-11 or 22-24) [18]. Patients will be excluded if they have severe pain likely to be exacerbated by the use of the weighted blanket, have significant burns or wounds for which weighted blanket use could potentially be detrimental, or are admitted on a 72-hour involuntary hold. Participants can be enrolled at any point during their hospitalization. Hospitalizations will not be prolonged for the purpose of the study. To reflect real-world conditions, all other usual medical care will be continued at the discretion of the primary medical or psychiatric team.

Intervention

Participants will be randomized 1:1 to either the usual care group or the weighted blanket group. The weighted blankets used are commercially available and purchased for the study. Patients randomized to the weighted blanket group will be provided with either a 10 lb, 15 lb, or 20 lb weighted blanket, ensuring that the weight is not more than 10% of the participant's body weight. Participants will be withdrawn from the study if they refuse the blanket or are unable to tolerate it for more than 2 hours on the first night after enrollment. Participants can also be withdrawn from the study at any time if the primary team feels that further participation will jeopardize patient safety. Enrolled participants will use the blanket for a total of 3 consecutive nights, or until the time of discharge if that occurs sooner. Following participation in the study, participants will be allowed to keep the weighted blanket for future personal use. To reduce potential bias, the data analysis team will remain blinded to group assignment during statistical analyses, although investigators administering the questionnaires will not be blinded due to the nature of the intervention.

Primary Outcome

The primary end point will be the change in CMAI-O over the course of the 3-night study period. The CMAI-O is a validated scale published in 2020 by Griffith et al [18] to quantify neuropsychiatric behavior in patients with dementia. Observers rank the frequency of 29 behaviors grouped into categories: physical aggressive behaviors (questions 1-11), physical nonaggressive behaviors (questions 12-21), verbal aggressive behaviors (questions 22-24), and verbal nonaggressive behaviors (questions 25-29). The frequency of each behavior is ranked as 1 (never), 2 (less than once per h), 3 (once per h), and 4 (several times per hour).

Secondary Outcomes

Secondary end points will include change in Edmonton Symptom Assessment System Revised (ESAS-r) score and change in Clinical Global Impression (CGI) score as well as hours of sleep, use of antipsychotics and benzodiazepines, and incidence of delirium.

The ESAS-r was originally designed as a self-report tool in which patients rate the severity of 9 symptoms on a scale from 0 to 10 (10 being the most severe) [19]. The tool assesses the following nine symptoms: pain, tiredness, drowsiness, nausea lack of appetite, shortness of breath, depression, anxiety, and well-being. This assessment tool has been commonly used in palliative medicine and oncology settings, translated into several languages, and is well received by patients and nursing staff [19]. The ESAS-r captures the pattern of a patient's severity of symptoms at a point in time and may be repeated to track changes over time. Since patients with a diagnosis of dementia vary significantly in their ability to report symptoms, we have standardized the protocol by using caregiver (nurse or patient care assistant) input to complete the ESAS-r assessment tool [19].

The CGI scale is a brief, independent assessment initially designed to summarize a caregiver's view of a patient's global functioning before and after initiating an intervention [20]. The CGI consists of 2 one-item measures that evaluate the severity of psychopathology and change from the initiation of treatment on a 7-point scale. The CGI may be used to track clinical progress over time [20].

Further clinical data will be extracted from the medical record. Caregiver staff will estimate hours of sleep. Use of antipsychotics and benzodiazepines will be recorded based on the medical administration records. The incidence of delirium will be estimated based on documentation of a newly positive Brief Confusion Assessment Model (bCAM) assessment [21]. Delirium Triage Screen and bCAM assessments are performed to screen for delirium every 12 hours (once per nursing shift) in the hospital where this study will be conducted.

Study Timeline and Follow-Up

Identical study assessments will be completed by the patient's caregiver (either registered nurse or patient care assistant) for both the usual care group and the weighted blanket study group. Cohen-Mansfield Agitation Inventory (CMAI-O), ESAS-r, and CGI scores will be collected at 5 study time points (baseline, postnight 1, postnight 2, postnight 3, and a final assessment 48-72 hours after the last use of the weighted blanket). A total of 3 nights were determined to be sufficient for assessing trends in agitation, anxiety, and sleep, while also testing the feasibility of the intervention in a real-world clinical environment. Within 2-4 weeks following hospital discharge, study coordinators will contact the patient's legally authorized representative (LAR) to assess for continued use of the blanket. Refer to the patient timeline (Table 1).

Table 1. Patient timeline.

Assessment	Baseline (enrollment)	WB[a] day 1	WB day 2	WB day 3	Final within 72 hours of last use of WB (cohort 1) or no WB (cohort 2)	Within 2-4 weeks post discharge
CMAI-O[b]	✓	✓	✓	✓	✓	
ESAS-r[c]	✓	✓	✓	✓	✓

Posthospitalization phone call to assess continued weighted blanket use						✓

[a]WB: weighted blanket.

[b]CMAI-O: Cohen-Mansfield Agitation Inventory.

[c]ESAS-r: Edmonton Symptom Assessment System Revised.

[d]CGI: Clinical Global Impression.

Sample Size

We will target an enrollment of 30 participants in this pilot study. This sample size was chosen to balance the need for gathering preliminary data with the constraints of patient availability, time, and resources within our hospital setting. The sample size of 30 is sufficient to provide preliminary insights into the effects of weighted blankets on agitation, allowing us to explore trends and estimate effect sizes for future studies. Recruitment will be facilitated by daily review of hospital-wide behavior emergency response team activations and patient referrals from inpatient medicine and psychiatry primary services.

Data Collection, Management, and Confidentiality

Participants will be randomized 1:1 to the treatment and usual care groups via computer-generated sequence which will be concealed until after each patient's enrollment. Given the nature of the study, blinding of caregivers and study coordinators to treatment groups is not feasible.

Data will be collected by study personnel in a manner consistent with patient confidentiality. For patients withdrawn from the study, no further data will be collected but existing study data to the point of withdrawal will be included in the final analysis which will be performed based on intention to treat.

All data obtained will be entered into REDCap (Research Electronic Data Capture), a secure electronic database that is password-protected and accessible only to the study team. Each participant will be assigned a unique identification code to protect their identity, and only the code will be used for forms, reports, and data analysis. Paper records containing protected health information will be maintained in locked file cabinets in a secure room accessible only to research personnel. All patient information will be kept confidential and managed according to the Health Insurance Portability and Accountability Act of 1996 requirements.

Data Analysis

A per-protocol analysis will be used. Baseline characteristics of participants will be reported using percentages for categorical variables and mean with SD for continuous variables. Differences between the 2 treatment groups for the descriptive variables will be compared using chi-square tests for categorical variables and Kruskal-Wallis tests for continuous variables. The medications and dosages taken during the study will also be reported. The primary outcome of the CMAI-O score will be described at each of the 5 time points (baseline, day 1, day 2, day 3, and day 72 follow-up). A linear mixed effects model with time as a random effect will be used to analyze changes in the CMAI-O score over time. Both the unadjusted and an adjusted model with age, sex, and unit type as covariates will be reported. Age and sex were included as covariates as they are standard demographic factors that can influence behavioral outcomes. Unit type (medicine vs psychiatry) was included as it may impact patient management practices and potentially influence study outcomes. This model also allows for missing data which occurs in the dataset when a patient was discharged before the end of the study period. Secondary outcomes of ESAS-r and CGI scores will be analyzed in a comparable way with a linear mixed model. The end-of-study survey results will be described for each question. A per-protocol analysis will evaluate only the enrolled patients who followed protocol.

Monitoring

The principal investigator will conduct weekly meetings with the study coordinator and research team to review the status of the study, recruitment and enrollment of participants, protocol adherence, safety issues, and overall conduct of the study. The principal investigator will monitor, track, and report any adverse events, protocol deviations, and progress reports or continuing reviews to the institutional review board (IRB) with research regulations.

Ethical Considerations

This study follows the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) guidelines for reporting (see Multimedia Appendix 1). The study protocol was approved by the Mayo Clinic IRB (IRB 17-009951) and was registered with ClinicalTrials.gov (NCT03643991). Amendments to the protocol will be submitted to the Mayo Clinic IRB for approval before implementation. Written informed consent approved by the IRB will be obtained from the participant's LAR, who will be provided sufficient information regarding the risks and benefits of the study to make an informed decision about the participation of their loved ones in the study. The LARs will be fully informed about their right to withdraw participation at any time. No compensation is being provided to participants, although individuals randomized to the weighted blanket group are permitted to keep the weighted blanket. Study investigators will have access to the final dataset, which will include deidentified participant information only as outlined above in the "Data Collection, Management, and Confidentiality" section. Results will be submitted to a peer-reviewed journal and scientific conferences for the advancement of clinical care.

Results

Enrollment of participants began on April 23, 2023. As of November 2024, 24 participants have been enrolled in the study. Baseline characteristics of enrolled participants will be analyzed and reported upon completion of enrollment. We anticipate completing data collection by March 2026. The study results will be reported in a peer-reviewed journal upon completion.

Discussion

Primary and Secondary Outcomes

We hypothesize the use of a weighted blanket will reduce patients' behaviors and agitation; therefore, patients' CMAI-O scores will decrease. In addition, we anticipate patients' ESAS-r and CGI scores will decrease with the use of a weighted blanket. We hope with reduced behaviors and agitation that patients will have reduced antipsychotic and benzodiazepine administrations and decreased incidence of delirium.

Strengths and Limitations

There are several strengths of this study. This study is a randomized controlled trial being performed in both medical and psychiatric inpatient settings at an academic medical center. The study's intervention is a nonpharmacologic option that has minimal potential side effects. The study is a pilot study that can offer opportunities for further research studies. A couple of the study's limitations are the small sample size and performed at a single organization. In addition, the investigators are nonblinded and could lead to a potential bias. It is unclear if the results will be generalizable to all patients with agitation and dementia, other health care organizations, and outpatient settings.

Conclusions

This study addresses the important clinical issue of agitation in hospitalized patients with dementia. This study will contribute to the growing body of knowledge on nonpharmacological management of behavioral symptoms in older adults with dementia. This is important as the management of agitated and aggressive symptoms without primary reliance on antipsychotics and benzodiazepines remains a challenge. We anticipate that these study results will be used to inform health care professionals, caregivers, and family members regarding the potential usefulness of weighted blankets as a nonpharmacologic method to decrease agitation and distress in hospitalized older adults with dementia.

Acknowledgments

This is an investigator-initiated clinical trial by MIL. MIL is supported in part by a grant (R01AG061100) from the National Institute on Aging and has no financial relationships to disclose. The study is made possible by the generous support of a benefactor through Mayo Clinic Development, which serves as the primary source of funding for this research. Additional support is provided by the Mayo Clinic Center for Translational Science Activities through a grant (UL1 TR000135) from the National Center for Advancing Translational Sciences, a component of the National Institutes of Health (NIH). The study is supported by the Mayo Clinic Department of Medicine Research Hub and the Division of Hospital Internal Medicine. Abstract

Background: Digital health interventions have become increasingly popular in recent years, expanding the possibilities for treatment for various patient groups. In clinical research, while the design of the intervention receives close attention, challenges with research participant engagement and retention persist. This may be partially due to the use of digital health platforms, which may lack adequacy for participants.

Objective: This systematic literature review aims to investigate the relationship between digital health platforms and participant engagement and retention in clinical research. It will map and analyze key definitions of engagement and retention, as well as identify design characteristics that influence them.

Methods: We will carry out a mixed methods systematic literature review, analyzing qualitative and quantitative studies. The search strategy includes the electronic databases PubMed, IEEE Xplore, CINAHL, Scopus, Web of Science, APA PsycINFO, and the ACM Digital Library. The review will encompass studies published between January 2018 and June 2024. Criteria for inclusion will be the presence of digital health care interventions conducted through digital health platforms like websites, web and mobile apps used by patients, and informal caregivers as research participants. The main outcome will be a narrative analysis with key findings on the definitions of participant engagement and retention and critical factors that affect them. Quality assessment and appraisal will be done through the Mixed-Methods Assessment Tool. Data analysis and synthesis will follow the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) 2020 flow diagram. Quantitative data will be qualified and integrated into qualitative data, which will be analyzed using thematic analysis and synthesis.

Results: The study expects to map and summarize critical definitions of participant engagement and retention, and the characteristics of digital health platforms that influence them. The systematic review is expected to be completed in June 2025.

Conclusions: This systematic review will contribute to the growing discussion on how the design of digital health intervention platforms can promote participant engagement and retention in clinical research.

Introduction

In 2022, over 100,000 health care mobile apps were available in Apple and Google app stores combined [1]. Digital health care has transformed care delivery through a diverse fleet of technologies, from mobile apps and wearable devices to biosensors and the Internet of Things [2]. It offers a myriad of innovative ways to provide treatments, monitor health conditions, assist, and empower patients with diverse needs to be more in charge of their health, and enable health care professionals to deliver better service [3]. Following the expansion of the digital health care range, digital health (DH) interventions have also increased exponentially (Textbox 1). DH interventions are interventions delivered through digital technology for the treatment or management of physical or mental conditions [4].

Textbox 1. Key concepts.

Digital health intervention

- Interventions are delivered through digital technologies such as smartphones, websites, wearables, video games, or text messaging [2,5,6]. A digital health intervention offers guidance, information, and support for a diversity of physical or mental health conditions through a digital platform. Also commonly referred to as health informatics or eHealth interventions [7]; they are designed to help people avoid, recover from, or cope with disease and disability or to improve the quality and safety of health care [8], for example, as self-help or self-guided eHealth interventions [9,10].

Digital health platforms

- Websites, web-based or mobile apps used to access digital health interventions.

Digital clinical research

- Clinical research is conducted through digital health platforms. It may include digital health interventions, digital data collection, and electronic Case Report Forms, among other resources. Only digital clinical research encompassing digital health interventions will be considered for this study.

Research participant

- Recipients of intervention; for example, patients or informal caregivers.

Participant engagement

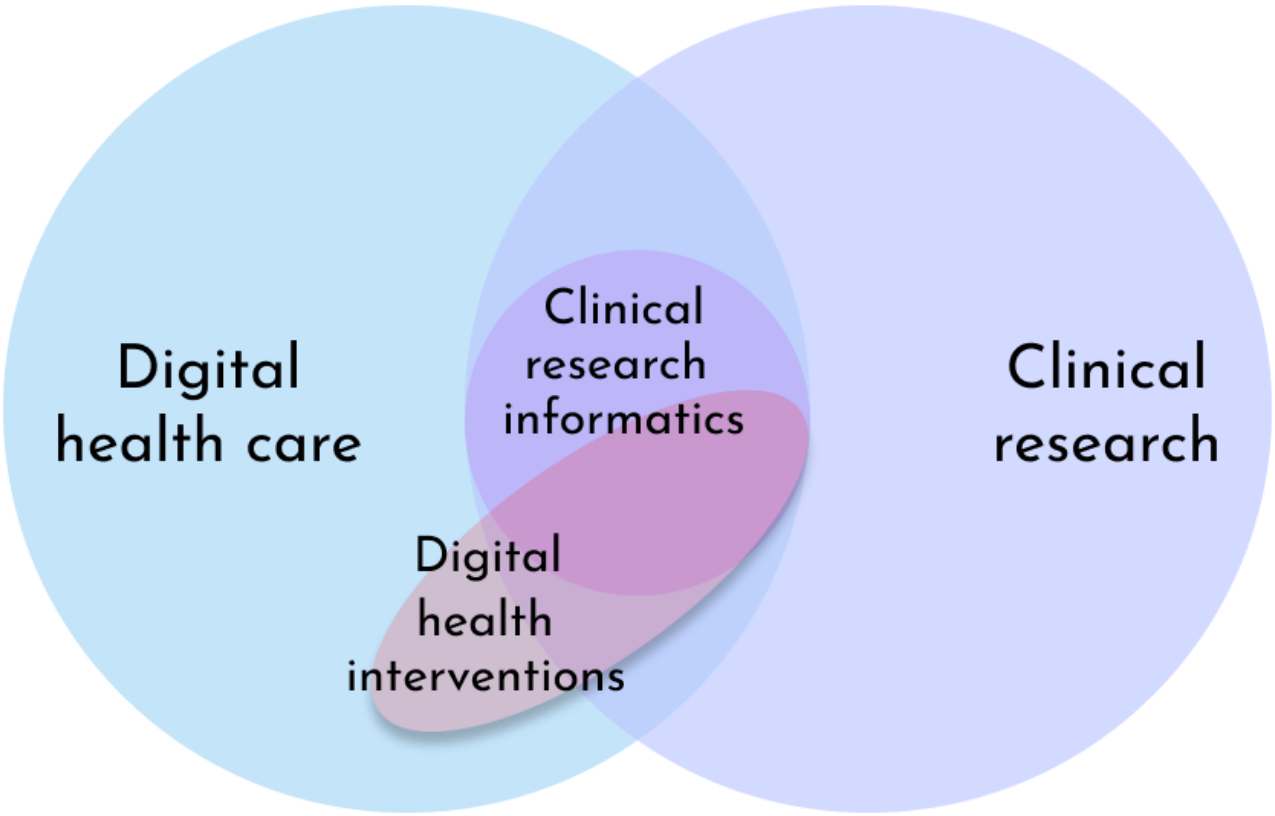
- Length and depth of participant's involvement with the digital health intervention.

Participant retention

- Duration and continuity of the participant's involvement with the digital health intervention.

Through online treatments, DH interventions promise to improve health care, enhancing accessibility, effectiveness, and personalization [2,11]. DH interventions are available in commercial applications, as easily accessible health care, and as part of clinical research (Figure 1). When conducted as part of clinical research, they share the same benefits as general digital health care. DH interventions also allow for the development of effective treatments for more patients [11], are more community-inclusive [12], decrease health disparities [13], and improve study generalizability and validity [14,15]. Successful clinical research generates evidence that, in turn, promotes health care improvements [16].

Figure 1. Digital health interventions are part of general digital health care and clinical research. The latter can be delivered through clinical research informatics or commercial health platforms and software.



In clinical research, DH interventions are designed following the principles of clinical research informatics (CRI) [4]. CRI is the use of informatics principles and techniques to conduct clinical research [4]. DH interventions have the potential to accelerate the process from initial research to "real world" outcomes, contributing to increasing scale and distribution, cost and resource optimization, and facilitating financial auditing processes [12,16-18]. These principles could also be applied to DH interventions.

Both engagement and retention of clinical research participants are crucial intervention research outcomes, but the concepts have varying definitions. Frequently, different terms for engagement are used interchangeably, like involvement, participation, acceptability, and completion rates, among others. Engagement can be described as the extent and manner in which people actively use a resource [19]. Perski et al [20] define engagement as two main concepts: (1) a subjective experience, meaning a state of focus and interest with a temporal dissociation, and (2) a behavior, described as usage over time. It is often connected to concepts like adherence, duration, and frequency that can be quantified through concrete measurements like opening or using a mobile app, frequency of times, or the duration of the use [21]. Participant retention, in turn, refers to the proportion of recruited participants who remained in the study until its end and at an optimal proportion that does not compromise the study's validity [22,23].

In DH intervention research, both engagement and retention can vary considerably. Intervention dropout from internet-based treatment for psychological disorders, for example, fluctuates between 30% and 50% [24]. While poor engagement or retention may be due to the intervention quality or outside factors, an often-overlooked component is the design of DH platforms. Appraising the DH platforms' design choices and how they impact participant engagement and retention could help make DH interventions better. In this context, there is an untapped opportunity to explore the practical factors that affect intervention success. This systematic literature review will focus on DH platforms' design choices concerning engagement and retention and their relationship with research participants' behavior.

The relationship between DH platforms and research participants is receiving growing interest, as evidenced by the increase in research. Studies have examined participant engagement and retention across various settings, for example, mHealth or web-based platforms [21,25], focusing on particular patient groups, for example, older adults with dementia or digital mental health interventions [26-29].

Still, a comprehensive literature review on the relationship between DH interventions and participant engagement and retention in digital clinical research has yet to be conducted. This review aims to fill the gap by studying DH platforms that have been used in digital clinical research. We will map the various definitions that capture the engagement and retention of research participants in DH interventions. We will further identify platform design factors and features that hinder or promote participants' engagement and retention. The key concepts relevant to the review are defined in Textbox 1.

Methods

This systematic review was submitted for registration with the International Prospective Register of Systematic Reviews (PROSPERO) on June 8, 2024 (CRD42024561650), to avoid bias in conducting and reporting findings. According to the study's progress, amendments will be made if necessary [30].

Review Question

The review question was elaborated using the Population-Exposure-Outcome (PEO) statement, as outlined in Textbox 2. We chose to apply the PEO as it is regarded as the more appropriate approach for qualitative inquiries [31]. It is also more suitable for the definition of associations between particular exposures and factors and related outcomes [32]. The overall review question is: What factors and aspects promote research participants' engagement with and retention in DH interventions in digital clinical research? This was further broken down into 2 specific research questions:

Research question 1: How are engagement and retention of research participants defined in DH interventions conducted for clinical research?

Research question 2: What user interface elements, interaction design, and platform characteristics influence research participants' engagement and retention in DH interventions?

Textbox 2. Population-exposure-outcome structure.

Population-exposure-outcome element and description
Population
Research participants who are patients, informal or family caregivers.
Exposure
User interface, interaction elements, and platform characteristics of digital health interventions conducted in clinical research.
Outcomes
Engagement and retention of research participants.

Methodology Choice Rationale

The choice to perform a mixed methods systematic literature review is due to the number of individual studies that have already been conducted in digital health care and DH interventions, providing substantial evidence for the review.

The methodology selected for this systematic literature review is the mixed methods systematic review (MMSR) [33]. It is a standard approach that allows to systematically combine qualitative and quantitative data [34]. By integrating the findings of effectiveness (quantitative data) with findings on participants' experiences (qualitative data), MMSR offers a comprehensive evaluation with balanced data insights [35].

We plan to carry out the MMSR as we expect both data types to be prevalent in the reviewed studies. By including both data types, we will adopt a holistic approach to defining engagement and retention. For instance, qualitative data can shed light on the context, patient and informal caregivers' experiences, and barriers to engagement and retention, which quantitative data alone may not fully capture.

Search Strategy

We will analyze studies that (1) offered a DH intervention; (2) used a DH platform component, such as a mobile app, website, or text-messaging process; (3) collected engagement and retention-related measurements–quantitative, qualitative, or both; and (4) presented a digital interface to the research participants—patients, and informal caregivers—to interact with the DH intervention. The DH platforms can be designed specifically for clinical research or not. Commercially available health applications will be considered if they are used for clinical research purposes.

The search strategy for this systematic literature review was developed in collaboration with Görel Sundström, a librarian from Uppsala University, and the researchers involved in this study, LT, AK, MH, and MIM.

The PEO statement was used to construct the search strategy (Table 1). The keywords refinement process involved different approaches: tests conducted by the librarian, consultation of referenced articles to analyze the keywords they used, and expert reviews conducted by the research team. The keywords selection process was performed to ensure the search would capture studies using various terminologies to address the same research questions (Multimedia Appendix 1).

Table 1. Preliminary Web of Science search strategy (to be adapted for the other databases).

Search number	Database search algorithm
User engagement, user retention, and metrics	
1	(“active user*” OR Attrition OR “Click rate” OR “Completion rate*” OR “Frequency of use” OR “Follow up” OR Login OR “log in” OR “Returning user*” OR “Session duration” OR “Sign in” OR “Study complet*” OR “Time spent” OR usage OR “User actions” OR “Use Rate*” OR “User metric*” OR “user session*”)

Combining all topics	
8	3 AND 6 AND 7

The search will be conducted across a range of electronic databases: PubMed, IEEE Xplore, CINAHL, Scopus, Web of Science, APA PsycINFO, and the ACM Digital Library. These databases are chosen based on their relevance to the research topic and their widespread use in academic and research communities.

In addition to the electronic database searches, the research team will use additional search methods to identify potential studies that may not be captured through the database searches. It includes hand search, which involves manually scanning relevant journals; back-forward citation tracking, where we examine the references of identified articles; and reference checking to ensure no valuable sources are overlooked during the review process.

This systematic literature review will not involve collecting sensitive personal data.

Study Selection Criteria

The PEO statement was used to outline the eligibility criteria for study inclusion and exclusion, delineating them by population, exposure, and outcomes (Table 2).

Table 2. Population-exposure-outcome inclusion and exclusion criteria.

PEO[a]	Inclusion criteria	Exclusion criteria
Population	Research participants, study participants, patients, informal caregivers, carers, caregivers, and users. No exclusion based on age or gender.	Researchers, physicians, doctors, nurses, social care workers, social workers, dentists, and health care professionals.
Exposure or environment	User interface and interaction design of DH platforms.	Engagement and experience related to the intervention or treatment itself. Experience with content quality (text and multimedia content).
Outcomes	Engagement and retention to the study.	Efficacy of the treatment, efficacy related to the intervention or treatment itself.
Study methods	Qualitative methods, quantitative methods, mixed methods.	Reviews (systematic, scoping, meta-analysis, etc)
Publication types	Formally published peer-reviewed journal articles, conference papers.	Grey literature, opinion pieces, protocols, reviews
Geographical considerations	Initially not limited to any geographical area.	

[a]PEO: Population-exposure-outcome.

Types of Studies

Qualitative Studies

Qualitative interviews, focus group discussions, usability studies, participatory research, participatory design, case studies, grounded theory research, thematic and content analysis of textual data, phenomenological studies, narrative research, and ethnographic observations.

Quantitative Studies

Randomized controlled trials, cohort studies, longitudinal studies, experimental studies, case-control studies, cross-sectional studies, and observational studies.

Mixed Methods Studies

Studies integrating qualitative and quantitative data collection and analysis methods within a single research design, encompassing but not restricted to convergent design, sequential explanatory design, and sequential exploratory design.

In the case of studies addressing the same DH intervention and cohort of individuals, only the study with more detailed data regarding engagement and retention-based measurements will be considered, unless the studies present different aspects of the 2 mentioned subjects.

Studies such as gray literature, editorials, letters, opinion papers, and theses and dissertations will be excluded.

Time Period

The study will consider articles published from January 2018 to June 2024. This 7-year publication window was chosen because of the rapid evolution in the technology and health informatics domain. The timeframe also covers DH intervention platforms developed before and after the COVID-19 pandemic [36].

Language

Due to resource constraints, the study will exclusively include articles published in English. The research team acknowledges that this approach limits the inclusion of studies performed in different parts of the world and published in other languages.

Study Screening

First, a search conducted by an independent librarian will identify potentially eligible studies based on predefined keywords that consider the inclusion and exclusion criteria. The results from this initial search will undergo deduplication: Duplicates will be identified and removed using EndNote (version 21; Clarivate), using the Bramer et al [37] guidelines. The remaining studies will then be imported into Covidence [38]. There, data will be screened in two steps: (1) title and abstract screening, and (2) full-text screening. During the first step, at least 2 reviewers will independently review the titles and abstracts, blinded to the authors' names, and each other's review decisions (ie, double-blinded) [38]. After, the potential articles will have their full text screened, filtered, and categorized according to the predefined inclusion and exclusion criteria. In the event of disagreements between the 2 reviewers, at either stage of the review process, a third reviewer (LT) will be consulted to reach a consensus.

Data Extraction

The data extraction will use a standardized data extraction form elaborated by the research team. The form is designed to capture study information such as (1) identification: study ID, authors, year, country, publication type, and analysis type (qualitative, quantitative, and mixed-methods); (2) characteristics: research participants' characteristics, age, sample size, intervention description, digital platform or software, and the medium used; (3) results: engagement and completion measurements, results and findings presented in qualitative and quantitative data, and measurement tools.

Other information may be added as the research team considers it relevant to the analysis. One reviewer will independently extract the data, and a second reviewer will check it for accuracy and completion. The extracted information will be organized in a previously formatted table in Microsoft Excel. Qualitative data regarding results and findings will also be collected. The qualitative data will be analyzed using NVivo (version 14; Lumivero) afterward.

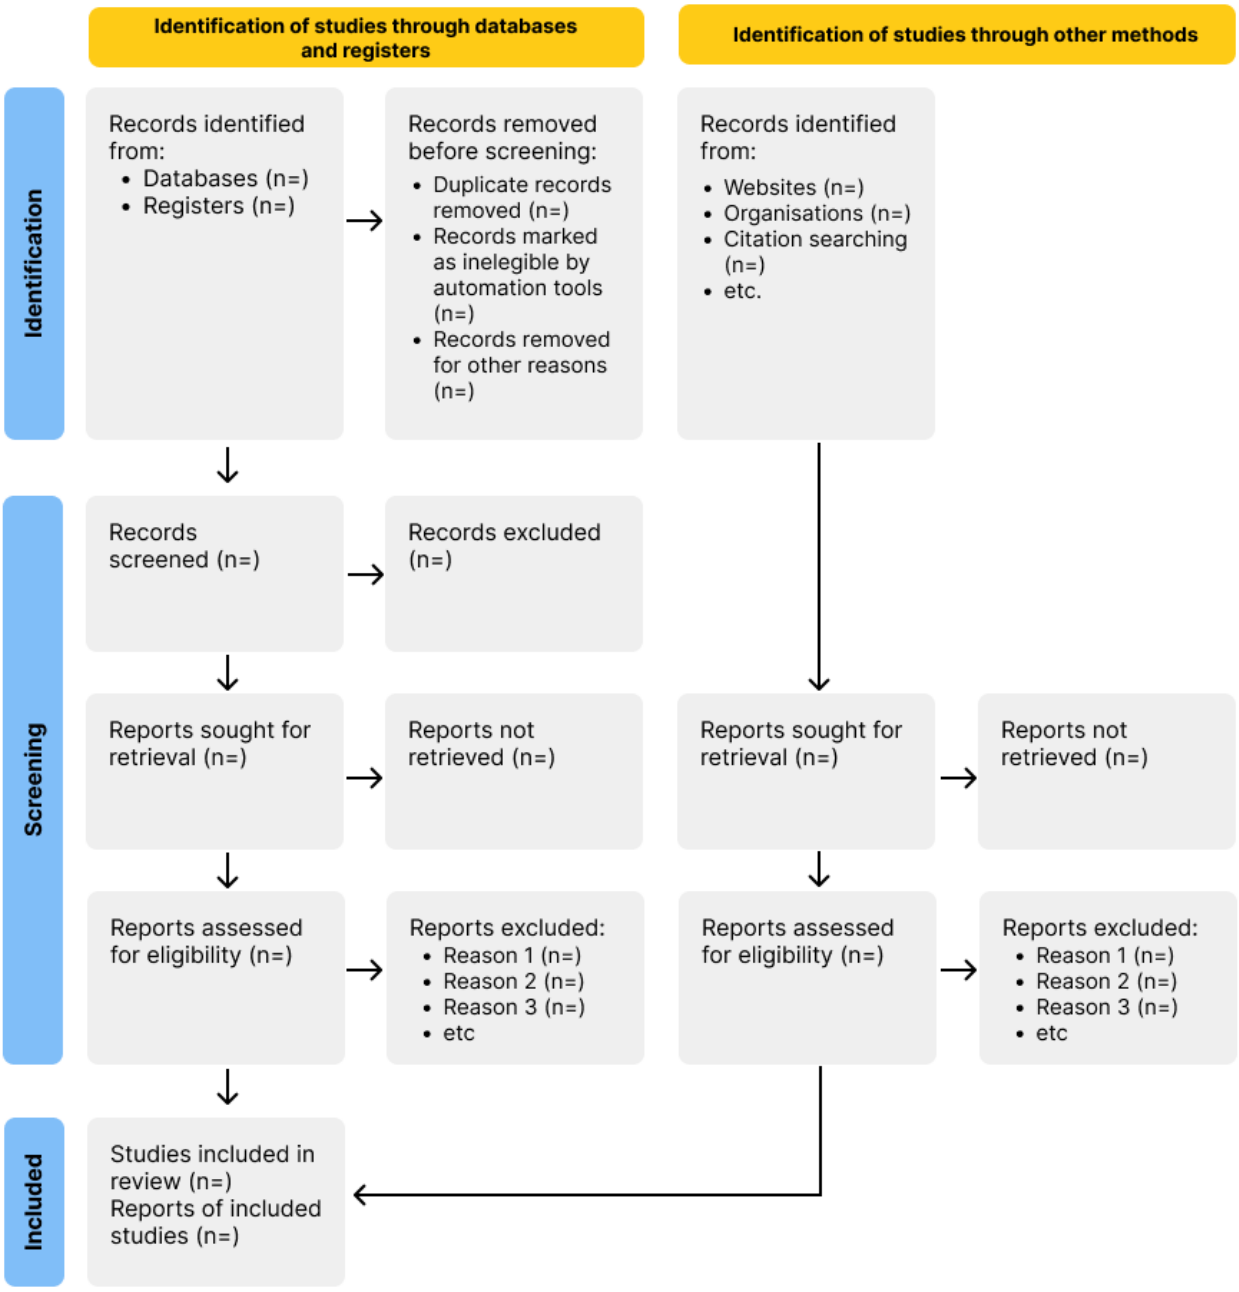
Quality Assessment and Appraisal

The study plans to use the mixed-methods assessment tool (MMAT) for quality assessment and critical appraisal [39]. MMAT provides a systematic approach to assessing quality criteria on a variety of study designs, such as qualitative studies, quantitative randomized controlled trials, quantitative nonrandomized, quantitative descriptive, and mixed-methods studies [40]. Using MMAT, we will evaluate the studies' clarity of the research question, appropriateness of the study design, data collection methods, data analysis, and interpretation of results.

Data Analysis and Synthesis

The study selection procedure will be visualized through the PRISMA 2020 flow diagram, as seen in Figure 2 [41].

Figure 2. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.



Data related to the identification of a given study and its characteristics will be organized in summary tables. As the review question stipulates the inclusion of a wide range of research designs, including qualitative and quantitative designs, the main results from our investigation will be organized into major themes and subthemes, and key findings on terms will also be presented. If significant differences and patterns arise, such as those related to health conditions, age, or digital literacy, thematic clusters for analysis will be delineated. Since the data will potentially arise from diverse study designs, quantitative data will be submitted to a data transformation process to be qualitized to be converted into qualitative data in the form of themes and categories and afterward summarized in a narrative synthesis to allow further integration with qualitative data [35,42,43]. Once qualitative and quantitative data are integrated, they will be compiled through a thematic analysis in order to identify the main concepts regarding engagement and retention. The codes for this investigation will be developed by one of the reviewers and checked by at least 1 member of the research team. The codes will be built using the Persuasive System Design framework developed by Oinas-Kukkonen and Harjumaa as a basis [44]. Kelders et al [25] have already applied this framework in the digital health area. A total of 2 independent reviewers will conduct the coding, and discrepancies and new codes will be discussed between the 2 reviewers. If no agreement is reached, a third reviewer will be consulted to reach a consensus. Afterward, the major themes and subthemes will be summarized in a narrative synthesis. One of the authors will compose the narrative synthesis, and a second author will assess and provide appraisal.

Dissemination Strategy

The results of this study will be disseminated as a scientific publication in a peer-reviewed journal and presented at conferences. Plain-language summaries will also be produced to share in various channels, such as social media, ResearchGate, and technology and health care websites.

Ethical Considerations

According to the Ethical Review Data (2003:460) by the Swedish Ethical Review Authority, ethical approval will not be required for this research.

Results

As of June 2024, the literature review has conducted 2 pilot searches to test and refine keywords and verify the initial quality of results. The results are expected to be published as a systematic literature review and submitted for publication in June 2025.

Discussion

Principal Findings

In light of the potential benefits of technology in clinical research, DH intervention design demands further investigation, to mediate the relationship between research participants and the technology. As highlighted by Johnson [45], connected technologies have provided many new opportunities in clinical research in recent years, such as increasing research awareness, recruitment options, and delivering interventions and treatments. Achieving a high rate of participation required to ensure the quality of an investigation is still a challenge. To meet these opportunities, CRI researchers and developers becoming more aware of the importance of developing adequate software for research participants to expand intervention. Although a "user-centric" approach has increased through participant-centered initiatives, digital clinical research is still on the journey to find ways to reduce the time and labor requirements that hinder participant involvement [14,46]. Offering a proper setting to a plurality of participants is fundamental to guaranteeing clinical research quality; otherwise, CRI risks increasing health care inequalities and disparities. DH interventions that do not consider socioeconomic factors such as financial situation, race, ethnicity, age, education, and digital literacy present higher chances of producing intervention-generated inequalities, increasing the digital divide, and may only benefit the already more advantaged populations [6,9,47].

