Abstract

Background: Regular pulmonary rehabilitation exercises are crucial for patients with lung cancer after surgery. However, poor adherence to outpatient exercises is difficult to address due to inadequate supervision. The integration of remote symptom management through electronic patient-reported outcomes (ePROs) offers a potential solution to improve adherence by enabling more effective monitoring and intervention.

Objective: This study aims to evaluate the impact of ePRO-based remote symptom management on enhancing adherence to outpatient pulmonary rehabilitation exercises following video-assisted thoracic surgery for lung cancer.

Methods: In this single-center, prospective, randomized controlled trial, 736 patients undergoing minimally invasive lung resection will be recruited. All patients will use a smartphone app for perioperative management, allowing periodic PRO measurement and recording of exercise participation. Upon discharge, patients will be randomly assigned 1:1 into either an intervention or control group. The intervention group will complete the Perioperative Symptom Assessment for Patients Undergoing Lung Surgery (PSA-Lung) scale on the day of discharge and postdischarge days 3, 7, 14, 21, and 28. Alerts will be triggered at the provider side if any of the 5 core symptoms (pain, cough, shortness of breath, sleep disturbance, and fatigue) scored ≥4, prompting remote symptom management. The control group will complete the PRO measures without triggering alerts. The primary outcome is the rehabilitation exercise adherence rate. Secondary outcomes include postdischarge pulmonary complication rate, 30-day readmission rate, trajectory of symptom severity changes, exercise participation rate, and patient satisfaction.

Results: The enrollment of study participants started in December 2023 and is expected to end in March 2025. The final comprehensive analysis of the results is planned for May 2025, after all data have been collected and thoroughly reviewed.

Conclusions: This study is among the first to investigate the feasibility and effectiveness of ePRO-based remote symptom management in enhancing rehabilitation adherence after video-assisted thoracic surgery for lung cancer. If successful, this approach could significantly influence postoperative care practices and potentially be adopted in similar settings.

Trial Registration: ClinicalTrials.gov NCT05990946; https://clinicaltrials.gov/study/NCT05990946

Introduction

Lung cancer remains a predominant cause of cancer-related morbidity and mortality worldwide. Specifically in China, the incidence rate reached 828,000 cases in 2016 [1]. Non–small cell lung cancer is the most prevalent subtype. With the increasing adoption of lung cancer screening, more patients are being diagnosed at early stages. Surgical resection is the gold standard for treating early-stage, non–small cell lung cancer, and the paradigm of enhanced recovery after surgery has been widely adopted in perioperative care [2].

While enhanced recovery after surgery effectively shortens inpatient stays, its benefits are often offset by inadequate outpatient management stemming from limited resources, which can adversely affect clinical outcomes and postdischarge quality of life [3]. One critical factor in postoperative recovery is adherence to pulmonary rehabilitation exercises. However, adherence rates are suboptimal due to insufficient supervision and guidance.

Following discharge, many patients face decreased exercise adherence rates, ranging from 50% to 70% according to studies focusing on patients with musculoskeletal disorders [4-6]. Several factors influence adherence, including self-efficacy, personal beliefs, sense of self-control, physical and psychological condition, clinical symptoms like pain, and perceived forgetfulness [7-11].

Moreover, many patients continue to experience symptoms such as coughing, pain, poor sleep, and breathlessness after discharge, which may substantially undermine their exercise adherence [12]. In the era of patient-centered care, remote symptom management through electronic patient-reported outcomes (ePROs) is emerging as a promising approach to improve outpatient quality of life and reduce postoperative complications [13-16]. By providing effective strategies for timely monitoring and managing patients' symptoms, ePRO-based interventions may help patients overcome barriers to exercise and enhance their self-efficacy and motivation, thus promoting exercise adherence [17].

There is a pressing need for research to investigate the impact of postoperative symptoms on exercise adherence and to evaluate whether ePRO-based remote symptom management can effectively improve adherence to outpatient rehabilitation exercises [18,19].

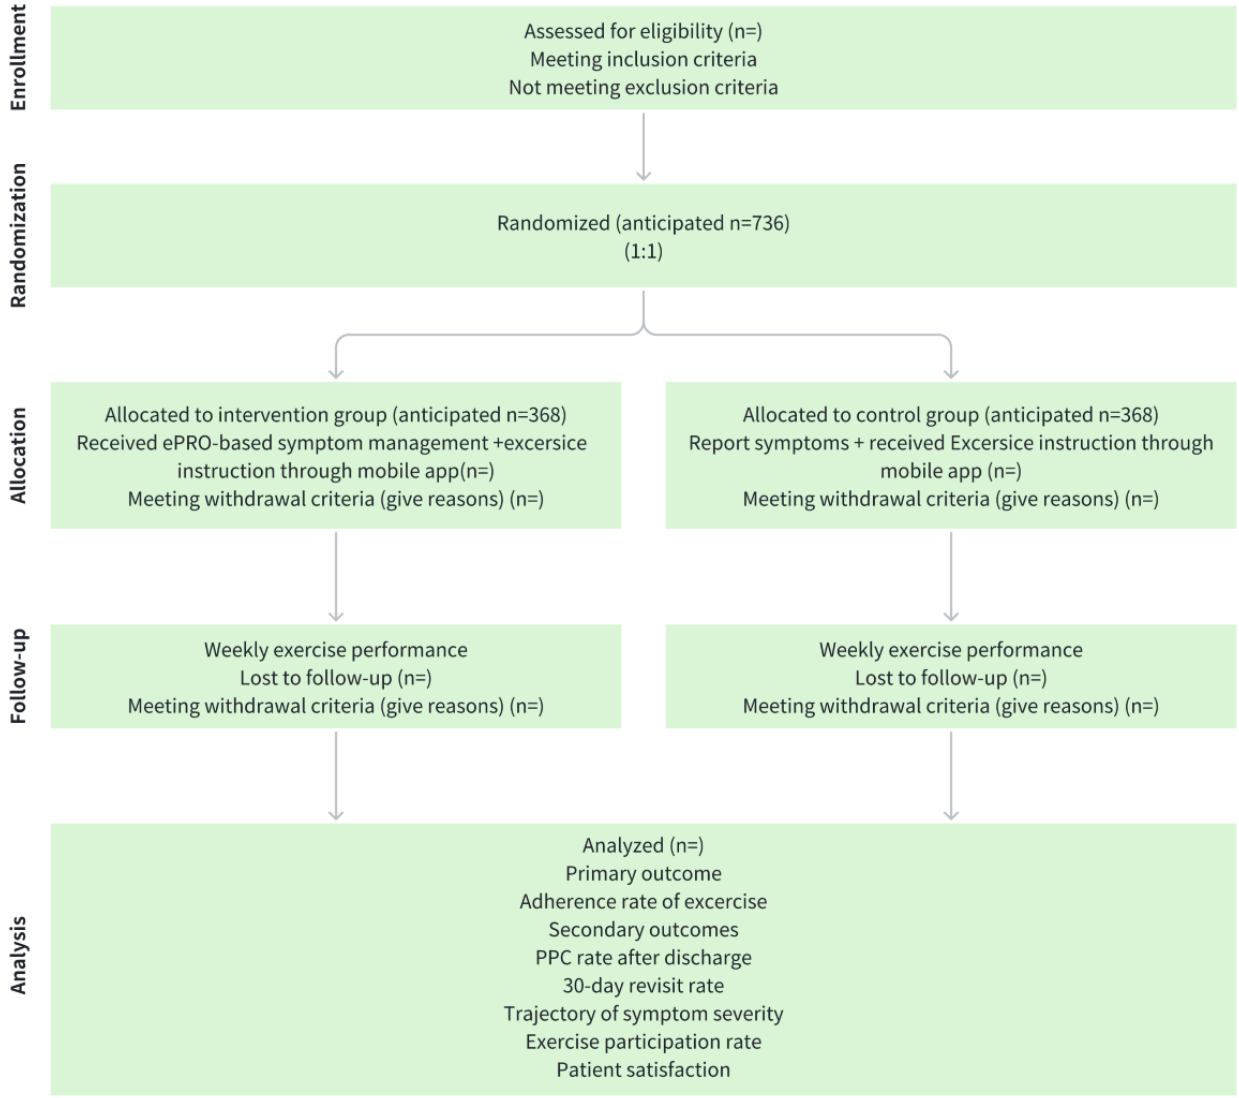
Therefore, this study aims to assess the feasibility and preliminary effects of remote symptom management based on ePROs on enhancing adherence to outpatient rehabilitation exercises after video-assisted thoracic surgery (VATS) for lung cancer. A prospective, randomized controlled trial study design is adopted to provide new strategies for rehabilitation management in patients with lung cancer. We hypothesize that remote symptom management based on ePROs can improve exercise adherence in patients with lung cancer after VATS compared with usual care.

Methods

Study Setting

This is a single-center, prospective, superiority, randomized controlled trial, consistent with the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) guidelines [20]. Participants will be recruited from the Department of Thoracic Surgery, Zhongshan City People's Hospital, Guangdong, China, which performs approximately 600 lung cancer surgeries annually. The findings will be reported based on the CONSORT (Consolidated Standards of Reporting Trials) guidelines [21]. The study flowchart is shown in Figure 1. This trial has been registered on ClinicalTrials.gov (NCT05990946), where detailed information about the study protocol, inclusion and exclusion criteria, interventions, outcomes, and ethical approval can be found. The trial registration process was completed before the enrollment of the first participant.

Figure 1. Flowchart of this parallel-group randomized controlled trial. ePRO: electronic patient-reported outcome; PPC: postdischarge pulmonary complication.



Eligibility Criteria

Inclusion criteria for the participants are (1) being aged 18-75 years; (2) undergoing VATS, including lobectomy or segmentectomy; (3) being able to use smart devices and completing electronic questionnaires; and (4) providing informed consent. The exclusion criteria are (1) conversions to open thoracotomy during surgery, (2) preoperative Eastern Cooperative Oncology Group score >1, (3) received neoadjuvant therapy, (4) previous thoracic surgery history, (5) unable to exercise due to physical impairments, (6) continuous systemic corticosteroid use within 1 month, (7) unresolved toxicity above grade 1, (8) significant medical history, (9) uncontrolled comorbidities, (10) postoperative length of stay >14 days, and (11) other unsuitable conditions in the investigator's judgment.

Participant Recruitment

Patient recruitment will commence before discharge, including preoperative patients awaiting scheduled surgery. Eligible patients will be randomly assigned before discharge after confirming they can properly operate the smartphone app. After discharge, patients will be reminded to use the app for symptom and exercise logging. The app provides an incentive for participating in the 4-week rehabilitation program between discharge and the first postoperative clinic visit.

Randomization and Allocation Concealment

Each potential participant will be assigned a unique 3-digit screening number in sequence. Eligible participants will be randomly allocated 1:1 to the intervention and control groups.

Randomization will be performed using a central Interactive Web Response System (IWRS), which is deployed on a third-party platform (Huawei Cloud) and was developed by the Shuyu app development team. The IWRS uses a block randomization algorithm to generate the allocation sequence and ensure balance between the treatment groups. After confirming eligibility, the study site will enter participant information into the IWRS and receive the allocation. Withdrawn participants will retain their randomization number without re-enrollment. The randomization code will be securely stored in the IWRS throughout the study.

Blinding

Due to the nature of interventions, blinding of participants and care providers is not feasible. However, data collectors and statisticians will be blinded to group allocation. The data collectors, who are research nurses, will be trained to administer questionnaires and collect data consistently according to the study protocol. They will collect data at baseline through in-person interviews and then weekly for 4 weeks after discharge through telephone interviews.

Interventions

Participants will use the app "Shuyu" (Module type: TH001, Developed by Shanghai CinoCore Health Technology Co) for perioperative management.

Preoperatively, nurses will instruct app use and provide education. The app will assign individualized exercises and prompt logging. Patients will complete baseline PRO measurements. The Perioperative Symptom Assessment for Lung Surgery (PSA-Lung) was used for PRO assessments. The PSA-Lung scale includes 7 symptom items (pain, coughing, shortness of breath, disturbed sleep, fatigue, drowsiness, and distress) and 2 functional items (interference of activity and walking). Each symptom's severity was rated between 0 (the absence of symptom) and 10 (the worst imaginable symptom). Similarly, functional items were also rated on a scale between 0 (no interference) and 10 (complete interference). The PSA-Lung scale development team has verified its reliability and validity in patients who undergo lung cancer surgery, and the research results suggested adequate reliability and validity. The relevant articles have been submitted for publishing, and the preliminary results were announced at the 28th Annual Conference of the International Society for Quality-of-Life Research [22]. Permission to use the PSA-Lung scale in this study has been obtained from the scale development team.

Postoperatively during hospitalization, nurses will guide app-based rehabilitation, doctors will supervise exercises and PROs, and patients will complete daily PROs without alerts.

Before discharge, the care team will evaluate if patients can properly operate the app. Eligible patients will be randomly allocated into groups by the nurse entering the patient's screening number and discharge date in the provider app. Based on the pregenerated randomization code from the central system, this process will automatically allocate patients into the intervention or control group, unlocking the corresponding outpatient module.

After discharge, the app continues to offer postoperative education and exercise logging, sending daily reminders at 9 AM and follow-ups at 5 PM if logs are incomplete. Weekly phone checks by staff will confirm exercise log accuracy. Noncompliance or inaccessibility after 3 phone attempts will result in protocol violation and withdrawal.

Reminders for PRO assessments are set for 9 AM on the day of discharge and on postdischarge days 3, 7, 14, 21, and 28. A follow-up reminder will be sent at 5 PM if the assessment remains uncompleted. These assessments must be completed on the specified days, and the analysis will include patients who have logged exercises but have not submitted PRO assessments. For participants who are unable to continue using the ePRO system, a manual follow-up plan will be implemented to collect PRO data through telephone or email on the day following the scheduled assessment days to avoid conflict with system reminders.

Comparison

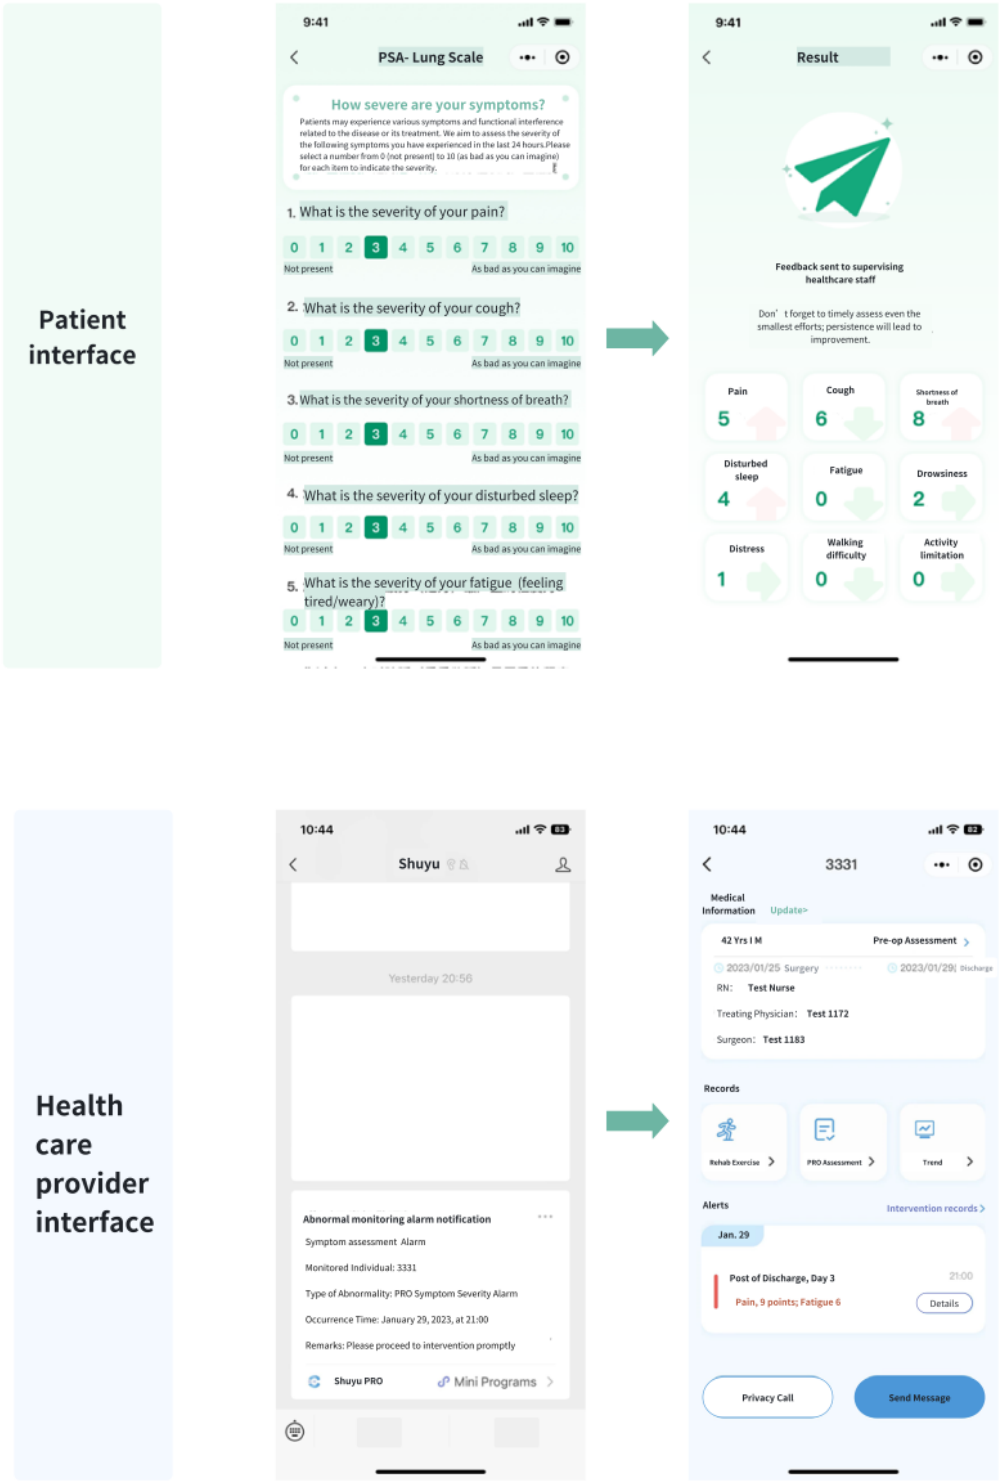
Intervention Group

The intervention group will be notified to complete the PRO measures on the designated days.