Intervention researchers have long experimented with strategies for engagement and retention. Intervention factors like acceptability and feasibility of devices and technology, system usability, visual design, content, and adaption to literacy levels have been found to affect participant behaviors. These factors commonly influence access conditions by minimizing attrition but do not necessarily guarantee engagement, retention, and adherence. Importantly, engagement and retention may be promoted by factors that pertain to the particular characteristics of the digital platforms and software. Here are included platform usability and design, but also and others are research-based strategies, such as compensation, incentives, or rewards [21]. Interaction features can also incentivize participant's engagement and retention. These could be in the form of (1) gamification, (2) reminders or notifications, (3) social support provided within the DH intervention, (4) personalization, and (5) content tailored to participants' physical and cognitive abilities [21,25,26]. Understanding how platform design choices interact with participant behavior in DH interventions has become a crucial consideration for intervention research.

Limitations

Summarizing the key DH platform factors that affect participant engagement and retention given the variability of intervention designs, target participant groups and DH platform mediums may be challenging. Given the heterogeneity of the reviewed studies, we may have to focus only on some participant populations or DH platforms or include only broad trends in the narrative synthesis. Preliminary research, however, showed that concepts like personalization and fit to participants' conditions and needs are commonly important design factors, as discussed in previous literature [11].

Implications

We foresee that this review will serve as a useful resource to those developing DH interventions, but may not be versed in DH platform design. By summarizing key platform design characteristics that affect participant behavior on the platform and, by proxy, the intervention, the review will be particularly relevant to intervention researchers.

Conclusions

Systematic reviews are considered one of the most informative sources of research evidence and have supported decision-making in health care in recent decades [40,48]. Acknowledging the relevance of this resource, this review aims to contribute to the growing field of digital clinical research and patient-centered design, providing a comprehensive reference for developing more engaging and effective digital platforms and software for clinical research.

Acknowledgments

The authors would like to thank Görel Sundström for assisting with the search strategy.

This work was supported by U-CARE, which is a strategic research environment funded by the Swedish Research Council (dnr 2009–1093).

Data Availability

Data sharing is not applicable to this article as no datasets were generated or analyzed during this study.

Authors' Contributions

LT, AK, and MH contributed to the idea conception. LT wrote the initial manuscript draft. Manuscript revision was performed by LT, AK, MH, and MIM, Visualization was done by LT. All authors reviewed and edited the manuscript and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: To successfully design, develop, implement, and deliver digital health services that provide value, they should be cocreated with patients. However, occasionally, the value may also be codestructed. In the field of health care, the concepts of value cocreation and codestruction still need to be better established within emerging digital health services. Studying these concepts is essential for developing effective and sustainable patient-centered care.

Objective: The aim of the study is (1) to understand the antecedents, decisions, and outcomes of value cocreation and codestruction in digital health services, (2) to define the dynamics between value cocreation and codestruction, and (3) to map future research areas of value cocreation and codestruction within digital health services.

Methods: The systematic review will be conducted in accordance with the Joanna Briggs Institute methodology for mixed method systematic reviews and the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) statement. The review considers scientific qualitative, quantitative, or mixed method studies published in English, Finnish, or Swedish that concern either value cocreation or codestruction in digital health services. Studies focusing on physical robotics and online health communities, as well as non–peer-reviewed and nonscientific papers, will be excluded. The searches were conducted using Scopus and MEDLINE during this protocol creation. Critical appraisal will be done using suitable checklists for qualitative, quantitative, and mixed method studies. The review will adhere to a convergent integrated approach as outlined in the Joanna Briggs Institute methodology for mixed methods systematic reviews.

Results: The searches resulted in a total of 837 records. The antecedents, decisions, and outcomes of value cocreation and codestruction in the context of digital health services will be described in a finalized systematic review. In the outcomes, our main interest is the effect on patient outcomes and experiences and professional experiences.

Conclusions: Since our study involves diverse scientific fields, there is a risk that our search does not capture all relevant papers. To mitigate this risk, we used 2 large databases for the searches. In addition, the value cocreation or codestruction terms may not have been used in all studies focusing on the collaborative roles of patients and providers, especially in the medical field, and that may be difficult to capture. The review reveals the current understanding of value cocreation and codestruction in digital

health services and shapes the research agenda for these phenomena. Value cocreation can be used to both design and efficiently use digital health services trying to maximize the value for patients.

KEYWORDS

value cocreation; value codestruction; telemedicine; eHealth; systematic review

Introduction

Value cocreation and customers' interactive roles in the service exchange have been essential to understanding how value is created in services [1]. Rapid technological advances and digital transformation are transforming the context in which value is created [2]. Health care services had a significant transformation as digital health services rapidly expanded during the COVID-19 pandemic [3,4]. Digital health services can be defined as the use of information and communication technologies in health care products, services, and processes [5]. Digital services, including telemedicine interventions, mobile health apps, and remote monitoring devices, have been suggested as a potential solution to tackle issues related to accessibility, availability, and health care costs [6,7]. In addition to the technical development, it also changes the way of thinking and how services are provided and perceived [4].

Cocreation, a burgeoning paradigm within management literature, facilitates the joint creation of value by enterprises and consumers through interactive processes [8]. Since the onset of the 21st century, the concept of cocreation has proliferated extensively, evidenced in scholarly discourse and empirical inquiries, thereby challenging established tenets of capitalist economies. In such economies, value traditionally tends to be predetermined prior to market transactions [8,9]. Health care is a complex service where defining and operationalizing value presents significant challenges [10,11]. Since Porter [12] introduced the idea of measuring health care value as patient-relevant outcomes per costs associated with the health problem, the concept has been widely discussed for its potential to unify the objectives of various stakeholders [11]. In the context of digital health services, value may be more closely related to outcomes and experiences, with costs being more pertinent at the system level.

From the standpoint of cocreation, suppliers and customers are no longer perceived as adversaries but rather as collaborators engaging with each other to foster the emergence of novel business prospects [13]. During the last decade, Yi and Gong [14] established the significance of value cocreation behavior, which provides a multidimensional framework encompassing diverse value cocreation activities, such as information seeking, information sharing, responsible behavior, and personal interaction, that help explain how customers and firms, or patients and health care providers in this case, interact and collaborate.

Additionally, the digitalization of services within health care ecosystems is altering how value is created, delivered, experienced, and evaluated [15,16]. Understanding value cocreation and the interactive roles of customers in the service exchange is crucial for comprehending how value is created in services [1], with value cocreation being conceptualized as a joint problem-solving process [17]. For instance, value cocreation in digital health services can be depicted through customer engagement, encompassing emotional, active, and cognitive dimensions [18].

However, value is not always cocreated. Value codestruction signifies that not all interactions and relationships yield positive or value-creating results; occasionally, these engagements may even lead to adverse outcomes [19,20]. Value codestruction refers to an interactive process between service systems that leads to a reduction in the well-being of at least 1 of the systems, which can affect either individuals or organizations depending on the nature of the service system [20]. For example, value codestruction may manifest in the inability to search for, understand, and use health information gathered on the web [21]. Additionally, the assumption that telemedicine can negatively impact doctor-patient relationships inevitably leads to value-in-use destruction [21].

As digital services differ significantly from traditional services, there is a need to understand how to enhance value cocreation between a service provider and its users in digital services [22,23]. Tuunanen et al [23] identified 5 mechanisms to support value cocreation in the design of digital services, namely social use, customer orientation and decision-making, service experience, service use context, and customer values and goals.

In response to evolving population needs, it is evident that the role of patients within digital health services and health care at large has transitioned toward a collaborative partnership between professionals and patients [24,25]. According to Huber et al [26], the definition of health is also changing from "complete mental, physical, and social well-being" toward "the ability to self-manage and adapt." According to van Druten et al [27], a similar multifaceted approach to Huber's concept of positive health was shared by many perspectives. Nevertheless, upon closer examination, it was observed that the core elements of positive health, namely "the ability to adapt and to self-manage," were also acknowledged in other health concepts, regardless of perspective. These health concepts described "the ability to adapt" as, for instance, adjusting to changing physical conditions like aging, illness, or disability, maintaining emotional balance, and viewing health as a dynamic state requiring adaptation to circumstances. "The ability to self-manage" was often described as autonomy or independence. Through the value cocreation process, professionals and patients can make a significant contribution to health outcomes as partners [28]. For example, patients can provide perspectives on areas of the care process

that are invisible to health care professionals [29,30]. Previous literature has discussed many consequences of value cocreation related to health outcomes, service experience, perceived service quality, and service engagement [31].

While value cocreation has also been studied in health care, less attention has been given to the investigation of value codestruction [29,32]. As the field of health care is constantly becoming more digitalized, examining value cocreation and value codestruction in digital services would provide valuable insights into developing such services. Peng et al [31] conducted a systematic review of value cocreation in health care and digital services before the COVID-19 pandemic. They also encouraged researchers to explore further opportunities for value cocreation in both web-based and hybrid environments. Even so, the review by Peng et al [31] did not address value codestruction, which, in conjunction with value cocreation, could aid in enhancing the efficiency of digital health services. Several authors have highlighted the necessity of gaining a more comprehensive understanding of value codestruction and integrating it with the research on value cocreation [33,34]. Considering the pandemic's impact on digital service expansion [3,4], increasing resource constraints due to rising chronic illnesses, and aging populations [35,36], conducting a new systematic literature review could provide a contemporary perspective on value cocreation in health care. Furthermore, this review aims to provide a more comprehensive understanding of value codestruction.

So as to gain a more current understanding of both value cocreation and value codestruction in digital health services, this review seeks to identify scientific studies published between 2020 and 2024, using the Joanna Briggs Institute's (JBI) guidance for mixed method systematic reviews [37] and adhering to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) checklist for reporting systematic reviews [38] The objectives of the review will be (1) to understand the antecedents, decisions, and outcomes (ADO) of value cocreation and value codestruction, (2) to define the dynamics between value cocreation and value codestruction in digital health services, and (3) to map future research areas of value cocreation and value codestruction within digital health services. To answer the first research question, this review uses a systematic literature review framework, namely, the ADO framework by Paul and Benito [39]. The ADO framework aims to identify the known aspect of any phenomenon, which in the case of this review is value cocreation and value codestruction in the context of digital health services. Our research questions are (1) What are the ADO of value cocreation and value codestruction in digital health services? (2) What are the dynamics between value cocreation and value codestruction in digital health services? (3) What are the most promising future research areas in value cocreation and value codestruction within digital health services?

Methods

Overview

The systematic review will be conducted in accordance with the JBI methodology for mixed method systematic review [37] and the PRISMA statement [38,40] (Multimedia Appendix 1). This protocol has been registered in PROSPERO (International Prospective Register of Systematic Reviews; 549303). During this review protocol, the searches have been conducted, but the screening, quality assessment, and analysis will be carried out in the finalized systematic review.

Search Strategy

Using the search strategy developed by Peng et al [31] as a foundation, adjustments were made to include value codestruction. The search strategy aimed to identify peer-reviewed scientific studies and was conducted in 3 steps. First, to ensure an optimal search strategy for both value cocreation and value codestruction, an initial limited search of MEDLINE and Scopus was conducted on May 21, 2024, which resulted in 48 and 247 papers, respectively. MEDLINE and Scopus were selected since they collectively provide extensive coverage of publications on digital health services, value cocreation, and value codestruction. Second, relevant papers were identified through title, abstract, and index term analysis. An information specialist was consulted during the development of the final search strategy. Keywords were truncated as necessary, and index terms such as MeSH were used in MEDLINE (Multimedia Appendix 2). Additionally, the reference lists of all included studies will be screened to identify additional relevant studies.

Eligibility Criteria

This study will include studies that investigate either value cocreation, value codestruction, or both in digital health services. This review will consider scientific qualitative, quantitative, or mixed method studies. Papers published in English, Finnish, and Swedish will be eligible for inclusion. Only papers published between January 1, 2020, and the present (June 2024) concerning value cocreation were considered, as an earlier review covered the period from 2008 to 2019 [31]. Regarding value codestruction, the limitation period extends from January 1, 2008, to December 31, 2008, since the earlier review did not address value codestruction. Studies focusing on physical robotics, as well as non–peer-reviewed and nonscientific papers, will be excluded.

Study Selection

The results of the search are presented in a PRISMA flow diagram [38]. All citations identified through the described search strategy were compiled and uploaded into Rayyan (Al Rayyan Company), which was also used to remove duplicate entries. Titles and abstracts will then undergo independent screening by 2 team members (NH and JP) using predefined inclusion and exclusion criteria. For papers lacking abstracts, the full text will be obtained. Following the title and abstract screening, potentially relevant studies will be retrieved in full. Two independent reviewers (NH and JP) will thoroughly assess these studies and determine their suitability based on the inclusion criteria. Exclusion reasons will be documented for studies that do not meet the inclusion criteria. Any discrepancies during the study selection or any other process will be resolved through discussion or by consulting a third team member (EL

and PT). All search methods, strategies, and sources will be detailed or named in the final report, ensuring replicability.

Assessment of Methodological Quality

Before being included in the review, papers will undergo evaluation by 2 separate reviewers (EL and M Vanhanen) to ensure methodological soundness. We will use the JBI checklists for qualitative and quantitative studies and the Mixed Methods Appraisal Tool for mixed method studies [41]. In cases where necessary, authors of papers will be contacted to request missing or additional data to ensure clarity. The outcomes of critical appraisal will be presented both in narrative form and in a table format. Data extraction and synthesis will be conducted for all studies, irrespective of their methodological quality assessment outcomes, whenever feasible.

Data Extraction and Synthesis

Two independent reviewers (EL and M Vanhanen) will extract both quantitative and qualitative data from the studies included in the review. The extracted data will encompass specific details about populations, study methods, phenomena of interest, context, and outcomes relevant to the review questions. Quantitative data will include outcomes derived from descriptive and inferential statistical tests. Additionally, qualitative data will comprise verbatim themes or subthemes accompanied by corresponding illustrations and will be assigned a level of credibility. Authors of papers will be contacted up to a maximum of 2 times to request missing or additional data, as necessary.

Data Transformation

The quantitative data will undergo a process of "qualitization," which entails transforming it into textual descriptions or narrative interpretations that directly address the review questions.

Data Synthesis and Integration

This review will adhere to a convergent integrated approach as outlined in the JBI methodology for mixed methods systematic reviews. This approach involves integrating the qualitized data with the qualitative data. The assembled data will be categorized and pooled based on similarity in meaning, ultimately generating a set of integrated findings presented as the line of action statements. We will classify the data using the ADO framework [39]. Additionally, we will synthesize the current knowledge of each dimension and formulate a future research agenda based on the findings.

Ethical Considerations

Since concept analyses solely rely on secondary publicly available data sourced from primary research studies, there is no requirement for research ethics approval.

Validity and Rigor

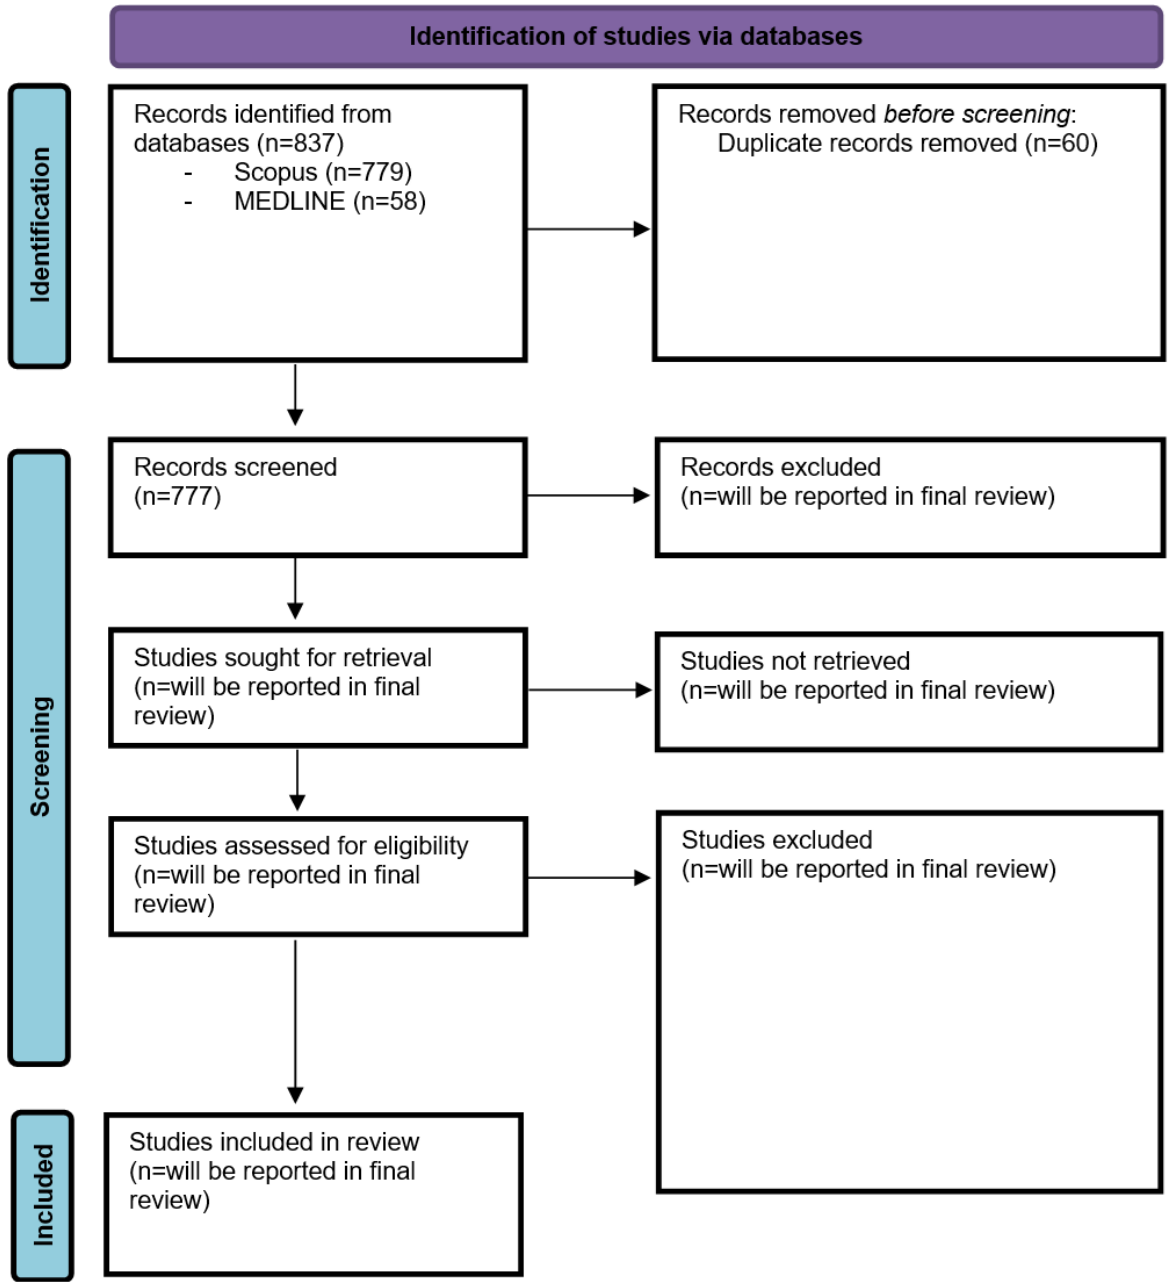
The following activities will be performed to enhance the review's validity and rigor:

1. Method: The systematic review will be conducted following the JBI guidelines [37] and following the PRISMA statement [38].
2. Search: To increase the reliability of the review, an information specialist with expertise in health care, value cocreation, and value codestruction will be consulted. Additionally, several database sources will be included in the final search to ensure the richness of the data to be analyzed.
3. Screening, data extraction, and synthesis: Each of the previously mentioned phases will be conducted independently by at least 2 independent team members (NH and JP), which will enhance the reliability of the review.
4. Process: The research team members (EL, TT, M Vanhanen, NH, JP, MJ, M Vesinurm, and PT) will continuously review the paper during ongoing meetings throughout the process.

Results

The review started in May 2024 and will be completed in a time frame of 8 months. This time phase includes the following phases: screening, data extraction, quality assessment, and data synthesis. The literature search was conducted entirely during the review protocol process and reported in the PRISMA diagram. The final search in MEDLINE and Scopus on June 6, 2024, resulted in 58 and 770 papers, respectively (Figure 1). As Peng et al [31] omitted value codestruction in their search, a supplementary search focusing exclusively on value codestruction was conducted on September 19, 2024, covering the years 2008 to 2019. This search yielded 9 papers from Scopus and none from MEDLINE. In total, 837 records were detected. The systematic review is anticipated to be ready for submission by December 2024.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram.



Discussion

Principal Findings

Our review will reveal the current understanding of value cocreation and codestruction in digital health services and shape the research agenda for these phenomena. In their review, Peng et al [31] focused on studies published prior to the COVID-19 pandemic, a period after which the number of digital health services has significantly increased. Consequently, our review will provide the most recent insights into value cocreation and value codestruction within digital health services. The ADO framework [39] assists in producing a knowledge map outlining the associations between ADO of value cocreation and codestruction in the context of digital health services. The ADO of value cocreation and codestruction will be described. In the outcomes, our main interest is the effect on patient outcomes and experiences and professional experiences. The more detailed results will be determined based on the finalized review.

Value cocreation can be used in both designing as well as the efficient use of digital health services trying to maximize value for patients. In other digital services, value cocreation and codestruction have been studied more thoroughly, as most of the services nowadays are digital, and the world has already been described as digital-first [42].

As the field of health care is constantly more digitalized, examining value cocreation and codestruction in digital services would provide valuable insights into developing such services. To support the cost-effectiveness of the services and try to minimize the effects of digital exclusivity, it is crucial to understand value cocreation and codestruction better in digital health services.

Strengths and Limitations

Since our study is crossing the scientific fields, there is a risk that our search does not capture all relevant papers. To mitigate this risk, we include multiple databases for the searches. However, only peer-reviewed studies will be included in this review, which excludes gray literature [43]. In addition, the value cocreation or codestruction terms may not have been used in all studies focusing on the collaborative roles of patients and providers, especially in the medical field, and that may be difficult to capture.

Acknowledgments

The authors would like to thank Aalto University Library for consulting with the search strategy. Open access is funded by the Helsinki University Library.

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

The review protocol was conceived and supervised by EL and PT. EL, TT, MJ, M Vanhanen, NH, JP, M Vesinurm, and PT planned the review and formed the aim and research question. PT, NH, and JP developed the search strategy and conducted the search. EL, NH, JP, and PT screened papers. EL and PT drafted the main text. All authors contributed revisions.

Conflicts of Interest

None declared.

Abstract

Background: The Patient Education Materials Assessment Tool (PEMAT) is a reliable and validated instrument for assessing the understandability and actionability of patient education materials. It has been applied across diverse cultural and linguistic contexts, enabling cross-field and cross-national material quality comparisons. Accumulated evidence from studies using the PEMAT over the past decade underscores its potential impact on patient and public action.

Objective: This systematic review aims to investigate how the quality of patient education materials has been assessed using the PEMAT.

Methods: This review protocol follows PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols) guidelines. PubMed, MEDLINE, Cumulative Index to Nursing and Allied Health Literature (CINAHL), APA PsycInfo, and Web of Science Core Collection will be searched systematically for articles published since September 2014. Two independent reviewers will conduct the search to yield a list of relevant studies based on the inclusion and exclusion criteria. Rayyan QCRI software will be used for screening and data extraction.

Results: The results will be included in the full systematic review, which is expected to start in September 2024 and be completed to be submitted for publication by early 2025.

Conclusions: The findings are expected to identify the quality of materials evaluated by the PEMAT and the areas under evaluation. This review can also highlight gaps that exist in research and practice for improving the understandability and actionability of the materials, offering deeper insights into how existing materials can facilitate patient and public action.

KEYWORDS

patient education; health communication; health information; behavior change; understandability; actionability Patient Education Materials Assessment Tool; PEMAT; medical information; health literacy; patient education materials

Introduction

Patient education materials, such as brochures, websites, videos, and apps that provide health and medical information to patients and the general public, are used in various clinical and public health areas. Given the known relationship between health literacy and health outcomes [1], assessing the quality and usefulness of the materials to patients or general public is

worthwhile. Particularly, Healthy People 2030 emphasized organizational health literacy [2], which represents organizational competencies that enable people to access, understand, appraise, and use health information and services [3].

Therefore, medical institutions, companies, and government agencies providing health care information need to produce higher quality materials to support the health behaviors of patients and the general public.

A range of tools have been designed to assess the effectiveness of patient education materials. Garner et al [4] outlined a three-step process that characterizes the audience's interaction with such materials: (1) reading to the end, (2) constructing a coherent understanding, and (3) responding to the content. In response to these processes, they introduced an evaluation framework of readability, comprehensibility, and communicative effectiveness [4]. Among these 3 factors, readability formulas, which focus on the aspect of "reading to the end," have been used since the 1930s. Later, following the establishment of the concept of health literacy, comprehensibility indicators were developed to assess whether materials align with audience's health literacy demands. These indicators consider not only the wording of the material but also its structure and style; notable examples include suitability assessment of materials [5] and the CDC (Centers for Disease Control and Prevention) Clear Communication Index [6]. However, understanding the material alone is insufficient; a separate evaluation is necessary to determine whether audience can translate the material's content into actionable behavior.

The Patient Education Materials Assessment Tool (PEMAT) is a reliable and validated tool to evaluate and compare the understandability and actionability of patient education materials [7,8]. Understandability refers to the likelihood that the reader or viewer will be able to understand and explain the material's key messages. Actionability refers to the likelihood that the reader or viewer will know how to act on the information presented in the material. The PEMAT calculates a material's understandability and actionability scores as a percentage. There are 2 types of PEMAT: PEMAT-P for printable materials and PEMAT-A/V for audiovisual materials. The PEMAT consists of 26 items in total. For PEMAT-P, items 1-12 and 15-19 assess understandability, while items 20-26 evaluate actionability. For PEMAT-A/V, understandability is assessed using items 1, 3-5, 8-14, and 18-19, while actionability is evaluated with items 20-22 and 25. On the practical side, the PEMAT visualizes the challenges of materials to find the most understandable and actionable materials among the many available. It also supports experts in improving their materials. The original version of the PEMAT was developed in 2013 [7], and as of 2024, Brazilian Portuguese [9], Bahasa-Malay [10,11], Japanese [12], Chinese [13], and Turkish [14] versions are available. The PEMAT has been used to analyze materials for patients of various cultural and linguistic backgrounds, allowing quality comparisons of materials across clinical fields and nations. For example, our study on internet-based materials for Japanese patients with chronic kidney disease found that, unlike trends in English-speaking countries, materials published by for-profit companies were easier to understand and act upon than those published by public organizations [15].

Despite the large number of PEMAT analyses, to date, previous studies have not systematically integrated and compared the findings obtained by the PEMAT. In addition, scoping reviews have comprehensively introduced indicators for assessing the quality of health care information [16-18]; however, no systematic reviews have assessed the understandability and actionability of patient education materials using the PEMAT. This study reviews how the quality of materials has been assessed using the PEMAT in previous patient education materials. We pose the following research questions: "in which areas (eg, clinical areas, types of media, and target populations) have patient-education material quality assessment studies been conducted using the PEMAT?" "what is the degree of understandability and actionability of materials based on the PEMAT in previous studies?" and "what gaps in research and practice should be filled in the future? (eg, in which areas should understandability and actionability of materials be examined and in which areas should understandability and actionability be improved?).

Methods

Study Design and Registration

We designed the study protocol following the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols) guidelines [19]. A PRISMA-P checklist is available as Multimedia Appendix 1. Once this protocol is accepted for publication in a peer-reviewed journal and fixed, it will be registered with the International Prospective Register of Systematic Reviews (PROSPERO). We plan to begin the literature search on September 1, 2024, and complete the analysis by late 2024.

Literature Search

We will search the following databases: PubMed, MEDLINE, Cumulative Index to Nursing and Allied Health Literature (CINAHL), APA PsycInfo, and Web of Science Core Collection. We will search abstracts and titles using a combination of keywords related to previous studies: (PEMAT) OR (Patient Education Materials Assessment Tool) OR (understandability) OR (actionability) OR (comprehensibility). Since the development study of the original version of the PEMAT was published in September 2014, the inclusion period will be limited to September 2014 through September 2024. Details of search queries in each database are shown in Table 1. We will import all search results into Rayyan QCRI software to ensure a systematic literature selection process [20]. We will include all publications covered from the time the database search is initiated to the time of the final search. We will search the reference lists of identified eligible studies to supplement the database searches and identify any additional potentially eligible literature.

Table 1. List of search queries.

Database	Interface	Search queries
PubMed	NLM	("PEMAT"[All fields] OR "patient education materials assessment tool"[Title/Abstract] OR "understandability"[Title/Abstract] OR "actionability"[Title/Abstract] OR "comprehensibility"[Title/Abstract]) AND (2014/9/1:2024/6/30[pdat])
MEDLINE	Web of Science	(pemat) OR (AB patient education materials assessment tool) OR (AB understandability) OR (AB actionability) OR (AB comprehensibility) Limit - Publication date: 20140901-20240631
Web of Science	Web of Science	(ALL= (PEMAT))) OR AB=(patient education materials assessment tool)) OR AB=(understandability)) OR AB=(actionability)) OR AB=(comprehensibility)) Timespan: 2014-09-01 to 2024-06-30
CINAHL	EBSCOhost	(pemat) OR (AB patient education materials assessment tool) OR (AB understandability) OR (AB actionability) OR (AB comprehensibility) Limit - Publication date:20140901-20240631
APA PsycInfo	EBSCOhost	(pemat) OR (AB patient education materials assessment tool) OR (AB understandability) OR (AB actionability) OR (AB comprehensibility) Limit - Publication date:20140901-20240631

Inclusion and Exclusion Criteria

This proposed systematic review covers studies that analyzed health and medical information by the PEMAT. The inclusion and exclusion criteria are as follows (Textbox 1):

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

Evaluating patient education materials or decision aids (brochures, website, videos, apps, social networking posts, and artificial intelligence tool responses).

Using the Patient Education Materials Assessment Tool (PEMAT) as an evaluation tool.

Published in peer-reviewed scientific journals.

Exclusion criteria

Intervention studies using PEMAT or brush up on existing educational materials by PEMAT.

Articles on the development of original and translated versions of PEMAT.

Systematic review or meta-analysis.

Patient education material itself.

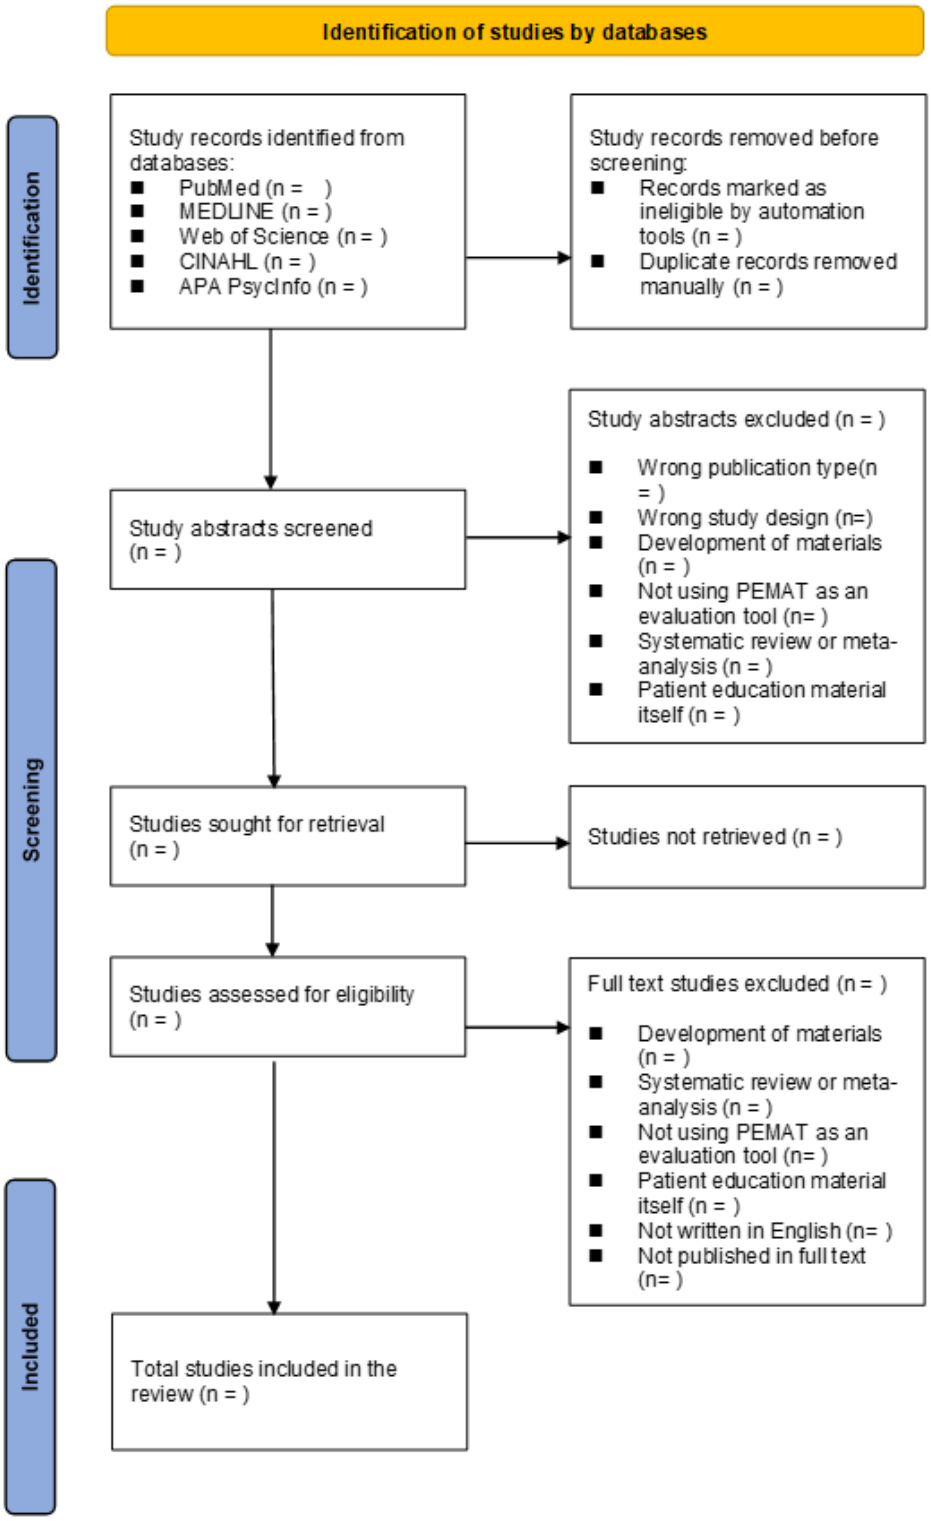
Non-English articles.

Not published in full text.

Screening of Studies

We will conduct study selection using Rayyan QCRI software [20]. Two independent reviewers [EF and ML] will screen the titles and abstracts of all studies initially identified according to the eligibility criteria. Disagreements will be resolved by consensus; the opinion of a third reviewer [HO] will be sought when necessary. A PRISMA-P flow diagram will outline the number of included and excluded studies in each stage of the study (Figure 1 [19]).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram of the studies.



Data Extraction

The extracted data will include study characteristics (eg, author, year of publication, country, type of publication, and study design), material characteristics (eg, intended audience, language, number, media [eg, text, audio, and video], clinical field, and type of source), evaluation methods (eg, evaluation tools or indicators alongside the PEMAT, the evaluators' expertise, and material evaluation by the audience [if any]), and main results of the evaluation (eg, PEMAT scores, scores of other tools or indicators, quantitative or qualitative material evaluation by audience [if any]), and a summary of the characteristics of contributing studies will be tabulated in the above order.

Data Synthesis

The numerical summary will describe the characteristics of the included studies. We will summarize the findings in tables and

synthesize them in a descriptive, narrative review, using the framework to answer the research questions. We will use descriptive statistics (means, SDs, and proportions) to summarize the characteristics of the retrieved studies. PEMAT scores are expressed as 0%-100% and therefore, considered continuous variables. We will express the estimate of the PEMAT score as the mean difference with 95% CI.

We will conduct subgroup analyses based on material type, clinical field, and type of source as these group comparisons are essential to explore the determinants of material quality. We perform a test of normality when integrating the data. When data are normally distributed, we will use ANOVA for subgroup analysis. If significant differences are found, we will use Tukey multiple comparisons. When data are not normally distributed, we will use the Kruskal-Wallis test. For a post hoc comparison, a 2-arm comparison using the Mann-Whitney U test will be performed with Bonferroni adjustment. We will conduct all statistical analysis using R software (version 4.4.0; R Foundation for Statistical Computing).

For each study, we will assess heterogeneity using a tool for assessing Risk Of Bias due to Missing Evidence in a synthesis (ROB-ME) [21]. ROB-ME provides a systematic method for evaluating the risk of bias when particular methods or results within studies are missing from a meta-analysis due to the *P* value, magnitude, or direction of the study results. Although the studies included in this view are not systematic reviews in a strict sense, their authors have included multiple materials and conducted “reviews” based on certain indicators. The ROB-ME can be used to evaluate the appropriateness of the inclusion criteria and consistency of the description of the results in the included studies. The risk of bias will then be integrated with ROBVIS, a risk-of-bias assessment summary table [22].

Ethical Considerations

This study will be exempted from the Research Ethics Committee of The University of Tokyo Graduate School of Medicine and Faculty of Medicine as the studies under review are publicly accessible and do not involve patient records.

Results

The results will be included in the full systematic review, which started in December 2024 and be completed to be submitted for publication by early 2025.

Discussion

Principal Findings

Since the development of the PEMAT a decade ago, evidence of studies that have evaluated materials using the PEMAT has accumulated. This review is the first to systematically evaluate and analyze studies that have reviewed materials with the PEMAT, providing deeper insight into the potential of existing materials to support action for patients and the general public.

Limitations

This systematic review has several potential limitations. First, the limitations of the PEMAT itself include the fact that it is based on expert evaluation and therefore does not fully reflect the patient’s perspective. Second, the studies used different methods for measuring materials, with differences observed in the assessment approaches used alongside the PEMAT and in the methods for group comparisons. As such, they may have a high degree of heterogeneity. In addition, comprehensiveness may not be fully ensured as we exclude studies written in languages other than English. Despite these limitations, this review will present implications for improving the quality of health information targeted at patients and the general public.

Conclusions

We will carry out a systematic review to examine how the understandability and actionability of existing materials have been assessed using the PEMAT.

Acknowledgments

This work is supported by the Japan Society for the Promotion of Science KAKENHI (grant number 24K23676). We used generative AI, Grammarly, in a limited way, to clarify topic sentences and improve grammar, punctuation, and concision. We have reviewed each suggestion before adopting it. For additional quality control, we discussed professional proofreaders in Forte [23].

Data Availability

The datasets generated during and analyzed during this study will be available from the corresponding author on reasonable request.

Authors' Contributions

EF contributed to conceptualization, methodology, investigation, writing – original draft, and funding acquisition. TO handled methodology, writing – original draft, and writing – review and editing. ML managed investigation and writing – review and editing. HO performed investigation and writing – review and editing. TK contributed to writing – review and editing, resources, and supervision. All authors read and approved the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Although existing disease preparedness and response frameworks provide guidance about strengthening emergency response capacity, little attention is paid to health service continuity during emergency responses. During the 2014 Ebola outbreak, there were 11,325 reported deaths due to the Ebola virus and yet disruption in access to care caused more than 10,000 additional deaths due to measles, HIV/AIDS, tuberculosis, and malaria. Low- and middle-income countries account for the largest disease burden due to HIV, tuberculosis, and malaria and yet previous responses to health emergencies showed that HIV, tuberculosis, and malaria service delivery can be significantly disrupted. To date, there has not been a systematic synthesis of interventions implemented to maintain the delivery of these services during emergencies.

Objective: This study aimed to synthesize the interventions implemented to maintain HIV/AIDS, tuberculosis, and malaria services during public health emergencies in low- and middle-income countries.

Methods: The systematic review was registered in the international register for prospective systematic reviews. It will include activities undertaken to improve human health either through preventing the occurrence of HIV, tuberculosis, or malaria, reducing the severity among patients, or promoting the restoration of functioning lost as a result of experiencing HIV, tuberculosis, or malaria during health emergencies. These will include policy-level (eg, development of guidelines), health facility–level (eg, service rescheduling), and community-level interventions (eg, community drug distribution). Service delivery will be in terms of improving access, availability, use, and coverage. We will report on any interventions to maintain services along the care cascade for HIV, tuberculosis, or malaria. Peer-reviewed study databases including MEDLINE, Web of Science, Embase, Cochrane, and Global Index Medicus will be searched. Reference lists from global reports on HIV/AIDS, tuberculosis, or malaria will also be searched. We will use the GRADE-CERQual (Grading of Recommendations Assessment, Development, and Evaluation—Confidence in Evidence from Reviews of Qualitative Research) approach to report on the quality of evidence in each paper. The information from the studies will be synthesized at the disease or condition level (HIV/AIDS, tuberculosis, and malaria), implementation level (policy, health facility, and community), and outcomes (improving access, availability, use, or coverage). We will use the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) checklist to report findings and discuss implications for strengthening preparedness and response, as well as strengthening health systems in low- and middle-income countries.

Results: The initial search for published literature was conducted between January 2023 and March 2023 and yielded 8119 studies. At the time of publication, synthesis and interpretation of results were being concluded. Final results will be published in 2025.

Conclusions: The findings will inform the development of national and global guidance to minimize disruption of services for patients with HIV/AIDS, tuberculosis, and malaria during public health emergencies.

Introduction

Background

The effective management of disasters requires deliberate investment across the phases of the disaster management cycle including mitigation or prevention, preparedness, response, and recovery [1]. In public health disaster management, several frameworks have been developed to provide a blueprint for investments to improve capacities for preparedness, response, and control of public health emergencies. The most widely applied framework is the World Health Organization (WHO) Joint External Evaluation of the International Health Regulations core capacities [2]. Others include the Global Health Security Index [3], the Health System Resilience Index [4], and the Epidemic Preparedness Index [5]. Taken together, the frameworks are comprehensive insofar as prescribing the mechanics or the hardware of a country's capacity to respond to and control health emergencies. For example, investment in building diagnostic capacity, establishing emergency operations centers, investing in health workers, and having a coordination structure are all critical for both preparedness and response to emergencies. However, little attention is paid to issues such as leadership and trust [6], gender and equity [7], and continuity of other services [8]. Health service maintenance during public health emergencies is critical to minimize preventable disease mortality and morbidity. During the 2014 Ebola outbreak in West Africa, there were 11,325 reported deaths due to the Ebola virus [9] and yet the disruption in access to care also caused more than 10,000 additional preventable deaths due to measles, HIV/AIDS, tuberculosis, and malaria [10]. The 2009 H1N1 pandemic increased the risk of adverse neonatal outcomes among pregnant women [11] and increased emergency department visits [12]. The COVID-19 pandemic also reduced overall health care use across 20 countries by about a third [13]. Furthermore, a systematic review of the effects of the COVID-19 pandemic on service delivery and treatment outcomes of people living with HIV [14] noted that there were challenges in accessing services in health facilities, loss of adherence to drugs, and increase in mortality due to COVID-19–related complications. And yet, several modeling studies [15,16] predicted that even brief interruptions to services such as antiretroviral therapy (ART) and condoms could increase HIV/AIDS–related morbidity and mortality in both the short and long term. Previous researchers have described this failure as the "tyranny of the urgent" [7,17] where the response to the public health emergency is prioritized over other health system functions like routine service delivery. In fact, prior to the COVID-19 pandemic, service continuity was not part of the standard operations of an emergency response [18], and the WHO monitoring and evaluation framework for assessing the effectiveness of a response did not have indicators for monitoring continuity of delivery of other services [19]. Our aim is not to contend that services are delivered during the emergency in the exact same way as in normal settings but to recognize the need for modifications and adaptations to service delivery to maintain demand for and continued access to services. Since the WHO International Health Regulations (2005) governing framework for global health security was established [20], the events that have been declared public health emergencies of international concern include the H1N1 pandemic influenza of 2009, Ebola outbreak in West Africa (2013-2015), Ebola outbreak in the Democratic Republic of Congo (2018-2020), Zika virus outbreak (2016), poliomyelitis (2014 to present), the COVID-19 pandemic [21], and the monkeypox outbreak (2022-2023). Previous studies have consistently shown the impact these public health emergencies have on access to HIV, tuberculosis, and malaria services [22-26]; in addition to the already high mortality and morbidity due to these diseases in low- and middle-income countries [27]. To date, there has not, to our knowledge, been a systematic synthesis of the interventions implemented to maintain the demand for and delivery of HIV, tuberculosis, and malaria services during emergencies. Recent reviews have primarily focused on the challenges [28] or the interventions [29] for the delivery of maternal and child health services during emergencies. The findings from this review will inform the development of national and global guidance on the maintenance of services for HIV/AIDS, tuberculosis, and malaria during public health emergencies.

Review Question

What interventions have been implemented to maintain the delivery of HIV/AIDS, tuberculosis, and malaria services during public health emergencies in low- and middle-income countries?

Objective

This study aims to identify strategies and interventions used to maintain the delivery of and access to HIV/AIDS, tuberculosis, and malaria services during public health emergencies of international concern including H1N1 2009, Ebola 2014, Zika 2015, and the COVID-19 pandemic in low- and middle-income countries to inform efforts for incorporating essential health services maintenance as a key preparedness and response strategy.

Methods

Study Design

The proposed systematic review will be conducted following the guidance given by the Cochrane Handbook for Systematic Reviews of Interventions [30]. The systematic review has been registered in the International Register for Prospective Systematic Reviews (PROSPERO Registration #CRD42023408967).

Inclusion Criteria

Concept

For purposes of this systematic review, we will define interventions as any strategies or activities undertaken to improve human health either through preventing the occurrence of HIV, tuberculosis, or malaria, reducing the severity of HIV, tuberculosis, or malaria among patients, or promoting the restoration of functioning lost as a result of experiencing HIV, tuberculosis, or malaria [31]. The interventions for the continuity of HIV/AIDS, tuberculosis, and malaria services will include policy-level interventions (eg, development of guidelines), health facility–level interventions (eg, service rescheduling), and community-level interventions (eg, community drug distribution). We will define service delivery in terms of improving access (physical and economic ability to use services), availability (physical presence of services), use (quantity of services used), and coverage (proportion of people who access a needed service) [32].

We will report on any interventions to maintain services along the stages of the HIV care cascade including improving testing, linkage to care, retention in care, ART adherence, and viral suppression [33]. Similarly, we will report any interventions implemented to maintain services along any of the stages of the tuberculosis care cascade including tuberculosis testing, linkage to treatment, retention in treatment, posttreatment survival, and achieving durable cure [34]. For malaria, we will include interventions aimed at prevention (eg, vector control), diagnosis, or treatment according to the WHO malaria guidelines [35]. We will include studies reporting any quantitative assessment of service delivery processes (screening, testing, linkage to care, retention in care, and ART adherence) or outcomes (viral suppression, cure, and case counts).

Context

This systematic review will include studies conducted to maintain delivery of and access to HIV, tuberculosis, and malaria services during public health emergencies of international concern in low- and middle-income countries according to the World Bank classification of countries by income level [36].

Types of Sources

This systematic review will consider both quantitative and qualitative studies that use cross-sectional, case-control, randomized and nonrandomized control trials, or cohort study designs. Other designs such as before and after, interrupted time series, and analytical observational studies will be considered for inclusion. Global disease-specific reports published by the Joint United Nations Programme on HIV/AIDS, WHO, or any other global bodies will be considered for inclusion. Editorials, preprints, abstracts, study protocols, commentaries, webinar papers, or opinion pieces will not be eligible for inclusion in the study. Studies conducted among animals or studies assessing the direct effects of emergencies will also be excluded as the review focuses on the maintenance of services for HIV/AIDS, tuberculosis, and malaria.

Search Strategy

A test search was conducted in PubMed to identify published papers on the maintenance of HIV, tuberculosis, and malaria services during public health emergencies. Thereafter, we developed a full search using words in the titles and abstracts of the papers we identified to be relevant (Multimedia Appendix 1). The search strategy will be used to identify relevant papers in each of the other databases. We will include only studies published in English. In addition, we will restrict the search to studies published between 2009 (when the H1N1 pandemic happened) and the end of March 2023.

Peer-reviewed study databases including MEDLINE, Web of Science, Embase, Cochrane, and Global Index Medicus will be searched. Two experienced librarians at Karolinska Institutet's University Library provided guidance about the choice of article databases that would provide the most relevant studies related to the research question. In addition, we will review reference lists of eligible studies, specific journals, and Google Scholar for relevant studies. Reference lists from Global Reports for HIV/AIDS, tuberculosis, or malaria will also be searched for relevant papers. The search will be guided by 2 experienced librarians from Karolinska Institutet's University Library. We anticipate that this search will be completed by the end of May 2023.

After the search is completed, the citations of all identified studies will be exported to Endnote X7 (Clarivate) and screened to remove any duplicates. Thereafter, the search will then be exported to Rayyan [37]—a web-based software that was developed by the Qatar Computing Research Institute and uses semiautomation to expedite the process of screening studies. Two reviewers will independently apply the inclusion and exclusion criteria and select studies based on the title and abstract. Disagreements between the individual judgments of the reviewers will be resolved through a discussion. After consensus building on studies based on titles and abstracts, additional studies may be excluded at full-text review.

Data Extraction

A data abstraction form will be used to obtain information from each of the relevant studies (Multimedia Appendix 2). The data to be extracted from each paper includes the year of publication, first author, year of study, journal or other publication source, country or countries, title, study design, target population, circumstance or outbreak, disease category (HIV/AIDS, tuberculosis, malaria, or a combination of these), list of measures implemented to maintain services, and limitations and strengths. The other information to be extracted about the interventions include the implementer (facility health workers and community health workers), the level at which the intervention is implemented (facility and community), the measure of assessment of the intervention (eg, number of people initiated on ART, number of people tested, and viral load coverage), and the type of indicator (process: number receiving drugs or outcome: number virally suppressed). The number of variables and the order in which they are presented will be adjusted depending on the amount of relevant information we find in the identified studies.

Risk of Bias or Quality Assessment

We will use several strategies to ensure the quality of studies included in the systematic review. First, we will involve 2 reviewers to screen the studies that will be included in the review. The reviewers will have experience in research related to HIV/AIDS, tuberculosis, and malaria service delivery as well as response and control of public health emergencies. In addition, since we do not anticipate quantitatively combining the relevant studies, we will use the GRADE-CERQual (Grading of Recommendations Assessment, Development, and Evaluation—Confidence in Evidence from Reviews of Qualitative Research) approach [38] to assess the quality of each paper. Each study will be assessed for quality in terms of the methodological quality, coherence, adequacy, and quality of the data collected and the relevance of results in line with the review question. The overall assessment of the quality of each study will be graded as either high, moderate, low, or very low.

Data Synthesis and Presentation

Findings from the systematic review will be presented using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-analyses) checklist and flow diagram [39]. The data extracted for the review studies will be summarized and presented in tabular or graphic form as appropriate. The synthesis of the data will be conducted at various levels. These will include at disease or condition level (HIV/AIDS, tuberculosis, malaria, or a combination of these), at the implementation level (policy, health facility, and community), and outcomes (improving access, availability, use, or coverage of services)

Results

The initial search for published literature yielded 8119 studies from web-based databases. This search was conducted between January 2023 and March 2023. At the time of publication, synthesis and interpretation of results were being concluded. Final results will be published in 2025.

Discussion

Expected Findings

We will discuss the findings and their implications for strengthening both preparedness and response, as well as strengthening health systems in low- and middle-income countries. Specifically, we will discuss interventions that are common to the 3 disease programs and how such interventions can support the response to a public health emergency but also be scaled up to strengthen service delivery beyond the emergency. We will also discuss how the interventions have been assessed by comparing process indicators (such as number of people tested) and outcome indicators (such as number of people with viral suppression).

Previous literature has tried to synthesize the challenges [28] and interventions [29] for the delivery of specific service delivery programs like delivery of maternal and child health services during emergencies. However, the scope of essential health services is broad and includes services for noncommunicable diseases like diabetes and hypertension, services for older adults as well as health promotion and referral services. This protocol will provide a structure and framework for the synthesis of the literature for the continuity of essential health services more broadly beyond HIV/AIDS, tuberculosis, and malaria.

Limitations

The main limitation of the review will be the exclusion of studies conducted in languages other than English. In addition, the review will include only studies publishing information about interventions implemented during public health emergencies of international concern. However, a public health emergency need not be declared to be of international concern to cause disruption of access and delivery of HIV, tuberculosis, and malaria services. Nonetheless, the identified interventions will be transferrable to contexts in which an emergency is local and does not pose a threat to the international community. In addition, the development of the protocol followed the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analysis Protocols) checklist (Multimedia Appendix 3).

Conclusions

The findings will inform the development of national and global guidance to minimize disruption of services for patients with HIV/AIDS, tuberculosis, and malaria during public health emergencies. The protocol will also inform studies conducted to synthesize interventions to maintain other health programs beyond HIV/AIDS, tuberculosis, and malaria.

Acknowledgments

The authors are grateful to Emma-Lotta Säätelä and Love Strandberg at Karolinska Institutet's University Library for the technical and administrative support during the process of conducting and refining the literature search from the various databases.

Authors' Contributions

SNK, RKW, and TA were involved in idea conceptualization. RKW, HL, NR, JMS, and TA were involved in the review of technical content and supervision. SNK wrote the first draft of the manuscript. All authors reviewed and approved the final version of the manuscript.

Abstract

Background: In patients with atherosclerotic occlusive diseases, systematic reviews and meta-analyses of randomized controlled trials (RCTs) report that antiplatelets, statins, and antihypertensives reduce the risk of major adverse cardiac events, need for revascularization procedures, mortality, and health care resource use. However, evidence suggests that these patients are not prescribed these medications adequately or do not adhere to them once prescribed.

Objective: We aim to systematically review and meta-analyze RCTs examining the effectiveness of implementation or adherence-supporting strategies for improving health care provider prescription of, or patient adherence to, guideline-recommended cardiovascular medications in patients with atherosclerotic occlusive disease.

Methods: We designed and reported the protocol according to the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis-Protocols) statement. We will search MEDLINE, Embase, The Cochrane Central Register of Controlled Trials, PsycINFO, and CINAHL from their inception. RCTs examining implementation or adherence-supporting strategies for improving prescription of, or adherence to, guideline-recommended cardiovascular medications in adults with cerebrovascular disease, coronary artery disease, peripheral artery disease, or polyvascular disease (>1 of these diseases) will be included. Two investigators will independently review identified titles/abstracts and full-text studies, extract data, assess the risk of bias (using the Cochrane tool), and classify implementation or adherence-supporting strategies using the refined Cochrane Effective Practice and Organization of Care (EPOC) taxonomy (for strategies aimed at improving prescription) and Behavior Change Wheel (BCW; for adherence-supporting strategies). We will narratively synthesize data describing which implementation or adherence-supporting strategies have been evaluated across RCTs, and their reported effectiveness at improving prescription of, or adherence to, guideline-recommended cardiovascular medications (primary outcomes) and patient-important outcomes and health care resource use (secondary outcomes) within refined EPOC taxonomy levels and BCW interventions and policies. Where limited clinical

heterogeneity exists between RCTs, estimates describing the effectiveness of implementation or adherence-supporting strategies within different refined EPOC taxonomy levels and BCW interventions and policies will be pooled using random-effects models. Stratified meta-analyses and meta-regressions will assess if strategy effectiveness varies by recruited patient populations, prescriber types, clinical practice settings, and study design characteristics. GRADE (Grading of Recommendations, Assessment, Development, and Evaluation) will be used to communicate evidence certainty.

Results: The search was completed on June 6, 2023. Database searches and the PubMed "related articles" feature identified 4319 unique citations for title/abstract screening. We are currently screening titles/abstracts.

Conclusions: These studies will identify which implementation and adherence-supporting strategies are being used (and in which combinations) across RCTs for improving the prescription of, or adherence to, guideline-recommended cardiovascular medications in adults with atherosclerotic occlusive diseases. They will also determine the effectiveness of currently trialed implementation and adherence-supporting strategies, and whether effectiveness varies by patient, prescriber, or clinical practice setting traits.

Introduction

Background

Atherosclerotic occlusive disease is common worldwide, increasing in global prevalence, and characterized by arterial stenosis (narrowing) and occlusion secondary to the buildup of lipid-rich plaque within arterial walls [1]. This disease may be further categorized by anatomic location, with atherosclerotic plaque buildup within the arteries of the extracranial and intracranial circulation, heart, and peripheral arteries being referred to as cerebrovascular disease (CVD), coronary artery disease (CAD), and peripheral artery disease (PAD), respectively [1]. An estimated 101 million [2], 197 million [3], and 113 million [4] individuals have CVD, CAD, and PAD worldwide, respectively. CVD, CAD, and PAD are associated with a significantly increased risk of hospitalization; need for coronary, carotid, or lower limb revascularization; major adverse cardiac events (MACEs) and major adverse limb events (MALEs); stroke; and cardiovascular and all-cause mortality [5,6].

International, evidence-based clinical practice guidelines strongly and consistently recommend that adults with CVD, CAD, PAD, and polyvascular disease be prescribed and take antiplatelets and statins (ie, hydroxymethylglutaryl-CoA reductase inhibitors) [7-11]. They also recommend antihypertensives for those patients with concurrent hypertension [7-11]. These recommendations are based on high-quality data from randomized controlled trials (RCTs) and systematic reviews and meta-analyses of RCTs that reported a significantly lower risk of MACE; MALE; need for coronary, carotid, and lower limb revascularization procedures; cardiovascular and all-cause mortality; and health care resource use when these patients are prescribed these medications [12-14].

Despite this, evidence suggests that many patients with atherosclerotic occlusive disease are not prescribed these medications adequately or do not adhere to them after prescription [15-18]. More specifically, only approximately 40% to 90% of patients with any form of atherosclerotic occlusive disease are prescribed any antiplatelet, 30% to 60% any statin, 40% to 60% any antihypertensive, and 10% to 40% all three guideline-recommended cardiovascular medications [15,16]. Studies also report that patient adherence percentages to these medications range from ~70% to 80% for antiplatelets, ~50% to 60% for statins, ~40% to 70% for antihypertensives, and ~20% to 40% for all three guideline-recommended cardiovascular medications [17,18]. Those with PAD are also significantly less likely to be prescribed these medications and adhere to them compared to those with CVD and CAD [19]. The increased frequency at which patients with PAD are underprescribed and nonadherent to guideline-recommended cardiovascular medications may partially explain why studies demonstrate persistently higher risks of cardiovascular-related hospitalization (eg, for atherothrombotic events), MACE, stroke, and cardiovascular mortality in patients with PAD compared to those with CVD or CAD [20].

To improve the use of guideline-recommended cardiovascular medications among patients with atherosclerotic occlusive disease, RCTs [21-48] have evaluated implementation strategies (interventions directed at the health system and health care providers) and adherence-supporting strategies (interventions aimed at patients directly) [49] to improve health care provider prescription of and patient adherence to guideline-recommended cardiovascular medications, respectively. However, the design [21-24], length of follow-up [24,27,31], setting [21,24-26], and implementation or adherence-supporting strategies examined [21,26,27,30-32,36,40-48] varies considerably across published trials. Existing RCTs have also examined implementation and adherence-supporting strategies aimed at improving prescription of or adherence to different medication classes (antiplatelets [25,28,29], statins [27-29], antihypertensives [25,28,42], or all guideline-recommended medications [27,29,43,44]) among patients with different diagnoses (CVD [31-33], CAD

[24,26,27], PAD [34,35], and polyvascular disease [36,37]). Further, the implementation and adherence-supporting strategies examined within published trials target different types of health care providers (ie, cardiovascular specialists [38,39] or noncardiovascular specialists [21,23]) and health care provider behaviors [31,33,38,40]. Given this interstudy heterogeneity, evidence-synthesis efforts are needed to interpret the results of the above RCTs collectively.

Rationale

Two updated, comprehensive, and methodologically rigorous systematic reviews and meta-analyses are needed to determine the effectiveness of implementation and adherence-supporting strategies for improving health care provider prescription of, and patient adherence to, guideline-recommended cardiovascular medications for atherosclerotic occlusive diseases. All forms of atherosclerotic occlusive disease (CVD, CAD, PAD, and polyvascular disease) will be examined within both systematic reviews as the underlying pathophysiology [50-52], and guideline-recommended cardiovascular medications for medical management of these diseases [7-11] are nearly identical. Further, patients with these atherosclerotic occlusive diseases tend to have similar demographics (ie, frequently past or current smokers, often male, and typically over 65 years of age) and comorbidities [53-55]. Finally, these diseases often coexist together [56,57], and similar prescribers are involved in their medical management [58-60]. The results of these systematic reviews will help identify promising implementation and adherence-supporting strategies for each and all classes of cardiovascular medications recommended for patients with atherosclerotic occlusive diseases. The systematic reviews will facilitate an effective comparison of implementation and adherence-supporting strategies by classifying them according to established taxonomies [61,62].

Objectives

The primary objectives of the two systematic reviews are to synthesize the effectiveness of implementation and adherence-supporting strategies for improving health care provider prescription of, and patient adherence to, guideline-recommended cardiovascular medications among patients with atherosclerotic occlusive disease, including CVD, CAD, PAD, or polyvascular disease. We conceptualized the desired behavior changes for our primary objectives and key actors involved in bringing about these desired behavior changes using the Action, Actor, Context, Target, Time (AACTT) framework [63] (see Table 1 for the underprescription systematic review AACTT framework and Table 2 for the nonadherence systematic review AACTT framework).

Table 1. AACTT[a] behavior specification framework [63] for the systematic review of implementation strategies for improving health care provider prescription of guideline-recommended cardiovascular medications to adults with atherosclerotic occlusive disease.

AACTT domains	Examples among the systematic review of implementation strategies for improving health care provider prescription of cardiovascular medications
Action	Prescription of guideline-recommended cardiovascular medications (antiplatelets, statins, or antihypertensives)
Actor	Health care providers responsible for managing patients with atherosclerotic occlusive disease
Context	Any setting where prescribers are responsible for prescribing medication to patients with atherosclerotic occlusive diseases (eg, primary care practices, tertiary academic hospitals, or pharmacies)
Target	Patients with an atherosclerotic occlusive disease (cerebrovascular disease, coronary artery disease, peripheral artery disease, or polyvascular disease) in whom one or more guideline-recommended cardiovascular medications is indicated
Time	During encounters between prescribers and patients with atherosclerotic occlusive disease

[a]AACTT: Action, Actor, Context, Target, Time.

Table 2. AACTT[a] behavior specification framework [63] for the systematic review of adherence-supporting strategies for improving patient adherence to guideline-recommended cardiovascular medications in adults with atherosclerotic occlusive disease.

AACTT domains	Examples among the systematic review of adherence-supporting strategies for improving patient adherence to cardiovascular medications
Action	Adherence to guideline-recommended cardiovascular medications for atherosclerotic occlusive disease (antiplatelets, statins, or antihypertensives)
Actor	Patients with a diagnosed atherosclerotic occlusive disease (cerebrovascular disease, coronary artery disease, peripheral artery disease, or polyvascular disease)
Context	Any setting in which patients (or their caregivers) are responsible for managing their own medications
Target	Patients who have been prescribed one or more guideline-recommended cardiovascular medications for management of their atherosclerotic occlusive disease by a health care professional
Time	Following prescription of guideline-recommended cardiovascular medications by a health care professional

[a]AACTT: Action, Actor, Context, Target, Time.

The AACTT framework [63] was developed to describe the action (ie, the behavior to change), actor (ie, who is involved in performing the behavior), context (ie, the physical, social, or emotional settings where the behavior is performed), target (ie, the person or people for or with whom the behavior is performed), and time (ie, when the behavior is performed) of

behaviors targeted for change in clinical practice. Describing desired behavior changes using the five elements of the AACTT framework [63] provides a concise overview of which individuals at what organizational levels need to do what differently to ensure the effective implementation of desired best practices. Secondary objectives are to determine whether (1) the effectiveness of implementation or adherence-supporting strategies at improving health care provider prescription of or increasing patient adherence to guideline-recommended cardiovascular medications for atherosclerotic occlusive disease varies by patient characteristics, prescriber traits, medication classes, atherosclerotic occlusive disease diagnoses, or clinical settings; and (2) improved health care provider prescription of or patient adherence to guideline-recommended cardiovascular medications improves patient outcomes and reduces health care resource use.

Methods

Registration and Reporting

This protocol was created following recommendations from the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols) statement [64] (a completed PRISMA-P checklist is provided in Multimedia Appendix 1). The protocols for the systematic reviews of implementation and adherence-supporting strategies for improving health care provider prescription and patient adherence were registered separately on PROSPERO (underprescription systematic review: CRD42023461317; nonadherence systematic review: CRD42023461299). We chose to create a single protocol paper describing the methods of the two planned systematic reviews and meta-analyses as we felt that their background, rationale, and methods overlap significantly. However, as scout searches suggested that one systematic review may include over 100 RCTs, we plan to report their results separately to summarize the results of these evidence syntheses in sufficient detail.

Eligibility Criteria

Eligibility criteria for the two systematic reviews were created according to the Population, Intervention, Comparison, Outcome, and Design framework [65]. Their specific inclusion and exclusion criteria are presented in Table 3 (underprescription systematic review) and Table 4 (nonadherence systematic review).

Table 3. Inclusion and exclusion criteria for systematic review examining implementation strategies for improving health care provider prescription of guideline-recommended cardiovascular medications to patients with atherosclerotic occlusive disease.

PICOD[a] framework domain	Inclusion criteria[b]	Exclusion criteria[c]
Population	• Prescribers (ie, physicians, nurse practitioners, or pharmacists) involved in the management of adults (≥18 years of age) with atherosclerotic occlusive disease (defined as cerebrovascular disease, coronary artery disease, peripheral artery disease, or polyvascular disease).	• >20% of the patient population had nonatherosclerotic cardiovascular disease (eg, aneurysmal disease). This 20% threshold was selected based on prior literature [66]. • Studies examining the prescription of nonguideline-recommended medications. • Prescribers involved in the management of people exclusively <18 years of age.
Intervention	• Any implementation strategy aimed at increasing health care provider prescription of guideline-recommended cardiovascular medications to patients with atherosclerotic occlusive disease. An implementation strategy will be defined as any "method or technique to enhance the adoption, implementation, and sustainability of a clinical program or practice" [49].	• Studies examining implementation strategies directed exclusively at patients.
Comparison	• Health care providers prescribing guideline-recommended cardiovascular medications to patients with atherosclerotic occlusive disease without the use of an implementation strategy, patients receiving the same implementation strategy at a lower intensity or shorter duration than the intervention group, or patients receiving a different implementation strategy than the intervention group.	• Studies examining implementation strategies directed exclusively at patients.
Outcomes	• Primary[d]: Effect estimates (or data required to calculate) describing differences in health care provider prescription between implementation strategy and control arms of each (ie, antiplatelets, statins, or antihypertensives) or all classes of guideline-recommended cardiovascular medications. • Secondary[d]: Effect estimates (or data required to calculate these) describing differences between patients in the implementation strategy and control arms regarding adverse clinical outcomes (eg, major adverse cardiac events, revascularization procedures, amputations, cardiovascular mortality, or all-cause mortality) and health care resource use outcomes (eg, emergency department visits, hospital admission or readmission, or length of hospitalization).	• Studies not reporting effect estimates (or data required to calculate) describing differences in guideline-recommended cardiovascular medication prescription between prescribers in the implementation strategy and control arms.
Design	• Study designs will include RCTs[e] and cluster-RCTs.	• Nonrandomized studies (eg, prospective cohort studies). • Studies published in abstract form only and unpublished studies (ie, gray literature).

[a]PICOD: Population, Intervention, Comparison, Outcome, and Design.

[b]Inclusion criteria formulated according to the Population, Intervention, Comparison, Outcome, and Design framework for posing clinical questions [65].

[c]Studies meeting one or more of the following criteria will be excluded.

[d]Effect estimates (and measures of variation, such as 95% CIs) will be extracted as reported and may include weighted mean differences or standardized mean differences for continuous outcomes; odds ratios, relative risks, and risk differences for binary outcomes; and hazard ratios for time-to-event data.

[e]RCT: randomized controlled trial.

Table 4. Inclusion and exclusion criteria for systematic review examining adherence-supporting strategies for improving patient adherence to guideline-recommended cardiovascular medications in patients with atherosclerotic occlusive disease.

PICOD[a] framework domain	Inclusion criteria[b]	Exclusion criteria[c]
Population	• Adults (≥18 years of age) with atherosclerotic occlusive disease (cerebrovascular disease, coronary artery disease, peripheral artery disease, or polyvascular disease) prescribed one or more guideline-recommended cardiovascular medications (eg, statins, antihypertensives, or antiplatelets).	• >20% of patients had nonatherosclerotic cardiovascular disease (eg, aneurysmal disease). This threshold was selected based on prior literature [66]. • Studies where ≥20% of patients were pediatrics (<18 years of age). • Studies examining adherence to medications not recommended within relevant clinical practice guidelines.
Intervention	• Any adherence-supporting strategy aimed at increasing adherence to guideline-recommended cardiovascular medication in patients with atherosclerotic occlusive disease. An adherence-supporting strategy will be defined as any "method or technique to enhance the adoption, implementation, and sustainability of a clinical program or practice" [49].	• Studies examining adherence-supporting strategies directed at health care providers or the health care system without components directed toward patients.
Comparison	• Patients taking guideline-recommended cardiovascular medications for atherosclerotic occlusive disease management without a concurrent adherence-supporting strategy, patients receiving a different adherence-supporting strategy than the intervention group, or patients receiving the same adherence-supporting strategy at a lower intensity or shorter duration than the intervention group.	• Studies examining adherence-supporting strategies directed at health care providers or the health care system without components directed toward patients.
Outcomes	• Primary[d]: Effect estimates (or data required to calculate) describing differences in medication adherence between adherence-supporting strategy and control arms of each (eg, antiplatelets, statins, or antihypertensives) or all classes of guideline-recommended cardiovascular medications. • Secondary[d]: Effect estimates (or data required to calculate these) describing differences between patients in the adherence-supporting strategy and control arms regarding adverse clinical outcomes (eg, major adverse cardiac events, revascularization procedures, amputations, cardiovascular mortality, or all-cause mortality) and health care resource use outcomes (eg, emergency department visits, hospital admission or readmission, or length of hospitalization).	• Studies not reporting effect estimates (or data required to calculate) describing differences in medication adherence between patients in the intervention and control arms.
Design	• RCTs[e] and cluster-RCTs.	• Nonrandomized studies (eg, case-control studies). • Unpublished studies (ie, gray literature) and studies published in abstract form only.

[a]PICOD: Population, Intervention, Comparison, Outcome, and Design.

[b]Inclusion criteria formulated according to the Population, Intervention, Comparison, Outcome, and Design framework for posing clinical questions [65].

[c]Studies meeting one or more of the following criteria will be excluded.