If any of the 5 core symptoms (pain, cough, shortness of breath, sleep disturbance, and fatigue) scored ≥4 in the ePRO questionnaire, alerts will be triggered on the provider end, prompting the assigned doctor and nurse to initiate remote guidance and intervention through the app through text or phone call within 24 hours following standardized procedures in the operation manual. Interventions will be based on PRO scores and include recommendations for self-management, medications, and clinic visits. In addition, patients who report any of the 5 core symptoms will immediately receive automated internet-based self-management suggestions generated by the system after submitting the PRO questionnaire.

The intervention will focus on the management of these 5 core symptoms since they were identified as critical symptoms for postoperative management in previous studies on remote PRO-based symptom management after lung cancer surgery in China [16]. Based on recommendations from the National Comprehensive Cancer Network and published studies, symptom scores ≥4 are considered moderate severity or above [23,24]. Therefore, a symptom score of 4 is set as the threshold for triggering alerts. Details of the patient self-reporting process and health care provider alert interface are shown in Figure 2.

Figure 2. Workflow of patient self-reporting via the shuyu app and healthcare provider alert interface.



Symptom management in the intervention arm will adhere to the latest guidelines and be standardized across providers through standard operating procedure manuals, as shown in Multimedia Appendix 1. In cases of severe symptoms, physicians may advise patients to temporarily pause or adjust their exercise plans to ensure safety.

Control Group

The control group will complete PRO measures on the same days without triggered alerts or self-management suggestions.

All patients, regardless of group assignment, will receive guidance on seeking medical attention through conventional means for severe symptoms. Severe symptoms are defined as individual symptom scores ≥6 on the PSA-Lung scale.

Withdrawal Criteria

Participants meeting the following withdrawal criteria will be removed from the analysis: (1) no primary lung cancer on pathology, (2) non-microscopically complete resection, (3) stage IV disease, (4) initiation of adjuvant therapy during follow-up, (5) severe protocol violation (nonadherence to instructions, random responses, etc), and (6) voluntary withdrawal.

Study Outcomes

Primary Outcome

The primary outcome is the rehabilitation exercise adherence rate over 4 weeks after discharge, defined as the proportion of patients completing the prescribed outpatient exercise regimen. Exercise completion will be ascertained based on patient self-reports through the app and verified through weekly phone follow-ups. Referencing exercise guidelines for cancer survivors from the American Cancer Society, ≥150 minutes of moderate to vigorous intensity physical activity per week (equivalent to 150 minutes of brisk walking) is considered adherent [25].

Secondary Outcomes

Secondary outcomes are listed in Textbox 1.

Textbox 1. Secondary outcomes and their measurement criteria.

- Postdischarge pulmonary complication (PPC) rate
  - Proportion of patients experiencing pulmonary complications within 30 days after discharge. Complications will be graded using the Clavien-Dindo classification [26], categorizing PPCs into 5 grades, as shown in Multimedia Appendix 2.
- 30-day revisit rate
  - Proportion of nonscheduled revisits within 30 days after discharge.
- Trajectory of symptom severity
  - Changes in symptom and interference scores on the electronic patient-reported outcome questionnaire from discharge to 30 days after discharge.
- Exercise participation rate
  - Number of days with exercise logged within 4 weeks after discharge. Any day with exercise logged is considered participation, regardless of whether the target duration is achieved.
- Patient satisfaction: score on the 4-item questionnaire including
  - Whether the app helped with rehabilitation and symptom control;
  - Overall satisfaction rating;
  - Whether the app caused daily life disruption; and
  - Likelihood of recommending the app to others. Each item is rated from 0 to 10.

Other Data

The study will record time intervals from alert to provider intervention in the app backend. Questionnaires and interviews will also survey provider acceptance of the app. Participant demographic information, tumor characteristics, clinical management, treatment outcomes, adverse events, and follow-up data will be collected at different time points. All adverse events will be evaluated and managed by thoracic surgeons.

Sample Size

The primary outcome is the rehabilitation exercise adherence rate, defined as the proportion of patients completing the prescribed exercise regimen. Adherence is defined as completing the prescribed exercise regimen, calculated from self-reported app data and verified through weekly follow-ups.

The sample size was calculated to detect a 10% difference in adherence rates between the intervention and control groups, with 80% power and a 2-sided significance level of .05. The control group adherence rate was assumed as 70% based on previous studies [27-30]. The 10% clinically important difference was determined through expert consultation, considering their practical experience and the potential impact on patient outcomes, despite limited direct literature support. The dropout rate was estimated as 20% from previous digital intervention trials (from 3.75% to 18.3%) [31-33]. Dropouts include discontinuation of app use and loss of follow-up.

Using a z test with a 10% proportion difference, 80% power, 5% type I error, and 20% dropout rate, the required sample size is 368 per group, 736 in total.

Data Analysis

Statistical analyses will be performed based on both the intention-to-treat principle and the per-protocol principle. The intention-to-treat population will include all randomly assigned participants, while the per-protocol population will include participants who provide baseline PRO data and measures for at least 2 additional time points, with at least 1 calculable weekly exercise duration logged. Participants meeting withdrawal criteria will be excluded from all analyses. Statistical inferences

will adopt 2-sided tests at a significance level of .05, with 2-sided 95% CI for estimation. The primary outcome, exercise adherence rate, will be compared between groups using the Pearson χ^2 test or Fisher exact test. Secondary outcomes will be analyzed as follows: PPC rate and 30-day revisit rate will be compared using χ^2 test or Fisher exact test; symptom severity trajectory, which involves repeated measurements, will be assessed using linear mixed effects models to account for within-subject correlation; exercise participation rate will be compared using Wilcoxon rank sum test; and patient satisfaction scores will be compared using the Student 2-tailed *t* test or Wilcoxon rank sum test. The time from alert to intervention and provider acceptance will be summarized descriptively. Baseline characteristics will be compared using 2-tailed *t* test, Wilcoxon rank sum test, χ^2 test, or Fisher exact test, as appropriate. Missing data will be handled through multiple imputation or maximum likelihood estimation methods.

Data Monitoring and Interim Analysis

A Data Safety Monitoring Board will be set up, including 1 clinical physician and 1 data manager, to conduct independent data monitoring. No interim analysis is planned considering the low-risk nature and short study duration.

Patient and Public Involvement Statement

Patients and the public will not be involved in the design, recruitment, or implementation of this study. Study results will be disseminated to applicants. As disseminating results to participants is not standard practice in China, we have no plans for participant-directed dissemination. Study participants will be informed that final results can be accessed through our future publications.

Ethics Considerations

The study protocol was approved by the Ethics Committee of Zhongshan City People's Hospital in December 2022 (approval K2022-285). All recruited patients will be required to give written informed consent. Any subsequent amendments to the protocol will be submitted for further review and approval. Study findings will be disseminated through peer-reviewed publications and conference presentations.

Results

The enrollment of study participants started in December 2023 and is expected to end in March 2025. An interim analysis is planned to assess the feasibility and preliminary effects of the intervention. The final comprehensive analysis of the results is planned for May 2025, after all data have been collected and thoroughly reviewed.

Discussion

Conclusions

This study primarily investigates the impact of outpatient symptom management on exercise adherence after minimally invasive lung surgery. Remote symptom monitoring based on ePROs provides an innovative approach to improve patient self-management and rehabilitation compliance. While previous digital interventions have focused on education and coaching, this study explores a new precision rehabilitation model that actively monitors patient-reported symptoms and provides timely medical feedback. Although symptom-related exercise interruptions may occur in both groups, the ePRO-based interventions are designed to help manage symptoms and provide personalized exercise guidance, which may potentially mitigate the impact of symptoms on exercise adherence.

Potential findings from this preliminary study include (1) providing initial evidence on whether ePRO-based remote symptom management can improve outpatient exercise adherence, which has been a neglected area in previous research; (2) demonstrating the feasibility and acceptability of implementing such a personalized symptom-exercise comanagement model in local patients; and (3) exploring its potential to reduce patient symptom burden and postoperative complications. The findings from this study will provide valuable insights into the barriers and facilitators of implementing ePRO-based symptom management in real-world settings, informing future efforts to expand and optimize outpatient care for postoperative patients. The planned analyses will also help elucidate the complex relationships between symptom alerts, symptom management, and exercise adherence in this context. Understanding these relationships is crucial for optimizing the design and implementation of integrated symptom-exercise management interventions for postoperative patients. If the findings support the feasibility and potential effectiveness of this innovative rehabilitation approach, it could inform future larger-scale studies and efforts to improve postoperative care for a broader patient population. The research framework and findings will contribute to advancing telehealth for patient-centered and digitally enabled care models.

Limitations

This study also has some limitations. First, the single-center design may limit generalizability. Second, the strict inclusion or exclusion criteria may restrict the eligible population, such as excluding patients unable to use smartphones or with poorer reading comprehension. Third, the eligibility criteria may cause selection bias and limit external validity, although stringent criteria and verification of exercise data are adopted. Further pragmatic trials in more heterogeneous populations are warranted to validate broader generalizability and effectiveness. Fourth, the lack of blinding for researchers and participants may introduce bias into the results. Fifth, the short follow-up precludes evaluation of potential long-term impacts on exercise habits.

In summary, this unblinded randomized controlled trial aims primarily to provide preliminary evidence on the effects of ePRO-based symptom management on outpatient exercise behaviors, evaluating the feasibility of this management approach. Larger studies in real-world diverse populations are needed to further validate its generalizability and effectiveness.

Acknowledgments

The authors acknowledge the efforts and software support of the Shanghai CinoCore Medical Technology Co., Ltd, especially thanks to Mr. Kaishen Chen, Ms. Jing Gao, Mr. Kun Wang, and Mr. Qi Yang. This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

Data Availability

The data sets generated during and/or analyzed during this study are available in the ClinicalTrials.gov repository. The protocol will be published on an open-access repository.

Authors' Contributions

All authors contributed to the design of this protocol. XY and JS initiated the project. XY drafted the protocol and will be responsible for manuscript preparation. JS, YL, and CY contributed to the study design and methodology and will provide critical revision of the manuscript. QZ was involved in the statistical design and will be responsible for data management and analysis. WJ, GL, and YC will contribute to research coordination, ongoing patient enrollment, outpatient research follow-ups, and data collection. All authors have read, refined, and approved the final manuscript.

Conflicts of Interest

Abstract

Background: Young patients aged 16 to 25 years with type 1 diabetes (T1D) often encounter challenges related to deteriorating disease control and accelerated complications. Mobile apps have shown promise in enhancing self-care among youth with diabetes. However, inconsistent findings suggest that further evidence is necessary to confirm the effectiveness of app-based interventions.

Objective: This study aims to evaluate the effectiveness of the Healthcare CEO app in patients with T1D transitioning from adolescence to early adulthood.

Methods: A 2 arms, double-blind, randomized controlled trial will be conducted over a 9-month period, with strategies designed to enhance treatment fidelity. The study expects to enroll 96 patients with T1D, aged 16 to 25 years. Participants will be randomly assigned to either the experimental or control group through central randomization. The intervention will be implemented using the Healthcare CEO app, which consists of 11 interfaces. The research will compare differences in disease control outcomes, confidence in self-management, self-care behaviors, emotional distress, quality of life, and specific diabetes-related knowledge between the 2 groups at baseline and 3, 6, and 9 months after intervention. Additionally, changes within the experimental group will be analyzed before and after the intervention.

Results: The study was funded in August 2020. It was originally scheduled from August 2020 to July 2022 but was interrupted by the COVID-19 pandemic after enrolling 38 participants, with preliminary results anticipated for publication by November 2024. Recruitment resumed in August 2023, with findings expected to be finalized by July 2025.

Conclusions: The Healthcare CEO app is a comprehensive solution tailored specifically for individuals with T1D transitioning from adolescence to early adulthood. This innovative app has the potential to improve the quality of care for adolescents with T1D during this critical stage and may serve as valuable evidence in support of app-based intervention strategies.

Introduction

Overview

Type 1 diabetes (T1D) is the most common type of diabetes among youth younger than 18 years [1]. The incidence of T1D has exhibited a decline in the 0-9 years age group and an increasing trend in the 10-14 years age group [2,3]. Notably, T1D accounts for approximately 0.59% of all diabetes cases in Taiwan, and its incidence in patients aged 19 years or younger is 5.17 out of 100,000 while its prevalence is 0.05%. The prevalence and incidence of T1D in patients aged 19 years or younger increased significantly from 2005 to 2014 [4]. With this increase, the demand for care during the transition phase between adolescence and early adulthood is also expected to increase [5]. Therefore, understanding the life experiences and health care needs of adolescents with T1D in this transition phase and comprehending the customization of interventions to meet these needs is crucial in T1D care.

Background

Encounters and Challenges of Patients With T1D in the Transition Phase From Adolescence to Early Adulthood

A transition phase is when an individual encounters significant life events or environmental changes. It is fraught with uncertainty and requires adaptation by learning new skills and strategies [6]. In nursing, the antecedents of the transition process are transition events that can be classified into 4 categories: developmental, situational, health‐illness, and organizational transitions [6]. Moreover, providing nursing support to patients in transition may contribute to role mastery and maintenance of physical and emotional well-being [7].

The encounters and challenges of patients with T1D transitioning from adolescence to early adulthood are wide-ranging and possess unique characteristics. The developmental transition from adolescence to early adulthood is often characterized by a rapid increase in height and body weight, as well as dramatic hormonal changes. Therefore, individuals with T1D in this transition commonly face the physiological challenge of maintaining stable blood glucose levels [5,8] and are at a high risk of poor disease control [9,10]. A study of individuals registered in the T1D Exchange Clinic Registry (a large-scale registry of patients with T1D in the United States) revealed that the mean hemoglobin A_{1c} (HbA_{1c}) level in 18- to 25-year-olds was 8.7% (SD 1.9%) [11], which is higher than the average. The inability to achieve optimum blood glucose control is one of the greatest stressors faced by patients with T1D and may even cause anticipatory nervousness, which in turn affects sleep quality [12]. Other key stressors include the quest for independence, the burden of disease-related self-care, and the implementation of disease self-management [13,14]. Challenges faced by young patients with T1D in situational transition include the deconstruction of peer relationships caused by education system transition, establishment of sexual relationships, worries regarding the health and genetic inheritance of offspring, and reconstruction of physician-patient relationships due to workplace changes or home relocation [13,15,16]. During health-illness transition, especially from late adolescence to early adulthood, patients often become hospitalized owing to acute complications such as ketoacidosis and hypoglycemia. The need for frequent blood glucose monitoring and the transition from hospitalization to discharge often causes disruptions to life routines [5,16,17]. Young patients with T1D often experience an organizational transition, from family-centered care to patient-centered care, at 16-25 years [18,19]. Difficulties faced during this transition period often include the lack of a comprehensive transition-phase care plan that meets patient requirements, negative health care–seeking experiences in adult care systems, termination of health insurance, and loss to follow-up [10,20,21]. In Taiwan, the pediatric care model is adopted for most patients with T1D transitioning from adolescence to early adulthood. Many patients consider the transition from pediatric to adult care unnecessary owing to trust in physician-patient relationships and the familiarity of medical environments. Moreover, approximately 25% of patients reported that physicians should engage in active discussions with patients and provide assistance for referrals to adult care [5].

Needs and Effectiveness of App-Based Interventions Among Patients With T1D in the Transition Phase From Adolescence to Early Adulthood

Support from health care providers and primary caregivers is crucial for patients with T1D in the transition phase [14,22]. Patients with T1D, their primary caregivers, and health care providers agree that the provision of technology-based care and the development of specific apps for T1D self-management are important health care needs that should be addressed [23,24]. Studies have shown that diabetes-related knowledge, diabetes-specific and general life stress, and emotional disorders can affect self-care behaviors, disease management effectiveness, and HbA_{1c} control among patients in the transition phase [25-28], with higher severity of emotional distress

associated with poorer HbA_{1c} control and quality of life (QoL) [29,30]. Therefore, app-based intervention measures should aim to address these factors.

Among the studies on the use of app-based interventions for youth with T1D or those in the transition phase, Goyal et al [31] and Veazie et al [32] reported that app-based interventions improved HbA_{1c} levels. Additionally, Frøisland et al [33] found that app-based interventions resulted in a better understanding of disease-related knowledge, whereas app usage seemed to positively affect diabetes self-care. However, some longitudinal studies have revealed that app interventions had no significant effects on HbA_{1c} levels [34,35], frequency of hypoglycemic events [31], diabetes-related QoL [31,34], self-perceived diabetes management ability, and diabetes-related emotional distress [35]. Although young patients with T1D generally provide positive ratings for the usability and feasibility of user-centered apps [35,36], these inconsistent results indicate that further evidence is necessary to support the effectiveness of app-based interventions.

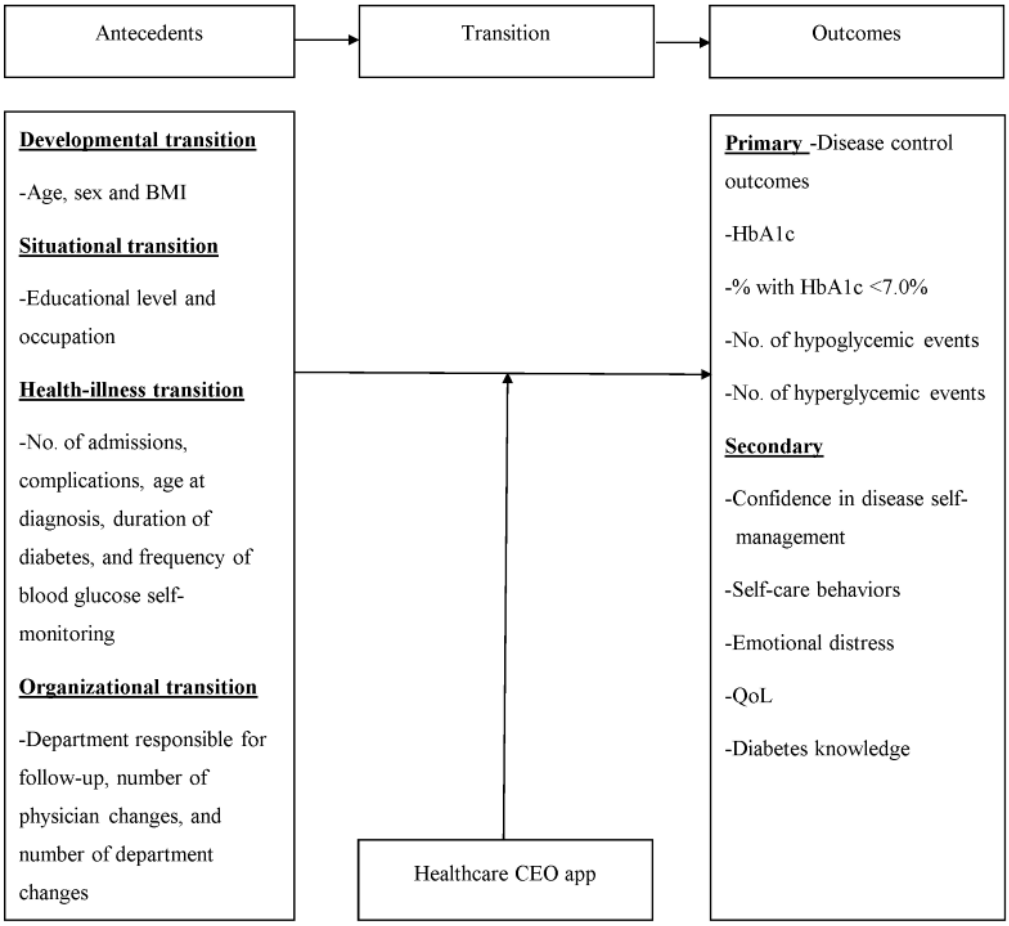
Knowledge Gaps

Currently, the available apps for diabetes management can be broadly classified into 5 categories: nutrition, physical activity, blood glucose monitoring, insulin titration, and insulin injection. Most apps merely possess a single function, although there is an increasing trend toward integration [37]. Additionally, the majority of Chinese-language apps provide general diabetes knowledge, which may not be applicable to adolescents or young adults, and do not cater to the specific needs of patients with T1D in the transition phase [5]. Furthermore, the effectiveness of such apps should be validated by long-term empirical evidence [24,38], and few studies have mentioned the adoption of strategies to enhance treatment fidelity [31,35]. Health apps developed for intervention should incorporate evidence-based content while fulfilling the needs and protecting the privacy of the target age groups to enhance effective disease self-management [39]. To address the specific needs of patients in the transition phase, we developed the Healthcare CEO app using a user-centered approach. This app targets challenges such as poor glycemic control; pressures related to self-care; effective disease self-management; and interpersonal issues, including the establishment of romantic relationships, concerns about the health and heredity of future generations, workplace adaptation, parent-child conflicts, and enhancing QoL. This study aims to present a comprehensive protocol for evaluating the efficacy of the Healthcare CEO app. This will involve a series of detailed analyses, including (1) comparing disease control outcomes, confidence in self-management, self-care behaviors, emotional distress, and QoL between the experimental and control groups, and (2) a comparison of differences in preintervention and postintervention disease control outcomes, confidence in self-management, self-care behaviors, emotional distress, and QoL in the experimental group.

Conceptual Framework of the Study

Based on the literature described above, the transition phase theory was used as the framework of this study [6,40]. According to the transition phase theory, antecedents that trigger transition can be classified into 4 categories: developmental, situational, health illness, and organizational transitions. The Healthcare CEO app will be used as an intervention measure for patients with T1D transitioning from adolescence to early adulthood, and the effectiveness of the intervention in improving disease control outcomes, confidence in disease self-management, self-care behaviors, emotional distress, and QoL will be investigated, as shown in Figure 1.

Figure 1. Conceptual framework of the study. HbA_{1c}: hemoglobin A_{1c}; QoL: quality of life.



Methods

Design

A 9-month, 2-arm, parallel-group, double-blind, randomized controlled trial will be conducted. Participants will be randomly assigned to the experimental or control groups, and treatment fidelity monitoring strategies will be adopted to enhance the consistency and fidelity of intervention measures.

Participants

Inclusion and Exclusion Criteria

Participants will be enrolled from the outpatient clinic and wards of the Department of Pediatric Endocrinology and Metabolism, at a medical center in Northern Taiwan. The inclusion criteria are as follows: (1) a confirmed diagnosis of T1D from an endocrinologist before the age of 16 years and a disease duration of >6 months; (2) aged 16-25 years; (3) mean HbA_{1c} level ≥7.5% one year before inclusion; (4) ability to communicate in Chinese or Mandarin; (5) owning a smartphone with internet access; (6) agreeing to voice recording while explaining the treatment process; and (7) signing the informed consent sheet prior to participation—for minors, a legal representative must provide consent and sign the informed consent sheet. Patients with T1D with concomitant metabolic diseases, chromosomal aberrations, major illnesses, and cognitive impairment will be excluded from the study because their health care needs during the transition phase may differ from those who experience T1D only.

Sample Size

The required sample size was estimated using the G*Power program (Heinrich-Heine-Universität Düsseldorf) for repeated measures with 2 groups, 9 measured variables, power of 0.80, α set at .05, an estimated Cohen effect size of 0.25, and a correlation coefficient of 0.5. The sample size for each group was calculated as 36. By allowing for a potential 25% dropout rate, as suggested by Goyal et al [31], a final sample size of 96 participants (48 participants in each group) was established.

Sample Accessibility

The cumulative number of patients in the transition phase, aged 16-25 years, at the study site is expected to exceed 300. For each enrolled participant, the study explanation and data collection process is expected to last approximately 1 hour. Based on our research team's qualitative research experience, the on-site interview length for each participant was 1-1.5 hour, whereas the refusal rate is expected to be approximately 10%. Therefore, each week, approximately 8 patients who fulfill the inclusion criteria will participate in the study. Thus, the number of valid samples expected each month is roughly 28-32.

Randomization and Blinding

Randomization of the participants will be performed by a statistician, using the central randomization method in SPSS (IBM Corp). During participant enrollment, participants will

be randomly assigned to the experimental or control groups in accordance with the instructions provided on the phone by the statistician; the participants and data collectors will be blinded to allocation. Blinding strategies include the following. First, the statistician will not be allowed to disclose the randomization results to others. Second, once a physician referral is received, the participant will be promptly taken to a private room. The data collection assistant will complete their duties and leave the room, and then 2 research assistants will come in and take over to administer the intervention phase. Third, participants of both the experimental and control groups will download the app, but the app content will differ. Fourth, to avoid differential demand characteristics, research assistants will emphasize to all participants that app usage is potentially beneficial for disease management.

Description of the Intervention

Overview

The Healthcare CEO app was developed guided by the user-centered information systems research framework and comprised 3 key cycles: Relevance, Rigor, and Design [41]. It was named after the self-expectations of patients in diabetes management, as patients with T1D often wished to become the "Chief Executive Officers" of their disease. The development and testing process of the Healthcare CEO app is detailed in published articles [42]. The app content was designed based on the results of previous qualitative and Delphi studies [5,23] and consisted of 11 interfaces (as shown in Figure 2): CEO's Profile; Health Tracking; CEO Knowledge Base; Barrier-free Communication; See Here: Diet and Exercise; Help Me, Detective!; CEO Chat Room; CEO's Secretary; Who's the Best CEO; SOS Calls; and Q&A. The evidence-based content aims to enhance disease knowledge among individuals in the transitional phase, improve self-care behaviors, and bolster confidence in disease self-management. These were combined with interpersonal communication skills training, to alleviate disease-related emotional distress, ultimately improving disease control outcomes and QoL. The content, objectives, and expected outcomes of each interface are detailed in Table 1.

Figure 2. Interfaces of the Healthcare CEO app. CEO: chief executive officer.

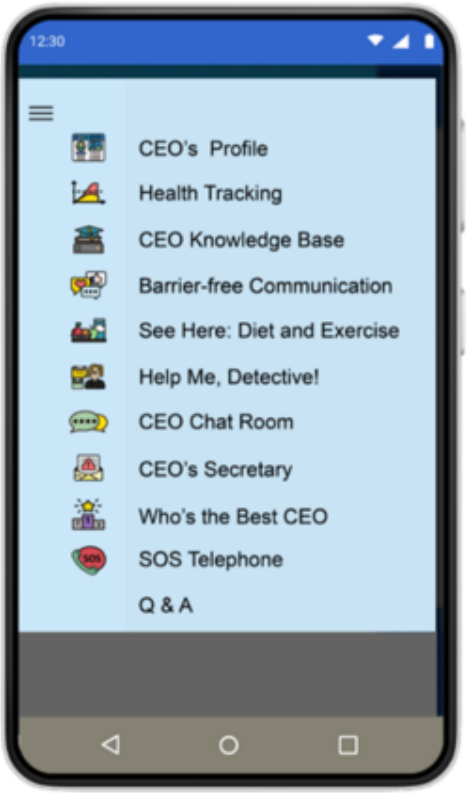


Table 1. Content of Healthcare CEO app.

Interface	Description of content	Purposes and expected outcomes
CEO's Profile	Personal and disease data, including the following: name, nickname, date of birth, occupation, duration of disease, hospital, and attending physician. The patient can select the data to be openly displayed.	1. Establish basic data 2. Review and confirm basic disease information through data entry
Health Tracking	Upload or enter data on blood glucose level, blood pressure, body weight, and insulin dosage. HbA_{1c}[a] targets can be set, and changes in HbA_{1c} can be analyzed and displayed as trends.	1. The status of HbA_{1c} control can be checked to enhance self-care motivation and confidence in disease self-management
CEO Knowledge Base	Basic and advanced knowledge of interest to patients with T1D[b] in the transition phase is provided in the e-book format. Examples of basic knowledge include the following: impact of secondary sex characteristic development on blood glucose; blood glucose control targets in T1D; and tips for dieting, exercise, and travel during puberty. Examples of advanced knowledge are as follows: matters related to sex, genetics, gestation, and employment among patients with T1D. Both a pretest and posttest must be completed to determine the learning effectiveness of each article before the next article can be accessed.	1. Patients can enhance T1D-related knowledge on a need basis 2. Patients can boost their confidence in disease management by accumulating disease-related knowledge. This will enhance self-care behaviors, disease control outcomes, and disease-related QoLc
Barrier-free Communication	Guidance for techniques in parent-child, peer, and workplace interactions is provided through video and e-book links. Questions and scenarios are designed to prompt patients to reflect on their communication methods and think about/enact their strategies for effective interaction.	1. Improve communication skills, enhance ability to deal with interpersonal difficulties, and reduce emotional distress
See Here: Diet and Exercise	Carbohydrate and calorie calculators and a food swap guide are provided. The calorie contents of preferred foods and calories burned in preferred exercises of patients in the transition phase are displayed in images. Patients can keep records using the handy checkbox interface or uploading photos.	1. Assist in disease management and self-care, which will in turn improve disease control outcomes and disease-related QoL
Help Me, Detective!	When the blood glucose level is not within the expected range or emergency complications occur, this interface allows for the recording of the time of event occurrence, uploading of blood glucose readings, photographs of the patient's diet, exercise, or patient condition during the event, and documentation of the treatment measures adopted. These data can serve as a reference for discussion with the physician during outpatient visits, and physician advice can be input into the interface to guide the handling of future emergencies.	1. By recording and analyzing the causes of acute complications, the patient may devise improvement measures to enhance disease control, which will gradually enhance confidence in disease self-management and improve disease control outcomes
CEO Chat Room	An optional second password can be set to achieve 2 levels of privacy protection, which may be very important to patients in the transition phase. Two chat rooms named the "insider chat room" and "outsider chat room" have been designed. The insider chat room is reserved for patients using the app, with 2 themed chats organized monthly. Patients may invite individuals whom they trust (eg, attending physicians, close friends, or primary caregivers) and can engage in heart-to-heart talk using the outsider chat room, to develop their interpersonal networks and exchange views and ideas.	1. Provide interpersonal support and enhance disease-related knowledge and management strategies through experience sharing, which will alleviate emotional distress and strengthen disease self-management ability
CEO's Secretary	This consists of 2 functions, namely "Reminders" and "Online consultations." (1) Reminders: When trends of exceedances related to blood glucose occur, such as excessively high postdinner blood glucose level for 3 consecutive days, noninput of health data for ≥3 days, fewer blood glucose measurements than the required number of measurements for 3 days, and on the day before a scheduled outpatient visit, patients and app administrators will receive notifications and text message reminding them to perform relevant tracking actions. Reminders can also be set based on the needs of the patients; (2) Online consultations: The timing and theme of online consultation sessions can be booked in advance. Online consultations involve the clarification of doubts related to disease care through interactions with health care professionals.	1. Assist in disease management and provide individualized knowledge to enhance disease-related knowledge and confidence in self-care, thereby alleviating emotional distress and improving disease-related QoL 2. Conditions for reminders can be set to reduce annoying reminders, to prevent resentment of app use

Interface	Description of content	Purposes and expected outcomes
Who's the Best CEO	One point is awarded every time the user performs data input on time, reads an article, devises a communication technique, and correctly enters data into the Help Me, Detective! interface, or enquires about online consultation. Ten points are awarded when the target HbA_{1c} level is reached. The patients with the highest number of points are listed weekly. At the end of each month in our study, the top 3 patients with the highest number of points will each receive an NT $300 (approximately US $9.24) voucher. Moreover, at the end of the study, the top 3 patients with the highest number of points will receive an NT $1000 (approximately US $30.79) voucher.	1. Enhance motivation and effort in self-care
SOS calls	Patients can set up 3 contact numbers to call for help quickly when necessary.	1. Assist in disease management and self-care, thereby improving disease control outcomes
Q&A	Patients who may be unaccustomed to asking questions in the chat room can have their queries answered via the provided email account.	1. Assist in disease management and self-care to improve outcomes

[a]HbA_{1c}: hemoglobin A_{1c}.