[d]Effect estimates (and measures of variation, such as 95% CIs) will be extracted as reported and may include weighted mean differences or standardized mean differences for continuous outcomes; odds ratios, relative risks, and risk differences for binary outcomes; and hazard ratios for time-to-event data.

[e]RCT: randomized controlled trial.

Guideline-recommended cardiovascular medications will be defined as any medications recommended within evidence-based clinical practice guidelines cited within the included studies. In studies where evidence-based clinical practice guidelines are not cited, guideline-recommended cardiovascular medications will be defined as antiplatelets (eg, aspirin or clopidogrel), statins, and antihypertensives (eg, angiotensin-converting enzyme inhibitors, angiotensin receptor blockers, β-blockers, calcium-channel blockers, or thiazide diuretics), as these medications are consistently recommended for individuals with CVD, CAD, PAD, and polyvascular disease across multiple evidence-based clinical practice guidelines [7-11].

Clinical Questions

Primary Clinical Questions

The primary clinical questions are as follows:

1. What is the effectiveness of different implementation strategies for improving health care provider prescription of guideline-recommended cardiovascular medications to

adults (≥18 years of age) with atherosclerotic occlusive disease, including CVD, CAD, PAD, or polyvascular disease?
2. What is the effectiveness of adherence-supporting strategies for increasing adherence to guideline-recommended cardiovascular medications among adults with atherosclerotic occlusive disease?

Secondary Clinical Questions

The secondary clinical questions are as follows:

1. Does the effectiveness of implementation and adherence-supporting strategies for improving health care provider prescription of and patient adherence to guideline-recommended cardiovascular medications to adults with atherosclerotic occlusive diseases vary by study design, prescriber characteristics, patient characteristics, atherosclerotic occlusive disease diagnosis, or clinical practice setting?
2. Does the use of implementation or adherence-supporting strategies aimed at improving health care provider prescription of or patient adherence to guideline-recommended cardiovascular medications to adults with atherosclerotic occlusive disease improve patient outcomes or reduce health care resource use?

Information Sources

We will search MEDLINE, Embase, The Cochrane Central Register of Controlled Trials, PsycINFO, and CINAHL from their inception. We will also use the PubMed "related articles" feature and manually search reference lists of included studies and relevant reviews identified during the search.

Search Strategy

Our electronic search strategy was designed in consultation with an information scientist. Using combinations of Medical Subject Headings (National Library of Medicine) or Emtree (Elsevier) terms and keywords, we constructed search filters covering the themes "atherosclerotic occlusive disease" and "medication prescription or adherence." These search filters were then combined with a validated RCT search filter from the Cochrane Handbook for Systematic Reviews of Interventions [67]. The search strategy was subsequently piloted and refined by adding additional thesaurus or indexing terms to the nonsearch filter themes when new, relevant citations were located during iterative pilot searches. The penultimate search strategies were peer-reviewed by another medical librarian in accordance with the Peer Review of Electronic Search Strategies framework [68] (see Multimedia Appendix 2 for final search strategies).

Study Selection and Management

Titles and abstracts of identified citations will be reviewed by two independent reviewers using Rayyan Systematic Review Software [69]. Citations deemed potentially relevant by either reviewer during title/abstract screening will be subject to independent full-text review using relevant inclusion and exclusion criteria (see Tables 3 and 4). Disagreements regarding study inclusion will be resolved by consensus.

Outcomes

The primary outcome for the underprescription systematic review will be the health care provider's prescription of each (eg, antiplatelets, statins, or antihypertensives) or all classes of guideline-recommended cardiovascular medications between the implementation strategy and control arms. The primary outcome of the nonadherence systematic review will be the patient adherence to each (eg, antiplatelets, statins, or antihypertensives) or all classes of guideline-recommended cardiovascular medications between the adherence-supporting strategy and control arms. Secondary outcomes for both systematic reviews will be differences in patient outcomes and health care resource use between the implementation or adherence-supporting strategy and control arms. Patient outcomes will include MACE [70] (defined as nonfatal myocardial infarction, stroke, or cardiovascular mortality), MALE [70] (defined as limb ischemia requiring revascularization or above-ankle lower limb amputation), stroke, revascularization procedures, amputations, patient-reported outcome measures, cardiovascular mortality, all-cause mortality, and any other patient-important outcomes reported by study authors. Health care resource use outcomes will include emergency department visits, hospital admission or readmission, length of hospitalization, and any other health care resource use outcomes reported by study authors.

Data Items and Selection Process

Two investigators will independently extract data using a predesigned electronic data extraction spreadsheet (see Tables 5 and 6 for data items to be extracted from the underprescription and nonadherence systematic reviews, respectively).

When potentially relevant articles published in languages other than English are identified, translators will be recruited to review the full texts and extract data if identified studies meet inclusion criteria. Effect estimates and their 95% CIs (or data required to calculate these measures) describing associations between implementation or adherence-supporting strategy use and primary and secondary outcomes will be extracted as reported in studies and may include weighted mean differences or standardized mean differences for continuous outcomes; odds ratios (ORs), relative risks (RRs), and risk differences for binary outcomes; and hazard ratios (HRs) for time-to-event data. Where studies do not provide effect estimates and their 95% CIs (or data required to calculate these measures) within the text or summary tables but summarize this information within figures, data will be extracted independently by two investigators using ImageJ software (National Institutes of Health) [72] and then their results will be averaged across investigators. Where data are not provided in the text, summary tables, or figures, these data will be sought from the supplementary materials of included trials or from trial registration repositories. In cases where data cannot be found using the above methods, study authors will be contacted in a final attempt to obtain all relevant study data. Discrepancies between investigators regarding data extraction will be resolved by consensus.

Table 5. Data items to be extracted from included studies when reported for systematic review examining implementation strategies for improving health care provider prescription of guideline-recommended cardiovascular medications to adults with atherosclerotic occlusive disease.

Data item theme	Items to be extracted
Study design	• Country of origin • Recruitment period • Study design (eg, RCT[a] or cluster-RCT) • Setting (eg, primary, secondary, or tertiary) • Number of health care providers, patients, or clusters • Follow-up duration • Clinical practice guidelines followed (eg, 2016 American College of Cardiology/American Heart Association PAD[b] guidelines [7])
Prescriber characteristics	• Health care provider specialty (cardiovascular specialist or noncardiovascular specialist) • Health care provider subspecialty (eg, family medicine, general internal medicine, cardiology, or vascular surgery) • Number of female health care providers • Mean years of health care provider practice
Patient characteristics	• Number of patients with different atherosclerotic occlusive diseases (cerebrovascular disease, coronary artery disease, PAD, or polyvascular disease) • Mean or median patient age • Mean or median patient BMI • Number of female patients • Number of non-White patients • Number of patients with low socioeconomic status[c] • Number of past or current smokers • Whether patients were inpatients, outpatients, or long-term care residents • Number of patients who are overweight[d] or obese[e] • Number of patients residing in rural areas • Number of patients with specific comorbidities (dyslipidemia, diabetes mellitus, hypertension, congestive heart failure, chronic kidney disease, or chronic obstructive pulmonary disease)
Guideline-recommended medications	• Classes of guideline-recommended medications examined (antiplatelets, statins, antihypertensives, or all medications) • Types of guideline-recommended medications examined (eg, clopidogrel, simvastatin, or β-blockers)
Implementation strategies	• Implementation strategy classification according to refined Effective Practice and Organization of Care taxonomy [61]
Effect measures	• Effect measures (eg, weighted mean differences, standardized mean differences, odds ratios, relative risks, risk differences, or hazard ratios) and measures of variability (eg, 95% CIs) describing the effect of implementation strategies on primary and secondary outcomes
Risk of bias	• Risk of bias for the 7 domains of the Cochrane risk of bias tool [71]

[a]RCT: randomized controlled trial.

[b]PAD: peripheral artery disease.

[c]As defined by study authors.

[d]Defined as a BMI ≥25 kg/m^2.

[e]Defined as a BMI ≥30 kg/m^2.

Table 6. Data items to be extracted from included studies when reported for systematic review examining adherence-supporting strategies for improving patient adherence to guideline-recommended cardiovascular medications in adults with atherosclerotic occlusive disease.

Data item theme	Items to be extracted
Study design	• Country of origin • Study design (eg, RCT[a] or cluster-RCT) • Setting (eg, primary, secondary, or tertiary) • Recruitment period • Number of patients, prescribers, or clusters • Clinical practice guidelines followed (eg, 2022 Canadian Cardiovascular Society PAD[b] guidelines [9]) • Duration of follow-up
Patient characteristics	• Atherosclerotic occlusive disease diagnoses (cerebrovascular disease, coronary artery disease, PAD, or polyvascular disease) • Whether patients were inpatients, outpatients, or long-term care residents • Mean or median age • Mean or median BMI • Number of patients with low socioeconomic status[c] • Number of female patients • Number of non-White patients • Number of past or current smokers • Number of patients who are overweight[d] or obese[e] • Number of patients residing in rural areas • Number of patients with specific medical comorbidities (dyslipidemia, diabetes mellitus, hypertension, congestive heart failure, chronic kidney disease, or chronic obstructive pulmonary disease)
Prescriber characteristics	• Specialty of health care providers (cardiovascular specialist or noncardiovascular specialist) • Subspecialty of health care providers (eg, family medicine, general internal medicine, cardiology, or vascular surgery) • Mean or median years of health care provider practice • Number of female health care providers
Guideline-recommended medications	• Classes of guideline-recommended medications examined (statins, antiplatelets, antihypertensives, or all guideline-recommended medications) • Types of guideline-recommended medications examined (eg, aspirin, rosuvastatin, or angiotensin-converting enzyme inhibitors)
Adherence-supporting strategies	• Adherence-supporting strategy classification according to the Behavior Change Wheel [62]
Effect measures	• Effect measures (eg, weighted mean differences, standardized mean differences, odds ratios, relative risks, risk differences, or hazard ratios) and applicable variation measures (eg, 95% CIs) describing the effect of adherence-supporting strategies on primary and secondary outcomes
Risk of bias	• Risk of bias for 7 domains of the Cochrane risk of bias tool [71]

[a]RCT: randomized controlled trial.

[b]PAD: peripheral artery disease.

[c]As defined by study authors.

[d]Defined as a BMI ≥25 kg/m^2.

[e]Defined as a BMI ≥30 kg/m^2.

Risk of Bias

Two independent investigators will assess the risk of bias for all included trials using the Cochrane risk of bias tool [71]. Discrepancies between investigators regarding risk of bias assessment will be resolved by consensus.

Data Synthesis

Qualitative

Before considering meta-analyses, we will first perform thematic clustering [73] of all included studies. We will classify implementation or adherence-supporting strategies used within both the intervention and comparator arms of identified trials based on (1) the levels and categories of the refined Effective Practice and Organization of Care (EPOC) taxonomy [61] (for implementation strategies for improving health care provider prescription); or (2) the nine intervention functions (education, persuasion, incentivization, coercion, training, restriction, environmental restructuring, modelling, and enablement) and seven policy categories (communication or marketing, guidelines, fiscal, regulation, legislation, environmental or social planning, and service provision) of the Behavior Change Wheel (BCW) [62] (for adherence-supporting strategies for improving patient adherence). The refined EPOC taxonomy was selected

because it was designed to assist reviewers in selecting papers for inclusion in systematic reviews of implementation strategies [61]. It has also been used in systematic reviews examining RCTs of implementation strategies for patients with other chronic conditions [74,75] and allows for an adequate description of complex and multiple implementation strategies [61]. The BCW was selected because it was constructed by behavior change experts through systematic analysis and synthesis of 19 previously existing adherence-supporting strategy classification frameworks [62]. The BCW also satisfies three usefulness criteria not completely satisfied by any of the 19 individual frameworks on which it is built (comprehensiveness, coherence, and links to an overarching model of behavior) and can classify every adherence-supporting strategy that has been developed [62]. Further, linkage to an overarching model of behavior (the capability, opportunity, and motivation model) may allow for the selection of adherence-supporting strategies more likely to achieve the desired behavior change [62]. The BCW has also been shown to be reliable for classifying adherence-supporting strategies across a wide range of clinical contexts [62]. Implementation and adherence-supporting strategies will be classified by 2 independent investigators. Disagreements regarding implementation or adherence-supporting strategy classification will be resolved through consultation with a health psychologist.

Following implementation and adherence-supporting strategy classification, we will tabulate studies [73] based on the implementation strategies contained within their intervention and comparator arms. This will allow us to narratively summarize [73] how the implementation or adherence-supporting strategies used within the intervention and comparator arms of included studies differ regarding (1) the type and number of implementation or adherence-supporting strategies used; or (2) the intensity and duration of implementation or adherence-supporting strategy use. It will also allow us to describe which and how frequently specific implementation or adherence-supporting strategies are used in combination (ie, how frequently they co-occur together in complex implementation or adherence-supporting strategies). Studies will also be tabulated [73] by the classes of guideline-recommended cardiovascular medications that their implementation or adherence-supporting strategies are designed to improve the prescription of or adherence to, the predominant diagnoses of the patients included in this study (CVD, CAD, PAD, and polyvascular disease), and whether their implementation strategy was aimed at cardiovascular or noncardiovascular specialists (for implementation strategies for improving health care provider prescription).

Quantitative

Descriptive data will be summarized using weighted means and SDs, medians and IQRs, or counts and percentages where appropriate. Where minimal clinical interstudy heterogeneity exists [76], DerSimonian and Laird [77] random effects models will be used to pool effect estimates whenever two or more studies report on the effect of implementation or adherence-supporting strategies of the same type (according to the refined EPOC taxonomy [61] [underprescription systematic review] or the BCW [62] [nonadherence systematic review]) on similar outcomes. We will preferentially summarize the pooled effects of implementation or adherence-supporting strategies on the primary and secondary outcomes using RRs for dichotomous outcomes, weighted mean differences for continuous outcomes, and HRs for time-to-event outcomes (along with their 95% CIs). Where substantial interstudy clinical heterogeneity exists [76], we will summarize the results of included studies narratively [73] by reporting effect estimates (along with their 95% CIs) describing the effectiveness of implementation or adherence-supporting strategies at improving primary or secondary outcomes.

Where studies report effect measures other than RRs (ie, ORs or HRs), we will use corresponding raw data describing the cumulative incidence of underprescription or nonadherence or secondary outcomes to calculate RRs from ORs or HRs using validated methods [78,79] as has been done previously [80,81].

For included cluster-RCTs, we will calculate a design effect (DE) for each study using an established formula ($DE = 1+ [n - 1] \times \rho$) [82,83]. This DE will then be used to reduce the total sample size to an "effective sample size" (*effective sample size = n/DE*) to account for clustering effects [82]. If an interclass correlation coefficient (ICC; ρ) is not reported in one or more of the included studies, a single conservative ICC value will be used [84]. The value of this single conservative ICC will be based on ICCs from similar studies [84] and will be imputed separately for RCTs examining provider-level or health care system-level strategies (ie, those targeting underprescription) and patient-level strategies (ie, those targeting nonadherence) [85].

Interstudy heterogeneity will be assessed by inspecting forest plots and calculating I^2 statistics [86]. We will consider I^2 statistics >25%, >50%, and >75% to represent low, moderate, and high degrees of heterogeneity, respectively [86]. We will also conduct stratified meta-analyses and meta-regressions using several prespecified risk factors for underprescription and nonadherence selected based on the findings of related systematic reviews [87-92] and methodological considerations [15,16,93-103]. The following risk factors will be used within these analyses to determine whether they may be effect modifiers: (1) whether the predominant atherosclerotic occlusive disease was CAD or another atherosclerotic occlusive disease (CVD, PAD, or polyvascular disease) [15,16]; (2) whether most prescribers were cardiovascular specialists (eg, cardiologists or vascular surgeons) or noncardiovascular specialists (eg, family physicians, general internal medicine physicians, pharmacists, or nurse practitioners) [96-98]; (3) whether studies originated from high or low-middle income countries [99,100] (according to the list provided by the World Bank in 2023) [93]; (4) the proportion of female [101-103], non-White [101-103], and low socioeconomic status [101-103] patients; (5) whether the mean age of patients was ≥65 years of age instead of <65 years of age (or whether ≥50% of the population was aged ≥65 years versus <50% of the population was aged ≥65 years) [101-103]; (6) study setting (primary care versus tertiary care) [101-103]; (7) whether participants were predominantly inpatients, outpatients, or long-term care residents (nonadherence systematic review only) [101,102]; (8) whether there was a high or unclear versus lower risk of bias related to random sequence generation,

allocation concealment, and blinding of outcome assessors [73]; and (9) whether information regarding medication adherence was obtained using objective methods (eg, biochemical assays [94,95], electronic pill bottle openings [94,95]) or participant self-report [94] (eg, Morisky Medication Adherence Scale [104], Medication Adherence Report Scale [105] [nonadherence systematic review only]).

Publication Bias and Small-Study Effects

The presence of publication bias will be evaluated using the Egger test and by visually inspected produced funnel plots from primary outcomes [106].

Statistical Software

All analyses will be conducted using Stata Standard Edition (version 17.0; Stata Corp). Risk-of-bias graphics will be generated using Review Manager Systematic Review Software (version 5.4; The Cochrane Collaboration).

Certainty in the Cumulative Evidence

We will use the GRADE (Grading of Recommendations, Assessment, Development, and Evaluation) [107] to rate certainty in outcome estimates. First, we will assess the risk of bias, imprecision, inconsistency, indirectness, and publication bias in outcome estimates [107]. The overall certainty in these estimates will then be judged as high ("further research is very unlikely to change our certainty in the estimate"), moderate ("further research is likely to have an important impact on our certainty in the estimate and may change the estimate"), or low ("further research is very likely to have an important impact on our certainty in the estimate and is likely to change the estimate") [107].

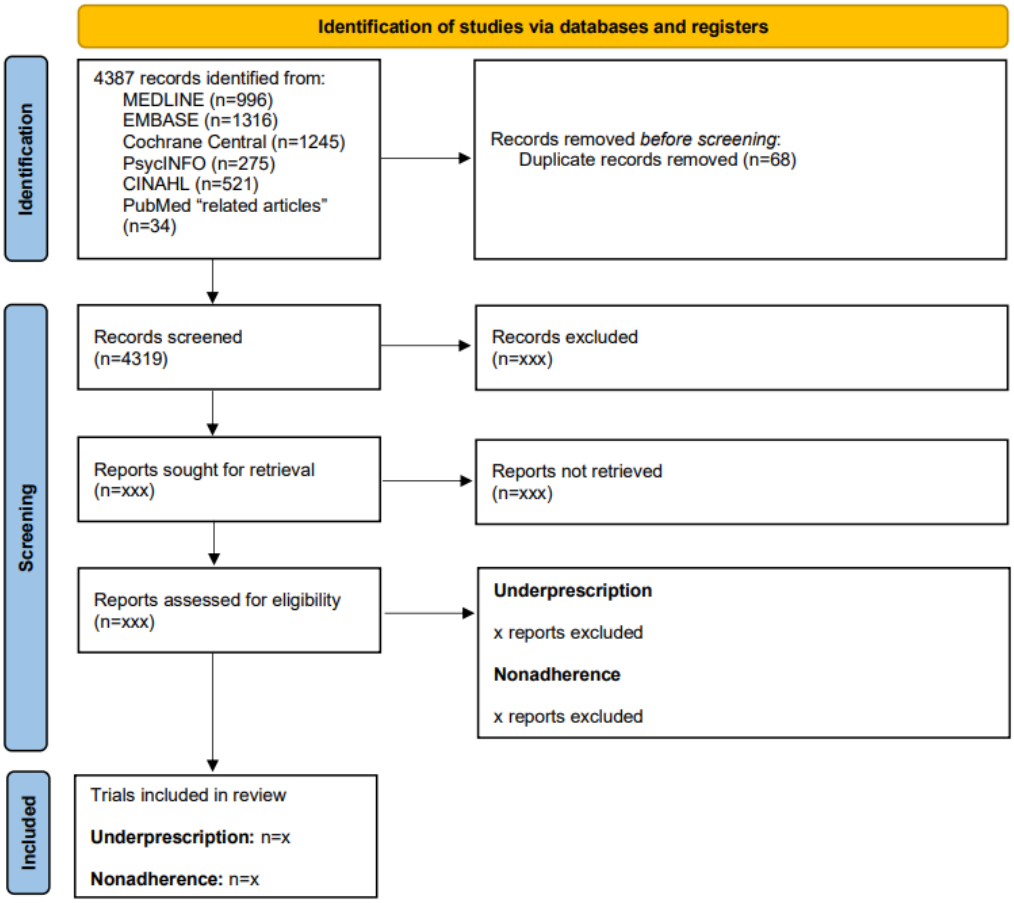
Ethical Considerations

These systematic reviews will examine previously published data and are therefore exempt from ethics approval at our institution.

Results

We conducted the database and PubMed "related articles" search on June 6, 2023. Database searches identified 4353 total citations (n=996 from MEDLINE; n=1316 from Embase; n=1245 from Cochrane Central; n=275 from PsycINFO; and n=521 from CINAHL). The PubMed "related articles" feature identified another 34 citations. After removing duplicates, 4319 unique citations remain for title/abstract screening (see Figure 1 for our PRISMA [Preferred Reporting Items for Systematic Review and Meta-Analysis] flow diagram). We are currently in the process of performing title/abstract screening. We hope to complete analyses for the two systematic reviews by mid-2025.

Figure 1. PRISMA flow diagram describing the flow of articles through the systematic reviews. PRISMA: Preferred Reporting Items for Systematic Reviews and Meta-Analyses.



Discussion

Future Directions and Anticipated Principal Results

Our systematic reviews will assess all RCTs examining the effectiveness of implementation and adherence-supporting strategies for improving health care provider prescription of, and patient adherence to, guideline-recommended cardiovascular medications among adults with atherosclerotic occlusive diseases. We also aim to determine the effectiveness of implementation strategies at improving medication prescription across different classes of health care providers working across different clinical practice settings. We anticipate that clinician education may be a particularly effective strategy for improving prescription among those working in primary care settings, given that these types of practitioners may have relatively reduced awareness of guideline recommendations for the management of patients with atherosclerotic occlusive disease relative to cardiovascular specialists [108]. As patients treated at tertiary medical centers tend to have complex electronic medical records [109], we anticipate that a facilitated relay of information to clinicians may be particularly effective for improving medication prescription among cardiovascular specialists and clinicians working in tertiary academic centers. Strategies anticipated to be promising for improving guideline-recommended cardiovascular medication prescription across different health care provider types and clinical practice settings include audit and feedback, provider reminder systems, and organizational changes given the promise these interventions have demonstrated for improving medication prescription among patients with varied cardiovascular diseases [87,88].

We will also examine whether the effectiveness of adherence-supporting strategies varies across patients with different types of atherosclerotic occlusive diseases (CVD, CAD, PAD, and polyvascular disease). In particular, identifying promising adherence-supporting strategies for improving medication adherence among patients with PAD is of crucial importance given that research has shown that those with PAD are less likely to be prescribed guideline-recommended medications compared to those with CVD or CAD [19]. As patients with PAD tend to have worse awareness of their condition and relevant secondary medical prevention options compared to those with other atherosclerotic occlusive diseases [110], we anticipate that patient education may be a particularly promising strategy for improving medication adherence among patients with PAD. Adherence-supporting strategies involving fiscal components (eg, medication copayment) may also be a particularly promising strategy for improving medication adherence among patients with PAD given the high costs of guideline-recommended cardiovascular medications [111]. Further, as patients with atherosclerotic occlusive disease tend to be older [53-55], strategies that remind patients to take their prescribed medications may serve as promising adherence-supporting strategies across patients with atherosclerotic occlusive disease in general.

Comparison With Previous Work

Although systematic reviews have examined the effectiveness of implementation and adherence-supporting strategies for improving health care provider prescription of [87,88], and patient adherence to [89-92], guideline-recommended cardiovascular medications for atherosclerotic occlusive diseases, they have important limitations. One systematic review of implementation strategies for improving health care provider prescription [87] characterized its implementation strategies according to the EPOC taxonomy [112], which was developed to help authors classify implementation strategies in systematic reviews. However, it aggregated implementation strategies together to assess whether they collectively increased health care provider prescription of guideline-recommended medications instead of examining whether strategy effectiveness varied within different EPOC taxonomy [112] levels (ie, professional, organizational, financial, and regulatory). This systematic review [87] also only examined patients with CAD. Although a second systematic review [88] on the effectiveness of implementation strategies for improving health care provider prescription also characterized implementation strategies using the EPOC taxonomy [112], it examined the effectiveness of improving physician adherence to "guideline-recommended care" (eg, use of cardiovascular risk assessment tools or following guidelines for cardiovascular disease screening) in addition to medication prescription [88]. It also included patients with nonatherosclerotic cardiovascular diseases. Limitations of the existing systematic reviews of adherence-supporting strategies for improving patient adherence is that many include patients "at risk" of developing an atherosclerotic occlusive disease or with nonatherosclerotic cardiovascular diseases (eg, hypertension or congestive heart failure) [91,92]. Further, many only examine specific adherence-supporting strategies (eg, polypills, text-message reminders, or patient education) [89,90,92] or adherence to specific cardiovascular medications among patients with CVD or CAD [89-92]. Many also did not categorize their adherence-supporting strategies according to an established taxonomy [91]. Finally, many relevant RCTs have been completed since the publication of prior underprescription [87,88] and nonadherence [89-92] systematic reviews.

Strengths and Limitations

Our proposed systematic review has potential limitations. First, we anticipate that it may be difficult to pool the results of some studies due to interstudy heterogeneity [113]. We anticipate that many relevant RCTs [21-48] may have reported different primary and secondary outcomes at different time points and using different outcome measurement scales. Should we be unable to pool our quantitative results, we will summarize our results narratively instead of using the methods outlined above [73]. Second, it may be argued that including patients with all forms of atherosclerotic occlusive disease in our study population may introduce clinical heterogeneity due to small differences in underlying disease pathophysiology [50-52] and epidemiology [53-55]. Nevertheless, the patient populations in our proposed systematic reviews are more similar regarding disease pathology, epidemiology, and medication requirements than others in previously published systematic reviews [87-92]. Further, these conditions commonly coexist within patients [56,57] and similar prescribers are involved in their medical management [58-60]. Finally, although the use of self-reported

data to quantify medication adherence introduces the possibility of outcome misclassification bias [94], we plan on performing stratified meta-analysis and meta-regression to determine whether observed differences in medication adherence vary by whether studies quantified medication adherence using objective methods versus participant self-report.

Conclusions

In conclusion, we will perform systematic reviews and meta-analyses of RCTs examining implementation and adherence-supporting strategies designed to improve health care provider prescription of, and patient adherence to, guideline-recommended cardiovascular medications among patients with atherosclerotic occlusive diseases. These systematic reviews will also determine the effect of these interventions on patient-important outcomes and health care resource use. Finally, they will determine whether effectiveness varies by patient characteristics, prescriber traits, and clinical practice setting.

Acknowledgments

The authors would like to thank RS and her colleagues for their help in designing, peer-reviewing, and executing the electronic literature search strategies. This research is supported by a 2024 Vanier Canada Graduate Scholarship (awarded to AMK and supervised by DJR). DJR's research program is also supported by funding from the Physician Services Incorporated foundation; The Ottawa Hospital Academic Medical Organization; and the Division of Vascular and Endovascular Surgery, and the Department of Surgery, University of Ottawa. This study's sponsor (University of Ottawa) played no role in the design of this study or drafting of this study's protocol.

Data Availability

Data from the systematic review will be provided by study authors upon reasonable request.

Authors' Contributions

AMK and DJR conceived this study, and AMK, DJR, DAF, JP, and DIM developed this study. AMK, RS, and DJR designed the search strategy and the qualitative and quantitative data synthesis plan, which DAF, JP, and DIM further refined. AMK wrote the initial draft of the protocol, which was critically reviewed by DAF, JP, DIM, and DJR. AMK submitted the protocol to PROSPERO. All of this study's authors have critically read and approved the final version of this protocol.

Conflicts of Interest

None declared.

Abstract

Background: In recent years, the intersection of natural language processing (NLP) and public health has opened innovative pathways for investigating social determinants of health (SDOH) in textual datasets. Despite the promise of NLP in the SDOH domain, the literature is dispersed across various disciplines, and there is a need to consolidate existing knowledge, identify knowledge gaps in the literature, and inform future research directions in this emerging field.

Objective: This research protocol describes a systematic review to identify and highlight NLP techniques, including large language models, used for SDOH-related studies.

Methods: A search strategy will be executed across PubMed, Web of Science, IEEE Xplore, Scopus, PsycINFO, HealthSource: Academic Nursing, and ACL Anthology to find studies published in English between 2014 and 2024. Three reviewers (SR, ZZ, and YC) will independently screen the studies to avoid voting bias, and two (AS and YX) additional reviewers will resolve any conflicts during the screening process. We will further screen studies that cited the included studies (forward search). Following the title abstract and full-text screening, the characteristics and main findings of the included studies and resources will be tabulated, visualized, and summarized.

Results: The search strategy was formulated and run across the 7 databases in August 2024. We expect the results to be submitted for peer review publication in early 2025. As of December 2024, the title and abstract screening was underway.

Conclusions: This systematic review aims to provide a comprehensive study of existing research on the application of NLP for various SDOH tasks across multiple textual datasets. By rigorously evaluating the methodologies, tools, and outcomes of eligible studies, the review will identify gaps in current knowledge and suggest directions for future research in the form of specific research questions. The findings will be instrumental in developing more effective NLP models for SDOH, ultimately contributing to improved health outcomes and a better understanding of social determinants in diverse populations.

International Registered Report Identifier (IRRID): DERR1-10.2196/66094

KEYWORDS

social determinants of health; SDOH; natural language processing; NLP; systematic review protocol; large language models; LLM

Introduction

Rationale

Social Determinants of Health

Social determinants of health (SDOH) are the nonmedical conditions in which people are born, grow, live, work, and age [1]. These circumstances are shaped by the distribution of money, power, and resources at global, national, and local levels, and are primarily responsible for health inequities—the unfair and avoidable differences in health status seen within and between countries. As a result, one of Healthy People 2030's five overarching goals is specifically related to SDOH: "Create social, physical, and economic environments that promote attaining the full potential for health and well-being for all" [2]. Studies have shown that SDOH has powerful influences on health [3] and well-being at the individual and population levels [4]; therefore, it is important to capture them. Such information is valuable to a range of stakeholders including patients, health care providers, policymakers, and insurance companies. For instance, clinicians might modify a patient's medication regimen if they learn that the patient has difficulty affording their prescriptions or lacks reliable transportation to the pharmacy. It is important to note here that SDOH concepts are often described using a variety of synonyms, paraphrases, or language variations [5], which makes it difficult for simple keyword-based methods to capture all relevant instances. Moreover, many SDOH indicators are not directly stated but implied through context.

Natural Language Processing

Natural language processing (NLP) is a subfield of artificial intelligence and computer science that enables computers to understand, interpret, and generate human language in a way that is both meaningful and useful. NLP encompasses a wide range of tasks, including but not limited to language translation, sentiment analysis, speech recognition, text summarization, and information extraction. NLP offers a promising tool to systematically analyze vast amounts of unstructured text data, including electronic health records (EHRs), social media, public health reports, and others [6]. Such tools and techniques can, therefore, be used to extract socioeconomic factors, environmental conditions, and personal lifestyles that significantly impact an individual's health outcomes. NLP models trained on labeled datasets can learn to recognize these patterns, which can improve extraction accuracy. SDOH information is often embedded within patient narratives or longer descriptions. NLP can assist in parsing and understanding context, coreferences, and the relationships between text parts. Unlike a manual review (time-consuming, labor-intensive, and prone to human error), NLP enables the rapid and scalable analysis of large datasets with greater accuracy and consistency [7,8].

NLP for SDOH

Multiple studies exist that showcase the application of NLP to various SDOH-related tasks in addressing health disparities. One key application is the identification and extraction of SDOH factors from EHRs, where NLP techniques have been used to classify and analyze clinical notes for social needs, behavioral factors, and other determinants that influence patient outcomes [9-12]. In the context of public health, NLP has been used to explore the impact of external events (eg, the COVID-19 pandemic) on marginalized communities by analyzing social media data [13]. Additionally, NLP has been leveraged to identify SDOH in specific populations, such as pediatric patients [14,15], patients living with Alzheimer disease [11], and individuals with lower back pain [16]. Advanced models such as the recent GPT and transformer-based models have further refined the extraction of SDOH from patient records and contributed to more precise and scalable analyses [17,18]. Moreover, NLP has been used to find out the underlying social factors in clinical social work notes [19] and emergency medical services records [20] that further enhance the understanding of how social determinants influence health care delivery.

Despite the promise of NLP in the SDOH domain, the literature is dispersed across various disciplines. Hence, a systematic review is necessary to consolidate existing knowledge, identify knowledge gaps in the literature, and inform future research directions in this emerging field. Our systematic review will focus on studies from 2014 onwards which is well-supported by the significant advancements in NLP techniques and the conceptual evolution of SDOH research that have occurred during this period. The development and introduction of Word2Vec [21] and the subsequent introduction of transformer models [22] marked a point of great improvement in NLP research. In addition, the rise in popularity of large language models (LLMs) such as BERT [23] and GPT [24] has driven substantial progress in the field of NLP. By limiting the review to this decade, the systematic review will capture the evolution of NLP approaches and their application in SDOH tasks, thereby providing a comprehensive and up-to-date study of the literature.

Objectives

This systematic review has two major objectives. First, to identify and highlight distinct NLP techniques, including LLMs (commercial, as well as open-sourced), which are used for tasks including but not limited to augmentation, organization, annotation, prediction, trend analysis, detection, identification, extraction, or classification of SDOH in a given dataset. The NLP model can be used in conjunction with other techniques, but at minimum, the NLP element should be there. The second objective is to report the effectiveness of such techniques or models, identify potential knowledge gaps, and design research questions for future studies.

Methods

Protocol and Registration

The study has been registered in PROSPERO (CRD42024578082) and will be carried out under PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines [25]. This protocol was developed using the 2015 PRISMA-P recommended checklist (Multimedia Appendix 1) for systematic review protocols [26]. However, we omit items 16 (meta-biases) and 17 (confidence in cumulative evidence), given we will not synthesize the outcomes of studies. The review team is composed of researchers across disciplines with diverse backgrounds.

Eligibility Criteria

The eligible publications for this review are restricted to peer-reviewed published literature (observational studies, algorithm validation studies, computational model evaluations, experimental, and qualitative), including journal studies and full conference papers such as ACL anthology. The study must be written in English, although the language of the textual dataset used can vary. The publication period of the included studies was restricted to the last decade, that is, from 2014 to 2024. To be included, a study should answer a research question on the design, development, and application of NLP in health data analysis for SDOH and have used (1) a dataset containing health care data including but not limited to EHRs, social media posts, and clinical notes or narratives, and (2) NLP techniques or models or LLMs (commercial, as well as open source) for tasks including but not limited to augmentation, organization, annotation, prediction, trend analysis, detection, identification, extraction, or classification of SDOH in a given dataset. The NLP model can be used in conjunction with other techniques, but at least the NLP element should be there. Comparisons will be performed against studies included in the review.

For this review, we focused primarily on peer-reviewed literature to ensure the reliability of quantitative information. However, as part of the final systematic review, we will incorporate relevant preprints published between the last search query and up to one month before publication. This approach balances the inclusion of recent advancements while maintaining methodological rigor.

Information Sources

We conducted a systematic search of the following databases from January 1, 2014, to August 9, 2024, across 7 databases: PubMed, Scopus, Health Source: Nursing/Academic, PsycINFO, Web of Science, ACL Anthology, and IEEE EXPLORE. Preprints (arXiv/bioRxiv), forewords, prefaces, table of contents, programs, schedules, indexes, call for papers or participation, lists of reviewers, lists of tutorial abstracts, invited talks, appendices, session information, obituaries, book reviews, newsletters, lists of proceedings, lifetime achievement awards, erratum, systematic reviews, scoping reviews, and notes will be excluded. We will screen relevant review studies based on eligibility criteria. We will further screen studies that cited the included studies (forward search). We will perform hand searches.