[b]T1D: type 1 diabetes.

[c]QoL: quality of life.

Experimental App Intervention

The complete Healthcare CEO app will be used to intervene in the experimental group. Two trained research assistants will supervise each other to guide the participants in the following aspects, according to the standard treatment manual: (1) account setup; (2) viewing of operation guidance videos; (3) demonstration of all app functions, getting participants to perform app operations, and clarifying doubts about app usage; (4) explaining troubleshooting methods; (5) providing contact information of app administrators; and (6) setting a HbA_{1c} control target. Between every 2 rounds of data collection, the research assistants will contact the participants to check if they have encountered issues or difficulties when using the app, although they will not exchange disease care-related information. After the completion of data collection, the app will be remotely uninstalled by the administrators at the backend.

Control App Intervention

Participants in the control group will only install the "CEO's Profile" and "Health Tracking" interfaces of the Healthcare CEO app. In addition to explanations for the account setup and the use of the 2 interfaces, the research assistants will not provide any app-related information to the control participants. The status and difficulties of app use will also not be tracked. After the last round of data collection, the full version of the Healthcare CEO app will be provided to the control group participants, according to their preferences. The app will be remotely uninstalled at the backend by the administrators after 9 months.

Measures

Overview

All survey questionnaires will be accessed via QR codes and answered online, with all fields set as mandatory to prevent nonresponses. The tools to be used in this study are as follows.

Demographic Questionnaire

This self-designed questionnaire has been developed based on the conceptual framework of this study. It includes questions on age, sex, BMI, educational level, occupation, number of hospital stays, complications, age at diagnosis, duration of diabetes, frequency of blood glucose self-monitoring, department responsible for follow-up, number of physician changes, and number of department changes.

Primary Outcomes

These include HbA_{1c} levels, percentage with HbA_{1c} <7.0%, and the number of hyperglycemic and hypoglycemic events.

HbA1c

HbA_{1c} will be recorded as a percentage; data will be obtained through venous blood analysis.

Percentage With HbA1c <7.0%

The percentage of HbA_{1c} readings below 7.0% for each participant will be calculated.

Hyperglycemic Events

The number of events with blood glucose >200 mg/dL or "high" on the glucometer or diagnosed ketoacidosis will be calculated for each participant.

Hypoglycemic Events

The number of events with blood glucose <60 mg/dL or "low" on glucometer or diagnosed hypoglycemia will be calculated for each participant.

For hyperglycemic and hypoglycemic events, during the data collection period, the blood glucose readings will be downloaded from the blood glucose meters of the participants, and the number of hyperglycemic and hypoglycemic events will be calculated. Considering that changes in blood glucose levels may be tracked only after adopting treatment measures, 2 researchers will perform a manual inspection of the data simultaneously. Only the first recorded reading, among all

readings taken within the same measurement period, will be analyzed.

Secondary Outcomes

Perceived Diabetes Self-Management Scale

The original questionnaire was developed by Wallston et al [43]. It consists of 8 items scored on a 5-point Likert scale ranging from 1 (strongly disagree) to 5 (strongly agree), of which items 1, 2, 6, and 7 are reverse scored. The total score ranges from 8 to 40, with higher scores indicating higher confidence in diabetes self-management. Lin et al [44] translated the scale into Chinese to assess 168 patients with T1D and type 2 diabetes (T2D). The translated questionnaire has content validity, Cronbach α, and test-retest reliability values of 0.75, 0.93, and 0.97, respectively.

Self-Care Behavior Assessment Scale

This scale was originally developed in Chinese by Wang [45] to measure self-care behaviors of adolescents with T1D. It comprises 7 dimensions: pharmacological treatment–insulin injections; healthy diet–diet control; blood glucose monitoring–self-monitoring; physical activity and exercise–regular exercise; problem-solving–risk reduction; healthy coping–psychological and social adaptation; and stress adaptation. A total of 39 items are scored on a 5-point Likert scale ranging from 1 (not achieved at all) to 5 (completely achieved), of which items 26 to 35 are reverse scored. The total score ranges from 39 to 195, with higher scores indicating better self-care behaviors. Cronbach α and the content validity value are 0.87 and 0.92, respectively.

Diabetes Distress Scale

The original scale was developed by Polonsky et al [46]. The Chinese version consists of 17 items across 4 subscales: emotional burden, physician-related distress, regimen-related distress, and diabetes-related interpersonal distress. Items are scored on a 4-point Likert scale ranging from 1 (no distress) to 4 (severely distressed), with higher scores indicating more severe emotional distress. Cronbach α and test-retest reliability values of the Diabetes Distress Scale are 0.89 and 0.81, respectively [47].

Diabetes Quality of Life

The original scale was developed for use in the Diabetes Control and Complications Trial and translated into Chinese by Cheng et al [48]. The Chinese version consists of 42 items with the following subscales: satisfaction, impact, and diabetes-related worry. Each item is scored on a 5-point Likert scale, with 1 and 5 representing “very dissatisfied” and “very satisfied” in the satisfaction subscale, “never” and “always” in the impact subscale, and “never worried” and “always worried” in the diabetes-related worry subscale, respectively. Higher scores are indicative of a higher QoL. The Cronbach α and test-retest reliability values of the scale and subscales are within the ranges of 0.76-0.92 and 0.94-0.99, respectively.

Diabetes Knowledge Questionnaire

The original questionnaire was developed by Garcia et al [49]. The Chinese version comprises 24 items that are answered “Yes,” “No,” or “I don’t know”; 1 point is awarded for each correct answer. The total score ranges from 0 to 24 points, with higher scores indicating more excellent knowledge of diabetes. In a study that adopted the 24-item Diabetes Knowledge Questionnaire (DKQ) for assessing 108 patients with T2D, the results indicated reliability and Cronbach α values of 0.78 and 0.89, respectively [50]. Currently, the DKQ is used chiefly for patients with T2D. However, when we sequentially inspected all items of the DKQ to determine its applicability to patients with T1D, it was found that the correct answer for Item 6, “If I am diabetic, my children have a higher chance of being diabetic,” needs to be changed to “No,” and for Item 13, “Medication is more important than diet and exercise to control my diabetes,” needs to be changed to “Yes.” In contrast, the remaining items and answers remain applicable to patients with T1D and are considered essential knowledge among such patients. Therefore, the DKQ will be used in this study following the above-mentioned modifications.

App Use Data

During the data collection period, the administrators will also download app-use data at the backend. Such data include log-ins to the Healthcare CEO app, the number of e-books read in the CEO Knowledge Base, the number of online consultations with the CEO’s Secretary, and the content of the chats in the CEO Chat Rooms.

Data Collection

Three research assistants with a background in health care, who have a basic understanding of T1D, have undergone training, and are not involved in the provision of health care, will be responsible for the data collection. Attending physicians of patients with T1D will provide referrals of patients who meet the inclusion criteria. One research assistant in charge of data collection will then approach the patients to explain the purposes of the study and the research process. Patients who agree to participate will subsequently fill out the informed consent sheet and undergo the preintervention test (T0) in an undisturbed environment. The second research assistant will obtain the randomization results from the statistician by phone and assist participants in downloading the Healthcare CEO app onto their smartphones based on their group assignment. The third research assistant will check and remind the second research assistant of the intervention steps to ensure the accuracy and completeness of the intervention. Considering that HbA_{1c}, the critical indicator of blood glucose control, is measured once every 3 months, the time points for the postintervention data collection for both groups are set at 3 months (T1), 6 months (T2), and 9 months (T3) after the intervention.

Treatment Fidelity

Overview

To monitor the faithfulness and fidelity of the intervention process and enhance intervention effectiveness evaluation, we formulated strategies for the inspection of treatment fidelity in the 5 areas proposed by Bellg et al [51] at the National Institution of Health Behavior Change Consortium.

Treatment Design

A standard treatment manual was formulated to explain the purpose of the study, the processes, and the details. Standardized interaction content of the interventions was established.

Training Provider

Research assistants received 16 hours of standardized training in accordance with the roles they will serve in the study. The standard training sessions attended by all research assistants included treatment of patients with T1D in the transition phase, research ethics, and 2 observational visits to the outpatient clinic for familiarization with the study settings. Individual training sessions included data collection techniques or the development, methods of use, and troubleshooting of the Healthcare CEO app. In addition, during the data collection process for the first 10 participants, the research assistants will be accompanied by senior researchers to confirm their techniques and abilities in participant inclusion and ensure faithfulness in the implementation of the intervention measures, and strategies for improvement will be provided after observation.

Delivery of Treatment

An intervention step checklist has been formulated and will be provided to research assistants for the sequential inspection and confirmation of the level of completion and completeness of the intervention measures. Another assistant will inspect the fidelity and faithfulness of the intervention process using an intervention process checklist and perform voice recordings of the entire treatment process for researchers to conduct random analyses, evaluations, and feedback.

Receipt of Treatment

Participants will be asked to perform operations in the app and discuss and clarify any doubts that they may have. An intervention content checklist will be provided to the participants after the completion of the intervention to confirm that they have received the complete intervention and determine their level of understanding and app use abilities.

Enactment of Treatment Skill

To ensure that participants are capable of using the app in everyday life, the following will be carried out: weekly monitoring of the frequency of app content usage and the level to which app usage has been correctly completed, documenting usage issues and suggestions highlighted by participants during routine telephone follow-up, and downloading and analyzing app use data during each round of data collection.

Data Analysis

Statistical Analysis

The intention-to-treat principle will be used for the data analysis; that is, all participants will be included in their initially assigned groups for analysis, regardless of whether they withdraw from the study for any reason or are lost to follow-up. Data will be analyzed using IBM SPSS 26.0 for Windows, with differences considered statistically significant at $P<.05$. Demographic and disease status data, including age, gender, BMI, age at diagnosis, disease duration, and HbA_{1c}, along with metrics on the app usage to evaluate treatment fidelity, such as the log-ins to the app, frequency of use for each interface, number of e-books read in the CEO Knowledge Base, and number of online consultations in CEO's Secretary, will be presented through descriptive statistics. This will include frequency distributions, percentages, means, SDs, and maximum and minimum scores. Homogeneity in the essential attributes of the 2 groups will be compared and analyzed using inferential statistics, such as the chi-square test and ANOVA. Owing to the longitudinal nature of this study, repeated data measurements will be taken. Dependencies may exist among the data at different time points, and data loss may also occur. Using generalized estimating equation models, repeated measurements can be simultaneously included in the regression analysis. Through the variance correction process, consistent estimates of the regression parameters and their variance can be provided to correct for dependencies, and participants with missing values can still be included in the analysis [52]. Therefore, a generalized estimating equation will be used for data analysis to compare the differences between the experimental and control groups at both preintervention and postintervention time points, as well as the differences in the scores of the experimental group before and after intervention.

Healthcare CEO App Chat Room Data Analysis

Chats in the CEO Chat Rooms will first undergo thematic categorization, beginning with a review of the chat content to gain an initial understanding. Relevant patterns will then be identified and labeled through initial coding, and similar codes will be grouped to form broader themes. These themes will be reviewed and refined for relevance and consistency with the data, and each theme will be clearly defined. Finally, the frequency of each identified theme will be calculated.

Ethical Considerations

The study will follow the Declaration of Helsinki and has received approval from the Ethics Committee of the Chang Gung Foundation Institutional Review Board (submission reference: 202100050B0; March 9, 2021). It will uphold key ethical principles, including informed consent, with participants receiving comprehensive information about the study. For minors, consent will be obtained from a legal guardian simultaneously, and efforts will be made to minimize any undue influence from guardians or family members to guarantee voluntary participation. Participants may withdraw at any time without impacting their medical care. The study prioritizes participant safety through self-reported questionnaires and a mobile app that poses no risks. Justice is maintained by ensuring equal medical care for all participants, with the control group accessing the app after the study. Privacy is protected with data secured in locked storage and coded identifiers used in publications to ensure anonymity. Participants will receive a voucher worth NT $300 (approximately US $9.34) for each completed questionnaire as an appreciation for their time and effort.

Validity and Reliability

The study design and participant enrollment process were formulated in accordance with the recommendations of the CONSORT (Consolidated Standards of Reporting Trials)

statement. We also formulated strategies based on the National Institution of Health Behavior Change Consortium guidelines to monitor the faithfulness and fidelity of the intervention process. The research tools used in this study also exhibit good validity and reliability. In the measurement of the primary outcome variables, this study differs from previous works on diabetes management apps in that "% with HbA_{1c} <7.0%" data will be calculated for the first time for analysis. This allows for greater objectivity and rigor in evaluating the effectiveness of the Healthcare CEO app.

Results

After a comprehensive review, the National Science and Technology Council, Republic of China (MOST 109-2314-B-182-057-MY2), and Chang Gung University (NMRPD1K1021) provided financial support for this research project. The project was initially scheduled to run from August 1, 2020, to July 31, 2022. However, owing to the widespread impact of the COVID-19 pandemic, the study was abruptly halted after the enrollment of 38 participants. Details of the recruitment and randomization processes can be found in the CONSORT flowchart (Figure 3). We anticipate that the preliminary results will be compiled and submitted for publication by November 2024. The recruitment of participants resumed in August 2023, with findings expected to be finalized by July 2025. At present, each experimental and control group includes 13 participants.

Discussion

Principal Findings

The Healthcare CEO app distinguishes itself as one of the few evidence-based, multifunctional integrated apps specifically designed for individuals aged 16-25 years managing T1D. This study uses a double-blind, randomized controlled trial intervention, with anticipated outcomes aimed at enhancing disease knowledge, improving self-care skills, and strengthening self-efficacy in disease management. Additionally, training in effective communication skills is intended to reduce interpersonal and emotional distress, enhance QoL, and ultimately improve glycemic control outcomes. The strengths and limitations of this study are elaborated in the following sections.

Strengths

The 6 major aspects of diabetes self-management are physical activity, nutrition, blood glucose testing, medications or insulin injections, health feedback, and education. However, existing diabetes management apps focus only on 2 to 3 of these aspects on average. App developers should work closely with health care providers and patients to ensure that the developed apps address patients' health care needs [53]. Our app differs from the majority of commercially available apps in that it contains the following distinctive features: (1) the app content has been designed based on a series of empirical studies [5,23,42] to ensure that it fulfills the needs of the users; (2) the app contains diverse content across 11 interfaces instead of being limited to 2 or 3 aspects; (3) the See Here: Diet and Exercise interface allows for easy and convenient recording of carbohydrate and calorie intake and exercise intensity; (4) the CEO Knowledge Base contains specific content targeted at patients in the transition phase, which is divided into basic and advanced knowledge, for perusal on a need basis; (5) themed discussions can be organized in the CEO Chat Rooms interface, during which users can discuss their needs and expert suggestions can be provided; (6) an SOS Calls function is provided for users transitioning from the dependence to independence phases, so that they can seek help from trusted individuals when needed; and (7) a points system, in which points can be exchanged for gift vouchers, is used to reward users for app use. With the above features and added emphasis on enhancing treatment fidelity, we anticipate that our results will indicate high effectiveness in diabetes self-management among patients with T1D in the transition phase due to our app-based intervention.

Limitations

This study design has several limitations. First, the app usage may be limited by an unstable internet connection, which could impact the effectiveness of our app-based intervention. Second, in addition to providing gift vouchers to enhance the motivation and efforts of the participants, we also factored in an allowance during sample size estimation to minimize the effects of participant withdrawals. Third, because of the nature of the study, the researchers cannot be blinded during the study implementation, which may lead to potential biases. To address this issue, researchers must adhere to strict intervention principles to minimize the impact on the study results. Finally, the Healthcare CEO app was developed and will be evaluated based on Taiwanese participants with T1D in the transition phase. Therefore, caution will have to be exercised, and cultural differences will be considered when interpreting the study results.