Search Strategy

The database search strategies were developed by a health sciences librarian (HR) with expertise in literature searches. Known relevant studies collected by the authors were analyzed to select keywords for the search query. The initial search strategy in PubMed was then iteratively developed by adding or removing additional keywords until all known relevant studies were retrieved by the search query. Textbox 1 shows a draft of the search strategy to be used for the PubMed database, including planned limits. The full search strategies for all information sources are provided in Multimedia Appendix 2.

Textbox 1. Search strategy on PubMed.

Filters

- Manuscript language: English
- Publication years: 2014-2024
- Other: exclude preprints

In addition, a refreshed search strategy will be implemented to ensure that the systematic review includes the most up-to-date and relevant studies. If a significant amount of time has elapsed between the initial literature search and the subsequent stages of citation screening or paper preparation, a secondary search will be conducted. This refreshed search will follow the same search strategy as the initial one, using the same databases, search terms, and inclusion or exclusion criteria. Any newly

identified studies will undergo the same rigorous screening process as those identified in the original search to ensure their relevance and quality before inclusion in the final analysis.

Study Records

Data Management

Potentially relevant citations will first be imported into EndNote (Clarivate) and then exported as an XML file to Covidence (Veritas Health Innovation Ltd), which will identify and remove duplicate records.

Selection Process

Three reviewers (SR, ZZ, and YC) will independently screen each study for eligibility by marking it as a "yes" (for inclusion), "no" (for exclusion), or "maybe" (in case of uncertainty about relevance) in the Covidence platform. Two senior reviewers (AS and YX) will resolve potential discrepancies during any screening step. All voting is blinded, meaning the colleagues cannot see votes until they have cast their own, and vice versa. In the first stage, the reviewers will screen the titles and abstracts of each study as identified in the databases by our search strategies. In the second stage of screening, the team will obtain and screen the full-text papers as per the eligibility criteria. Studies that do not meet the eligibility criteria will be moved to an exclusion folder. The final corpus of selected studies will be then approved by the consensus of all reviewers involved in this study and sent to an expert consultant for potential suggestions. The selection process will be displayed in a PRISMA flowchart.

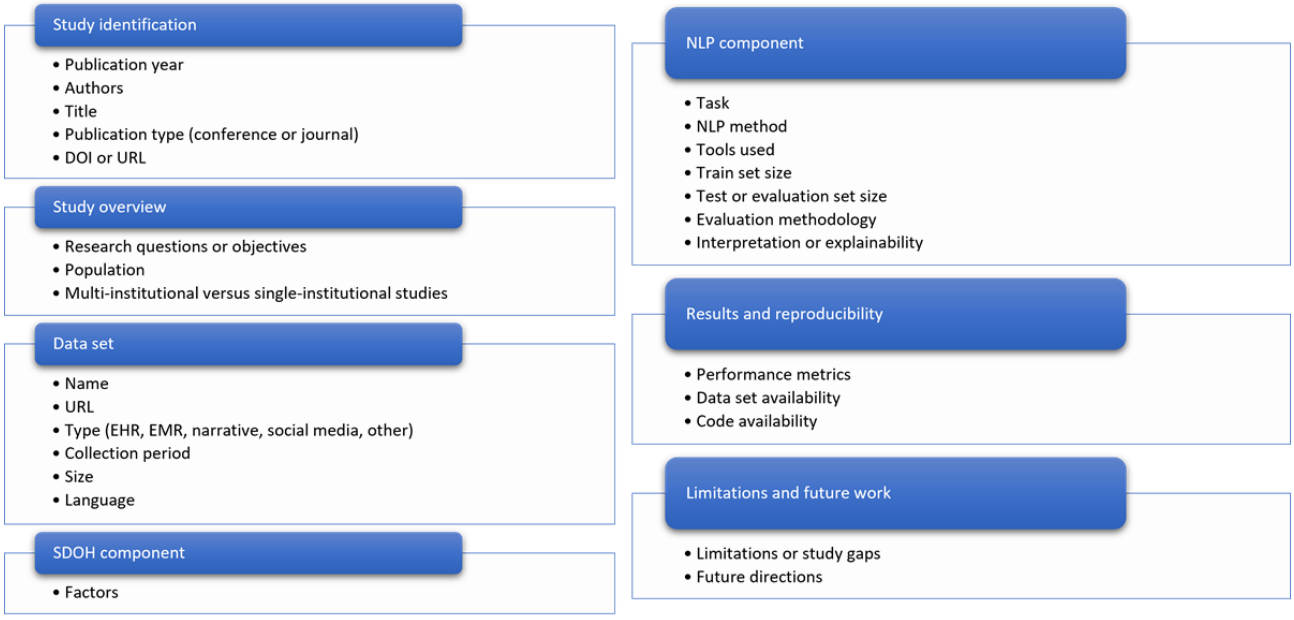
Data Collection Process

Two independent researchers (SR and ZZ) will extract data from the final included full texts. Before formal data extraction, one reviewer (SR) will pilot the data extraction form with a sample of five papers to identify and address any issues in the form to ensure it is comprehensive. The data extraction will then be conducted independently by both reviewers using the finalized form. Any disagreements between the two reviewers will be discussed and resolved through consensus. If consensus cannot be reached, a third reviewer will mediate. In cases where data is incomplete or unclear, the original study authors may be contacted to request additional information or clarification. All data will be managed using Covidence or via a shared Excel (Microsoft Corp) sheet to ensure consistency throughout the process.

Data Items

Figure 1 outlines a preliminary list of variables for which data will be collected, including study identifications (eg, year of publication and type), dataset details (eg, sample size and type), intervention specifics (eg, type of NLP technique and SDOH task), and outcomes (eg, accuracy and precision). Each variable is defined to ensure consistency across studies. During the data extraction process, any assumptions made (such as imputing missing values or converting data into a common format) will be documented and justified. If necessary, modifications to the list of variables will be made during the review, and these changes will be detailed in the final systematic review report.

Figure 1. The data to be extracted. EHR: electronic health record; EMR: emergency medical services; NLP: natural language processing; SDOH: social determinants of health.



Outcomes and Prioritization

We will focus on evaluating the effectiveness and accuracy of various NLP techniques and models applied to SDOH tasks. The primary outcomes of interest will include key performance metrics such as precision, recall, F_1-score, and others, as these are critical indicators of the success of NLP models. Secondary outcomes will involve assessing the integration of NLP techniques with other computational models, such as machine learning and deep learning approaches, to determine their combined impact on model performance. In cases where metrics are not reported, the review will include a qualitative assessment of the study's findings, focusing on the reported outcomes and their relevance to the SDOH task.

Risk of Bias Assessment

We anticipate that the studies included in the review may vary significantly. For instance, some may use complex NLP algorithms while others rely on rule-based systems. Hence, it is challenging to name one specific tool for assessing bias at this stage. We will prioritize assessing key factors that could introduce bias, such as the quality of the datasets, the transparency in reporting the models' performance, and the robustness of the evaluation metrics such as precision and recall.

In addition to assessing general risks of bias, this review will evaluate potential algorithmic bias across individual studies. Algorithmic bias can arise from imbalanced datasets, where certain populations or social determinants are underrepresented, leading to biased predictions. We will examine whether studies report efforts to mitigate such biases.

Data Synthesis

For this systematic review, a narrative synthesis approach will be used. Data from the included studies will be analyzed by two reviewers, with any disagreements resolved through discussion or consultation with a third reviewer if necessary. Given the diverse methods used in the selected studies, the synthesis will focus on identifying and describing common patterns, trends, and knowledge gaps. The analysis will be divided into the following parts:

- Characteristics of the studies (such as the number of studies, types of datasets, NLP techniques, outcomes, and potential biases).
- Contributions of these studies to the development and application of NLP models for SDOH. As this review is intended to be qualitative, no (or minimum) statistical tools will be applied.

Ethical Considerations

No ethical approval is required for this protocol and proposed systematic review, as we will only use data from previously published papers that have received ethics clearance and used proper informed consent procedures. The systematic review's results will be disseminated through publication in a peer-reviewed journal and shared on a publicly accessible GitHub repository [27].

Results

As of December 2024, the systematic review is in progress (SR, ZZ, and YC started screening studies) and is expected to be finished by March 2025. Our final paper is expected to be submitted to peer-reviewed journals by spring 2025.

Discussion

Anticipated Principal Findings

This systematic review is expected to reveal valuable insights into the current state of NLP applications in SDOH tasks. We anticipate identifying the most effective NLP techniques and models across various types of health care data, as well as the common challenges and limitations associated with these approaches. Specifically, we expect to find that the integration of NLP with other computational models, such as machine learning and deep learning, often enhances performance and results in more robust outcomes. We also anticipate that the review will reveal significant variability in model performance based on the type of data used (eg, EHRs vs social media posts) and the specific SDOH being targeted (eg, socioeconomic status vs housing stability). It is important to investigate these factors separately because the challenges in data processing and model effectiveness can vary significantly across different contexts. Investigating these subgroups will provide insights into which NLP techniques are most effective for specific types of data and SDOH, which will enable a more targeted approach in future model development and application. We anticipate that the GitHub repository will offer a platform where researchers can contribute new studies and insights, facilitating ongoing dialogue and collaboration in the field of NLP for SDOH.

Limitations

One limitation of this study is the selection of studies published between 2014 and 2024. Although this timeframe is chosen to focus on recent advancements, it may limit the historical context. We focus on peer-reviewed papers to ensure the inclusion of high-quality and rigorously evaluated studies. While this approach emphasizes established research, it may mean that some recent studies (such as preprints) will not be captured. By prioritizing peer-reviewed literature, we base our findings on research that has undergone thorough scrutiny.

Acknowledgments

We are grateful to the anonymous reviewers at JMIR Research Protocols for their helpful feedback. YX is supported by the National Institute of Mental Health (RF1MH134649), the American Foundation for Suicide Prevention (YIG-2-133-22), the Mental Health Research Network, Google, and the National Institutes of Health (1OT2OD032581-02-259). AS is supported by the National Institute on Drug Abuse (R01DA057599).

Data Availability

All data generated or analyzed during this study will be included in the final systematic review publication and its supplementary information files.

Authors' Contributions

SR developed the study concept and methodology, conducted the investigation, wrote the original manuscript, and created Figure 1. ZZ reviewed the papers, did a literature review, and wrote the manuscript. YC reviewed the papers and wrote the manuscript. HR provided data for Textbox 1 and handled search query curation. AS and YX conceptualized the study, resolved study review conflicts, and provided overall supervision and project administration. All authors reviewed the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Individuals with hearing impairments may face hindrances in health care assistance, which may significantly impact the prognosis and the incidence of complications and iatrogenic events. Therefore, the development of automatic communication systems to assist the interaction between this population and health care workers is paramount.

Objective: This study aims to systematically review the evidence on communication systems using human-computer interaction techniques developed for deaf people who communicate through sign language that are already in use or proposed for use in health care contexts and have been tested with human users or videos of human users.

Methods: A systematic review will be performed based on a literature search in MEDLINE, Web of Science, ACM, and IEEE Xplore as well as top-tiered conferences in the area to identify relevant studies. The inclusion criteria are the description of the development of a sign language recognition system in a health care context and the testing with human users. Independent investigators (LFRO, LRV, and LMMSR) will screen eligible studies, and disagreements will be solved by a senior researcher (MSM). The included papers will undergo full-text screening. A PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) flow diagram will be presented to visually summarize the screening process, ensuring clarity and transparency in presenting the results. Additionally, a comprehensive chart table will be constructed to consolidate essential data related to the key variables extracted from the studies. These results will be meticulously analyzed and presented descriptively, offering insightful interpretations of the information encapsulated within the table.

Results: A preliminary search was performed in April 2024. Researchers concluded the study selection by July 2024. Data extraction, synthesis, report, and recommendations are expected to be finished by February 2025.

Conclusions: This systematic review will identify human-machine systems that enable communication in health services involving deaf patients, presenting the framework that includes usability and application in human contexts. We will present a comprehensive panel of findings, highlighting systems used to tackle communication barriers and offer a narrative comparison of current implementation practices.

Introduction

The term “disabling hearing loss” refers to any type of hearing problem that is considered to be at least moderate (greater than 40 dB), including deafness, and that requires some type of health device to allow adequate communication with the individual [1]. According to the World Health Organization, approximately 430 million people, which accounts for over 5% of the world’s population, have some disabling hearing loss [2]. It is estimated that by 2050, over 700 million people will have some hearing impairment [2].

The scientific literature highlights numerous inequalities faced by the deaf community regarding access to health care services [3-5]. A qualitative study involving 93 deaf adults primarily communicating in American Sign Language revealed that most participants struggled with understanding medical instructions due to communication challenges [6]. Despite often being accompanied by family members during medical appointments, participants expressed dissatisfaction with their effectiveness as communication facilitators. They reported feeling excluded from conversations and expressed privacy concerns when using interpreters [6], a pertinent issue regarding the confidentiality of medical interactions.

In this context, it becomes evident that individuals with hearing impairment are more likely to experience preventable health issues, including adverse problems in acute care and chronic diseases, such as obesity, hypertension, cardiovascular disease, diabetes, smoking, and alcoholism [7,8]. A scoping review of 2022 revealed a gap in the interpretation of sign language for health care and showed that this area is underresearched [9]. Thus, several studies have been committed to the development of assistive technologies, using artificial intelligence techniques, aiming to mitigate the inequalities related to health accessibility experienced by the deaf community. Among these technologies, it is important to highlight that the creation of communication systems that allow translation between sign language and written text, has shown to be very promising [10]. However, despite all the progress attained, the current literature has also shown a huge gap regarding the use of these strategies with deaf people, especially in health care contexts. For this reason, it seems obvious that the creation and implementation of communication systems to enable better interaction between the deaf population and health care workers are paramount. This study aims to systematically review the evidence on communication systems using human-computer interaction techniques developed for deaf individuals who communicate through sign language that are already in use or proposed for use in health care contexts and have been tested with human users or videos of human users.

Methods

Study Design

This is a systematic review protocol. The study design is a systematic search of the medical and other technical literature followed by a narrative synthesis of the results. The research protocol was registered in the Open Science Framework (OSF) [11]. It followed guidance from the Cochrane Guidelines and the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analysis) statement [12]. The PRISMA-P (PRISMA Protocols) checklist can be seen in Multimedia Appendix 1.

A multidisciplinary team comprising researchers from health and computing domains, along with linguistic specialists in sign language, will collaboratively conduct the systematic review. Two members (ELAB and RAAC) of the team are linguistic specialists and sign language researchers, of whom one is deaf (RAAC). Both of them revised the terminology used in this review and revised the methodology critically to ensure that the needs of deaf people have been taken into account.

Strategy for Preparing the Research

Phases of this review are as follows: (0) identification of the need for a review, (1) preparation of a proposal for a review, (2) development of a review protocol, (3) protocol registration in OSF, (4) identification of research, (5) selection of studies, (6) study quality assessment, (7) data extraction, (8) data synthesis, and (9) report and recommendations.

Research Question

The primary research question is as follows: What technologies have been developed and tested in real-world settings to translate sign and oral languages, facilitating communication between deaf patients who primarily use sign language and health care workers?

The specific questions are as follows:

- Question 1: In which context of health care have these technologies been used?
- Question 2: Which languages (sign and oral) can these technologies translate?
- Question 3: Which technologies are required
in loco
for it to be used?
- Question 4: How were they developed?
- Question 5: How were they deployed and tested?
- Question 6: How has the communication between health care workers and deaf people been improved by using these technologies?
- Question 7: How was the efficacy of these technologies evaluated?
- Question 8: Is the system or technology “bidirectional”?

Search Strategy

The search process will commence following registration on the OSF [10]. Independent reviewers will meticulously search the following databases: Web of Science, MEDLINE, IEEE Xplore, ACM, and Google Scholar.

A draft of the search strategy was developed by 5 of the authors (MSM, LFRO, LRV, ROP, and ZSNR), using Medical Subject Headings (MeSH), and text words related to the topic of interest were defined. The proposed search strategy is shown in Multimedia Appendix 2.

Studies published from the inception of the database onward will be inclusively considered, without imposing restrictions on the time frame or publication date, as well as language. Searches will be rerun before the final analysis to ensure comprehensiveness. Additionally, in the event of unpublished studies, authors will be contacted. Reference lists of eligible studies will be thoroughly explored to identify additional eligible studies.

Detailed search data for the identified studies and information for each phase will be presented in a flowchart, accessible in Multimedia Appendix 3, following the guidelines outlined in the PRISMA method [12].

Eligibility Criteria

To be included in the systematic review protocol, a study must be prospective, retrospective, or descriptive; describe the development of communication systems applied to deaf people who communicate through sign language in a health care encounter context; and include testing with human users or videos of human users. The human users of the identified technologies should encompass individuals of any age who are deaf and primarily communicate through sign language.

Correspondences, short communications, and conference abstracts will also be included. Studies that do not align with the research questions specified earlier, fail to report use within health care encounters, do not involve testing with human users, or lack videos of human users will be excluded from the review.

Outcome Definition

The primary anticipated outcome will consist of a compilation of reports detailing technologies using human-computer approaches aimed at facilitating communication for deaf patients during health care encounters. Secondary outcomes will involve conducting a narrative comparison of the identified technologies.

Study Selection

In the screening phase, studies will be selected based on the predetermined inclusion and exclusion criteria after reviewing their titles, abstracts, and full texts. Researchers will independently screen titles and abstracts, with full-text review conducted if uncertainty arises from the abstract. Papers deemed potentially eligible based on title and abstract will undergo full-text screening for final eligibility determination. Eligible papers will be included in the study. Any disagreements regarding eligibility will be resolved by a senior member (MSM) of the team (MSM). The study selection process is represented using the PRISMA flow diagram, which can be found in Multimedia Appendix 3. Included studies will subsequently be selected for qualitative and quantitative analysis during the inclusion phase.

Risk of Bias and Methodological Quality Analysis

The review will conduct a descriptive analysis. There is no specific risk of bias tool for the type of study we expect to find. If applicable, we use the mobile health evidence reporting and assessment checklist in the individual studies [13].

Data Extraction and Data Synthesis

Independent reviewers (LFRO, LRV, and LMMSR) will extract data from the full text of eligible manuscripts using a predefined model. Any uncertainties or divergences will be resolved by a senior researcher (MSM). The following data items will be extracted from each publication: first author, journal and year of publication, country, the aim of the study, whether it was a multidisciplinary study team, corpus of terms used to develop the communication system, corpus examples, communication system development, intervention and testing, languages involved (oral and sign), evaluation or use in a real context, sample size (number of users), preconditions to use the technology and technology needed (hardware or software), development technology (artificial intelligence, imaging processing, etc), which health context (eg, general, emergency, and teleconsultation), technology readiness level (development and testing or if it is being marketed), testing: human users or video of human users, accuracy measures, metrics for evaluating communication effectiveness and parameters to assess to what extent innovation is addressing the communication needs of deaf persons, and ethical and software security issues. These data are detailed in Multimedia Appendix 4. Whenever possible, we will also seek to infer systems' characteristics of flexibility and scalability in various health care settings. Additionally, the research team will email researchers from all individual studies included in the systematic review to update the current status of their systems and to ensure the accuracy and relevance of the information presented in the systematic review. A qualitative analysis of the usability results will be performed for the review.

Results will be presented in a PRISMA flow diagram and a descriptive format (using tables and diagrams, if necessary) aligned with the objective and scope of the review. Results will be presented to carry out a descriptive analysis of the information in the table. For each variable extracted, a narrative summary will be provided, describing how the results relate to the review's objective.

Data Management

The abstracts and full text of manuscripts identified from the search will be uploaded to Rayyan software from Qatar Computing the Research Institute, a software developed specifically to expedite the screening of titles, abstracts, and manuscripts using a process of semiautomation [14]. After uploading the search results, duplicates will be removed in the Rayyan environment [15]. A data extraction form will be developed in Microsoft Excel and piloted before use.

Description of Statistical Methods and Software Used

If feasible, we intend to conduct statistical analysis to aggregate accuracy measures. However, we anticipate that this approach may not be sufficient. In such instances, the systematic review will proceed with a narrative review of the evidence, providing a qualitative synthesis of the findings.

Ethical Considerations

The systematic review does not require ethics approval, as all data used will be provided from published documents. The authors are committed to reporting any outcomes, even the unexpected ones, to ensure transparency and responsibility.

Results

A preliminary search was performed in April 2024. Researchers concluded the study selection by July 2024. Data extraction, synthesis, report, and recommendations are expected to be finished by February 2025. The review timeline is shown in Multimedia Appendix 5.

Discussion

Expected Findings

Communication barriers persist for deaf individuals in health care, urging solutions. In this context, this review aims to summarize the current literature on communication systems using human-computer interaction techniques for sign language users, in a health care context. As the main finding, we aim to reveal the current state of communication systems dedicated to improving health care interactions with deaf people and using a variety of advanced models to enhance accuracy and usability. Additionally, we seek to identify existing gaps in the development of these systems. We anticipate that the predominant focus on technical aspects or innovations may lead to a scarcity of manuscripts addressing communication outcomes, which should ideally be the primary focus, as it determines the effectiveness of communication.

Strengths

Sign language recognition is often considered less advanced compared to other recognition systems like facial or speech recognition. Several characteristics are important to enhance communication with deaf people using systems and devices, such as adequate screens, stable internet connection, qualified and trained professionals, interoperability of the system, safety for the patient and professional, and extensive testing [9]. Research in this field must focus on models that improve the accuracy of recognition systems and, more importantly, communication. To investigate these factors, a multidisciplinary staff including health, linguistic, and technology teams will participate in the search process, conducting and validating its progress. This would strengthen the results, as it broadens the results landscape. Another important strength to highlight is that the systems assessed in this review will not depend on a translator, as is the case for video remote interpretation. We believe that, if proven effective, these systems could enhance the autonomy of deaf individuals in managing their health care. Furthermore, these systems have the potential to surmount barriers related to patient privacy concerns and communication challenges. With the escalating integration of artificial intelligence techniques in health care, there is growing recognition that capturing signs or gestures and converting them into audio or written language, and vice versa, can significantly enhance accessibility to health care services, ranging from primary care facilities to emergency departments. Identifying information regarding the availability, usability, and implementation specifics of such systems stands as a crucial outcome to be unearthed.

In response to this urgent demand, our research group is diligently conducting a comprehensive and high-caliber systematic review. While the ultimate goal must consider context and innovation, it is paramount to prioritize meeting the needs of the ultimate end users: individuals who are deaf.

To identify and delineate these systems, along with associated contextual possibilities, use methods, required equipment, and technological development and testing, we will present a comprehensive findings panel and conduct a narrative comparison. This approach aims to facilitate a comprehensive overview and deeper understanding of the current state of the art. Our results are poised to offer valuable insights into the landscape of systems and the evolution of human-computer–assistive technologies used in aiding deaf patients.

In emergency care units, timely access to information is crucial for defining patient routes, conducting necessary examinations, and providing critical interventions and advice. Previous studies have shown that preventable adverse events are more likely to occur in cases with communication problems, particularly in emergency situations [7]. Despite the pressing need for studies in this area, testing interventions in emergency contexts is more complex, leading us to anticipate fewer analyses in this critical domain.

Limitations and Future Directions

This systematic review, while intended to be comprehensive, may encounter limitations impacting its conclusions. First, the diversity of sign language dialects, and the specificity of their use, might limit the generalizability of the findings across different cultural contexts. Additionally, the rapid evolution of technology in the field of sign language recognition systems may also mean that some of the reviewed technologies quickly become outdated.

With the results of this review, we expect to advocate future directions for the creation of more adaptive and inclusive communication systems, capable of learning from a broader spectrum of sign language dialects and styles. However, it specifically targets individuals who use sign language. This approach may not represent the entire deaf community, as some individuals may prefer lip reading, writing, or other forms of communication due to unfamiliarity with or reluctance to use sign language. Further studies should explore technologies aimed at enhancing communication for individuals with varying degrees of hearing impairment and differing abilities in sign language proficiency. Expanding research in this direction can

contribute significantly to addressing the diverse communication needs within the deaf and hard-of-hearing community.

Our team plans to disseminate the protocol and findings of this research in forums with public authorities, academies, and the population to present solutions for improving effective communication in health services, especially involving the most vulnerable populations. In addition, as social media has a relevant impact on our society, all the results will be posted on social media as well to be available to the population.

Acknowledgments

This study was funded in part by the National Institute of Science and Technology for Health Technology Assessment (*Instituto de Avaliação de Tecnologias em Saúde*)/National Council for Scientific and Technological Development (*Conselho Nacional de Desenvolvimento Científico e Tecnológico*; grant 465518/2014-1), *Financiadora de Estudos e Projetos* (grant 01.21.0097.00), and SignumWeb Comunicação Inclusiva Ltda, as part of the project "*Captar-Libras: Sistema de Comunicação por vídeos para surdos aplicado ao pré-atendimento médico*." MSM, MFMC, and LRV were supported in part by *Conselho Nacional de Desenvolvimento Científico e Tecnológico* (grant 310561/2021-3, grant 316841/2021-8, and grant 134878/2023-0, respectively). The funding sources had no role in the design of this study and will not have any role during its execution, analyses, interpretation of the data, or decision.

Data Availability

All data generated or analyzed during this study are included in this published paper and its supplementary information files.

Authors' Contributions

MSM, LFRO, LRV, ROP, and ZSNR developed a draft of the literature search, which was executed by LFRO and LRV. MSM, ROP, ZSNR, TBCS, and MFMC guided the construction of the protocol, and MSM is a guarantor of the review. MSM, LFRO, LRV, and LMMSR drafted the manuscript; all the other authors performed critical revisions. ELAB is a linguistic professor who is a specialist in sign language. She has revised the whole manuscript to ensure that language complies with disability and deaf literature. All authors read and approved the final manuscript.

Abstract

Background: Injectable platelet-rich fibrin (i-PRF) has the capacity to release great amounts of several growth factors, as well as to stimulate increased fibroblast migration and the expression of collagen, transforming growth factor β, and platelet-derived growth factor. Consequently, i-PRF can be used as a bioactive agent to promote periodontal tissue regeneration.

Objective: We aim to compare and evaluate the effectiveness of i-PRF in periodontal tissue regeneration.

Methods: We will conduct an electronic search in the following databases: PubMed, Cochrane Library, Google Scholar, Semantic Scholar, Scopus, and Web of Science. Papers will be restricted to those in English and to those that are randomized controlled trials comparing PRF or any other biomaterial with i-PRF for periodontal regeneration during dental treatment. The included papers in this review and the reference lists of pertinent reviews will be manually searched. The selection of studies, data extraction, and assessment will be carried out separately by 2 reviewers using the Risk of Bias 2 tool for the included research.

Results: The success of i-PRF will be evaluated by comparing the mean difference in periodontal regeneration of soft and hard tissues in terms of gingival recession, probing pocket depth, clinical attachment level, bone gain, and gingival width. The combined effect size measurements and the associated 95% CIs will be estimated using a random-effects model. The synthesis or work for this systematic review started in October 2023 and will last until December 2025.

Conclusions: i-PRF may play a role in dentistry and could enhance soft and hard tissue regeneration.

KEYWORDS

injectable platelet-rich fibrin; pulp regeneration; periodontal regeneration; periodontium; tissue engineering

Introduction

Rationale

A leucocyte-enriched platelet-rich concentrate called injectable platelet-rich fibrin (i-PRF) has recently been researched and developed to help in wound healing and increase the success of periodontal tissue regeneration [1,2]. The objective of developing an i-PRF formulation is to provide specialists with a platelet concentration in liquid form that is simple to administer and may be mixed with various biomaterials or used alone [3-6]. By adopting slower and shorter centrifugation rates, i-PRF yields significantly more regenerated cells and higher concentrations of growth factors than prior PRF formulations that used faster centrifugation speeds [7]. i-PRF has been shown

to produce more fibroblast migration and have higher levels of growth factor production, as well as superior antibacterial adhesive action against a range of periodontal disease pathogens [8].

i-PRF is a novel platelet-rich concentrate that enhances periodontal tissue regeneration due to its "supraphysiological" growth factors and cell concentrations [1]. The slow release of growth factors is possible due to the dynamic fibrin liquid gel that i-PRF delivers, which embeds platelets rich in leucocytes, collagen type I, osteocalcin, and growth factors even in their liquid phase. i-PRF can improve intrinsic tissue regeneration by generating human mesenchymal stem cells (MSCs) and starting osteogenic differentiation in MSCs [9]. By allowing the inclusion of grafts without the need for additives or anticoagulants, i-PRF creates a well-agglutinated "sticky bone graft" [1].

The applicability of i-PRF as a promising regenerative adjuvant in periodontal tissue regeneration has been validated by clinical research [2]. Liquid PRF permits other alterations, like incorporating different biomaterials, in an injectable form [10]. One of the components that makes up i-PRF is fibronectin, which is an extracellular glycoprotein with a high molecular weight (approximately 440 kDa) [4,6,11]. It has been demonstrated that i-PRF centrifugation at a horizontal angle is far more effective than traditional fixed-angle centrifugation at accumulating more cells and growth factors. The physician can construct customized clotted PRF membranes (biografts) by manipulating i-PRF before clotting, which can then be combined with different regenerating agents [9].

Objective

This systematic review will determine the effect of i-PRF in the management of soft and hard tissue periodontal defects in the context of periodontal tissue regeneration. The review will highlight the use of i-PRF as a bioactive agent capable of stimulating periodontal tissue regeneration.

Methods

Overview

We aim to ascertain whether i-PRF is effective in soft and hard tissue regeneration in periodontics by conducting a systematic review of the literature.

Eligibility Criteria

We will examine eligible studies and describe how i-PRF is used for the treatment of pulp and periodontal tissue regeneration. The publications that qualify will be limited to those published in English. There will be no restrictions on publication date. We will search the identified publications' reference lists for more papers that might meet the eligibility requirements. This review will cover the research designs of clinical randomized controlled trials (RCTs).

Information Sources

We will search the following electronic databases for papers that fit the review's eligibility requirements: PubMed, Cochrane Library, Google Scholar, Semantic Scholar, Scopus, and Web of Science.

Search Strategy

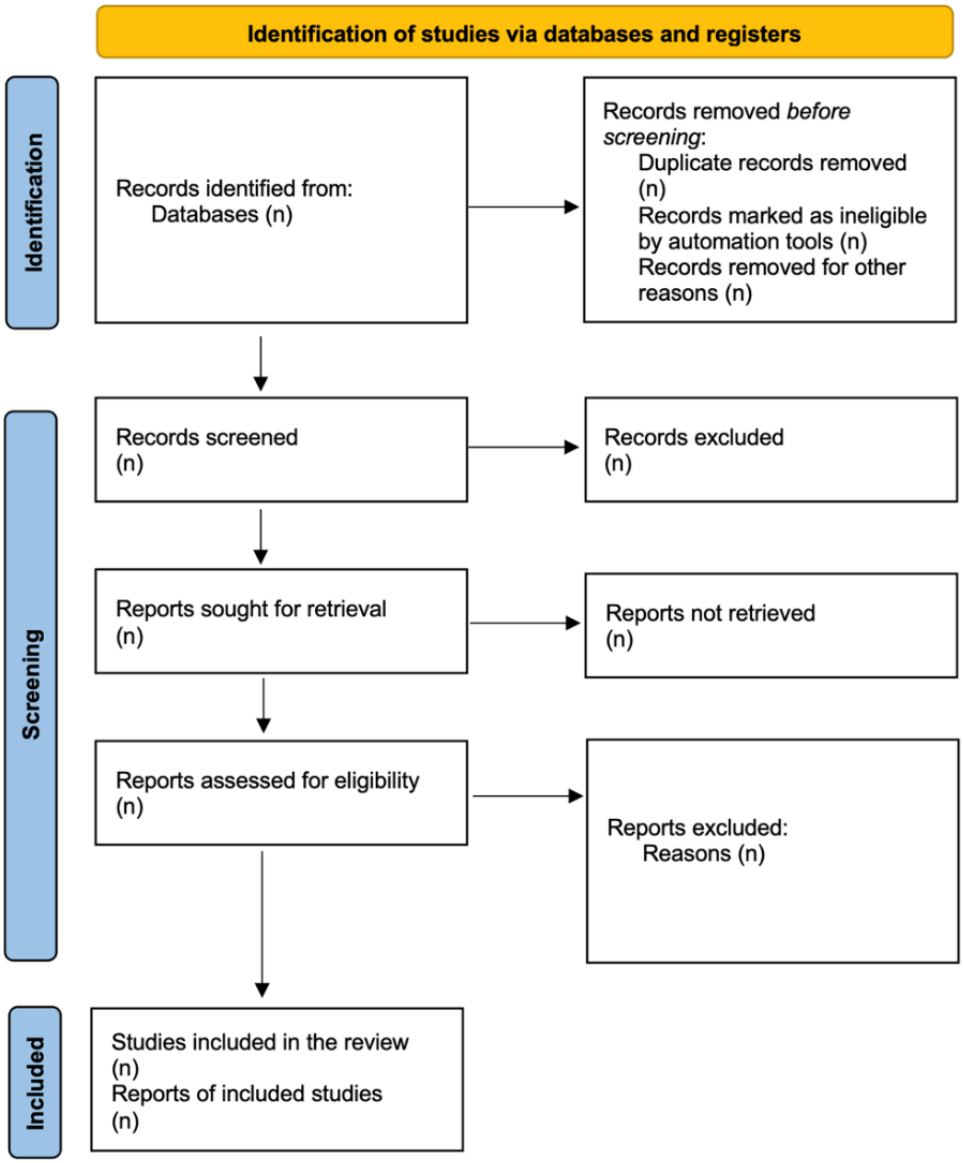
First, a restricted search of MEDLINE was carried out to find applicable papers. A comprehensive search method was developed using words found in the titles, abstracts, and keywords.

Study Selection, Data Management, and Data Collection Process

When choosing which studies to include, the 3 reviewers (US, PB, and MW) will refer to the eligibility criteria. Records management and duplicate removal will be facilitated by the recording of selections. Blind screening of studies will be used, and differences will be settled through discussion. Two researchers will load the retrieved studies and perform title and abstract screening. Two authors will conduct a full-text review, and any disagreements will be settled by discussion or, if necessary, a third reviewer. A summary of the study selection procedure is given in Figure 1.

Reviewers will be guided by a data extraction tool applied to the included articles. Systemically healthy patients and patients receiving periodontal or pulp regenerative therapy will be included in the RCTs. Patients with a history of systemic illness, as well as pregnant women, will be excluded. A narrative summary of the results from the included research will be provided. We will assess methodological, statistical, and clinical heterogeneity. If there is enough homogeneity among the included studies, a quantitative synthesis, or meta-analysis, will be carried out.

Figure 1. Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols (PRISMA-P) flowchart.



Data Items

Two separate, blinded reviewers (US and PB) will each record the extracted data in duplicate. The extracted data, which will include publication details, the research study's setting, the regeneration agent, adjunctive treatment, and the defect type, will be entered into a Microsoft Excel spreadsheet. Clinical determinants will include periodontal clinical parameters, osseous defect fill, and soft tissue parameters.

Outcomes and Prioritization

The primary outcome is to determine the role of i-PRF in soft and hard periodontal tissue regeneration in dentistry. The secondary outcomes will be whether i-PRF improves probing pocket depth reduction, gain in clinical attachment loss, and osseous fill in periodontal osseous defects.

Risk of Bias

The Risk of Bias 2 (RoB 2) tool will be used to evaluate the risk of bias in included studies and to verify the methodological quality of the reviews. The assessments will be completed by 2 different reviewers (US and MW), with the 2 other reviewers (PB and MP) acting as arbiters to settle any disputes. The entire process will be concealed from the reviewers.

Data Synthesis and Assessment of Heterogeneity

Statistical heterogeneity will be assessed with a random-effects model. If there is enough homogeneity among the included studies, a quantitative synthesis, or meta-analysis, will be carried out. The goal is, if at all feasible, to carry out a subgroup analysis based on the effects of various i-PRF preparation protocols on the regeneration of hard and soft tissues by varying centrifugation force, revolutions per minute, and time. Using statistical software, the results will be aggregated and computed according to the statistical guidelines cited in the most recent edition of the *Cochrane Handbook for Systematic Reviews of Interventions*.