Conclusions

Patients with T1D transitioning from adolescence to early adulthood are in extreme need of support from health care providers and primary caregivers. The Healthcare CEO app developed in this study differs from current commercially available apps in that the functions desired by transitioning adolescent patients, as indicated by the empirical results obtained from previous qualitative and quantitative studies, have been integrated into the app to the best of our ability. In other words, this app is the first multifunctional app targeted at the needs of patients with T1D in the transition phase from adolescence to early adulthood. Our study protocol consisted of strategies formulated to enhance the treatment accuracy of the intervention measures. Such strategies make it possible to increase the objectivity of intervention effectiveness evaluation. The findings can serve as a reference for further applications to the clinical care of patients in the transition phase.

Acknowledgments

The authors thank all participants and acknowledge funding support from the National Science and Technology Council, Republic of China (MOST 109-2314-B-182-057-MY2), and Chang Gung University (NMRPD1K1021).

Abstract

Background: Podcasts are an unconventional method of disseminating information through audio to the masses. They are an emerging portable technology and a valuable resource that provides unlimited access for promoting health among participants. Podcasts related to health care have been used as a source of medical education, but there is a dearth of studies on the use of podcasts as a source of health information. This study will provide new perspectives by implementing the SANGYAN podcast, which contains information about COVID-19 and other health conditions.

Objective: The study aims to determine the usefulness and effectiveness of the SANGYAN podcast as a digital health intervention to address misinformation related to COVID-19 and other health conditions among individuals in Chennai, Tamil Nadu, India.

Methods: An implementation and evaluation study will be conducted with 500 participants from the Panimalar Medical College Hospital & Research Institute (PMCHRI) and Rural Health Training Centre in Chennai. Among individuals aged 18 years and older, those residing in the selected urban and rural settings who visit the outpatient department of the PMCHRI and Rural Health Training Centre will be recruited. For participants who consent to the study, their sociodemographic details will be noted and their health literacy will be assessed using the Rapid Estimate of Adult Literacy in Medicine scale. Once the participants have listened to the podcast, the usability, acceptance, and user satisfaction of the podcast will be assessed. Descriptive analysis will be used for continuous variables, and frequency analysis will be used for categorical variables. Bivariate analysis will be conducted to understand the correlation of sociodemographic features in response to perception, usefulness, acceptance, and user satisfaction of the podcast. All analysis will be performed using SPSS (version 24), and the results will be reported with 95% CIs and $P<.05$.

Results: As of December 2024, the SANGYAN podcast has been launched for voluntary usage in the PMCHRI.

Conclusions: The finding from this research project will aid in the development and implementation of data-driven, evidence-based, and human-centered behavior change interventions using podcasts to address public health challenges among populations living in diverse settings. This would also help in enhancing the acceptability of podcasts as a source of health-related information.

KEYWORDS

podcast; human-centered behavior; pandemic; coronavirus; intervention; digital health; usefulness; effectiveness; usability

Introduction

Background

The term "podcast," coined in 2004, is derived from the terms iPod and broadcast. It was chosen as the word of the year by the New Oxford American Dictionary in 2005 [1,2]. It is an unconventional means of distributing information to the general public via audio. Podcasting is a relatively new portable technology. It has established itself as a reliable channel for knowledge and information exchange. Podcasts are classified under Web 2.0 tools among other tools such as wikis and blogs, which comprise the latest generation of web-based collaboration [3]. Technology-enabled approaches to managing lifestyle have begun to emerge with the increased development and use of electronic media. Public health practitioners are now using mobile health technology to deliver health-related interventions [4]. However, there are hurdles to offering web-based interventions since they often need research participants to have a mobile phone, a certain level of education, and the capability of properly comprehending textual material [5]. The development of audio or video material for an audience that wants to listen to what they want, when they want, where they want, and how they want is the heart of podcasting [6].

India has reported a significant shift in the number of podcast users over the years. A report states that India holds the third-largest podcast user population after China and the United States, with over 57.6 million users [7]. Podcasting is becoming increasingly popular due to its ability to communicate health-related data and information for educational reasons [3]. Podcasting represents a largely untapped conduit for promoting health information to the general public with internet access and those who are not comfortable seeking face-to-face knowledge, treatment, and guidance. The COVID-19 pandemic played a significant role in increasing the consumption of podcasts by 29.3% in India [8]. Podcast use in entertainment, lifestyle, health, society, and culture is widespread according to a Spotify report. While in regard to health care [9-11], podcasts in India have seen increasing use in medical education and training, but not in other aspects of health care [12]. There is a dearth of research showing the use of podcasts to address misinformation, especially in an Indian context. A medium like a podcast provides screen-free alternatives even during the COVID-19 pandemic's restrictive environment. Podcasts are becoming increasingly popular among the younger population as a source of entertainment, self-improvement, and awareness.

Why Use a "Podcast" to Deliver Public Health Intervention?

According to user control theory, allowing flexibility boosts learning as compared to traditional instruction such as print. Podcasting may be more effective than the web because such a platform can decrease cognitive load [13]. Podcasts can encourage users' positive knowledge, attitude, and practice by allowing them to listen to the podcast anywhere, anytime. Podcasts promote knowledge dissemination by allowing podcast channel owners to communicate knowledge even when movement is restricted (eg, during a pandemic). The most prominent reason for the podcast boom is the connection between the host and listener. Podcast technology is a valuable resource that provides unlimited access for promoting health among participants. It also plays a significant role in public health and global health, where challenging and critical situations demand simple, effective, and concise information delivery. Numerous studies have examined the acceptability or feasibility of this modality for learning; however, limited studies have focused on podcast use for knowledge sharing [14]. Also, journals such as The *New England Journal of Medicine* [13] and *Lancet* [15] currently use podcasts to support medical and nonmedical information dissemination.

Need for the Study

The COVID-19 pandemic has shown that misinformation spread via social media and other digital platforms is a more significant threat to global public health than the virus itself [16]. Studies show that female individuals are more likely to accept misinformation than male individuals. A higher education level also decreases the possibility of accepting misinformation. Thus, older people with a higher level of education are less likely to accept misinformation [17,18].

This research will provide new perspectives through implementing the SANGYAN podcast, which contains information about the COVID-19 pandemic and other health conditions. The research project's findings will directly benefit individuals and researchers in developing tailored intervention models aimed at addressing misinformation.

Study Objectives

The study aims to determine the usefulness and effectiveness of the SANGYAN podcast as a digital health intervention to address misinformation related to COVID-19 and other health conditions among individuals in Chennai, Tamil Nadu, India.

Methods

Study Design and Population

An implementation and evaluation study will be conducted at the outpatient department of the Panimalar Medical College Hospital & Research Institute (PMCHRI) and Rural Health Training Center (RHTC) in Chennai. The participants will be recruited through convenience sampling in a paper-based format, by the researchers or trained data collection team from the RHTC and PMCHRI. A total of 500 individuals (250 each from the PMCHRI and RHTC) will be enrolled for the study. The data will be collected at a single time point by administering the study questionnaire to the eligible study participants. For participants who consent to the study, their sociodemographic details will be noted and their health literacy will be assessed

using the Rapid Estimate of Adult Literacy in Medicine (REALM) scale. Once the participants have listened to the podcast, the usability, acceptance, and user satisfaction will be assessed.

The eligible study participants will comprise individuals (1) aged 18 years and older, (2) residing in the selected urban and rural settings who visit the outpatient department of the PMCHRI and RHTC, and (3) consenting to participate in the study. Individuals with any mental or physical challenges that might affect their ability to participate in the study will be excluded.

Variable Assessment

Sociodemographic Profile

Sociodemographic data will be gathered, including participants' age, gender, income level, education level, employment status, occupation, region of residence, marital status, parenthood, and religion.

Health Literacy

The REALM scale is one of the most widely used tools to measure health literacy. Statistically, the REALM scale appears to provide a highly reliable data [19]. The study will use this scale as a screening instrument to assess an adult patient's ability to read common medical words. It is designed to assist medical professionals in identifying patients with poor literacy skills [20].

Use of Podcast or Other Mediums for Health Information

This measure will help us gather data on prior use of podcasts or other sources by participants to gather health data.

Usability

A Likert-scale System Usability Scale (SUS) survey will assess user acceptance. The SUS is a 10-item questionnaire with 5 response options, ranging from strong agreement to strong disagreement on a scale of 0 to 4, for each question. The total score will be calculated by adding the converted responses for each user and multiplying that total by 2.5. This will restore the range of possible values to 0-100 instead of 0-40 [21].

Client Satisfaction Questionnaire-8

The Client Satisfaction Questionnaire-8 (CSQ-8) is an 8-item measure of client satisfaction with services. The items for the CSQ-8 were selected on the following basis: ratings on information seeking by participants for a number of items that could be related to client satisfaction and a subsequent factor analysis. The CSQ-8 is unidimensional, yielding a homogenous estimate of general satisfaction with services [22].

SANGYAN Podcast

The SANGYAN podcast comprises audio content that will be delivered over a network via a free subscription.

The steps for developing the SANGYAN podcast are as follows: (1) file production, (2) podcast publication, (3) podcast delivery, and (4) podcast playback. File production involves planning, writing, recording and editing content, and file compression. Recording requires hardware like a recording microphone, and editing requires software like Audacity (The Audacity Team) and Premiere Adobe Pro (Adobe). The feed would be a simple XML file that lists the location of the podcast's COVID-19 episodes. The meta-tagging will have file information like the producer details, date of publication, title, and description of each episode. The RSS feed then will be posted to the web server of SMAART Rapid Tracker [23]. The podcast is hosted by the Foundation of Healthcare Technologies Society with a team of researchers that curate evidence-based content. Listeners will be able to subscribe, access, and download the podcast file.

Data Collection, Data Entry, and Quality Assurance

Data will be collected using a structured questionnaire. The questionnaire will be presented to the participants in the local Indian dialects to help increase the usefulness and generalizability of the study data. Data collection and data entry will be performed by a team of data collectors and data management personnel. To ensure efficiency and high-quality data collection and processing, the following data management protocol is in place: a clearly defined study manual, a well-trained team of data collectors, weekly meetings with the research team, weekly data checks, maintenance of study participants contacts, and data instrument logs.

Expected Outcomes

The proposed research study will help explore the usability and acceptability of a health-related podcast. Further, it will help evaluate the SANGYAN podcast's usability as well as satisfaction toward information delivery through a podcast. The results of the study will help design and develop a podcast platform that can deliver health educational information to facilitate podcast acceptance in varied settings. The expected study outcomes include the acceptability of using a digital health podcast to obtain tailored and evidence-based health information related to COVID-19 and other health conditions.

Data Analysis Plan

The gathered data will be presented in tables comprising the recorded characteristics of all variables. These tables will serve the purpose of data quality control to find inconsistencies in the data patterns and outliers or any missing data. Descriptive analysis will be conducted to report the means and SDs of the continuous variables (such as SUS scores), and frequency analysis will be conducted for the categorical variables (such as CSQ-8 scores and data on the use of podcasts and other mediums for health information). Bivariate analysis will be conducted to understand the correlation of sociodemographic features in response to perception, usefulness, acceptance, and user satisfaction of the podcast. All analysis will be performed using SPSS (version 24; IBM Corp), and the results will be reported with 95% CIs and $P<.05$.

Project Timeline and Milestones

A detailed study timeline is presented in Table 1.

Table 1. Project timeline and milestones.

Task	Month

Recruitment and training of the data collector team		✓													
Recruitment of the target sample		✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓	✓		
Data analysis														✓	
Results write-up and preparation of the manuscript														✓	
Dissemination														✓	✓

Ethical Considerations

This study (protocol PMCHRI-IHEC-056) gained approval from the PMCHRI Institutional Human Ethics Committee (Central Drugs Standard Control Organization Registration ECR/1399/Inst/TN/2020) in February 2022, with approval PMCH&RI/IHEC/2021/078 (dated February 18, 2022).

The institutional review board–approved informed consent form will be administered by the research team to the eligible individuals for the study. The research team will explain the study, the time commitment necessary, and the advantages of the study results to participants. Those willing to participate and give their consent will be enrolled in the study. Written informed consent will be obtained in both English and local Indian dialects. The data gathered will be stored securely, ensuring data privacy and confidentiality. No compensation will be provided.

Dissemination

The study's findings will be disseminated through peer-reviewed publications and national and international conference presentations. Results will also be disseminated to the local community health leaders, state officials, and policy makers for data-driven, evidence-based, and informed decision-making.

Results

As of December 2024, the SANGYAN podcast has been launched for voluntary usage in the PMCHRI.

Discussion

Podcasts are rapidly being used as a tool for information distribution by a wide range of organizations and associations, including medical and dentistry schools, research institutes, and scientific journals. There is a need for robust strategies to boost podcast acceptability and provide community-specific information on misconceptions about public health concerns. The study would help assess the acceptability of podcasts as a source to obtain tailored and evidence-based health information.

The study findings will elucidate the association of the acceptance and usability of podcasts with various sociodemographic factors such as education level, gender, and occupation, for which there is a dearth of data in the Indian context. The findings will also provide insight into people's awareness of podcasts and other digital sources of health information prior to the study.

The rollout of the protocol may see some limitations, in that it is a one-time implementation of the SANGYAN podcast and adherence is not assessed. Another limitation could be in its implementation within a limited geographical setting; thus, future studies regarding the usability, acceptance, and adherence can be carried out at a larger scale across various states in India.

Studying the spread of misinformation (or infodemics) in India remains critical considering the booming use of social media in the wake of the COVID-19 pandemic. India, along with 132 member states of the United Nations, has endorsed fighting infodemics especially during COVID-19 [24]. This study relevant to this endorsement, as the study findings will contribute to the development and implementation of data-driven, evidence-based, and human-centered behavior change interventions using podcasts to address public health challenges among populations living in diverse settings. Further, this study would aim to expand the use of the SANGYAN podcast as source of evidence-based health information for the public.

Data Availability

The data supporting this study's findings are available on request from the corresponding author.

Authors' Contributions

All authors have contributed to the study's design, development of the questionnaire, and preparation of the manuscript and have approved the manuscript for publication.

Conflicts of Interest

Abstract

Background: Postpartum depression remains a significant concern, posing substantial challenges to maternal well-being, infant health, and the mother-infant bond, particularly in the face of barriers to traditional support and interventions. Previous studies have shown that mobile health (mHealth) interventions offer an accessible means to facilitate early detection and management of mental health issues while at the same time promoting preventive care.

Objective: This study aims to evaluate the effectiveness of the Leveraging on Virtual Engagement for Maternal Understanding & Mood-enhancement (LoVE4MUM) mobile app, which was developed based on the principles of cognitive behavioral therapy and psychoeducation and serves as an intervention to prevent postpartum depression.

Methods: This single-blinded, pilot randomized controlled trial includes 64 mothers recruited from the postnatal ward and randomized using a 1:1 ratio to receive either postpartum care (treatment as usual) or postpartum care (treatment as usual) plus the self-guided LoVE4MUM mobile app. The primary outcome is the effectiveness of the mobile app at improving postpartum depression. Secondary outcomes are changes in the mental health literacy score and negative automatic thoughts, which are collected using a self-reported questionnaire.

Results: Patient recruitment began on September 1, 2024. As of January 1, 2025, recruitment was successfully completed, with a total of 72 participants enrolled: 36 in the intervention group and 36 in the control group . The final results are anticipated to be available by March 2025, and publication is expected by the end of 2025.

Conclusions: By examining the LoVE4MUM app alongside standard postpartum care, this pilot randomized controlled trial seeks to offer preliminary evidence on the potential of mHealth tools to improve maternal mental health as well as to reduce postpartum depression symptoms. The findings are expected to contribute to the future development of effective, accessible, and scalable interventions for mothers.

Trial Registration: ClinicalTrials.gov NCT06366035; https://clinicaltrials.gov/study/NCT06366035

Introduction

The global pooled prevalence of postpartum depression (PPD) was as high as 34% in a recent systematic review [1]. In Malaysia, the National Morbidity and Health Survey 2022 reported that 11.2% of mothers had depression [2] and an alarming 90% were unaware of their symptoms. Moreover, PPD results in detrimental consequences not only for the mother but also for the baby and their future bonding and relationship [3,4].

Meeting the increasing demand for mental health care is particularly challenging. These challenges encompass issues such as a lack of privacy, limited access to mental health experts, insufficient knowledge, and cultural stigma [5-8]. Consequently, mothers do not receive the necessary assistance that they require [5]. Mobile health (mHealth), a component of eHealth [9], has emerged as a crucial means to provide accessible health care solutions, especially with the advent of technologies like smartphones, web-based platforms, and text messaging [10,11]. These tools have become helpful for offering health care services and making health care more flexible, private, and readily available. This is particularly relevant in countries with high mobile internet penetration rates, such as Malaysia where rates of mobile internet coverage reached 128% in 2021 [12].

Interventions for depression range from pharmacotherapy to psychotherapy as well as lifestyle modifications [13]. Over the years, service delivery has evolved with the use of smartphone apps, web-based applications, and text messaging services to deliver therapeutic content [14,15]. Psychotherapies such as cognitive behavioral therapy (CBT) [16-18], mindfulness [19], and psychoeducation [20,21] using these technologies have previously been reported. A systematic review found that mHealth interventions can significantly improve depressive symptoms, highlighting their potential as accessible and cost-effective treatment options [22]. Additionally, more recent reviews concurred that mHealth interventions can effectively reduce PPD, as evidenced by improvements in Edinburgh Postnatal Depression Scale (EPDS) scores among these mothers [23,24].

Women in the perinatal period are less likely to seek help for mental health issues than women at other life stages due to lower postpartum mental health literacy [25]. Mental health literacy has evolved from being defined merely as knowledge and beliefs about mental disorders to attitudes toward these disorders and efficacy in seeking help [26,27]. Kutcher et al [27] highlighted that poor mental health literacy leads to underutilization of mental health services, noting the critical role of help-seeking attitudes. mHealth platforms can boost mental health literacy by offering resources that heighten awareness of mental health issues, treatments, and self-care. For example, Chan et al [28] showed that mHealth is effective at enhancing mental health knowledge, attitudes, and behaviors, thus bridging the educational gap and reducing stigma. A systematic review emphasized the need for interventions to improve mental health literacy among perinatal women, due to a widespread lack of awareness about PPD symptoms, hesitance toward seeking professional help, a preference for informal support, and numerous other obstacles to accessing care, which are further compounded by marked stigma surrounding mental health issues [29].

Within the CBT framework, our thought processes are usually framed by our beliefs, which have a profound impact on how we feel and act in response to life's challenges [30]. Past experiences shape beliefs that can distort interpretations of events, leading to emotional disorders. In stress-triggering situations like the postpartum period, these beliefs trigger automatic negative thoughts and worsen depressive symptoms, underscoring the need to target these thoughts through depression management. By altering negative thought processes and maladaptive behaviors into more positive emotional outcomes, CBT offers improvements for depression management [31,32]. In addition, digital interventions, including exercises, thought diaries, and educational materials, facilitate the identification, confrontation, and modification of these negative cognitive patterns. A study demonstrated that smartphone-based CBT interventions could significantly reduce negative automatic thoughts and improve cognitive restructuring skills for users [33]. Mental health experts also advocate for short-term preventive CBT interventions, tailored for perinatal concerns, as a robust therapeutic strategy [34-36].

CBT's traditional reliance on mental health professionals is challenged by cost and availability barriers. Due to health care personnel limitations, Mohammad-Alizadeh-Charandabi et al [37] highlighted the shortcomings of midwife-led phone interventions due to inconsistent quality and time constraints. In contrast, Niksalehi et al [38] effectively deployed structured automatic text messages with optional phone support, significantly enhancing depression scores and showcasing the potential of accessible, self-guided support. Complementing this, Carona et al [39] introduced a low-intensity, self-guided CBT program as an effective firstline intervention to help perinatal women, resulting in more improved depression scores in the intervention group than in the control group. Another study that used internet-based CBT [40] reported significant differences between the intervention and control groups.

It is noteworthy that the majority of studies on mHealth interventions were conducted in urban and academic settings in high-income countries [14]. Therefore, the generalizability of the outcomes is limited to the local population and might not apply to other settings such as Malaysia, which has a diverse cultural and religious background. Furthermore, these technologies frequently lack a user-centered design [41] and are primarily developed in western countries, which impacts their adaptability and sustainability in local contexts [14]. To culturally tailor appropriate mHealth interventions, meticulous development is required, engaging not only health care professionals to shape evidence-informed intervention priorities but also patients to enhance the effectiveness and widespread adoption of these interventions [42].

Initiatives in Malaysia include the TIARA MURNI project [43], which involves health care workers for its delivery. However, there is a notable absence of self-guided mental care solutions for mothers during the postpartum period especially in the Asian setting. This highlights an opportunity to improve mental health care access especially in areas with limited resources [38,44,45].

This study protocol intends to assess a user-centered, self-guided mental health app and compare it with standard postpartum care. It aims to determine the app's preliminary effectiveness at improving depression and mental health literacy and addressing negative thoughts among mothers in the postpartum period.

Methods

Type and Design

This study is a single-blind, pilot randomized controlled trial with participants randomized using a 1:1 ratio.

Study Location

The study includes postpartum mothers located in the postnatal ward of tertiary hospitals in the Selangor state of Malaysia. According to the Department of Statistics Malaysia, Selangor has the highest birth rate in the country, with a total of 95,211 live births in 2019 [46]. The National Morbidity and Health Survey 2022 survey indicated that urban mothers have a higher risk of depression. Considering Selangor's birth statistics and status as a highly urbanized state, we considered it to be the ideal location for our research. We selected 2 hospitals from urban locations using a computerized random number generator.

Ethics Approval and Ethical Considerations

Approval to conduct the study was obtained from the Medical Research and Ethics Committee, Ministry of Health Malays (ref number 24-00924-HPO, dated April 04, 2024). Written informed consent was obtained from all participants prior to their involvement in the study. Participants are fully informed of their right to opt out at any time without any consequences. All participant data are anonymized to ensure privacy and confidentiality. No identifiable information is collected nor stored during the study. Protective measures, including secure data storage, were implemented to safeguard participant information. Participants are compensated MYR 10 (US $2.15) for each questionnaire returned, to acknowledge their time and effort. Participation is entirely voluntary, without any form of coercion.

Recruitment

Mothers were recruited from the obstetric wards by the investigators. Mothers received comprehensive information about the study, including its aims, procedures, risks, and benefits. Sufficient time was given to ensure informed consent was obtained in the ward. Those agreeing to participate were enrolled in the pilot randomized controlled trial, and reasons for refusal were documented.

Patients were screened for eligibility based on the study criteria. Mothers (1) scoring between 9 and 11 on the EPDS, (2) who had access to a smartphone, (3) who possessed home wireless internet or could access internet connectivity, (4) who planned to continue routine postpartum care in the government primary health facility, and (5) who were literate in both English and Malay were included in the study. Mothers (1) with a history of drug abuse; (2) who had been diagnosed with depressive illness in the current pregnancy; (3) who were undergoing treatment for depression, bipolar disorder, or any other psychiatric disease at the time of participation; and (5) whose infant experienced intrauterine death or death immediately after birth were excluded from the study.

Randomization and Blinding

Participants were randomized (1:1) into 2 groups (ie, intervention and control groups). The researchers were blinded to the randomization process. Randomization was conducted by an independent assistant using a prearranged sealed opaque envelope. The envelopes contained a QR code linking to either a mobile app (the intervention group) or a WhatsApp communication channel (the control group). Both groups continue to receive treatment as usual (TAU) postpartum care.

Intervention Group

The intervention group receives TAU postpartum care and the Leveraging on Virtual Engagement for Maternal Understanding & Mood-enhancement (LoVE4MUM) mobile app intervention.

The LoVE4MUM app represents an innovative self-guided approach to postpartum mental health care and offers a comprehensive, tailored intervention for maternal mental health during the postpartum period. It is available in English and the local Malay language. It was developed using a prior rigorous research process that included in-depth interviews with mothers who had symptoms of PPD and guidance from a multidisciplinary expert panel including clinical psychologists, psychiatrists, obstetricians, family health specialists, public health specialists, and epidemiologists with further input from previous literature [13,47-50]. This app-based intervention is grounded in psychoeducation, intrapersonal therapy, and CBT principles.

The app was validated by a panel of 4 experts. The content underwent detailed item-by-item validation to ensure its relevancy and clarity. In this face validation process, the majority of the items garnered unanimous approval, which was reflected in a content validity index and kappa coefficient of 1.00. Nevertheless, items 12 and 16 had content validity index and kappa scores <0.7, necessitating their revision to enhance relevancy within the module content. Additionally, item 18 was modified to provide better clarity. The expert panel reviewed the revisions and subsequently approved the finalized module. See Multimedia Appendix 1 for details of the validation process.

A linguistic expert translated the content into the Malay language to ensure that it was culturally and contextually appropriate. The app was developed on a self-developed website platform using a mobile phone interface. Snippets of the mobile app are available in Multimedia Appendix 2 and Multimedia Appendix 3.

The app is structured around 5 main modules that provide flexible and accessible support over a 6-week period. It does not require sequential module completion and allows for personalized pacing. Each module targets critical aspects of postpartum mental well-being and is delivered in several formats including video, infographics, notes, and worksheets. Each module takes approximately 20 minutes to 30 minutes to complete. Automated reminders incorporated into the app and

linked to users' emails encourage regular user engagement with app. The modules are described in Table 1.

Table 1.

Module	Module description	Skills learned	Worksheet
Module 1: Learn to Love Yourself	This module emphasizes self-care, establishing goals, and navigating social comparisons while addressing typical challenges like managing expectations, hospital admissions, and handling baby feeding and care. It aims to empower mothers to prioritize their well-being.	Self-care practices, goal formulation, effective communication for seeking help, and strategies for tackling common issues	Setting goals and listing things you love
Module 2: Understanding Postpartum Depression	This module offers foundational knowledge about postpartum depression, aiming to increase awareness and reduce stigma.	Identifying postpartum depression, seeking help, treatment options, and assertive communication with partners and family	—[a]
Module 3: Addressing Unhelpful Thinking	This module integrates cognitive behavioral therapy (CBT) concepts, guiding mothers to recognize and question negative thinking and understand how thoughts influence behaviors.	Identifying unhelpful thinking habits and mechanisms to improve thought patterns	Encourages describing specific situations and working on improving the associated thoughts
Module 4: Mood Tracker	This module engages mothers in monitoring their mood and provides strategies for mood improvement.	Identifying emotions, identifying healthier responses, and learning how to perform deep breathing	—
Module 5: I Need Help Now	This module guides users in accessing immediate calming techniques, help, and essential information for assertive communication with health care providers.	Calm breathing, communication with health providers, and information on seeking help	—

[a]Not applicable.

All data in the mobile app are stored in a password-protected, secured data cloud handled by the app developer. To register to use the app, participants must create a password that is requested after every time they sign in. Only administrative personnel have access to the encrypted password data.

Control Group

Both groups receive TAU postpartum care during the study. According to The Malaysian Perinatal Care Manual (fourth edition), at least 5 postnatal home visits and 1 clinic visit are conducted for normal cases, and the frequency increases for high-risk mothers and babies [51,52]. Routine postnatal care services include lactation consultation in the ward and postnatal visits by health care workers at home. Each postnatal check should assess the mother's overall, psychological, and emotional health, asking about any concerns, and evaluate the baby's well-being, feeding, and development to promptly identify any issues [53]. Participants are advised that they are free to withdraw from the study at any point for any reason.

Measurements

The study uses a questionnaire delivered online (Google form) and divided into 3 outcome measurement tools.

Primary Outcome Measurement

The EPDS is a 10-item questionnaire extensively used to assess postnatal depression in both international and local contexts. It uses a 4-point Likert scale for responses, with higher scores indicating greater depressive symptoms. The scale has been translated into the Malay language [54], where a score of 11.5 was the optimum cut-off for 72.7% sensitivity, 95% specificity, and a positive predictive value of 80%. In our study, participants with an EPDS score ≥12 are categorized as having postpartum depressive symptoms.

Secondary Outcome Measurements

Postpartum Depression Literacy Scale (PoDLiS)

The Postpartum Depression Literacy Scale (PoDLiS) is a 31-item, self-administered questionnaire developed by Mirsalimi et al [55] to assess the understanding of PPD. It evaluates 7 attributes of PPD literacy, including recognition, knowledge of risk factors and causes, self-care activities, available professional help, attitudes toward recognition and help-seeking, and information sources. Responses are scored on a 5-point scale, with attribute scores calculated by averaging related item scores. The Malay version of PoDLiS has acceptable reliability, with a Cronbach α of 0.73.

Automatic Thought Questionnaire (ATQ)

The Automatic Thought Questionnaire (ATQ), which is available in the Malay language [56], assesses the frequency of negative automatic thoughts linked to depression and anxiety. This 17-item scale asks respondents to rate the occurrence of specific negative thoughts over the past week on a scale from 1 to 5. Higher total scores indicate more frequent negative thinking. The scale's internal consistency ranges from 0.83 to 0.93 [56]. The total score ranges from 17 to 85, with a higher score reflecting a higher frequency of negative thinking.

Data are conducted at baseline, 1 week postpartum, and 6 weeks postpartum using the Google form, which is delivered via either the mobile app or a Whatsapp number. The self-reported survey takes approximately 15 minutes to 20 minutes to complete. All answers are automatically storied in the Google drive, and only

the research team has access to the data. The schedule of enrollment, interventions, and assessments is summarized in Multimedia Appendix 4 and Multimedia Appendix 5.

Sample Size

Based on the recommendations of Whitehead et al [57], for a pilot trial with 90% power and a 2-sided significance level of 5%, the suggested sample size per treatment arm based on previous literature with a medium effect size (0.43) [58] is 25. Hence, a total of 72 participants (36 participants per arm) was required after taking into consideration a 30% nonresponse rate.

Statistical Analysis

Data will be analyzed using SPSS version 26, and significance is set at $P<.05$. Intention-to-treat analysis will be used. Categorical variables will be presented as the frequency and percent values, while continuous data will be presented as mean (SD). Baseline between-group comparisons will be conducted using Pearson chi square and Fisher exact tests for categorical data. Meanwhile, independent *t* tests will be used for continuous data. Repeated measures ANOVA will be used for within-group (time effect) and between-group (treatment effect) comparisons at 6 weeks. The mean difference and its corresponding 95% CI will be reported, with the significant level set at $P<.05$.

Risk Management

All participants were informed that the intervention serves as a supplementary self-help program and does not replace professional health care services. They are strongly encouraged to seek advice from their doctors or general practitioners regarding any concerns related to their mental or general health. Participants who experience symptoms of depression during the pilot trial are urged to promptly consult health care professionals and inform the research team of their condition. These measures allow for the appropriate management of any adverse effects and ensure the well-being of participants throughout the study.

For those screened and found ineligible for the trial, comprehensive support information was provided through a brochure containing information on PPD, immediate assistance, and emergency contact details. These individuals are also advised to consult their health care providers if they have concerns about their mental health. Specifically, mothers with an EPDS score ≥12 were excluded and referred to specialists for further evaluation and intervention in line with the Malaysian guideline for managing PPD.

Moreover, all participants continue to receive postpartum care by attending health care professionals at the Malaysia's Ministry of Health facilities, with care adhering to the standards set forth in the Perinatal Care Manual (fourth edition) [51].

Results

Participant recruitment began on September 1, 2024. As of January 1, 2025, recruitment was complete, resulting in a total of 72 participants enrolled: 36 in the intervention group and 36 in the control group. Data analysis and results are anticipated to be available by March 2025. The trial results are expected to be published by the end of 2025.

Discussion

Overview

PPD is influenced by a combination of intrapersonal, environmental, and physical factors that necessitates multifaceted interventions. The LoVE4MUM app represents a potential intervention for PPD prevention and uses an innovative approach that integrates the complexity of PPD with the unique cultural and societal contexts of Malaysia. The app combines psychosocial interventions, including CBT components, to address negative automatic thoughts and improve mental health literacy through engaging, educational content. The authors anticipate that participants receiving the LoVE4MUM app will demonstrate improvements in depressive symptoms, as measured by EPDS, compared with those receiving only standard postpartum care. Previous studies highlight the potential of mobile apps to improve mental health in perinatal populations [59]. Several reviews on mHealth interventions have revealed significant reductions in EPDS scores among postpartum mothers using mobile apps [23,60-62]. The LoVE4MUM app is designed to provide culturally relevant content. It also considers the barriers postpartum mothers in Malaysia face, such as limited access to face-to-face care and social stigma surrounding mental health.

The COVID-19 pandemic amplified the global prevalence of PPD, with rates within middle-income countries increasing from 20.8% before the pandemic to 34% during the pandemic [1,63] . This surge emphasizes the urgent need for remote health care solutions. The LoVE4MUM app leverages this shift by offering a self-guided platform that empowers mothers to engage in self-care from the convenience of their smartphones, circumventing the limitations of in-person care.

Lin et al [64] demonstrated that digital interventions promoting psychological empowerment and hedonic well-being are effective at driving these behavioral changes. In line with these findings, the LoVE4MM app encourages mothers to engage in activities that enhance their well-being while offering tools for cognitive restructuring. This approach is particularly crucial in a cultural context like Malaysia, where mental health stigma may prevent mothers from seeking professional therapy. Compared with the control group, we expect that mothers using the app will have improved EPDS scores; better scores for mental health literacy, as measured by the PoDLiS tool; and reductions in automatic negative thoughts.