Results

This study is to be completed from October 2023 to December 2025. Each stage of the procedure will involve the blinding of

2 reviewers. To resolve disagreements or conflicts between the reviewers, regular team meetings will be convened. This will help to improve the review process's transparency. Every conversation will be documented. The systematic review will be submitted for publication as soon as it is finished. The planned review has been registered with PROSPERO (CRD42023464250) and will be carried out in compliance with the guidelines provided in the Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols (PRISMA-P) checklist.

Discussion

Anticipated Findings

i-PRF in the periodontal regenerative process offers hope for improved patient outcomes and enhanced therapeutic interventions [12,13]. It might help to provide improved healing and periodontal tissue reconstitution in the context of improvement in osseous fill or bone gain, as well as soft tissue fill, by reducing probing pocket depth and increasing clinical attachment loss. i-PRF might potentially act as a bioactive agent capable of inducing tissue regeneration. Wang et al [14] contrasted i-PRF to conventional platelet-rich plasma (PRP) and examined the osteoblast behavior of a unique therapeutic i-PRF that was 100% natural and additive-free. They found a noticeable increase in the messenger RNA levels of osteocalcin, Runx2, alkaline phosphatase, and immunofluorescent staining of osteocalcin when comparing an i-PRF group to a PRP group. The results of that study favored the use of naturally formulated i-PRF in conjunction with anticoagulants over PRP [14].

Varela et al [15] investigated the blood cell composition, morphological characteristics, type I collagen gene expression, and growth factor release of i-PRF. Blood samples from 15 people were used to create i-PRF samples. The study found that i-PRF was a potentially effective treatment option for the healing of soft and mineralized tissues because it promoted the development of a 3D fibrin network comprising platelets, leukocytes, type I collagen, osteocalcin, and growth factors. Indeed, given its flowable mixing capabilities with other biomaterials and simplified procedures, i-PRF may be used in various dental applications [15]. Iozon et al [4] investigated how human gingiva–derived mesenchymal stem cells (MSCs) proliferated and underwent osteo-differentiation in response to i-PRF; they concluded that gingiva-derived MSC proliferation was promoted by 5% i-PRF, but that an overabundance of i-PRF may hamper osteogenic induction [4].

Strengths and Limitations

To the best of our knowledge, this is the first systematic review to focus on whether i-PRF aids in tissue regeneration. The integration of qualitative as well as quantitative data synthesis in this study will help in promoting oral and periodontal health.

Limitations of this systematic review may include variations in the study design, sample size, and methodological quality of the included studies, as well as potential bias in reporting outcomes related to the use of i-PRF for periodontal tissue regeneration. Additionally, heterogeneity in treatment protocols, variations in PRF preparation methods, and differences in follow-up duration may influence the generalizability of findings. Publication bias and the exclusion of non–English language studies could further affect the comprehensiveness of the review.

Conclusion and Directions for Dissemination

This study aims to assess whether i-PRF has the potential for regeneration of periodontal structures. If we find that the intervention has an effect, the results will aid in tissue engineering, maintaining and promoting osseous defect gain by osseous fill, and hastening healing. Results from this study will be published in national and international academic journals. This protocol follows the PRISMA-P guidelines (Multimedia Appendix 1).

Acknowledgments

The authors acknowledge the help from the Datta Meghe Institute of Higher Education and Research, as well as the databases and resources that are needed for the data synthesis. All authors declared that they had insufficient funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this article.

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed during this study.

Authors' Contributions

All authors contributed to the drafting and writing of the manuscript. US and PB conceptualized and registered the work. MW and MP worked on drafting the initial manuscript and on study design. Final study design and manuscript writing were done by US. All authors checked and finalized the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Gastric cancer (GC) is the fifth most prevalent neoplasm worldwide and the fourth with the highest mortality, and its geographical distribution is not homogeneous with high-risk, intermediate-risk (IR), and low-risk areas. Advanced stages at diagnosis are related to high mortality, but early detection greatly increases the chances of survival. Upper endoscopy with biopsy is the gold standard for GC diagnosis. Several studies have investigated the relevance of endoscopic screening and how to implemente it in IR countries. However, most Western societies recommend screening only in selected populations with high-risk factors for GC. No systematic reviews on GC endoscopic screening in IR countries exist.

Objective: We aimed to determine the effectiveness of endoscopic GC screening in IR countries.

Methods: We will include randomized and nonrandomized controlled trials, cohort studies, case-control studies, cross-sectional studies, and economic studies focusing on endoscopic screening of GC in the asymptomatic population of IR countries. The search will be conducted in MEDLINE, SCOPUS, Embase, and Web of Science. Other gray literature sources will be additionally searched. Studies published in English, Portuguese, or Spanish until September 2024 will be included. Two independent reviewers will screen the titles and abstracts of all search results. The selected studies will then be fully analyzed, and the data will be collected and coded in a database. To minimize the risk of bias, the included studies will undergo a quality analysis according to Cochrane risk of bias tools, RoB 2 of randomized trials and ROBINS-I for nonrandomized trials; Newcastle-Ottawa Quality Assessment Scale for case-control and cohort studies; and National Heart, Lung and Blood Institute study quality assessment tools for cross-sectional studies. The data collected will be cataloged in 2 categories: efficacy or effectiveness data and economic data, and separate meta-analyses will be performed for each category if appropriate.

Results: This study is expected to provide results on the efficacy, effectiveness, and cost-effectiveness of endoscopic screening in an IR population. To date, 969 studies were screened for title and abstract, 75 were selected for full-text screening, and 44 were retained for data analysis. Additionally, 2 studies were selected from our manual search. Currently, the study is in the early stages of data extraction and risk of bias assessment and is expected to be published in the first quarter of 2025.

Conclusions: To our knowledge, this review will be the first to provide evidence on the effectiveness of endoscopic GC screening in IR countries. In doing so, we believe we will help guide future research, inform health care decisions and assist policy makers in this area, and support future decisions to implement GC screening programs in this type of population.

KEYWORDS

gastric cancers; endoscopic screening; intermediate-risk countries; neoplasia; early detection; diagnosis; cancer screening; survival; meta-analysis; gastrointestinal cancers

Introduction

Gastric adenocarcinoma, also known as gastric cancer (GC), is a malignant neoplasm resulting from anarchic growth of gastric mucosal gland cells [1]. It is a heterogeneous disease with multiple clinical, histological, and molecular variables that influence its presentation [1,2].

According to data from The Global Cancer Observatory 2022, GC is the fifth most common and the fifth most lethal neoplasm worldwide [3]. Its geographical distribution is not homogeneous: there are high-risk areas with incidence 20 and more (age-standardized rate measured per 100,000 people-year; eg, Japan, South Korea, or Mongolia); intermediate-risk (IR) areas with age-standardized rate 10 and more and less than 20 (eg, Portugal or China); and low-risk areas with age-standardized rate 10 or less (United States, United Kingdom, Switzerland, or Germany) [2,3].

Diagnosis at an advanced stage and the aggressiveness of the disease result in a 5-year survival rate of between 20% and 40% [4]. In contrast, early-stage GC has an excellent prognosis, with a 5-year survival rate of greater than 90%, and can often be treated with minimally invasive and organ-sparing techniques such as endoscopic resection [5]. Therefore, early detection of cancer greatly increases the chances of successful treatment. The 2 components of cancer screening are early diagnosis and screening. The former focuses on detecting symptomatic patients as early as possible, while the latter involves testing healthy individuals to identify those with the disease before symptoms occur [6]. The symptoms of stomach cancer are nonspecific and usually develop late, meaning that detection based on symptoms would not detect the disease in its early stages. On the other hand, screening programs should be implemented when: their effectiveness has been demonstrated; the resources needed to implement them are sufficient to cover the target population; there are facilities to confirm the diagnosis, treatment, and follow-up of those with positive results; and the prevalence of the disease is high enough to justify the effort and cost of the screening program [6]. Therefore, the decision to implement the screening program requires that these conditions are met. Several methods have been proposed to screen for GC, namely serological markers, biomarkers, molecular or genetic tests, or more invasive techniques such as upper gastrointestinal endoscopy [7]. The latter, which allows direct visualization of the gastric mucosa and collection of biopsies for histological examination, is considered the gold standard technique for definitive diagnosis of GC [8].

In some high-risk countries, such as Japan and South Korea, GC screening programs have been in place for several years and have been shown to reduce mortality and increase early detection and 5-year survival rates [9-11]. The same has been demonstrated in screening programs developed in China [12,13].

In Western IR countries, several studies have been developed to determine the relevance of screening and how it might be developed. Of particular importance was the study developed by Areia et al [14], which showed that endoscopic screening for GC in IR countries can be cost-effective when combined with endoscopic screening for colorectal cancer. This has been included in the recommendations of the United European Gastroenterology and the European Society of Gastrointestinal Endoscopy [14-16]. Despite this evidence and the recommendations, most Western Societies continue to recommend screening only in selected populations with high-risk factors for GC [16,17]. Furthermore, and to the best of our knowledge, there are no systematic reviews on GC endoscopic screening in IR countries. With this systematic literature review, we aim to analyze the scientific evidence published until September 2024 on the cost-effectiveness of endoscopic screening for GC in IR countries.

This study aims to determine the effectiveness and economic viability of endoscopic GC screening in IR countries**,** which will answer the research question, “What is the effectiveness of endoscopic screening for GC in IR countries?”

These objectives are defined according to the Population, Intervention, Comparison, Outcome and Study Design (PICOS) framework (Textbox 1).

Textbox 1. Population, Intervention, Comparison, Outcome and Study Design (PICOS) framework for the systematic review and meta-analysis.

PICOS question: What is the effectiveness of endoscopic screening for gastric cancer (GC) in intermediate-risk countries?

- Population:

  Asymptomatic population of intermediated-risk countries (countries with incidence age-standardized rate 10-20 per 100.000 person/years: Tajikistan, Iran, Azerbaijan, Kyrgyzstan, Bhutan, Belarus, Peru, Mali, Chile, Costa Rica, Democratic People Republic of Korea, China, Kazakhstan, Russian Federation, Viet Nam, Estonia, Colombia, Portugal, Ecuador, Albania, Guadeloupe [France], Guatemala, Latvia, Armenia, Turkmenistan, Myanmar, Samoa, Turkey, Lithuania, Lao People's Democratic Republic, Sao Tome and Principe, Afghanistan, Martinique [France], Brunei Darussalam, Zimbabwe, and Uzbekistan), between 40 and 80 years of age, without diagnostic of GC or precancerous lesions.
- Intervention: Endoscopic screening for GC.
- Comparison: No screening for GC.
- Outcome: The effectiveness of endoscopic screening of GC is defined as the detection rate of Helicobacter pylori; detection rate of precancer lesions; detection rate of GC; detection rate of early GC; stage at diagnosis; mortality rate of GC of screened versus nonscreened patients; 5-year survival rate of GC screened; and costs of screening program.
- Study designs: Randomized controlled trials, nonrandomized controlled trials, cohort studies, case-control studies, cross-sectional studies, and cost-effectiveness studies.

Methods

This study will follow the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines [18] and PICOS criteria for comprehensive assessment.

Eligibility Criteria

The inclusion criteria include studies published as free full papers in English, Portuguese, or Spanish until September 2024, from countries with an IR for GC (countries with incidence age-standardized rate 10-20 per 100,000 person/years: Tajikistan, Iran, Azerbaijan, Kyrgyzstan, Bhutan, Belarus, Peru, Mali, Chile, Costa Rica, Democratic People Republic of Korea, China, Kazakhstan, Russian Federation, Viet Nam, Estonia, Colombia, Portugal, Ecuador, Albania, Guadeloupe [France], Guatemala, Latvia, Armenia, Turkmenistan, Myanmar, Samoa, Turkey, Lithuania, Lao People's Democratic Republic, Sao Tome and Principe, Afghanistan, Martinique [France], Brunei Darussalam, Zimbabwe, Uzbekistan); eligible study designs are randomized controlled trials, nonrandomized controlled trials, cohort studies, case-control studies, cross-sectional studies, and cost-effectiveness studies; and no filters or restrictions related to year of publication or publication status, will be applied.

The exclusion criteria include systematic reviews and other types of reviews, meta-analyses, case series, case reports, and other publication types such as editorials, commentaries, notes, letters, and opinions.

Information Sources

The information sources for this systematic review are electronic databases (MEDLINE, SCOPUS, Embase, and Web of Science). To capture additional studies (gray literature), manual searches will include published abstracts from the most relevant international gastroenterology and endoscopy conferences, clinical trial registries for ongoing studies, reference lists of included studies or other published reviews or meta-analyses. Authors of unpublished studies or published studies in which data are missing will be contacted to confirm eligibility.

Search Strategy

The search strategy follows the Peer Review of Electronic Search Strategies (PRESS) guidelines [19]. The search will be conducted in MEDLINE, SCOPUS, Embase, and Web of Science and the search strategy will be tailored to each database using database-specific search terms (Multimedia Appendix 1).

Selection Process

The references, including the abstract of studies retrieved after searching each database, will be imported to Rayyan (Rayyan Systems, Inc), an open-source software that allows several reviewers to blindly access the inclusion or exclusion of studies in literature reviews registering the entire process. This software will analyze and merge the potential duplicates, under operator validation. The initial selection process will be carried out by 2 independent reviewers (MBM and NP) based on the title and abstract. Studies will be classified as "included," "excluded," or "maybe." The selection process will be blinded and supervised by 2 other independent authors (FT and ABP). Conflicts and "maybe" assessments will be resolved between the 2 reviewers with the support of 2 authors (FT and ABP). After the final list of included studies is obtained, the full texts are retrieved. The full text of each study will be analyzed by 3 independent reviewers (MBM, NP, and ABP), and a decision taken on inclusion or exclusion. The list of items included is exported to a Microsoft Excel database where the data to be analyzed are entered.

The agreement rate will be calculated using Cohen κ, Egger regression, and Begg regression and will be reported at all stages of the selection process (title screening, abstract screening, and full-text screening).

Data Collection Process

Data from included studies will be collected by 2 reviewers (MBM and NP) and inserted into a Microsoft Excel database with data coding. The data collected will be cataloged in 2 categories: efficacy or effectiveness data and economic data, and separate meta-analyses will be performed for each of these categories.

For the statistical analyses and meta-analysis of the data collected, the authors will use SPSS (version 29.0.2.0; IBM Corp) and Jamovi (version 2.5; The jamovi Project). Bibliographic references will be managed in Zotero (Corporation for Digital Scholarship) software. Artificial intelligence tools may be used to extract and analyze data.

Data Items

The data collection form will include the items or variables defined in outcomes (Table 1) and other variables (Table 2).

Table 1. Variables related to outcomes of screening and cost-efficiency.

Variable	Definition or domain
Endoscopic screening	Number of individuals screened by endoscopy.
Frequency of screening	Frequency of endoscopic screening in years.
Age range covered by screening	Age at start and end of screening.
Screening adherence rate	Percentage of invited individuals that did the screening.
Number of biopsies	Total number of biopsies performed in the study.
Helicobacter pylori diagnosis rate	Percentage of individual screened that were diagnosed with *Helicobacter pylori*.
Detection rate of premalignant lesions	Number of premalignant lesions (atrophic gastritis, intestinal metaplasia and low-grade intraepithelial neoplasia, formerly low-grade dysplasia) / total number of upper endoscopies performed.
Gastric cancer detection rate	Number of gastric cancers diagnosed by screening endoscopy / total number of screening upper endoscopies performed.
Early gastric cancer detection rate	Number of early gastric cancers (high-grade intraepithelial neoplasia and mucosal adenocarcinoma) detected by endoscopic screening / total number of gastric cancers detected by endoscopic screening.
Lethality rate	Number of people who died from gastric cancer diagnosed by endoscopic screening / population at risk during the study period.
5-year survival rate in patients diagnosed with gastric cancer at screening	Percentage of patients diagnosed with stomach cancer at screening who live at least 5 years after diagnosis.
Incremental cost-effectiveness ratio	Value (in euro) of implementing the upper endoscopy screening program (or adding it to other existing screening programs, eg, endoscopic screening for colorectal cancer).

Table 2. Other variables

Variable	Domain
Study Bibliographic Reference	• Reference
Country or countries of origin of the study	• Country
Study design	• Randomized controlled trial • Nonrandomized controlled trial • Cohort • Case-control • Cross-sectional • Cost-effectiveness
Population or sample	• Base population potentially to be screened by upper endoscopy
Participants	• Age • Sex distribution

Risk of Bias in Individual Studies

To minimize the risk of bias, the included studies will undergo a quality analysis according to Cochrane risk of bias tools, RoB 2 of randomized trials and ROBINS-I, for nonrandomized trials; Newcastle-Ottawa Quality Assessment Scale [20] for case-control and cohort studies; and National Heart, Lung and Blood Institute study quality assessment tools [21] for cross-sectional studies. The Consensus on Health Economic Criteria (CHEC) list [22] will be used for the assessment of the methodological quality of cost-effectiveness studies.

Studies with low quality or high risk of bias will be reported and not be used for meta-analysis.

Data Synthesis

If it is possible to collect quantitative data from the selected studies, we will perform 2 separate meta-analysis: one to report the effect size of 5 outcomes in studies reporting efficacy or

effectiveness of endoscopic screening for GC (detection rate of premalignant lesions, detection rate of GC, detection rate of early GC, and 5-year survival rate and mortality of GC diagnosed in screening programs); other to report the effect size of cost-effectiveness of endoscopic screening for GC in IR countries.

If appropriate (at least 2 studies per outcome) [23], pooled rates and odds ratio along with 95% CIs will be calculated for GC detection, early GC detection, adherence to the screening program, and GC mortality using random-effects model, using SPSS, Jamovi, and Meta-Essentials for Microsoft Excel (Erasmus Research Institute of Management). The I^2 homogeneity will also be performed to check the need for subgroup analysis (moderation analysis).

If it is not possible to carry out a meta-analysis due to insufficient data, an executive summary is prepared that summarizes the data from the studies included in the systematic review.

Meta-Bias(es)

After evaluating the biases of individual studies and ensuring that all studies that may be of interest for their conclusions are integrated into the review, a summary of the risks of bias in the meta-analysis or meta-synthesis will be presented.

Confidence in Cumulative Evidence

The strength of the body of evidence will be assessed with Grading of Recommendations, Assessment, Development and Evaluation (GRADE) [24].

Results

Our initial search of the 4 electronic databases, using descriptors adapted for each database, identified 1615 studies of potential interest (Figure 1). After excluding duplicates, 969 studies were screened for title and abstract. Of these, 75 were selected for full-text screening. We retained 44 studies for data analysis and the remaining 31 studies were excluded for the following reasons: wrong population (n=2), same population as another study (n=2), wrong screening method (n=6), wrong outcome (n=18), wrong study design (n=2), and wrong publication type (n=1). In addition, our manual search identified 23 publications of potential interest, of which 2 were selected for the data extraction phase. Currently, the study is in the early stages of data extraction and risk of bias assessment and is expected to be published in the first quarter of 2025.

Discussion

This protocol outlines the methods for a systematic literature review and meta-analysis of published primary scientific studies on the effectiveness of endoscopic GC screening in IR countries.

This study will provide results on the following outcomes: frequency of screening, age range covered by screening, screening adherence rate, number of biopsies, *Helicobacter pylori* diagnosis rate, detection rate of premalignant lesions, GC detection rate, early GC detection rate, lethality rate, 5-year survival rate in patients diagnosed with GC at screening, and incremental cost-effectiveness ratio.

To the best of our knowledge, this is the first systematic review of the effectiveness of endoscopic screening for GC in IR countries and it is expected that the presentation of these results will shed light on the relevance of endoscopic GC screening in these populations. The benefit of performing screening upper endoscopy for asymptomatic individuals for GC remains

controversial [25]. Due to the high burden of GC, countries in East Asia such as Japan and Korea have implemented nationwide population-based GC screening strategies to reduce incidence and mortality [9,26]. Other studies have shown that endoscopic screening for GC is cost-effective in the IR to high-risk population [14,27]. However, to date, we have not found a systematic review that synthesizes the results of all studies conducted in IR countries, and for this reason, our systematic review is of particular interest to inform health policy makers in IR countries about the effectiveness of endoscopic screening for GC in this type of population.

An extensive search of databases and gray literature will be conducted to identify all relevant studies. However, this review may have some important limitations. First, it is important to bear in mind that the majority of IR countries, especially Western countries, do not yet have population-based screening for this pathology, which may make it difficult to obtain primary studies on this topic from these countries. Second, although China is an IR country with endoscopic screening for GC, some studies reporting the results of these screening programs are written in Chinese and cannot be included in our review. Nevertheless, we will conduct an intensive search of the databases to ensure that we obtain studies written in English, Portuguese, or Spanish that report the results of these screening programs. Third, on the other hand, the Chinese territory is so large that risk varies greatly between different areas of the country, which may introduce a significant bias if some included studies are based only on results of high-risk areas, as this type of population may have different characteristics from those observed in other areas of China or other IR countries. These limitations will be reported in the final paper of the systematic review so that our results can be interpreted rigorously and truthfully. The final paper of the systematic review and meta-analysis will be published in the first quarter of 2025.

With this systematic review and meta-analysis, we hope to contribute to the design of GC screening strategies in IR countries, with the primary goal of reducing mortality from this disease. In the future, it may be necessary to update this systematic review as a new consortium. Towards Gastric Cancer Screening Implementation in the European Union [28] has recently been established in Europe to study and implement GC screening in this area.

Acknowledgments

The protocol and systematic review publication are supported by the main author and her company TrueConnection Lda. The company's mission is to train health care professionals, provide medical services, and conduct clinical research. We are grateful to Master Ricardo Serra and Dr Ricardo Bagina for their collaboration at various stages of the revision of this manuscript. No artificial intelligence support was used in the creation of this manuscript, except for grammar and style corrections.

Data Availability

All data generated or analyzed during this study are included in this published article (and its supplementary information files).

Authors' Contributions

MBM was responsible for designing and writing the protocol. NP provided assistance with protocol design and writing. AB was responsible for reviewing the writing of the manuscript. FT provided assistance with protocol design. RC was responsible for designing the search expression in the various databases. IF and MA were involved in protocol design and manuscript review. RD was responsible for the revision of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Medical therapy and interventional approaches have improved outcomes in patients with acute myocardial infarction (MI). However, these strategies are inadequate for replacing cells lost during tissue ischemia, thereby leaving behind noncontractile scar tissue. The anti-inflammatory and immune modulating properties of mesenchymal stem cells (MSCs) may prove useful in inducing functional cardiac regeneration following acute MI.

Objective: This is a protocol for systematic review and meta-analysis that will aggregate and synthesize high-level clinical data on the effects of MSC therapy for acute MI. The findings of this study may serve as evidence for clinicians and researchers in guiding the use of MSC therapy as an adjunct to reperfusion and optimal medical therapy in patients with acute MI.

Methods: The proposed systematic review is registered with PROSPERO (International Prospective Register of Systematic Reviews). A systematic search of bibliographical databases, including Embase, PubMed, and Cochrane was conducted from inception to June 2023 to identify English-language human studies with adult patients receiving MSC therapy and optimal medical therapy for acute MI in comparison with respective controls. Article screening was performed using PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. Data on functional cardiac outcomes and major adverse cardiac events were extracted and analyzed as primary outcomes.

Results: Literature search and article screening commenced in June 2023. Data extraction and analysis will be completed by October 2024. The findings will be synthesized and reported by the end of November 2024.

Conclusions: This systematic review and meta-analysis will summarize the best available updated evidence from published randomized controlled trials on the effects of MSC therapy for the treatment of acute MI. The findings of this systematic review and meta-analysis may shed light on the efficacy of MSC therapy in improving cardiac functional and structural parameters and reducing adverse cardiac events following acute MI.

Introduction

Background

Acute myocardial infarction (MI) remains a significant cause of morbidity and mortality globally, with nearly 3 million people experiencing an acute MI annually worldwide [1]. During acute MI, blood flow to the myocardium is reduced, resulting in tissue hypoxia, ischemia, and eventual cell death, which in turn, may result in adverse consequences, including left ventricular (LV) dysfunction, heart failure, arrhythmias, cardiogenic shock, and death. Myocardial reperfusion with percutaneous coronary intervention is a standard treatment for acute MI. Time to reperfusion is directly correlated with prognosis; therefore, prompt revascularization should be pursued [2]. After reperfusion, patients receive optimal medical therapy, which has significantly improved outcomes since its advent [3]. However, reperfusion and medications are unable to replenish necrotic cardiac myocytes, and many patients still experience significant morbidity and mortality following acute MI [4]. Following significant tissue infarction, large areas of the myocardium are scarred and rendered nonfunctional, leading to the adoption of regenerative therapies as a possible solution.

Accordingly, regenerative therapies that aim to restore functional cardiac tissue continue to be a topic of clinical research interest. Recent evidence suggests that stem cells may be useful as a method of repairing damaged myocardial tissue [5,6]. In animal models, studies have shown the potential of Mesenchymal stem cells (MSCs) to differentiate into cardiac myocytes, to participate in regenerative signaling through immunomodulation, and paracrine actions [7-9]. So far, human clinical trials have yielded mixed results. Several randomized control trials (RCTs) in patients with acute MI have demonstrated improvement in LV ejection fraction (LVEF), remodeling, myocardial viability, and reduction in hospitalization rates following treatment with MSCs [10-13]. Conversely, other RCTs have shown no difference in LVEF between MSC-treated patients and the standard-of-care [14,15]. Concerns for safety has arisen with the novelty of regenerative therapy, and the evaluation of major adverse cardiac events (MACE) has been the hallmark for safety [10-15]. Particularly, mortality rates (periprocedurally and long-term), malignant arrhythmias, recurrent MI, cerebral vascular accident, and revascularization are among the most common evaluated adverse events [10-15]. Although with no significant difference was noted in previous RCTs, our meta-analysis aims to evaluate the safety of MSC therapy through the evaluation of MACE. There may be added benefit to decreasing MACE outcomes through the use of MSC therapy, which will also be evaluated.

While many clinical trials have examined the efficacy of MSCs in acute MI treatment, the data collection methods, timing of MSC administration, route of MSC administration, and evaluated end points have been heterogeneous. Several articles representing long-term follow-up of original studies have recently been published, which collectively provide additional insights. Aggregation and analysis of the updated data are needed to gain a better understanding of the effects of MSC administration in patients with acute MI.

Objectives

Several previous meta-analyses have been published on the outcomes of stem cell therapy for acute MI, however, these were based on studies with a heterogeneous mixture of stem cells, not exclusively MSCs. In addition, the existing meta-analyses included only original RCTs without the follow-up studies, thereby obscuring insights related to longer-term outcomes. The current systematic review aims to provide the most comprehensive and updated evidence regarding MSC transplantation solely for the treatment of acute MI, along with a meta-analysis focused specifically on RCTs, including follow-up RCTs to evaluate long-term outcomes of MSC therapy. The meta-analysis will compare the effects of MSC injection and standard therapy on LVEF, LV end-systolic volume (LVESV), LV end-diastolic volume (LVEDV), and MACE as primary end points. Secondary end points will include, but not limited to, myocardial viability, myocardial perfusion defect, and stroke volume.

Methods

Review Question

This study aimed to answer the following question: “What are the short-term and long-term effects of MSC therapy in patients with acute MI?”

Eligibility Criteria

Inclusion and exclusion criteria were initially determined using the PECOS (Population, Exposure, Comparator, Outcome, Study Design) framework. Detailed PECOS criteria for the meta-analysis are denoted in Multimedia Appendix 1.

The initial systematic review included RCTs, single-arm studies, and case series. The meta-analysis included RCTs and secondary reports based on the original studies. English-only original articles published before June 15, 2023, were included; case reports, abstract-only articles, systematic reviews, meta-analyses, animal studies, commentaries, position papers, opinions, and editorials were excluded from the meta-analysis. Studies enrolling adult patients aged 18 years and older with acute MI who received MSC therapy within 1 month of MI were included. Studies using MSCs, mesenchymal stromal cells, and mesenchymal progenitor cells as therapeutic substrates were included. Studies that included patients with recurrent MI in their study were excluded. Studies with other types of stem cells or combinatorial cellular mixtures were excluded. Studies that did not report the outcomes of interest were excluded.

Information Sources and Search Strategy

Bibliographic databases, including PubMed, Cochrane, and Embase were queried from inception to June 2023. The search strategy was guided by 2 librarian experts in medical sciences and was reviewed and devised in accordance with the Peer-Reviewed Electronic Search Strategy guidelines [16].

The original search strategy was formulated for PubMed and used PubMed syntax. Additional searches were modified and optimized for subsequent databases. Given the specificity of the question at hand, the search strategy used key search terms without the use of MeSH (Medical Subject Headings).

The full search strategy, including the development of the final search terms, can be found in Table S1 in the Multimedia Appendix 2. Keywords in the final search strategy included the following: mesenchymal stem cell, progenitor cell, mesenchymal stromal cell, ST-elevation MI, ST-elevation myocardial infarction, and acute MI.

Selection Process

All retrieved articles were reviewed by 2 independent investigators to check for inclusion and exclusion criteria in a stepwise process to include title screening, abstract screening, and full-text screening. Reasons for the exclusion of articles will be addressed in greater detail in the final publication.

Study Records

Data Collection Process and Management

Data extraction from the eligible full-text articles was performed by 2 investigators who independently extracted the data elements of interest to ensure accuracy and completeness. Extracted data and records are maintained in separate Microsoft Excel sheets by the 2 investigators, as well as a combined Microsoft Excel sheet after consensus.

Incongruencies in data extraction were resolved through discussion with a third senior investigator to achieve consensus.

Data Items/Elements

Data extraction elements for both systematic review and meta-analysis are outlined in Table S2, which can be found in Multimedia Appendix 3.

Information that required further clarification and/or required additional data were attempted to be resolved by contacting the corresponding authors of the respective articles; queries that yielded no response were not included in the data extraction or analysis.

Outcomes

The primary outcomes of the meta-analysis included (1) effects of transplantation on LVEF, (2) LVESV, (3) LVEDV, and (4) MACE.

The secondary outcomes that included (1) myocardial viability, (2) myocardial perfusion defect index, (3) coronary flow reserve, (4) adenosine-induced minimal vascular resistance index, and (5) stroke volume.

Quality Analysis

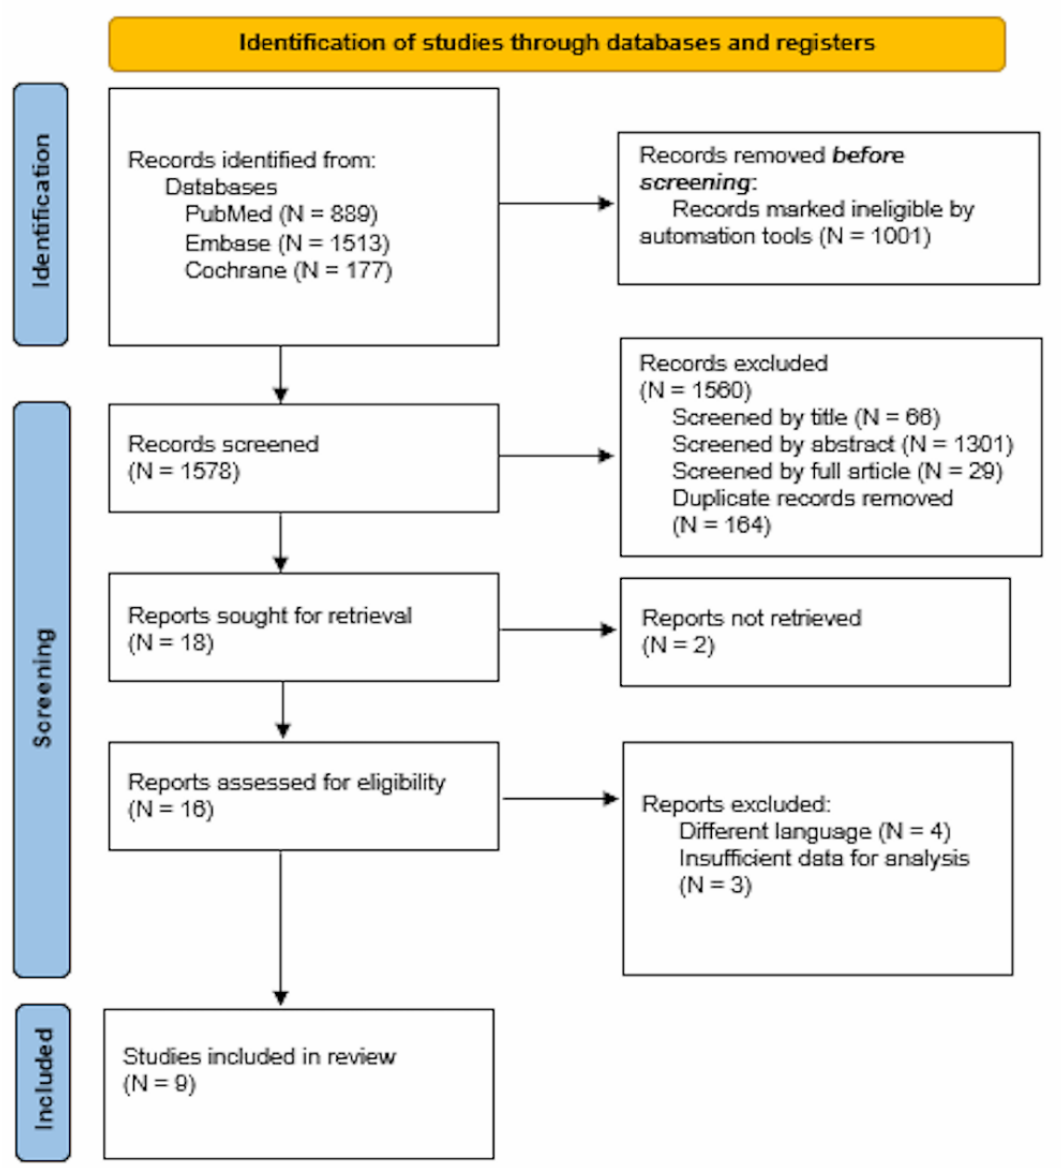
Overview

Quality assessments for strength of the body of evidence of all included studies will be performed using the National Heart, Lung, and Blood Institute (NHLBI) quality assessment tool. A total of 2 investigators will independently screen full texts for quality. Scoring will be performed independently. All essential components of original research studies will be evaluated using the NHLBI scoring checklist (Multimedia Appendix 4). Study quality will model the scoring protocol performed by Elks et al [17].

Risk of Bias Assessment

Within the quality assessment, articles selected for analysis underwent assessment for risk of bias. Bias was assessed by examining randomization and adequacy of randomization, blinding, and attrition. Specific questions are outlined in Figure 1 below. Meta-biases will be assessed as appropriate.

Figure 1. The PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram modified for the current study selection process.



Data Synthesis

First results of all finally included studies will be described succinctly in the form of a summary table. A random-effects model will be used to calculate pooled estimates as this is a more robust estimate regardless of heterogeneity [18]. Cochran Q and I^2 statistics will be used as indicators of heterogeneity. The pooled estimates of the primary end points (eg, LVEF, LVESV, and LVEDV) will be calculated as the weighted mean differences with 95% CIs using the Comprehensive Meta-analysis Package (CMA version 3.0). For dichotomous outcomes, Peto odds ratios will be used as this allows the inclusion of the continuity correction of 0.5 to all 0 cells outcomes and accounts for the expected rarity of events. Sensitivity analysis will be conducted to identify studies that may severely affect the pooled estimates. The Exploratory subgroup analyses by different moderator variables (eg, MSC source, MSC route of administration, location of MI, and duration of follow-up, etc) will also be conducted to examine sources of heterogeneity. A funnel plot and Egger linear regression test will be used to assess publication bias [19]. The significant level will be set as 2-sided and $P<.05$. Forest plots will be used to present the data.

Data Analysis and Presentation

Data will be presented in a tabular form and as a conclusive summary of our analysis. A data extraction form will be developed and agreed upon by all investigators before article analysis occurs. Selected articles will be present in the rows of the table, and variables will be present in the columns of the table. Quantitative analysis of all extracted variables will be performed.

Ethical Considerations

IRB or institutional review was not needed in this systematic review and meta-analysis since this design relies only on the findings from the previously published data and did not involve direct interaction with human participants. However, to adhere to a strict methodology, the protocol of this systematic review

and meta-analysis was registered with PROSPERO (International Prospective Register of Systematic Reviews) registration number CRD42024522398. PROSPERO is an international database of prospectively registered systematic reviews, which provides a unique permanent registration number to the protocol that prevents duplication, thereby reducing reporting bias. In addition, PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols) checklist was completed during the process to ensure comprehensive and quality results (Figure 2).

Figure 2. PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) checklist completed for the current study.

Section and topic	Item No	Checklist item	Completed? (Y or N)
ADMINISTRATIVE INFORMATION			
Title:			
Identification	1a	Identify the report as a protocol of a systematic review	Y
Update	1b	If the protocol is for an update of a previous systematic review, identify as such	N/A
Registration	2	If registered, provide the name of the registry (such as PROSPERO) and registration number	Y
Authors:			
Contact	3a	Provide name, institutional affiliation, e-mail address of all protocol authors; provide physical mailing address of corresponding author	Y
Contributions	3b	Describe contributions of protocol authors and identify the guarantor of the review	Y
Amendments	4	If the protocol represents an amendment of a previously completed or published protocol, identify as such and list changes; otherwise, state plan for documenting important protocol amendments	N/A
Support:			
Sources	5a	Indicate sources of financial or other support for the review	N/A
Sponsor	5b	Provide name for the review funder and/or sponsor	N/A
Role of sponsor or funder	5c	Describe roles of funder(s), sponsor(s), and/or institution(s), if any, in developing the protocol	N/A
INTRODUCTION			
Rationale	6	Describe the rationale for the review in the context of what is already known	Y
Objectives	7	Provide an explicit statement of the question(s) the review will address with reference to participants, interventions, comparators, and outcomes (PICO)	Y
METHODS			
Eligibility criteria	8	Specify the study characteristics (such as PICO, study design, setting, time frame) and report characteristics (such as years considered, language, publication status) to be used as criteria for eligibility for the review	Y
Information sources	9	Describe all intended information sources (such as electronic databases, contact with study authors, trial registers or other grey literature sources) with planned dates of coverage	Y
Search strategy	10	Present draft of search strategy to be used for at least one electronic database, including planned limits, such that it could be repeated	Y
Study records:			
Data management	11a	Describe the mechanism(s) that will be used to manage records and data throughout the review	Y
Selection process	11b	State the process that will be used for selecting studies (such as two independent reviewers) through each phase of the review (that is, screening, eligibility and inclusion in meta-analysis)	Y
Data collection process	11c	Describe planned method of extracting data from reports (such as piloting forms, done independently, in duplicate), any processes for obtaining and confirming data from investigators	Y
Data items	12	List and define all variables for which data will be sought (such as PICO items, funding sources), any pre-planned data assumptions and simplifications	Y
Outcomes and prioritization	13	List and define all outcomes for which data will be sought, including prioritization of main and additional outcomes, with rationale	Y
Risk of bias in individual studies	14	Describe anticipated methods for assessing risk of bias of individual studies, including whether this will be done at the outcome or study level, or both; state how this information will be used in data synthesis	Y
Data synthesis	15a	Describe criteria under which study data will be quantitatively synthesised	Y
	15b	If data are appropriate for quantitative synthesis, describe planned summary measures, methods of handling data and methods of combining data from studies, including any planned exploration of consistency (such as I^2, Kendall's τ)	Y
	15c	Describe any proposed additional analyses (such as sensitivity or subgroup analyses, meta-regression)	Y
	15d	If quantitative synthesis is not appropriate, describe the type of summary planned	Y
Meta-bias(es)	16	Specify any planned assessment of meta-bias(es) (such as publication bias across studies, selective reporting within studies)	Y
Confidence in cumulative evidence	17	Describe how the strength of the body of evidence will be assessed (such as GRADE)	Y

Results

The development of the search strategy for this systematic review and meta-analysis began in June 2023. The search strategy underwent peer-reviewed electronic search strategy review with 2 academic librarians in June 2023. The final search strategy was agreed upon by all investigators in July 2023. Databases were queried and articles were screened between September 2023 and October 2023. Data extraction took place between November 2023 and February 2024. Data analysis is currently taking place as of March 2024 with the final analysis anticipated to be completed in October 2024. It is anticipated that findings will be synthesized and reported by the end of November 2024. Findings will be organized, summarized, and submitted for publication in a peer-reviewed journal. The goal of this work is to provide a comprehensive analysis and enhance the understanding of the safety and effectiveness of MSC therapy in acute MI. A timeline is provided in Table 1.

Preliminary searches performed in PubMed, Embase, and Cochrane databases yielded 1578 articles after appropriate filters were applied. A total of 889 articles were returned from PubMed, of which 521 were human studies. A total of 1,513 articles were returned from Embase, of which 880 were human studies. A total of 177 articles were returned from the Cochrane

database, which were all reviews of human studies (Figure 1). A detailed step-by-step outline of our search strategy, including search terms, limit criteria, and results is provided in Table S1 of the Multimedia Appendix 2 (adapted from Page et al [20]).

Discussion

Overview

This systematic review and meta-analysis will be a comprehensive review and analysis of the existing relevant literature pertaining to the efficacy of MSC therapy in patients enduring from acute MI. We anticipate that the current findings will be congruent with the previous observations regarding the outcomes and safety of MSC therapy. We also aim to glean insights with regard to changes in LVEF, LVESV, and LVEDV as a result of MSC therapy. In addition, we will examine the pooled event ratio estimates of MACE, including death, recurrent MI, need for revascularization, and stroke, compared with control, to draw conclusions on the safety of MSC therapy.

In an attempt to ensure the comprehensiveness of the assessment of relevant data, a narrative synthesis of studies that lie at relatively lower levels of hierarchical evidence as compared with the gold standard (RCTs) was also performed. These additional qualitative findings allow us to gain a complete understanding of several factors, including timing and route of administration, source of cells, and other variables that may impact the outcomes of MSC therapy.

Significance

We anticipate that our results, by virtue of including data from recently published RCTs, will significantly advance the existing evidence regarding the safety and efficacy of MSC therapy. Previous meta-analyses examining the effects of MSC therapy in ischemic heart diseases often combined with chronic and acute ischemic heart diseases [21,22], whereas we plan to focus on acute MI therapy alone. In addition, previous meta-analyses reviewed a variety of regenerative cells [6] for the treatment of acute MI, whereas our focus specifically on mesenchymal stem and progenitor cells will allow us to comment on the efficacy of a specific cell type in the management of acute MI. Finally, while our meta-analysis examines primary RCTs, we have also included secondary/follow-up RCTs of original studies in our analysis, which will provide additional information regarding the longer-term and additional end points for subgroup analysis.

Limitations

This meta-analysis will have several limitations. First, there will be inherent heterogeneity among included studies due to the variability of research methodologies undertaken by each unique study. We anticipate heterogeneity in several variables, including the timing and route of MSC administration, the tissue source of MSCs, the methods used to measure primary and secondary end points (for example, echocardiogram vs angiography vs cardiac magnetic resonance imaging), and the follow-up period after MSC transplantation. Second, there is a risk that relevant literature will be missed because studies with insignificant findings or low sample size are seldom published, thus leading to publication bias. Finally, there will be inherent reviewer bias when selecting articles during the screening process, which will be mitigated by using an individualized screening process with 2 independent reviewers, along with a

third senior reviewer to resolve disagreements on article selection.

Dissemination Plan

The findings of this systematic review and meta-analysis will be submitted as a manuscript to a peer-reviewed journal by the end of 2024. Derivations of this work will be submitted as abstracts to academic conferences.

Conclusions

This systematic review and meta-analysis will provide a comprehensive review of the safety and efficacy of MSC therapy in patients with acute MI. It will include an analysis of data on clinically relevant primary end points pertaining to functional cardiac parameters, such as LVEF, LVESV, and LVEDV. It will also examine specific safety outcomes by performing a subgroup analysis on MACE. This review will also provide qualitative synthesis of evidence related to MSC therapy, which will generate additional insights toward its potential future clinical applications in a broader spectrum of cardiovascular pathologies.

Acknowledgments

The authors would like to acknowledge the Ana Coral and Aidybert Weeks at the University of Nevada, Las Vegas Library for their assistance with developing the search strategy and for conducting the PRESS (Peer-Reviewed Electronic Search Strategy) review. The authors did not use AI for any portion of manuscript generation.

Data Availability

The datasets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Abstract

Background: The goal of just-in-time adaptive interventions (JITAIs) is to use mobile, digital tools to provide individuals with personalized interventions at the optimal time and in the optimal context. Accordingly, JITAIs are promising for advancing accessible, equitable, and evidence-based treatment for behavioral health. To guide future inquiry in this space, a review of the literature is needed to describe the state of research on JITAIs for behavioral health.

Objective: This study aims to systematically review the literature to describe the landscape of existing JITAIs for behavioral health at any stage of intervention development. In addition, conditional upon a sufficiently homogeneous literature, we will conduct meta-analyses to investigate the effectiveness of JITAIs for promoting distal outcomes (here, aspects of behavioral health) and proximal outcomes (eg, emotion regulation).

Methods: This systematic review is being conducted in accordance with the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols). We developed our search strategy and executed the literature search in collaboration with biomedical librarians; 5 databases (PubMed, Embase, Cochrane Library, Web of Science: Core Collection, and APA PsycINFO) were searched, and results were managed using EndNote 20 (Clarivate). We are screening (title, abstract, and full text) all records in duplicate in Covidence according to eligibility criteria. Data items will be extracted, and risk of bias will be assessed in duplicate from the included articles in Covidence. We will summarize JITAI characteristics in tables and text. We will conduct meta-analyses for the distal and proximal outcomes conditional upon sufficient homogeneity in subgroups. Moderation (conditional upon sufficient heterogeneity of outcomes) and mediation (ie, whether changes in proximal outcomes mediate the relation between JITAIs and distal outcomes) will be conducted as appropriate. We will investigate publication bias and use the Grading of Recommendations Assessment, Development and Evaluation to characterize the quality of evidence of our estimates.

Results: The search strategy was developed between July 2023 and November 2023. The literature search was executed between November 2023 and December 2023. Title and abstract screening began in December 2023, and full-text screening began in May 2024. Data extraction and analyses have not begun.

Conclusions: Here, we propose a systematic review to assess the state of the literature on JITAIs for behavioral health. The insights derived from this study will describe the literature on JITAIs in promoting behavioral health, reinforce JITAI definitions, clarify JITAI elements, and inform the next steps in JITAI research.

Introduction

Background

Mental illness has devastating consequences for individuals, their families, and society. Those in need of treatment are woefully underserved, with a dearth of professionals relative to patients [1]. Race and ethnicity, geography, and socioeconomic status influence who can and who cannot access care [2]. For the subset of individuals who receive treatment, lack of evidence-based care [3] and issues with dropout [4] and nonresponse [5,6] limit recovery. New solutions are critical for reaching and equitably and effectively treating people suffering from mental illness. Technological advances may provide a pathway to more equitable evidence-based care at scale. While structural barriers (eg, cost and transportation) impede access to in-person health care, mobile devices are plentiful and may allow for greater population coverage [7,8]. Furthermore, while treatment may be perceived as stigmatizing, further reducing service use [9,10], research provides preliminary support for willingness to initiate and maintain engagement with digital interventions (even in severe mental illness) [11]. Beyond accessibility and acceptability, treatment delivered through technology allows for the provision of therapeutic support when and where it is most needed—outside of the clinic and within patients' daily lives [12,13]. After a prescribed treatment is delivered, technological solutions can be seamlessly integrated and accessed again to boost skills and maintain treatment gains [12,13].

Just-In-Time Adaptive Interventions

Despite the potential benefits of digital treatment delivery, evidence for the effectiveness of intervening using standalone mobile applications is limited [14]. Still, just-in-time adaptive interventions (JITAIs) are promising [15-18]. The goal of JITAIs is to target mechanisms for therapeutic change at the time and in the context that is optimal for the individual [19,20]. JITAIs have the potential to capitalize on states of vulnerability and opportunity [20]. That is, JITAIs can intervene when individuals are susceptible to negative or positive change. For example, capitalizing on a state of opportunity might be prompting an adult with social anxiety disorder to approach others while in a public place. JITAIs may be able to intervene when individuals are maximally receptive or most likely (willing and able) to accept a specific intervention [20]. To do so, JITAIs leverage real-time data collected passively or actively from smartphones, including or excluding paired wearable devices in combination with personalized algorithms [19-21].

JITAIs are defined by six elements: (1) distal outcome (long-term goal of the JITAI), (2) proximal outcome (short-term goal of the JITAI, which may be a mediator of the distal outcome), (3) tailoring variable (baseline or time-varying information on the individual that informs which interventions to deploy at which decision points), (4) decision point (time frame when an intervention option is, or is not, deployed), (5) decision rule (operationalization of which intervention option should be used, when, and for whom), and (6) intervention options (set of potential components that may be deployed toward behavior change at a given decision point). JITAIs are being developed for a variety of problems, including substance use [18,22], affective disorders [23], and stress management [24]. The potential impact of an intervention (here, a JITAI) is dependent on the potency of its mechanistic target. Some, but not all, JITAIs that aim to augment behavioral health outcomes describe doing so through purported proximal outcomes [23]. Importantly, to increase the likelihood that JITAIs will be effective, their development must be informed by well-established findings from psychiatric research. For example, deficits in emotion regulation, or efforts to modify the intensity or duration of an emotion, are a transdiagnostic pathway in the development and maintenance of psychopathology [25,26]. Importantly, emotion regulation is malleable in that it can be augmented with intervention [27]. As such, emotion regulation is a key exemplar candidate transdiagnostic treatment target for behavioral health. Emotion regulation skills are aspects of empirically supported treatments for psychopathology [28,29] and have been shown to mediate and moderate the effects of interventions on outcomes [27]. Increasingly, emotion regulation skills have been incorporated into digital health interventions [30-33].

There are 2 major gaps in understanding the potential use of JITAIs in behavioral health care [34]. Henceforth, we use the term "behavioral health" to refer to psychological disorders and symptoms (including substance use disorders), as well as physical symptoms related to life stressors and crises. First, little research has summarized the effectiveness of JITAIs for behavioral health conditions. Intervention development is a multistage process that involves iteratively tailoring a program through repeated evaluation and from accumulating evidence [35-37]. For example, the National Institutes of Health's Obesity-Related Behavioral Intervention Trials (ORBIT) model provides a framework for intervention development that starts with establishing a significant clinical question and progresses through design (ie, defining, refining), preliminary testing (eg, proof-of-concept, feasibility pilots), efficacy trials, and finally effectiveness research. At any stage, in the case of a suboptimal outcome, the model would dictate that the investigator returns to an earlier phase for intervention refinement. All considered, the development of an intervention can take over 10 years before the program settles into its finalized form. What's more, by design, a finalized form of an intervention may never be achieved. Interventions must be optimized to strike a strategic balance between effectiveness, affordability, scalability, and efficiency. That strategic balance may vary across time and context [36]. Frameworks like multiphase optimization strategy (MOST) can be used to guide these optimization efforts. Experimental designs should be matched to the research question and stage of development (eg, microrandomized trial [38] or sequential multiple assignment randomized trial [SMART] [39]

during optimization, randomized controlled trial during evaluation [35]). JITAIs as intervention frameworks were conceptualized 10 years ago [19]. Considering the intervention development process, the majority of published JITAIs likely either do not exist in their finalized form or are constantly evolving through optimization. Still, systematic reviews and meta-analyses exist that have examined the impact of JITAIs on the promotion of physical health, providing some early support for JITAIs as a digital health tool [15,16]. The extant systematic reviews relevant to behavioral health have evaluated JITAIs either within a larger health promotion framework or for a specific psychiatric disorder. In their meta-analysis of JITAIs for physical and mental health (eg, healthy diet, weight loss, diabetic management, addiction, bipolar disorder, and anxiety), Wang and Miller [17] found a large effect of JITAIs relative to a waitlist control (Hedges' g=1.653). In their systematic review of JITAIs for substance use, Perski et al [18] found mixed results. Second, few systematic reviews [23] have described JITAI proximal outcomes despite the important role that proximal outcomes play in elucidating intervention mechanisms of action [40]. Here, we propose a systematic review (and meta-analysis, as appropriate) of JITAIs targeting proximal outcomes (eg, emotion regulation) to improve behavioral health outcomes.

Objective

The objective of this review is to describe the state of the literature on JITAIs for behavioral health outcomes. Given that JITAIs originated in the past 10 years, our primary methodological approach for addressing our objective will be qualitative. That is, through a systematic review of the literature, we will extract, report, and describe the 6 elements (ie, distal outcome, proximal outcome, tailoring variable, decision point, decision rule, and intervention options) for each JITAI, regardless of the stage of intervention development (eg, preliminary testing, feasibility, clinical trial). In doing so, we will reinforce the existing JITAI framework [19,20] and provide a roadmap for the development of future JITAIs to improve behavioral health. Our secondary methodological approach for addressing our objective will be quantitative. That is, if it is determined that our included studies are sufficiently homogeneous, we will conduct meta-analyses to examine the effectiveness of JITAIs in promoting (1) aspects of behavioral health as distal outcomes and (2) proximal outcomes. We will examine moderators (eg, sociodemographic variables, symptom severity) conditional upon sufficient heterogeneity in outcomes. Given the importance of developing JITAIs incorporating empirically supported intervention targets, we will focus our discussion on emotion regulation as one proximal outcome of interest.

Methods

Overview

We used the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols) checklist to write this systematic review protocol [41]. Multimedia Appendix 1 shows the PRISMA-P checklist.

Eligibility Criteria

Textbox 1 shows the inclusion and exclusion criteria. After examining a subset of records, it became clear that we were unable to determine with certainty if interventions were JITAIs (ie, just-in-time and adaptive) and if behavioral health outcomes were reported by examining article titles and abstracts. As such, to prevent excluding relevant articles during title and abstract screening, we retained a subset of our inclusion and exclusion criteria for this stage. That is, we focused on identifying articles using digital methods and proposing specific interventions and articles of the correct format (eg, excluding reviews and case reports). The full eligibility criteria are being used for full-text screening.

Textbox 1. Eligibility criteria for systematic review.

Inclusion criteria:

- Population: All individuals, regardless of age, sex and gender, race and ethnicity, socioeconomic status, geographic location, and other aspects of identity.
- Intervention design: Just-in-time adaptive interventions (JITAIs), that is:
  - Just-in-time: deployed when the individual needs it.
  - Adaptive: incorporates time-varying or contextual or both types of information for individualization, leveraged through passively or actively collected data from smartphones or wearable devices.
  - Intervention: activities intended to modify behavior, thoughts, or emotions.
- Outcome: Behavioral health.
- Article format: All languages; empirical research studies; publication in a peer-reviewed journal.

Exclusion criteria:

- Population: None.
- Intervention design: No JITAI.
- Outcome: Physical health and wellness outcomes that do not directly focus on behavioral health.
- Article format: Reviews, meta-analyses, case reports, dissertations, theses, and conference abstracts.

Information Sources

A total of 5 databases were searched by a biomedical librarian (NT): PubMed/MEDLINE (US National Library of Medicine), Embase (Elsevier), Cochrane Library (John Wiley & Sons), Web of Science: Core Collection (Clarivate), APA PsycINFO (Dialog and Clarivate). To identify relevant articles missed by the search strategy, reviewers (LMH, MB-T, CEH, CNR, ET) will scan the bibliographies of included studies and relevant review articles. Protocols, feasibility studies, and acceptability studies were flagged during screening, and reviewers will revisit these records to determine if clinical outcomes were published. The final list of included studies, and additional, relevant studies, will be evaluated by the entire review team, along with relevant unaffiliated collaborators. Articles identified through these supplemental methods will proceed through the full screening process.

Search Strategy

A biomedical librarian (NT) with expertise in systematic review searches developed the search strategy in collaboration with the other members of the study team. A second librarian (Alicia A. Livinski, MPH, MLS) not otherwise affiliated with the project peer-reviewed the search strategy. The review team provided feedback on the search strategy. The search strategy incorporated keywords and controlled vocabulary terms (ie, EMTREE [Embase], MeSH [PubMed], Thesaurus of Psychological Index Terms [PsycNet]) for each concept of interest. The search strategy syntax was adapted for each database searched. Multimedia Appendix 2 shows the PubMed search strategy.

Study Records

Data Management

We used EndNote 20 (Clarivate) to collect and manage the results of the literature search and identify unique records. We used Covidence (Veritas Health Innovations), an internet-based tool for systematic review data management, for selection and data collection. Before selection and data collection, reviewers (LMH, MB-T, CEH, CNR, and ET) were trained in using Covidence.

Selection Process

Before each stage of screening (title and abstract, full text), a 20-article trial was conducted with all reviewers to pilot and refine the eligibility criteria to increase reliability. All reviewers are conducting screening using the stated eligibility criteria. For title and abstract screening, articles with missing abstracts automatically advanced to full-text screening. Following the title and abstract screening, the PDFs of the articles that were included were obtained and uploaded into Covidence for full-text screening. All articles are being double-coded for each stage of screening; that is, each record is independently screened by 2 reviewers. Screening discrepancies are being resolved during a group consensus meeting. Interrater reliability is being recorded in Covidence and will be documented in the final report.

Data Collection Process

Before data collection, a 15-article trial will be conducted with all reviewers (LMH, MB-T, CEH, CNR, and ET) to increase reliability. All reviewers (LMH, MB-T, CEH, CNR, and ET) will independently extract data items from records included after full-text screening. Each data item from each study record will be extracted in duplicate. Coding discrepancies will be discussed and resolved through dyadic consensus meetings, including the two relevant reviewers for each article. Discrepancies that cannot be resolved during dyadic consensus meetings will be resolved at a group consensus meeting. Data extraction forms will be published.

Data Items

Table 1 shows the data items that will be collected.

Table 1. Data items for systematic review

Category	Criteria
Article	Authors, title, journal, year.
Sample demographics	Where the study took place, sample size, age, gender, sex, race, and ethnicity.
JITAI[a] elements	Tailoring variable, decision points, decision rules (including static or adaptive status), intervention options, proximal outcomes (eg, emotion regulation), distal outcomes (eg, depression).
Study	Intervention development framework (eg, National Institutes of Health's ORBIT[b] model, MOST[c]), experimental design (eg, MRT[d], SMART[e]), where the JITAI was developed (eg, university, industry), was the JITAI delivered alongside other support (eg, in-person intervention), was the JITAI delivered alongside sensors or ambulatory devices, types of sensors used, JITAI delivery service (eg, iPhone, personal device), number of intervention days, payment structure (eg, flat fee), user engagement, user compliance (eg, response to prompts or frequency of JITAI use, or both), usability.

[a]JITAI: just-in-time adaptive intervention.

[b]ORBIT: obesity-related behavioral intervention trials.

[c]MOST: multiphase optimization strategy.

[d]MRT: microrandomized trial.

[e]SMART: sequential multiple assignment randomized trial.

Outcomes and Prioritizations

Our primary outcome of interest is the distal outcome of the JITAI. Here, we focus on JITAIs that target behavioral health outcomes. Examples of potential distal outcomes include affective, substance use, disruptive behavior, eating, trauma-related, personality, psychotic, and neurodevelopmental disorders; psychological symptoms (ie, not meeting criteria for a disorder); pain; and well-being. Multimedia Appendix 2 shows the full list of search terms related to behavioral health. Our secondary outcome of interest is the proximal outcome of the JITAI. All proximal outcomes will be collected. We will calculate effect sizes for both the distal and proximal outcomes.

Risk of Bias in Individual Studies

Tools appropriate to the study design of individual records will be used to determine risk of bias. For example, Version 2 of the Cochrane risk-of-bias (RoB 2) tool for randomized controlled trials will be used for randomized controlled trials, including SMARTs [42]; Risk Of Bias In Non-Randomized Studies - of Interventions (ROBINS-I) will be used for nonrandomized studies comparing the effects of two or more interventions [43]; and Risk Of Bias In Non-randomized Studies - of Exposure (ROBINS-E) will be used for observational studies [44]. Risk of bias will be evaluated by 2 reviewers for each study. Disputes will be resolved during dyadic consensus meetings, and discrepancies that cannot be resolved during dyadic consensus meetings will be resolved during group consensus meetings.

RoB 2 includes 5 domains: bias due to the randomization process, bias due to deviations from intended interventions, bias due to missing outcome data, bias in the measurement of the outcome, and bias in the selection of the reported result [42]. Each domain will be classified as low risk of bias, some concerns, or high risk of bias. ROBINS-I includes 7 domains: bias due to confounding, bias in the selection of participants into the study, bias in classification of interventions, bias due to deviations from intended interventions, bias due to missing data, bias in the measurement of the outcome, and bias in the selection of the reported result [43]. Each domain will be classified as low, moderate, serious, or critical risk of bias or no information. ROBINS-E includes 7 domains: risk of bias due to confounding, risk of bias arising from the measurement of exposure, risk of bias in the selection of participants into the study, risk of bias due to post-exposure interventions, risk of bias due to missing data, risk of bias arising from the measurement of outcome, and risk of bias in the selection of the reported result [44]. Each domain will be classified as low risk of bias, some concerns, high risk of bias, or very high risk of bias.

Data Synthesis

Elements (eg, tailoring variables and decision points) of each JITAI will be presented in tables and summarized in the text. Data synthesis will be explored based on outcomes, and a summary of findings table will be presented, as appropriate.

We will categorize studies by design type (eg, randomized controlled trial, observational). If studies in each subgroup are sufficiently homogeneous, meta-analyses will be conducted for the distal and proximal outcomes. Features of the studies collected will inform the selection of the measure of effect size (eg, Cohen's *d* and Hedges' *g*). Subgroup analyses will be considered based on characteristics, including age, gender, type of psychopathology, and type of JITAI. In addition, sensitivity analysis will be carried out, excluding studies of low methodological quality, if necessary.

I^2 statistic will be used to quantify heterogeneity across effect sizes, and *Q* statistic will be used to test heterogeneity reduction through the inclusion of moderators. To address potential heterogeneity, meta-regression will be used to assess clinical characteristics (eg, the severity of symptoms), individual JITAI features (eg, type of emotional regulation strategies used in the intervention), study quality, and demographic characteristics (eg, age, gender, race, and ethnicity) that might influence the effect sizes.

If appropriate, mediation analyses will be considered to investigate whether changes in proximal outcomes mediate the relation between JITAIs and distal outcomes.

Meta-Biases

Publication bias, resulting from selective publication or reporting, will be investigated through visual inspection of funnel plots. Statistical tests for assessing symmetry (eg, Egger's test) will be explored if 10 or more studies have evaluated the same outcome. Trim and fill analyses will be conducted as necessary.

Confidence in Cumulative Evidence

The quality of evidence of estimates will be rated using the Grading of Recommendations Assessment, Development, and Evaluation (GRADE) framework [45]. GRADE characterizes the quality of evidence according to publication bias, study limitations, inconsistency, imprecision, and indirectness [17]. Evidence of effectiveness outcomes will be rated from high to low quality by 2 reviewers. Disputes will be resolved during dyadic consensus meetings, and discrepancies that cannot be resolved during dyadic consensus meetings will be resolved during group consensus meetings. Results from GRADE ratings will be included in the summary of findings table.

Results

The search strategy was developed between July 2023 and November 2023, and the literature search was executed between November 2023 and December 2023. We retrieved 1243 records from our literature search. We excluded 91 duplicate records, leaving 1152 records for the selection process. Of note is that we performed a preliminary literature search for systematic reviews related to this topic and found no review identical to the one proposed. Title and abstract screening began in December 2023, and full-text screening began in May 2024. Data extraction and analyses have not begun.

Discussion

Principal Findings

In our systemic review, our objective is to describe the state of the literature on JITAIs for behavioral health outcomes. We

expect that there will be sufficient data available to take a qualitative approach, including describing the aforementioned 6 elements for each JITAI. Conditional upon sufficient homogeneity of the included studies, we will also take a quantitative approach to examine the effectiveness of JITAIs in promoting (1) aspects of behavioral health as distal outcomes and (2) proximal outcomes.

Strengths and Limitations

Our systematic review has numerous strengths, including a comprehensive search strategy, double coding in each stage of screening and data extraction by trained reviewers, assessment of risk of bias of the included studies by reputed tools, evaluation of publication bias, and ratings of quality of evidence of estimates derived from the review.

There are also potential limitations of our work. Primarily, some ambiguity exists in the use of the term "JITAI;" the definition of JITAI has evolved since it was coined in 2015 [19]; the term has been used inconsistently (eg, an intervention with all the characteristics of a JITAI being characterized as a "momentary intervention" or related term) and imprecisely (eg, an intervention labeled as a JITAI despite the lack of an adaptive element); and there is overlap in the definitions of JITAIs and similar intervention frameworks (eg, ecological momentary interventions). As such, we have developed a robust search strategy, including not only the term JITAI but also related terms (eg, ecological momentary intervention, real-time intervention; more details in Multimedia Appendix 2). Furthermore, we developed and implemented detailed eligibility criteria for screening. We also clearly describe the 6 elements that constitute a JITAI in this protocol and will describe each element for each included JITAI in the final report. Accordingly, this systematic review may provide the field with further clarity on the definition and elements of JITAIs. Another limitation is that due to the iterative design process that characterizes JITAIs (and interventions, in general), JITAIs included in this report may not reflect their finalized form. Future scholarship will be needed to capture further JITAI innovations and evaluations. Finally, although we did not limit our search to English language articles, most of our articles are written in English, so the samples and populations represented may be similarly homogeneous. Additional work may be needed to increase the representation of studies published in languages other than English in JITAI effectiveness research.

Comparison With Previous Work

Previous research has typically evaluated JITAIs as digital health tools for the promotion of physical health [15,16]. While a select few reviews have examined JITAIs for specific psychiatric disorders [13], research has yet to robustly summarize the impact of JITAIs on behavioral health conditions.

Conclusions

This systematic review will summarize the evidence on the effectiveness of JITAIs in improving distal (ie, behavioral health) and proximal (eg, emotion regulation) outcomes. Results will provide clarity on JITAI definitions and elements, describe the effectiveness of JITAIs for behavioral health, elucidate targeted proximal outcomes, and inform the development of future JITAIs.

Acknowledgments

This research is funded by the Intramural Research Program (IRP) of the NIMH (ZIA MH002969; MH002981) and the National Institutes of Health's (NIH) Library's and Office Research Service's support of the NIH IRP.

Data Availability

The datasets generated during or analyzed during this study will be available in the OSF repository [46].

Authors' Contributions

LMH, MB-T, CEH, CNR, ET, NT, MK, OM, MAB, and SLG contributed to conceptualization, methodology, writing–original draft, and writing–review, and editing. LMH, MB-T, CEH, CNR, ET, and NT performed the investigation. LMH and MB-T handled project administration. NT, MAB, and SLG handled resources and funding acquisition. MAB and SLG performed supervision.

Abstract

Background: Losing a loved one to suicide is an event that can have strong and potentially traumatic impacts on the lives of the bereaved survivors, especially regarding their grief, which can be complicated. These bereaved individuals are also less likely to receive social support following their bereavement. However, besides these adverse impacts, growing evidence supports the concept of posttraumatic growth following suicide bereavement. Posttraumatic growth is the personal improvement that occurs as a consequence of experiencing a traumatic or extremely challenging event or crisis. Only 1 systematic review and meta-analysis on posttraumatic growth following suicide bereavement has been conducted; this protocol is for the planned systematic review and meta-analysis update of the original systematic review and meta-analysis, as the original review collected its data in 2018.

Objective: This review aims to investigate demographic characteristics, correlational relationships, and facilitative factors of posttraumatic growth in individuals bereaved by suicide. In addition, as this is an update of a previous systematic review and meta-analysis, we aim to compare our findings with the original review and to identify any similarities or differences.

Methods: This protocol outlines the planned procedures of the updated systematic review and meta-analysis. MEDLINE, PsycINFO, Embase, CINAHL, Scopus, and Web of Science (Core Collection) were examined, and the search results were imported to Covidence, where title and abstract screenings and full-text screenings occurred. The inclusion and exclusion criteria for this updated review match those in the original review: (1) the study population must contain participants bereaved by suicide, (2) the study data must be quantitative, and (3) the study must report data on posttraumatic or stress-related growth. The original review conducted its search before 2019; thus, this updated review searched databases for the timeframe of January 2019 to January 2024. The updated meta-analysis will synthesize data from both the original and updated reviews to examine trends over time. The Newcastle-Ottawa Scale (NOS) will be used to assess publication quality. Random-effects meta-analyses will be conducted using RStudio (R Foundation for Statistical Computing).

Results: The review was funded in October 2023 and is currently in progress. Results are expected to be finalized in October 2024. There are 21 articles that have been included in the review and are being analyzed at this time. We aim to submit the full article for publication in December 2024.

Conclusions: The results of this updated systematic review and meta-analysis will be used to examine key relationships and findings regarding posttraumatic growth in individuals bereaved by suicide. The discussion will also investigate the findings of this updated review in comparison to the findings of the original review. Any differences would be highlighted. Limitations of the current review will be discussed, such as the quality of the articles included.

Introduction

When someone dies by suicide, those who lose this individual in their lives often face significant stress. These feelings can be inundating and are often accompanied by a sense of complicated grief and, at times, depression [1]. It is a tragic event that can generate negative emotions as well as many questions that may be left unanswered in the minds of these surviving individuals. In addition, this population of people bereaved by suicide is at an increased risk of suicidal behavior themselves [2]. Based on data that over 700,000 people die by suicide each year globally [3], and that for each suicide, there are from 6 family members to 135 community members considered to be bereaved or exposed, respectively [4,5], up to 94.5 million can be affected by suicide annually. Thus, many people affected by suicide loss each year are subsequently at increased risk of dying by suicide themselves.

There are commonalities between bereavement of suicide and other forms of death; however, some features of suicide bereavement are more pronounced, such as feelings of guilt, blame on self or others, or a longing for answers [6,7]. While all bereaved people may experience feelings of grief, loss, and depression, people bereaved by suicide specifically can begin to develop symptoms of posttraumatic stress disorder (PTSD) [8,9]. However, some individuals show signs of posttraumatic growth (PTG) more so than symptoms of PTSD. PTG is the personal improvement that occurs as a consequence of experiencing a traumatic or extremely challenging event or crisis. Literature has begun to show that, on average, PTG occurs more often than the development of pathological disorders following exposure to a traumatic event [10,11]. This is, of course, not to say that PTG is always the result of trauma, but rather, psychological suffering allows the opportunity for a person to grow and for new meaning to flourish in the face of trauma. An inverted U-shaped curve best describes the relationship between the developments of PTG—both too much and too little suffering are detrimental to the development of PTG [12,13]. This concept of PTG following a traumatic event [14] has since been applied to learning more about the bereavement experiences of individuals bereaved by suicide. Some authors have also used the phrase “personal growth” [15] or “stress-related growth” [16] in place of PTG. This study will use the terminology of PTG rather than personal growth or stress-related growth.

Determining a metric for PTG can be difficult as it is seen as both an ongoing process and a final result. However, the Posttraumatic Growth Inventory (PTGI) has been developed and shown to capture and highlight well many of the defining characteristics of PTG [10]. These characteristics are broken down into 5 domains: “greater appreciation of life and changed sense of priorities; warmer, more intimate relationships with others; a greater sense of personal strength; recognition of new possibilities or paths for one’s life; and spiritual development” [14]. It does not, however, fully account for all idiosyncratic differences that occur over time; in this regard, a more longitudinal approach for the measurement of such a complex construct (ie, PTG) could provide valuable insight [17].