Additionally, mHealth interventions alleviate depressive symptoms by improving social support [65,66]. Enhancing environmental support through assertive communication enables mothers to seek effective help from spouses and family members, reducing stress and improving mental health [67-69]. Similar to the CareMom app, which demonstrated a significant reduction in depressive symptoms through communication exercises, assertive requests within the CBT framework in the LoVE4MUM app are expected to improve emotional well-being during the postpartum period [70].

Anto et al [71] and Hartnup et al [72] showed that postpartum mothers often experience social risk and pressure through social

media, which can exacerbate stress by promoting unrealistic comparisons and idealized identities of motherhood. Many mothers feel pressured to project a “perfect” image, leading to feelings of inadequacy and increased mental strain. By addressing these concerns, the LoVE4MUM app emphasizes the importance of self-compassion and reinforces a supportive, nonjudgmental digital environment, encouraging mothers to focus on doing their best rather than striving for perfection, which is crucial for improving mental well-being in this vulnerable period.

The strength of this pilot trial lies in its integration of validated measurement tools—EPDS, PoDLIiS, and ATQ—which offer a comprehensive view of maternal mental health. We expect the LoVE4MUM app's CBT-based interventions to demonstrate the success seen in similar applications, such as the CareMom, MumMoodBoster, Sunnyside, and Mother and Babies Course apps, which have successfully used structured exercises and personalized feedback to reduce depressive symptoms [18,70,73-76].

Nevertheless, certain challenges remain. First, the reliance on self-reported measures may introduce bias, as participants may underreport symptoms due to stigma or discomfort. Second, as demonstrated with other mHealth interventions like the Happy Mother app, user engagement can be inconsistent, and low adherence rates may diminish the overall effectiveness of the intervention[77]. To address this, the LoVE4MUM app incorporates strategies to enhance user engagement, such as push notifications, scripts, and personalized feedback. Another critical aspect to consider is the influence of cultural factors on app engagement and perception, which may affect how Malaysian mothers interact with the app. Ensuring that the app’s content is culturally sensitive and tackles common misconceptions about PPD will be essential in maximizing its impact. Moreover, as a pilot trial, the sample size may not allow for definitive conclusions, and the study’s findings should be interpreted as preliminary evidence of the app's potential.

Conclusion

The LoVE4MUM app represents a promising, scalable solution to address PPD among Malaysian mothers. If successful, this app could serve as a model for culturally adapted digital interventions that empower mothers to manage their mental health, ultimately reducing the prevalence and impact of PPD. Future studies will be necessary to further refine the app’s features and evaluate its long-term impact on maternal mental health outcomes.

Acknowledgments

The authors would like to express gratitude for the support of the Department of Public Health Medicine, Faculty of Medicine University Kebangsaan Malaya and the Director General of Health Ministry of Malaysia for the approval for the publication of this manuscript.

Abstract

Background: Transitional-aged youth have a high burden of mental health difficulties in Canada, with Indigenous youth, in particular, experiencing additional circumstances that challenge their well-being. Mobile health (mHealth) approaches hold promise for supporting individuals in areas with less access to services such as Northern Ontario.

Objective: The primary objective of this study is to evaluate the effectiveness of the JoyPop app in increasing emotion regulation skills for Indigenous transitional-aged youth (aged 18-25 years) on a waitlist for mental health services when compared with usual practice (UP). The secondary objectives are to (1) evaluate the impact of the app on general mental health symptoms and treatment readiness and (2) evaluate whether using the app is associated with a reduction in the use (and therefore cost) of other services while one is waiting for mental health services.

Methods: The study is a pragmatic, parallel-arm randomized controlled superiority trial design spanning a 4-week period. All participants will receive UP, which involves waitlist monitoring practices at the study site, which includes regular check-in phone calls to obtain any updates regarding functioning. Participants will be allocated to the intervention (JoyPop+UP) or control (UP) condition in a 1:1 ratio using stratified block randomization. Participants will complete self-report measures of emotion regulation (primary outcome), mental health, treatment readiness, and service use during 3 assessments (baseline, second [after 2 weeks], and third [after 4 weeks]). Descriptive statistics pertaining to baseline variables and app usage will be reported. Linear mixed modeling will be used to analyze change in outcomes over time as a function of condition assignment, while a cost-consequence analysis will be used to evaluate the association between app use and service use.

Results: Recruitment began September 1, 2023, and is ongoing. In total, 2 participants have completed the study.

Conclusions: This study will assess whether the JoyPop app is effective for Indigenous transitional-aged youth on a waitlist for mental health services. Positive findings may support the integration of the app into mental health services as a waitlist management tool.

Introduction

Background

Transitional-aged youth refer to individuals aged roughly 15-26 years who are transitioning from childhood to adulthood, a time of developing independence and increased challenges [1]. In Canada, mental health difficulties among transitional-aged youth have increased across the past decade and during the COVID-19 pandemic [2,3]. Indigenous individuals within this age range experience a greater burden of mental health difficulties compared to their non-Indigenous peers [4,5], partly attributed to distal factors such as a family history of residential school attendance [6] and more proximal factors such as experiences of childhood adversity [7]. Stressors such as substance use, loss of culture, racism, socioeconomic status, and family instability also impact the well-being and mental health of Indigenous youth [8].

Mental health services are less accessible for youth living in remote and rural locations [9]. For instance, there is less use of outpatient-based mental health care and psychiatry services and higher rates of emergency department visits and hospital admissions for mental health-related reasons in Northern Ontario, a region of many different Indigenous communities [10]. In general, long wait times in Northern Ontario are similar to those experienced in other regions of the province [10]; however, wait times for counseling and therapy are particularly long in Thunder Bay compared to many other communities, with an average of 348 days [11]. Services that consider and incorporate culture are even more sparse. Long wait times for services not only delay care and contribute to prolonged distress and suffering but also affect interest and engagement in services once they are offered [12,13].

Mobile health (mHealth) innovations can increase access to mental health support. Specifically, smartphone apps can be an effective medium for improving mental health symptoms and quality of life [14,15] and for youth specifically [16]. Knowledge gaps exist, however, with respect to app effectiveness for those on a waitlist for services and for Indigenous youth. For instance, a recent review of waitlist interventions for youth did not include any app-based interventions [17]. Further, until recently, app evaluation studies seldom included Indigenous youth in the evaluations [18]. A review published in 2024 highlights several initial evaluations of apps with Indigenous youth that were focused on a variety of health-related outcomes, with a few of these focused on general mental health or coping and well-being [19]. Most of this research has been conducted with Indigenous populations outside of Canada, whose cultural values related to well-being may differ [20]. While there are apps geared toward Indigenous populations in Canada [21], they have not been evaluated among treatment-seeking youth, and some are primarily informational in nature or used for data collection only [22,23]. More research is needed to test the effectiveness of apps for addressing mental health among Indigenous youth [24].

In collaboration with an Indigenous-led agency informed by Anishinabek culture and located in Northern Ontario (Dilico Anishinabek Family Care; Dilico), in this study, the JoyPop app will be evaluated as a tool for supporting the mental health needs of Indigenous youth currently waiting for mental health services. The app was developed by researchers in collaboration with youth and service providers [25], and input from these stakeholders continues to inform its implementation and evaluation [26,27]. The app was designed to promote resilience to stress and adversity [25], targeting emotion regulation as part of this goal since it is linked to strengthening resilience [28]. Rather than targeting specific mental health diagnoses, focusing on emotion regulation is also in line with recommendations that apps target “transdiagnostic factors” to make the best use of resources [24], since difficulty with emotion regulation is common among different mental health concerns [29,30]. To accomplish this goal, app features include a mood rating feature to promote emotional awareness [31], breathing exercises to help with relaxation [32], relaxing sounds to help with sleep [33], a game and art feature helpful for distracting oneself from stressful situations [34,35], a journal focused on positive topics to promote well-being [36], and connection to one’s support network and professional helplines, if needed [37].

An initial evaluation of the JoyPop app showed that app use was associated with improvements in emotion regulation and depressive symptoms for transitional-aged youth starting university [38], who shared that they valued the opportunity to build awareness and regulation of emotions [39]. Another study conducted with an Indigenous community in Southern Ontario identified the potential utility of the app for youth in the community while also gathering knowledge on how cultural values were connected to the app features [26,27]. Prior to developing the current protocol, a pilot study was also conducted with Dilico and another local organization, in which youth identified benefits of using the app related to coping and mental health [40]. Service providers also expressed positive feelings about the app’s ease of use and how the app could be helpful for youth who are on the waitlist for services (eg, by increasing their comfort levels before services begin) [40].

In sum, it is important to identify beneficial transdiagnostic mental health supports for Indigenous transitional-aged youth in Northern Ontario. Considering past findings with the JoyPop app have been promising [26,27,38-40], a larger scale randomized controlled trial is warranted to more robustly evaluate its effectiveness. Providing this intervention while youth are on a waitlist for services may help reduce disengagement and the need to seek other services during this time.

Objectives

The objectives of the study are in response to the goals and needs identified by the community partner, Dilico. Specifically, the primary objective is to determine the effectiveness of the JoyPop app compared to usual practice (UP) in improving emotion regulation among Indigenous transitional-aged youth (aged 18-25 years) who are awaiting mental health services. We hypothesize that youth receiving the app will show improvement in emotion regulation (small to medium effect) greater than that observed for youth receiving only UP.

The secondary objectives are to (1) compare change in mental health difficulties and treatment readiness between youth in each condition to better understand the app's broader impact as a waitlist tool and (2) conduct an economic analysis to determine whether using the app while waiting for mental health services reduces other health service use and associated costs.

Methods

Overview of Study Design

This protocol was developed in collaboration with Dilico management and frontline staff to answer research questions of importance to the organization and the youth they serve. It was designed according to the Standard Protocol Items: Recommendations for Interventional Trials (SPIRIT) statement [41] (see Multimedia Appendix 1 for completed checklist). A pragmatic, parallel-arm randomized controlled superiority trial design will be used. Participants will be randomly assigned to the control (UP) or intervention (UP+JoyPop) condition in a 1:1 ratio using stratified block randomization. UP will involve waitlist monitoring practices at the study site, which include regular check-in phone calls to obtain any updates regarding functioning. In addition to UP, participants allocated to the intervention condition will receive the JoyPop app for 4 weeks and be asked to use it at least twice daily. Outcome measures will be administered to participants in both conditions during 3 assessments (first [baseline], second [after 2 weeks], and third [after 4 weeks]).

Setting and Participants

Data collection will take place at Dilico Anishinabek Family Care, an Indigenous-led organization that provides culturally informed child welfare, mental health and addictions, and health services to Anishinabek children and adults. Programs and services are provided at individual, family, and community levels. This self-governed organization is situated in Fort William First Nation in Northern Ontario.

Youth will be informed about the study by waitlist case managers and with flyers and letters mailed and emailed to them. Youth will be eligible for trial participation if they are on the waitlist for mental health services at Dilico and between the ages of 18-25 years.

Study Procedure

Table 1 describes participant progression through the study. A research assistant will contact interested youth by phone, text, or email to provide a brief description of the study. If a youth is interested and meets eligibility criteria, the research assistant will schedule their study orientation (as part of the baseline assessment). The research assistant will obtain informed consent during this orientation. As part of the informed consent process, youth will be made aware of local support services they can access should they experience distress during the study. They will also be made aware of the possibility that they are assigned to the control group so that they can make an informed decision about participation in light of this possibility.

Table 1. Participant timeline.

	–1	T1	T2	T3
Activity/assessment	Pre-study screening	Orientation/baseline assessment	2 Weeks/second assessment	4 Weeks/third assessment
Eligibility screen	✓			
Informed consent and condition allocation		✓		
Intervention (UP+JoyPop; or UP only)				
Outcomes measured: emotion regulation, mental health, treatment readiness, and service usage		✓	✓	✓
Outcome measured: app quality				✓—intervention group only
Control group participants given access to app				✓

Following consent, participants will complete the baseline assessment measures. They will be encouraged to respond as honestly and accurately as possible and not how they think researchers might want them to. Any participant that endorses suicidal thoughts during the first assessment will see an onsite counselor who will conduct a risk assessment and intervene as needed. Following completion of the assessment measures, the research assistant will access the allocation envelope from the locked filing cabinet, open it to determine the allocation, inform the participant, and proceed with associated study tasks. Participants allocated to the intervention condition will be supported in accessing and learning about the app. All participants will return to Dilico after 2 and 4 weeks to complete the second and third assessments. Once they have finished the

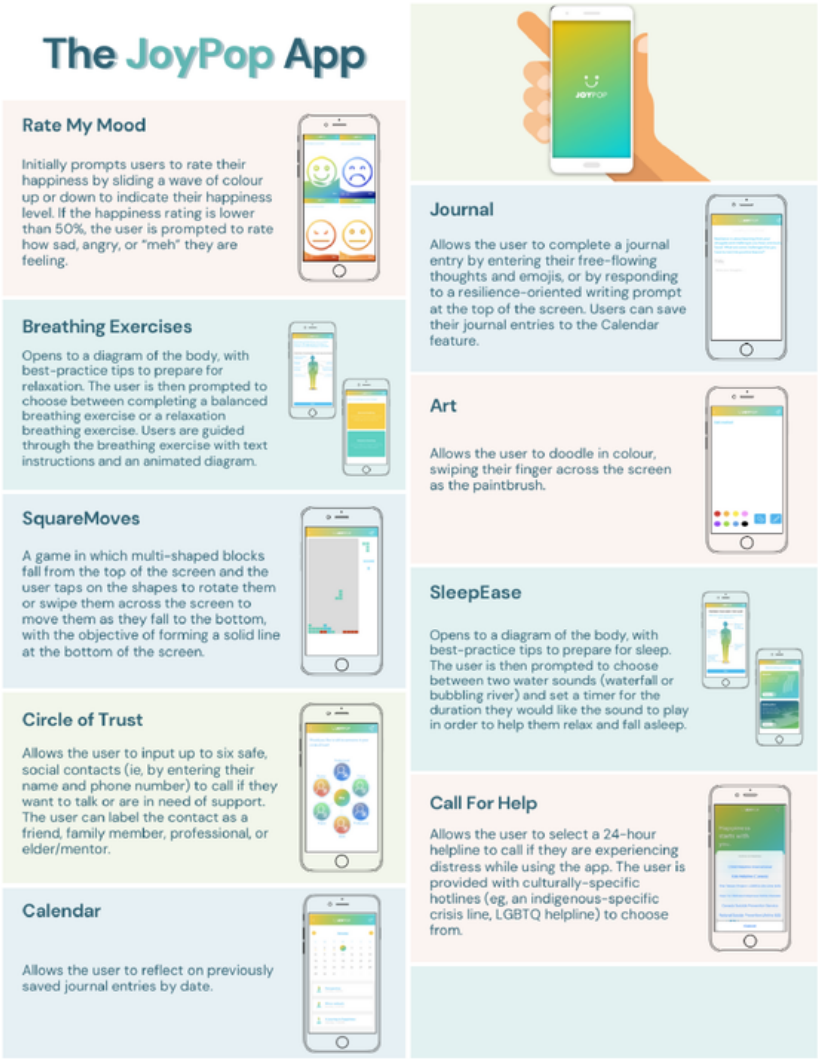
study at the end of their third assessment, participants in the control condition will learn about and receive access to the app.

To promote retention, participants will receive reminders about upcoming assessments via text and email. To incentivize completion [42,43], participants will receive cash compensation (CAD $20 [US $13.89] for baseline assessment; CAD $25 [US $17.36] for second assessment (after 2 weeks); CAD $30 [US $20.83] for third assessment (after 4 weeks); and an additional CAD $25 [US $17.36] if all assessments are completed). We will arrange transportation (taxis, bus fare) if required for participants. Promising retention rates were observed using these methods in a pilot study [44].

Description of Intervention and Control Conditions

Participants in the intervention condition will be able to use the JoyPop app by downloading it onto their own device (if suitable). Participants who do not have an iPhone will be given a refurbished one containing only the app to use for the duration of the study. Participants will be asked to use the app at least twice daily for 4 weeks. The JoyPop app has features that allow participants to rate their mood, engage in relaxation exercises (ie, breathing), prepare for sleep, journal, play a Tetris-like game, create art, and reach out to their support system or suitable helplines. Figure 1 further describes these features. Internet connection is not required to use the app.

Figure 1. JoyPop features. LGBTQ: lesbian, gay, bisexual, transgender, and queer/questioning.