For those who lose someone to suicide, there can be variables that affect their desire or willingness to seek both formal and informal help and work towards the development of PTG. Each of these variables can influence how well someone bereaved by suicide copes with and grows following their loss. For example, some individuals who have experienced suicide bereavement have reported that their primary support came from nonprofessional sources and that they were disappointed by their family and friends’ responses to their bereavement [18]. Suicide and the survivors’ grieving process can also be seen from a variety of perspectives depending on the culture from which someone comes, such as being seen as stigmatized, taboo, and isolating [19,20]. Along with these responses, some individuals have reported generally negative attitudes toward professional support systems, such as tactlessness and being unaligned in the grieving process [21]. Unfortunately, these detrimental experiences can be an additional stressor on top of what can already be a tragic and intense time of grieving. These factors could contribute to why up to 25% of people bereaved by suicide receive neither informal nor formal support [22]. Each of these variables (ie, poor support, stigmatization, tactless professional help, etc) can hinder PTG development.

This systematic review and meta-analysis is an update of a previous systematic review and meta-analysis conducted by Levi-Belz et al [23]. Our searches have found that the latter is the only one to ever be conducted on this topic. As their original review gathered data from literature before 2019, this review will include data found from searches between January 2019 and January 2024. This updated meta-analysis will synthesize data from both the original and updated reviews to search for any new or consistent trends. As some authors and databases call for a systematic review to be updated every 2 years [24], and with the paucity of understanding that exists on this subject, examining new literature, in conjunction with the previous review, could allow for a more in-depth understanding of which factors facilitate PTG in people bereaved by suicide. The aforementioned evidence suggests that PTG can and does occur following suicide bereavement; therefore, investigating further

which factors might facilitate, as well as detract from, PTG development could greatly benefit people bereaved by suicide.

We have three primary aims with this review: (1) to investigate whether PTG can occur in the aftermath of a suicide loss, (2) to examine the sociodemographic and psychological correlates of PTG among people bereaved by suicide, and (3) to observe which factors facilitate PTG in the aftermath of suicide bereavement.

Methods

Overview

This systematic review will locate and summarize applicable data from the peer-reviewed literature [25]. The findings will be reported using PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) [26] formatting and follow the PRISMA-P (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Protocols) checklist [27]. A meta-analysis will be conducted using the data extracted from this update as well as the data from the original review.

Inclusion Criteria

Population

Study populations must include individuals bereaved by suicide. No limitations on age will be implemented.

Study Design

In accordance with the original review, only quantitative studies that report data on PTG will be included. While qualitative studies could offer a more comprehensive perspective on the topic, this update excluded them in order to follow the criteria of the original review. Gray literature and dissertations will be excluded such that peer-reviewed studies will be the only data involved. This was also done to follow the parameters set by the previous review.

Concept

Studies must report data on PTG in individuals bereaved by suicide. Studies that report data on PTG following various forms of bereavement but which do not separate the effects of suicide bereavement from other forms of bereavement will be excluded.

Context and Date of Publication

This systematic review and meta-analysis is an update of a previous systematic review and meta-analysis that gathered data before January 01, 2019. This update reviews literature published on or after January 01, 2019, and uses the same inclusion criteria as the first study. This updated meta-analysis will include the data from the 2019-2024 range as well as the initial study's findings so as to paint a full picture.

Language and Location

There are no restrictions on language or location.

Search Strategy and String

As this review is an update of a previous systematic review, the inclusion criterion for the date range is publication on or after January 01, 2019. The initial systematic review, upon which this update is based, included all dates up to December 31, 2018, in its search. Databases searched include MEDLINE (through Ovid Platform), PsycINFO, Embase, CINAHL, Scopus, and Web of Science (Core Collection). We used the MeSH (Medical Subject Headings) terms "Posttraumatic Growth, Psychological," and "Suicide" in databases that allowed for them (ie, MEDLINE [through Ovid Platform] and [PsycINFO])—the rest of the search string was free text and was used for each of the 6 databases mentioned. Multimedia Appendix 1 shows the search included in each database.

Data Extraction

Using Covidence [28], a title and abstract screening was conducted by 2 reviewers (SW and BM) to exclude studies outside the criteria as well as to remove duplicate search results. A further full-text screening was performed in Covidence by the same 2 reviewers (SW and BM), and studies deemed inapplicable were excluded; reasons for exclusion of these studies were recorded. Any disagreements on the inclusion or exclusion of an article by the 2 reviewers were brought to the review team for further opinion to resolve the dispute. Data extracted included author's name, year, location (country), study design, sample size, participants' age and sex distribution, participants' time since onset of bereavement, participants' relationship to the deceased, outcome measures, names of the instruments used, and primary findings of the study. To allow for the analysis of subgroups, we also extracted information related to demographic factors, loss-related factors, intrapersonal factors, and interpersonal factors (see the *Analysis of Subgroups or Subsets* subsection). The authors of the original review shared their data from the first review; it will be used for the meta-analysis portion of this update.

Risk of Bias (Quality) Assessment

The risk of bias will be assessed using 2 adapted versions of the Newcastle-Ottawa Scale (NOS) [29]. One adapted version will be for cross-sectional studies (7 questions), and the other for longitudinal studies (8 questions). This tool allows for the overall quality of a study to be assessed by the summation of "stars," which each question can provide based on quality. Questions are broken into categories of "selection" (4 questions), "comparability" (1 question), and "outcome" (2 questions for cross-sectional and 3 questions for longitudinal). The highest grade a study can receive is 8 stars for cross-sectional studies and 9 stars for longitudinal studies. The total number of stars is then used to determine a quality ranking for each study, where quality levels range from poor (<5 stars), fair (5-6 stars), and good (6-8 stars) in cross-sectional studies and poor (<5 stars), fair (5-6 stars), and good (7-9 stars) in longitudinal studies. Studies from all quality levels will be included as there is a paucity of literature on this topic; however, the inclusion of any "poor quality" articles will be addressed in the limitations of this updated systematic review and meta-analysis.

Strategy for Data Synthesis

The analysis will be conducted in RStudio (R Foundation for Statistical Computing) [30]. When studies did not report *r* coefficients, raw effects will be converted to *r* coefficients using the R package *effectsize* (version 0.8.3) [31]. Before conducting the analysis, we will apply a Fisher's *r*-to-*z* transformation to

the extracted effect sizes. Sampling variances and standard errors for the effect sizes will be calculated using the R package *esc* (version 0.5.1) [32].

Random-effects meta-analyses will be conducted using the R package *metafor* (version 4.4.0) [33]. This approach posits that individual study effects deviate not solely due to sampling error but also stem from another source of variance [34]. Heterogeneity will be assessed by Cochran Q, I^2 statistics, τ^2, and prediction intervals as recommended by Borenstein [35]. Publication bias will be assessed visually through a contour-enhanced funnel plot [36] and also by Egger regression test. To identify and assess the impact of potential outliers on the pooled effect and heterogeneity, influential analysis will be conducted using the R package *dmetar* (version 0.1.0) [37], using the leave-one-out method and the Baujat plot.

Analysis of Subgroups or Subsets

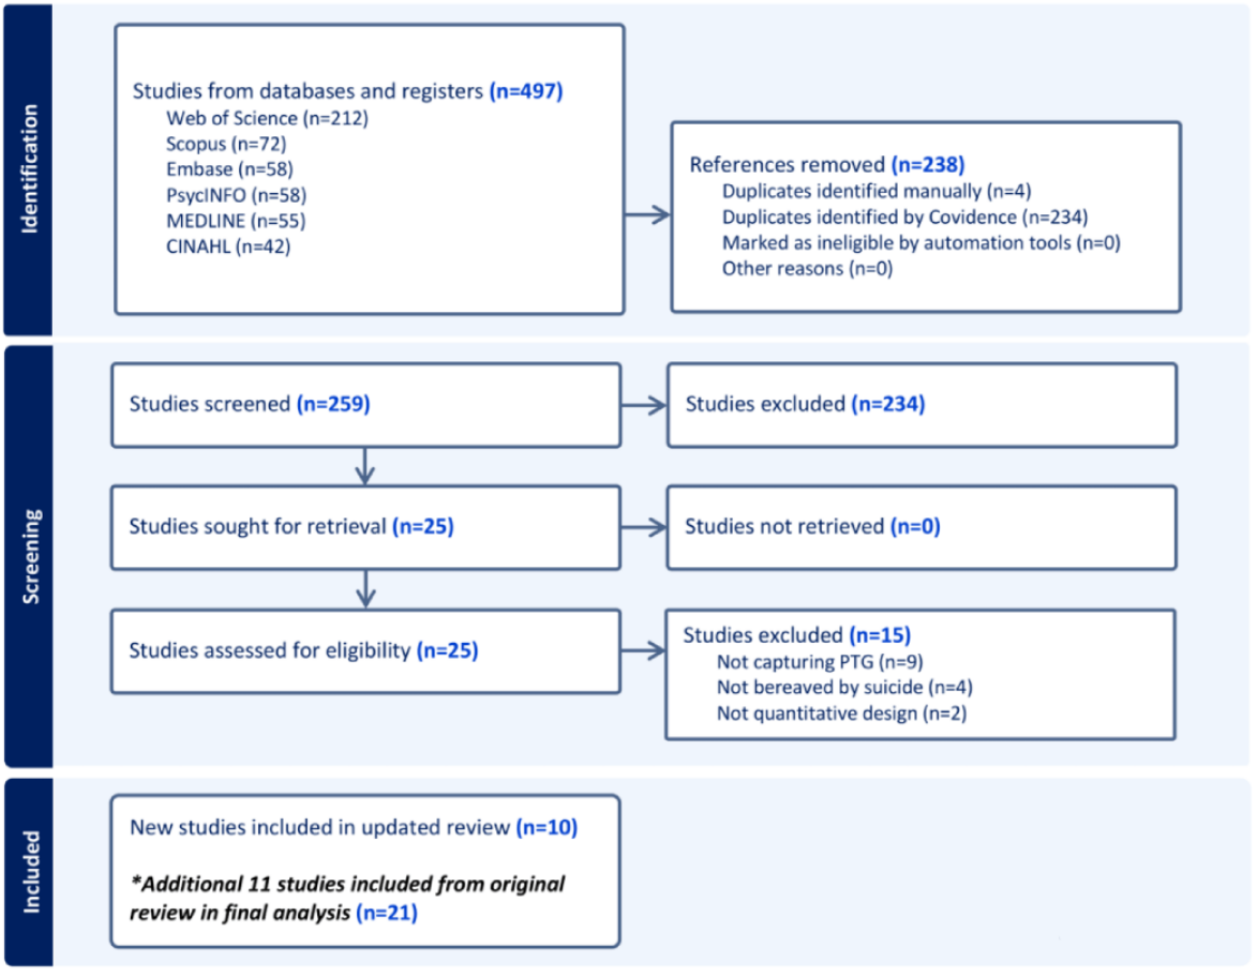
In line with the original review, moderating factors will be categorized into 4 categories, with effect sizes calculated for each subsequent variable. The following examples are from the original review:

1. Demographic factors (eg, age, gender, race, religious affiliation, educational level, marital status, and voting or civil involvement).
2. Loss-related factors (eg, grief experience, time since loss, and closeness to and type of relationship with the deceased).
3. Intrapersonal factors (eg, resilience, coping, rumination, personality, optimism, and emotional experience).
4. Interpersonal factors (eg, self-disclosure, social support, help-seeking, suicide stigma and secrecy, interpersonal burdensomeness, lack of belonging, and attachment style).

Results

This updated systematic review and meta-analysis was funded in October 2023 and is currently underway. It is expected to have results in October 2024. A total of 21 studies are included in this review; this will be reported by a PRISMA flow diagram (Figure 1). These 21 studies are currently being analyzed. All data produced in this review is included in Multimedia Appendix 2. A meta-analysis will be conducted using the data from both the studies of this updated search as well as the studies from the original review's search. Doing so will allow for any varying or static trends to be revealed. Moderating factors will be examined to determine which variables may influence PTG development in people bereaved by suicide. We aim to submit the full paper for publication in December 2024. The PRISMA-P checklist will be abided by to ensure a higher quality of research practices are followed (see Multimedia Appendix 3).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram. PTG: posttraumatic growth.



Discussion

We hypothesize that interpersonal variables of self-disclosure and social support, as well as the loss-related factor of time since loss and the intrapersonal variable of resilience, will have a positive influence on PTG. A full discussion will further examine these key relationships and general findings identified in the Results section. These findings will then be discussed in relation to 3 research aims identified in this review. The discussion will also investigate the findings of this updated review in comparison with the findings of the original review. Any differences would be highlighted and expounded upon to discover which factors have changed. Overall, we anticipate that the moderating variables will have varying effects on PTG and will deliberate on any potential correlational relationships, as this could emphasize which specific factors are correlated to greater PTG facilitation.

Implications and strengths, future work, and subsequent research, which could build upon the findings of this updated review will be discussed. The limitations of this review will be considered as well, such as the quality of the journal articles included in this review. Similarly, we will discuss how this systematic review has chosen to exclude qualitative articles as well as gray literature and dissertations and the strengths and limitations that follow this decision. We will also examine the impact of using solely the NOS for quality assessment of studies. While the NOS is a widely recognized tool for assessing the risk of bias, it may not fully capture the complexities associated with PTG. PTG involves multidimensional psychological, social, and emotional processes, which may be influenced by a variety of factors not entirely accounted for by the NOS. As such, relying solely on the NOS may limit the ability to assess the nuanced methodological challenges present in studies of PTG. Future research may benefit from supplementing the NOS with other bias assessment tools or qualitative methodologies to provide a more comprehensive assessment of study quality and the contextual factors influencing PTG outcomes. This paper will be submitted for peer-reviewed publication. It will also be part of a thesis submitted to the University of Strathclyde.

Acknowledgments

This PhD studentship is being funded by the University of Strathclyde's Global Research Award.

Data Availability

All data generated or analyzed during this study are included in this published article and Multimedia Appendices 1-3.

Authors' Contributions

This review is being completed as part of a PhD thesis by SW with the University of Strathclyde and is being supervised by SR, NC, and DT. The 3 authors of the original review—YL-B (Ruppin Academic Center), KK (University of Melbourne), and KA (University of Melbourne)—have joined this updated review as coauthors and team members. The meta-analysis is also under specific supervision by VS. BM is assisting in the screening, extraction of data, and writing of this article.

Abstract

Background: The increase in average life expectancy, aging, and the rise in the number of people living with dementia contribute to growing interest from the scientific community. As the disease progresses, people with dementia may need help with most daily activities and need to be supervised by their carer to ensure their safety. With the help of technology, health care provides new means of self-managing health that support active aging, allowing older people and people with dementia to live independently in their homes for a longer period of time. Although some systematic reviews have revealed some of the impacts of using digital interventions in this area, a broad systematic review that examines the overall results of the effect of this intervention type is mandatory.

Objective: The aim of this review is to further investigate and understand the acceptability and barriers to using technology to monitor and manage health conditions of people living with dementia and their caregivers.

Methods: A review of systematic reviews on acceptability factors and barriers for people with dementia and caregivers was carried out. Interventions that assessed acceptability factors and barriers to the use of technology by people with dementia or their carers were included. Each potentially relevant systematic review was assessed in full text by a member of a team of external experts.

Results: The analysis of the results will be presented in the form of a detailed table of the characteristics of the reviews included. It will also describe the technologies used and factors of acceptability and barriers to their use. The search and preliminary analysis were carried out between May 5, 2023, and August 1, 2024.

Conclusions: This review will play an important role as a comprehensive, evidence-based summary of the barriers and facilitators to the use of digital interventions. This review may help to establish effective policy and clinical guideline recommendations.

Introduction

The increase in average life expectancy and aging population give rise to numerous health problems, including a decline in physical performance; changes in sensory, cognitive, and psychological abilities; and changes in social interactions [1]. Decreased physical and cognitive function is associated with a high risk of falls, increased memory loss, and difficulty completing daily tasks such as eating, dressing, medication management, and shopping [1]. Deterioration in cognition may be important, resulting in interference with occupational, domestic, or social functioning [2], making it difficult to communicate and manage activities of daily living [3,4].

The number of people with dementia worldwide is expected to increase from 46.8 million today to approximately 131.5 million by 2050 [5-7]. According to the Global Dementia Observatory and World Health Organization (WHO), dementia is the seventh leading cause of death worldwide [8]. The impact of dementia on society is well known, so early detection, timely intervention, and prevention are extremely important [9]. This issue is attracting increasing interest from the scientific community [10] and WHO, and many policies [11] are being developed worldwide.

With advances in medicine and the aging population, there is a growing number of older adults with cognitive, motor, and sensory limitations who need support to continue to be at home and maintain some degree of autonomy. For these individuals, the alternative is to live in a residential structure for older adults, where (in theory) they will have more specialized support, free from the problem of managing a home or daily activities. However, the type of care provided is usually depersonalized, often not directed toward the disease and the patient, and often too basic and not specific to individual needs. Growing economic difficulties also imply greater difficulties in this solution. Therefore, many people choose to stay at home, being cared for by other people—family members or friends—who become informal caregivers [12].

It is increasingly important to realize how we can promote the independent living and safety of people with dementia. As the disease progresses, people with dementia may need help with most daily activities, and there is a need for caregiver supervision to ensure their safety [13,14]. However, in the face of rising demand and scarce resources, the ability of health care systems and caregivers to provide equitable, responsive, and timely postdiagnostic support on a sustainable basis is a growing concern [15].

The physical, psychological, social, and economic impacts on not only people with dementia but also their caregivers, families, and society in general are another point of alarm [12,16-18]. The characteristics and complexities of dementia give rise to concerns such as frustration, risk of psychological stress, depression, reduced quality of life (QoL), and poor health on the part of the caregiver, leaving them with a great deal of responsibility and less free time to look after themselves [13,16,17,19-21]. Individuals with dementia and their carers have a range of educational and support needs that vary throughout the different stages of dementia. Information resources, caregiver training or skills development, support groups, counseling, respite care, care coordination programs, transportation services, grocery and meal delivery, personal care, and care planning are essential to help and support caregivers and patients [14].

The COVID-19 pandemic highlighted the relevance of innovative technologies in guiding the interventions of professionals and carers and supporting frail older people. It seems essential to use technologies as a means of supporting and analyzing individual behaviors, identifying the need for and barriers to specific interventions by caregivers, and maintaining the QoL of people living with dementia and their caregivers and supporting active aging for people with dementia.

The use of the internet and digital technologies is increasing rapidly around the world, including among older adults [7,22]. Digital technology encompasses a range of interconnected innovations, including the Internet of Things with next-generation telecommunication networks (eg, 5G); big data analytics; artificial intelligence using deep learning; and blockchain technology [23]. These technologies play a crucial role in active aging, as digital interventions [10] and monitoring systems [11] have been reported to be important for enabling older people and individuals with dementia to live autonomously in their own homes for a longer period of time [10]. The complexity of behavior and context in which the most diverse situations occur makes measuring this effect challenging [11]. However, the importance of 24-hour monitoring of older people has been emphasized [11]. Technology is increasingly being used in health care, such as the provision of services, home monitoring, interactive communication (eg, between patient and doctor), the transfer of health information, and peer support [24]. The benefits of telehealth or information and communication technologies to support family carers at home are increasingly being studied [7]. In this way, digital interventions can offer several advantages, including the promotion of autonomy and self-management of health and allowing patients to maintain a certain degree of independence [12-14]. These types of digital tools can provide advantages and disadvantages of residential care by providing quick access to medical information and remote support for health care professionals, as well as reducing the need for in-person visits to doctors' offices and hospitals, resulting in transportation and other associated costs [12-14]. However, these interventions may also present limitations, such as technical barriers due to a lack of technical knowledge among older adults and caregivers, concerns about the privacy and security of personal and medical data, and accessibility and adaptation challenges, as all older adults neither have access to nor are adapted to the use of digital technologies, especially individuals with severe sensory or cognitive disabilities [12-14].

Considering the complexity of this issue, it is extremely important to understand what problems occur at this stage of life and how the use of technology can help people with dementia maintain their independent living and QoL, improve their health, and prevent possible emergencies [11]. However, the use of this type of technology to assist and monitor people with dementia and their carers should not be accepted uncritically. Older people are often referred to as reluctant users

or opponents of technological change [10], and the use of technology by carers reportedly increases their burden [15,16].

This knowledge is crucial for developing more effective and personalized strategies that can improve QoL for patients and their caregivers [13,17,19,25]. In this way, by better understanding the specific challenges faced by this population, both formal and informal caregivers can adapt technological interventions to ensure greater adherence and effectiveness, thereby promoting more integrated and patient-centered care [6,7,9,13,22].

With this umbrella review, we set out to gather the data available in the literature in detail, which will allow research teams and policymakers to identify the technologies that have been successful and the objections to their use in supporting active aging and carers. The main aim of this review is to investigate, understand, and summarize the acceptability and barriers to using technology to monitor and manage health conditions in people with dementia and their carers, using more recent data. Another aim is to contribute to a theoretical debate and offer suggestions for future research in this area of work, as well as categorize the barriers and motivations for using technology. This scientific evidence will help with clinical guideline development and support political orientations.

To the best of our knowledge, this is the first general review that specifically addresses issues related to acceptability factors and barriers to the use of digital technology in people with dementia and their caregivers. We will be able to summarize the effectiveness of digital technology to support people with dementia and their carers, which is a challenge that requires an umbrella review approach.

Several research questions will be addressed: (1) What are the barriers to implementing digital interventions for people with dementia and/or caregivers? (2) What are the facilitators in implementing digital interventions for people with dementia or caregivers? (3) What digital interventions have been proposed for people with dementia or caregivers? (4) How effective were these digital interventions in alleviating the targeted problems?

Methods

Study Design

With the increase in the number of publications and reviews on the use of technology by older people and people with dementia in recent years, we aimed to use an umbrella review to examine whether the evidence for our research question is consistent or contradictory. Umbrella reviews focus on research questions or clinical practice for which there is a rich, high-quality evidence base. By reviewing all the existing literature on our research questions, we will be able to provide an overview of the main research findings.

To implement this umbrella review, we used the Preferred Reporting Items for Overviews of Review (PRIOR) statement protocol [26]. We selected and analyzed the studies according to the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines. We used the Cochrane PICOS framework (population, intervention, comparison, outcomes, and study design; Table 1). The methods used in all stages of screening, selection and extraction, quality assessment, overlap management, analysis, and synthesis were referenced to ensure that our analysis can be replicated.

Table 1. Eligibility criteria for the inclusion of systematic reviews and meta-analyses.

Category	Specific criteria
Inclusion criteria	
Publication type, date, and language	Systematic reviews (or meta-analyses) published in a peer-reviewed journal
Study design	Systematic reviews and meta-analyses
Population	Male or female individuals with dementia (age ≥60 years) or their caregivers
Intervention	Interventions based on the evaluation of the acceptability and barriers to implement digital interventions for people with dementia or their caregivers
Outcomes	Outcomes will be extracted from systematic reviews that include these aspects. Reviews including effectiveness of implementing digital interventions for people with dementia or their caregivers (eg, Results from the Unified Theory of Acceptance and Use of Technology Questionnaire, Telehealth Satisfaction Questionnaire) and among them, if available, strategies impacting the implementation process (eg, results from the Mini-Mental State Examination, Zarit Burden Interview, Impact of Caregiving Scale, Caregiver Strain Instrument)
Exclusion criteria	
Study design	Articles that were not systematic reviews and meta-analyses were not included.
Time period	Reviews that used studies carried out during the COVID-19 pandemic
Intervention	Reviews using articles with robot intervention

Target Population

We included systematic reviews with or without a meta-analysis focusing on acceptability factors and barriers to the use of technology by people with dementia or carers. The inclusion and exclusion criteria for this umbrella review are presented in Table 1.

Our population includes adults aged 60 years and older with dementia who had been included in studies using technologies.

We did not limit the place (eg, home, clinics, academic centers, nursing home, rural populations) of intervention or the type of intervention carried out. We excluded analyses measuring acceptability factors and barriers of studies performed during the COVID-19 pandemic. The reason for this exclusion was to reduce the influence of compulsion or technology being the only way to access the intervention, which could influence the wanted results.

Intervention, Comparators, and Outcomes

We included all systematic literature reviews that present results on the factors that can limit or enhance the use of technology by older people with dementia and carers. Among these, we focused on factors of acceptability and barriers to use and implementation using technologies. This umbrella review focuses on dementia interventions that are delivered using digital technology. For the purpose of this review, digital technology is defined as technology interventions that use smartphone apps, wearable technology, or mobile text messaging to deliver health care. These digital technologies are developed to support the independence of older people living in the community, alleviating or preventing functional or cognitive impairment, thus limiting the impact of dementia on older people and their caregivers.

The following comparisons were analyzed: technology versus control (no technology), intervention environments, type of technology used, and intervention by carers. Where possible, the intervention of caregivers will be divided into formal and informal caregivers, including factors of acceptability and barriers to the use of technology. The outcomes will be divided into outcomes of people with dementia and outcomes of caregivers. Outcomes of people with dementia include the sociodemographic characteristics of the patients, cost efficiency of using the intervention, changes in health outcomes after using the intervention (eg, Mini-Mental State Examination), patients' adherence to and engagement with the intervention, adverse events, and barriers to using the intervention (eg, The Unified Theory of Acceptance and Use of Technology Questionnaire, Telehealth Satisfaction Questionnaire). Outcomes of caregivers include the quality and reliability of the interventions (eg, Zarit Burden Interview, Impact of Caregiving Scale, Caregiver Strain Instrument), patients' follow-up with health care services after using the intervention, caregivers' adherence to and engagement with the intervention, adverse events, and barriers to using the intervention (eg, Telehealth Satisfaction Questionnaire).

Publication Type, Date, and Language

Reviews published in peer-reviewed journals were included, without any date limitations.

Data Sources and Search Strategy

The search for this umbrella review aimed to identify all systematic reviews of the literature on our research question. ISI Web of Science, Scopus, and PubMed databases were used to search for scientific articles for the development of this umbrella review. In this search, articles were identified using keywords and MeSH words (for PubMed search), individually and/or in combination. The research strategy used in PubMed included the following: (((((Elderly) OR ("Older population")) OR ("Older people")) OR ("Geriatrics"[Mesh])) OR ("Aged"[Mesh])) OR ("Aging"[Mesh])(((("Telemedicine"[Mesh]) OR ("Mobile Applications"[Mesh])) OR ("health informatics")) OR ("healthcare technology")((((implementation) OR (Barriers)) OR (Acceptance)) OR (Adherence)) OR (Restriction)((((("Dementia"[Mesh]) OR ("Cognition Disorders"[Mesh])) OR ("mental deterioration*")) OR ("cognitive impairment*")) OR ("mild cognitive impairment*"))(((((((Elderly) OR ("Older population")) OR ("Older people")) OR ("Geriatrics"[Mesh])) OR ("Aged"[Mesh])) OR ("Aging"[Mesh])) AND ((((("Telemedicine"[Mesh]) OR ("Mobile Applications"[Mesh])) OR ("health informatics")) OR ("healthcare technology"))) AND (((((implementation) OR (Barriers)) OR (Acceptance)) OR (Adherence)) OR (Restriction))) AND (((((("Dementia"[Mesh]) OR ("Cognition Disorders"[Mesh])) OR ("mental deterioration*")) OR ("cognitive impairment*")) OR ("mild cognitive impairment*")).

The research strategy used in Web of Science and Scopus included (((((((Elderly) OR ("Older population")) OR ("Older people")) OR ("Geriatrics")) OR ("Aged")) OR ("Aging")) AND ((((("Telemedicine") OR ("Mobile Applications")) OR ("health informatics")) OR ("healthcare technology"))) AND (((((implementation) OR (Barriers)) OR (Acceptance)) OR (Adherence)) OR (Restriction))) AND (((((("Dementia") OR ("Cognition Disorders")) OR ("mental deterioration*")) OR ("cognitive impairment*")) OR ("mild cognitive impairment*")).

Data Exclusion

Data from the included studies were analyzed by 2 independent reviewers (MVP and RM) and extracted into Microsoft Excel according to the acceptability and barriers of new technologies, reported by people with dementia or their caregivers. Discrepancies will be resolved through discussion with a third author (NP).

Data Synthesis

Results analysis will aim to present the technology used and the factors of acceptability and barriers to its use to support people with mild cognitive impairment or dementia and their carers. It will describe in detail each of the studies analyzed, presenting the study population, site of the intervention, time of the intervention, technology used and its category, evaluation instruments, and site. It will also describe the intervention that was carried out, reasons for acceptability and barriers, impact of the intervention, and limitations or future research with people with dementia and their carers. If possible, we will use the Consolidated Framework for Implementation Research (CFIR) to organize and analyze the factors of acceptance, barriers, and impact of support technologies for people with mild cognitive impairment or dementia and their caregivers. The CFIR tool provides a comprehensive theoretical framework that will help categorize and interpret the results, promoting a deeper understanding of the factors that influence the acceptance of and challenges with implementing technologies for people with mild cognitive impairment and dementia as well as their caregivers.

Methodological Quality and Risk of Bias Assessment

The methodological quality of all the included studies was assessed using the AMSTAR-2 (A Measurement Tool to Assess Systematic Reviews) checklist [27]. The tool helps categorize the quality of reviews according to 7 critical areas and 9 noncritical areas. The assessment will be grouped into low, moderate, and high critical quality categories.

Patient and Public Involvement

No patients nor members of the public were involved in the development of this comprehensive review. However, the scope and methods of this review were based on the literature and discussed with experts.

Ethical Considerations and Dissemination

The proposed comprehensive review was based exclusively on published data from secondary sources and therefore did not involve any interactions with human beings.

The results of the umbrella review will be presented at international conferences in the fields of, for example, gerontology and geriatrics, health informatics, primary care, public health, and social sciences and will be published in a journal aimed at a wide audience. When the results are published, we will make the data generated by our research openly and publicly available. The team also intends to use social networks and the institutional websites of its research centers to disseminate its findings through websites, social media, and newsletters.

Results

We expect to find information on the facilitators and barriers to the implementation of digital interventions for people with dementia or their caregivers. We expect to provide information for politics and practice and to extract guidance for future research.

The search and preliminary analysis were carried out between May 5, 2023, and August 1, 2024. A total of 612 studies were identified across 3 databases. After the removal of duplicates, 400 articles remained. Title and abstract screening further reduced this number to 20 articles for full-text analysis. Ultimately, 5 studies met the inclusion criteria, focusing on the acceptability and barriers to technology use among individuals with dementia or their caregivers. Results were analyzed between August 2024 and October 2024, and the results are expected to be published later in 2025.

Discussion

Overview

As far as we know, this will be the first umbrella review addressing acceptance factors and barriers to the implementation of digital interventions in older people with dementia and their caregivers. Providing information on the facilitators and barriers to the implementation of digital interventions in people with dementia and their caregivers is extremely relevant from a clinical perspective [6,7,9,13,17,19,22,25]. This debate, present in the literature, encompasses several key issues: the effectiveness of digital interventions, the acceptability and usability of these technologies by older adults with dementia, and the various barriers to successful implementation, such as technological complexity and lack of digital literacy [12-14]. Additionally, there is concern about the potential for digital technologies to increase the burden on caregivers, who must learn and manage new technologies while providing care [12-14]. Discussions also focus on how digital technologies can improve QoL and health outcomes for people with dementia and their caregivers, including assessing clinical effectiveness and the impact on daily living and well-being [13,25]. Furthermore, the economic feasibility and broader social implications of implementing digital technologies in dementia care have been debated, including considerations of cost-effectiveness and potential health care cost reductions [6,7,25]. By systematically reviewing and synthesizing the available literature, this review seeks to provide a clearer understanding of these issues, thereby contributing to the theoretical debate and offering insights for future research and policy development.

Our umbrella review can significantly contribute in several ways, as noted in the following paragraphs.

It can identify barriers and facilitators. By synthesizing the results of various systematic reviews and meta-analyses, this review identifies common barriers and facilitators for implementing digital technologies in dementia care. This includes technical, financial, social, and psychological aspects that influence the accessibility and effectiveness of these interventions [12-14].

It can provide information for policies and practices. Insights obtained from this review can inform the formulation of policies and clinical practices, helping to shape guidelines that encourage the adoption of effective and sustainable technologies in dementia care [6,7,25].

Guidance for future research will be obtained. By highlighting gaps in the existing literature, this review can point to areas that need further investigation. This includes the need for studies exploring new technologies as well as studies examining diverse populations and different care contexts [12-14].

The review will also highlight research gaps in the field, pointing to associations and issues that have not been adequately explored. For example, there may be a lack of studies evaluating the impact of emerging technologies or considering the cultural and socioeconomic variability among different groups of patients and caregivers. Additionally, there may be a need for investigations into the long-term effects of using digital technologies in dementia care [12-14].

Overall, this umbrella review will contribute to the current debate on the value of a technological approach in dementia care. By providing a holistic view of the facilitators and barriers, this review can promote a more informed discussion on how to better integrate technology into geriatric care, potentially leading to better support for the autonomy and QoL of patients and their caregivers.

In summary, this review offers a unique opportunity to consolidate and critically evaluate the existing evidence on the

acceptance and barriers to digital interventions in dementia care. Its findings can influence both clinical practice and future research, contributing to a better understanding and implementation of these technologies in a context that continues to grow in importance due to the aging global population.

Limitations

To the best of our knowledge, this is the first general review that specifically addresses issues related to acceptability factors and barriers to the use of digital technology in people with dementia and caregivers. However, we expect to find difficulties: We expect to find systematic reviews with different protocols and different populations with different objectives. That will make the possibility of reaching final conclusions more difficult and, in certain cases, unobtainable.

Acknowledgments

This work was developed within the scope of the Centro de Investigação em Ciências da Saúde Universidade Beira Interior and Centro de Investigação em Desporto, Saúde e Desenvolvimento Humano.

Abstract

Background: Educational technology (EdTech) has been instrumental in the last few decades in promoting inclusive education by overcoming various learning barriers and offering tools and opportunities to all students, including those with special educational needs and disabilities (SEND). However, there is limited understanding of current classroom practices and policies and of the effects of the COVID-19 pandemic on EdTech use in the inclusive classroom.

Objective: This systematic review aims to outline the current knowledge on the use of EdTech to support the learning of students with SEND in inclusive primary schools in high-income countries.

Methods: We followed the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) and the Generalized Systematic Review Registration Form in reporting the details of this protocol. The inclusion criteria for the systematic review require that studies focus on students with SEND who are attending the primary stage of school in high-income countries. The studies can be qualitative or quantitative and should explore the design and use of EdTech with these students. Eligible studies must be published between 2016 and 2024, be peer-reviewed, and be available in English. We systematically searched the ACM, Directory of Open Access Journals, British Educational Index, ERIC, Google Scholar (first 100 records), IEEE, PsycINFO, Scopus, and Web of Science databases. The titles and abstracts of all records will be screened for relevance according to the inclusion criteria. Following this, the full text of the articles will be screened. To ensure the reliability of the screening process, an independent reviewer will screen a percentage of the records for the first screening round. The data extraction process for this systematic review will start with a pilot stage to validate and eventually update the list of entities to be extracted. Following the pilot stage, the final data extraction will be undertaken. An independent reviewer will extract data from a subsample of the records to ensure the reliability of the data extraction process.

Results: The database search was conducted in July 2024. The database search identified a total of 547 records. It is anticipated that the study findings will be submitted for publication in a peer-reviewed journal by the end of January 2025.

Conclusions: This study will provide up-to-date evidence of the use of EdTech in inclusive primary school settings in high-income countries and will describe the impact of the COVID-19 pandemic on the use of EdTech with students with SEND.

Introduction

Background

Educational Technology (EdTech) usually includes a number of broad definitions across disciplines. For the purposes of this systematic review, this term includes any use of information and communication technology and assistive technology. Information and communication technology refers to the technologies used for accessing, processing, and communicating information and encompasses a wide range of technologies, including (1) computers and software applications, (2) internet and network systems, (3) mobile phones and other handheld devices, (4) digital broadcasting technologies (radio and TV), and (5) email and other communication tools [1]. Assistive technology includes any item or piece of equipment that helps a person with a disability to increase, maintain, or improve their functional capabilities as a learner and any related assistive technology service [1].