To promote engagement, youth will receive an email and SMS text message twice per day (at 8 am and 8 pm) reminding them to use the app. Outside of recommending using the app near the start and end of their day, we will not instruct or prescribe participants to engage with the app for any specific duration or pattern. Our intention is to evaluate the effects of using the app under real-world conditions in which users choose when and how often to use the app. Prior research suggests youth do use the app for the majority of the 4-week period [38,39]. Youth will also receive the usual waitlist management practice (UP).

Participants allocated to the control condition will only receive the UP. We chose this comparator to assess whether the JoyPop app could be a complementary support for individuals waiting for mental health services. This comparison creates the opportunity to test whether those who receive the app experience improved outcomes compared to those who do not receive it, representing "true" change after accounting for the regression to the mean phenomenon likely to affect both groups [45]. The use of a control condition addresses the limitations of our

previous research in which all participants received the app [38].

Randomization and Blinding

Stratified block randomization will be used to randomize participants to the control or intervention condition in a 1:1 ratio. An independent researcher outside of the research team will create the randomization sequence using a computer-generated sequencing tool [46] and then place allocations into numbered, opaque, sealed envelopes. These will be stored in a locked filing cabinet and only accessed by the research assistant who is with the participant.

To protect against bias, the principal and coinvestigators and the statistician conducting the analyses will be blinded to conditions. Trial participants cannot be blinded given the nature of this trial in which they are actively using the app or not. Research assistants will also not be blinded, as the condition assignment determines study procedures such as showing the participant how to use the app and providing them with the correct measures.

Outcomes

The primary outcome is change in emotion regulation from the baseline assessment to the second assessment (after 2 weeks) and to the third assessment (after 4 weeks). Secondary outcomes are changes in mental health symptoms, readiness for treatment, and service usage from the baseline assessment to the second assessment and to the third assessment.

Measures

Descriptive Measures

During the baseline assessment, participants will complete a demographics measure asking about their age, ethnicity, family composition, highest level of education, gender, sex at birth, sexual orientation, and living situation. Demographic variables that could change over time (ie, gender, sexual orientation, family composition, and living situation) will be reassessed at subsequent assessments. We will also measure symptom presentation during the baseline assessment using a modified version of the *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders* [Fifth Edition]) Self-Rated Level 1 Cross-Cutting Symptoms Measures (DSM-5-CCSM) [47] to characterize symptoms across 12 psychiatric domains (ie, depression, anger, irritability, mania, anxiety, somatic symptoms, inattention, suicidal ideation, psychosis, sleep disturbance, repetitive thoughts and behaviors, and substance use). One item pertaining to past suicide attempts was removed at the request of Dilico partners. Using the DSM-5-CCSM measure, respondents will report how much (or how often) they have been bothered by symptoms during the past 2 weeks. Items are rated on a 5-point scale (from 0=none at all to 4=severe or nearly every day) with the exception of items related to suicidal ideation and substance abuse, which are rated as either "Yes" or "No." In a sample of adults receiving mental health services, most items in this measure except for the mania items have good test-retest reliability (intraclass correlation range=0.53-0.97) [48]. The measure also has good internal consistency (α=0.96) and criterion validity in terms of severity of impairment across life domains (r=0.84) in a community sample [49]. App usage data will be recorded in the JoyPop app with a timestamped record created each time the participant uses a feature.

Primary Outcome Measure

Emotion regulation will be measured with the Difficulties in Emotion Regulation Scale-Short Form (DERS-SF) [50,51], an 18-item self-report measure that asks respondents how often statements regarding their emotions have applied to them over the previous 2 weeks. Items are rated on a 5-point scale (ranging from 1="almost never" to 5="almost always"). Total scores range from 18 to 90, and subscale (strategy use, nonacceptance of emotion, impulsivity, ability to maintain focus on goals, awareness of emotions, and clarity of emotions) scores range from 3 to 15, with higher scores indicating greater difficulty regulating emotion. The DERS-SF demonstrates convergent validity via associations with symptoms of emotional disorders (eg, r=0.66 with the Beck Depression Inventory) [51,52]. In our pilot sample of Indigenous youth from Dilico, internal consistency for the total score ranged from α=0.87 to α=0.91 [53].

Secondary Outcome Measures

Mental health difficulties will be assessed with 2 measures: the Depression, Anxiety, and Stress Scale 21 (DASS-21) [54] and the Strengths and Difficulties Questionnaire (SDQ) [55,56]. The DASS-21 is a 21-item self-report measure that asks respondents how much specific statements regarding psychological distress applied to them over the past week. Items are rated on a 4-point scale (from 0="never" to 3="almost always"). Total scores range from 0 to 63, and subscale scores range from 0 to 21, with higher scores indicating greater distress. In clinical samples, this measure demonstrates convergent validity via correlations with other mental health measures (eg, r=0.85 between the Anxiety subscale and Beck Anxiety Inventory; r=–0.66 between the Depression subscale and Mental Health Questionnaire) [57,58]. In our pilot sample, internal consistency ranged from α=0.95 to α=0.96 across subscales. The SDQ is a 25-item self-report measure that asks respondents how true various statements have been for them. Items are rated on a 3-point scale (from 0="not true" to 2="certainly true"). Total scores range from 0 to 40, and subscale (emotional problems, conduct problems, hyperactivity, peer problems, and prosocial behavior) scores range from 0 to 10, with higher scores indicating greater difficulty (except for the prosocial scale for which the reverse applies). The SDQ has satisfactory internal consistency (α=0.80) and validity via its association with clinical diagnoses [56,59]. In our pilot sample, internal consistency was variable [53]; thus, we will ensure adequate psychometric performance in this study with a larger sample prior to analyses.

Treatment readiness will be assessed with the 4-item treatment readiness subscale of the Motivation for Youth's Treatment Scale (MYTS) [60]. Items are rated on a 5-point scale (from 1="strongly disagree" to 5="strongly agree"), with the total subscale score calculated as the mean of item scores; higher scores indicate greater readiness. Groups with prior mental health service use and higher symptom severity tend to have

higher average scores [60]. In our pilot sample, internal consistency ranged from α=0.80 to α=0.90.

Service usage will be assessed with 5 items generated by the research team that ask respondents how many times they accessed various health care services (ie, walk-in clinic, family doctor or nurse practitioner, emergency department, mental health counselor, and mental health hotline or phone support) over the previous 2 weeks.

Statistical Analyses

Descriptives

We will describe the sample by calculating means and frequencies across demographic variables such as gender. We will also calculate mean scores on the DSM-5-CCSM to describe presenting mental health across 12 psychiatric domains. We will report internal consistency estimates and correlations between all measures to provide an indication of their reliability and convergent validity in the sample, given a lack of prior validation with Indigenous samples. With respect to app use among the intervention group, we will calculate the average frequency and duration of app use both in general and for each feature.

Primary Outcome

We will calculate the change in overall emotion regulation using the DERS-SF total score and the change in specific domains via the DERS-SF subscale scores. An independent statistician will use linear mixed modeling to test whether the change in emotion regulation is greater for those in the intervention condition relative to those in the control condition by including an interaction term between time and group [61]. We will evaluate the final sample to determine whether it is also feasible to analyze gender and baseline mental health symptoms as subgroup effects via interaction terms [62,63]. Analyses will be conducted with an intent-to-treat approach. Missing data will be handled with full information maximum likelihood estimation, which is recommended for avoiding bias in parameter estimates [64,65].

Secondary Outcomes

We will calculate change in mental health using total scores from the DASS-21 and SDQ, while we will calculate change in specific domains using the DASS-21 and SDQ subscale scores. We will calculate change in treatment readiness using the treatment readiness subscale from the MYTS as described. Similar to the primary outcome analyses, linear mixed modeling will be used to test whether the change in mental health symptoms and treatment readiness is greater for those in the intervention condition relative to those in the control condition by including an interaction term between time and group [61]. Covariates of gender and baseline mental health symptoms will again be included. With respect to service usage, we will estimate the costs of services used among participants in each condition and conduct a cost-consequence analysis to determine the incremental costs or savings associated with receiving the app [66].

Sample Size

We calculated the required sample size for a 2 (between subjects; treatment condition) by 3 (within subjects; time) mixed design, roughly estimating the statistical power needed for the planned linear mixed model for the primary outcome under the assumption of compound symmetry. We used parameters of f=0.2 (small to medium effect), =0.05, and power=0.95, resulting in a suggested sample size of 66 to achieve necessary power. We estimate 60% retention throughout the study (40% attrition) based on our initial research [53]; as such, an initial sample of 110 will be recruited.

Ethical Considerations

Ethics Approval

The study protocol (version 1) was approved on December 16, 2022, by the Research Ethics Board at the Thunder Bay Regional Health Sciences Centre (file #100157). This Research Ethics Board acts as the Board of Record for clinical research projects led by Lakehead University researchers. The Research Advisory Committee at Dilico reviewed and approved all procedures. All participants will provide informed consent and will be made aware that they will receive counseling regardless of their choice to participate. Any required amendments would be reviewed by the Research Ethics Board, and participants would be informed by phone or email if such amendments directly impacted their experience in the study. We would also update the ClinicalTrials.gov registry (NCT05991154).

Mitigation of Harms

The risk of harm due to study participation is minimal. Participants may withdraw at any time by contacting the research team via phone or email. Any concerns or adverse events experienced or reported by participants to a research assistant would be reported immediately to the principal investigator (author ARM). The research team also meets weekly and will discuss any issues or concerns as they arise. All serious adverse events will be reported to the Thunder Bay Regional Health Sciences Centre Research Ethics Board using the Research Ethics Local Serious Adverse Event Reporting Form.

As described earlier, we will provide participants with contact information for local support services during the orientation, including walk-in counseling services and a local crisis line. Additionally, if recent suicidal thoughts are endorsed, an onsite counsellor will conduct a risk assessment with the participant and intervene as needed. As part of this risk assessment, the participant and counsellor will discuss whether continued study participation is recommended. Finally, as participants are on the waitlist for mental health services, they will be offered counseling services at some point following study completion (exact timing based on waitlist at the time).

Data Management and Confidentiality

Practices related to confidentiality follow the Canadian Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans [44] and ethical guidelines at the Thunder Bay Regional Health Sciences Centre and Lakehead University. During recruitment, names and contact information of potential participants will be kept in a list only accessed by the research

team. Once enrolled, the research assistant will assign each participant an ID number; both self-report and app data will contain only this ID number and no identifying information. The list connecting participant IDs to their names and contact information will be deleted upon study completion. The research assistant leading the orientation will inform participants about confidentiality and its limits during the informed consent procedure, including the procedure for notifying a staff member if recent suicidal ideation is endorsed; we will also provide this information in the information letter that is given to participants.

With respect to data management, a research assistant will enter responses from the hard-copy measures into a version of the measures hosted by Survey Monkey. Survey Monkey has SOC 2-accredited data centers [67] with physical security, including 24×7 monitoring, cameras, visitor logs, entry limitations, as well as dedicated cages for Survey Monkey hardware. Data in transit is encrypted using secure TLS cryptographic protocols. Usage data from the JoyPop app will be stored on a password-protected server within Canada and encrypted during transmission. In accordance with the Ownership, Control, Access, and Possession (OCAP) standards set by the First Nations Information Governance Centre [68], all data will be stored at Dilico; electronic measures and app data will be stored on a password-protected computer while hard-copy data will be stored in a locked filing cabinet. Data will not be shared with the public or outside third parties. Data will be retained for at least 7 years after study completion following Lakehead University policy.

Oversight and Monitoring

Author ARM, as the principal investigator, will oversee all trial activities and hold weekly meetings with research assistants to discuss the day-to-day running of the trial. Author ARM will consult with coinvestigators and meet on a quarterly basis to discuss the trial status and plan for future trial activities. Author ARM will also meet with collaborators from the local community partner (Dilico) to discuss ongoing implementation of the trial. Retention will be discussed on an ongoing basis with further strategies implemented if needed.

Results

This research is funded through a Brain Canada—2021 Future Leaders in Canadian Brain Research grant, which began in October 2022. Recruitment began September 1, 2023, and is ongoing. As of July 2024, two participants have completed the study and attended all assessments. When the trial is complete, our community partner, Dilico, will review the findings via their research advisory committee, which is in line with OCAP principles [68]. Pending approval by the committee, results will be disseminated through academic conferences and publications as well as media interviews to reach the broader community. We will also share a summary of findings with participants who selected that they would like to receive this, as well as with staff at Dilico who are interested in the information. Pending positive results, avenues for future funding to support scalability will also be discussed with community partners.

Discussion

Overview

The current research will explore the impact of the JoyPop app on emotion regulation, mental health, and treatment readiness among Indigenous youth waiting for mental health services. Positive change among these variables and demonstrated cost-effectiveness associated with using the app would support adopting the app into routine waitlist management practices within the current partner organization. The degree and magnitude of findings within this clinical sample of Indigenous youth will be compared to prior work within a non-clinical sample in which use was associated with positive change in emotion regulation and depression symptoms [38]. We will also compare findings to another trial studying the effectiveness of the app among younger Indigenous youth [69] and another with non-Indigenous youth [70]. Such comparisons will allow identifying how to best use the JoyPop app as a supportive tool. Finally, positive findings would also be consistent with a growing emphasis on transdiagnostic approaches to mental health care. Specifically, findings may increase our knowledge about the link between emotion regulation and various mental health–related difficulties among Indigenous youth [29].

Dissemination of Findings

When the trial is complete, our community partner, Dilico, will review the findings via their research advisory committee, which is in line with OCAP principles [68]. Pending approval by the committee, results will be disseminated through academic conferences and publications. We will also create infographics and videos to be shared broadly through team members' networks, on social media, and through public presentations, which we will invite youth from the study to help develop and participate in. We will use media interviews to reach the broader community. We will share a summary of findings with participants who selected that they would like to receive this, as well as with staff at Dilico who are interested in the information. Pending positive results, we will discuss further scalability and potential integration of e-mental health solutions into services with the community partner, such as seeking funding to conduct a hybrid implementation/effectiveness study. We will also share findings with decision makers from other organizations who are similarly seeking solutions to meet youth mental health needs.

Strengths and Limitations

Study strengths include the randomized controlled trial design, methods to promote retention and uptake of the intervention (eg, reminders and provision of phones and transportation), and evaluation of diverse outcomes, including both clinical outcomes and an analysis of service usage to understand the broader impact of the app within the health care system. The experimental design specifically improves upon the limitation of non-randomized earlier work [38]. An inherent study limitation is that participants are not blinded to condition assignment. A further limitation is that although the study was designed with few requirements surrounding app usage to allow for a more naturalistic examination, it is possible that in potential future nonresearch clinical settings, participants may engage

with the app to a lesser extent when they are not actively involved in attending research sessions.

Given the nature of the intervention, an additional consideration is whether implementing an app-based intervention may contribute to problematic mobile device use. While this is an important consideration, the app does differ from social media and communication apps, which some research indicates are among those identified as the most "addictive" [71]. Future research, however, could evaluate whether accessing an app such as JoyPop encourages greater smartphone use overall. Future research could also incorporate scales assessing the risk of smartphone app addiction [eg, 72].

Conclusions

Transitional-aged youth in Canada experience a heightened burden of mental health difficulties relative to adult populations, and Indigenous youth in this age range may be especially at risk [4,5]. Individuals who live in more remote or rural locations, such as in Northern Ontario, have less access to mental health care, which has negative impacts on well-being and engagement in future services [10,12]. This study, conducted in partnership with Dilico Anishinabek Family Care, will speak to whether adopting the JoyPop app as part of routine waitlist management practices may benefit Indigenous youth mental health and reduce additional service use during the waiting period. While an app is unlikely to remedy all mental health symptoms, it may be a useful tool for helping youth build skills and readiness in advance of formal counseling services.

Acknowledgments

This study was funded through a Brain Canada—2021 Future Leaders in Canadian Brain Research grant (ARM). The study was also supported through a Tier 1 Canada Research Chair in Addictions and Mental Health (SHS) and in-kind contributions by Dilico Anishinabek Family Care. ARM is the principal investigator and led the design of the study and protocol, while ASN, ET, FS, JVO, and SHS provided substantial contributions to the study design. ARM, ASN, AO, ET, FS, JVO, and SHS sought funding for the study. CD, ET, FS, KS, and TB provided guidance regarding implementing the study locally and recruiting and retaining participants at the local site. TN led the trial coordination and data collection with supervision from ARM and support from ET and IM. AM drafted the manuscript. ARM provided supervision and revisions on the manuscript. All authors reviewed and approved the final manuscript.

We would like to thank Dilico staff whose knowledge and experiences have informed the study design and who have supported the onsite implementation of the trial. We also thank the youth who have participated in our research and shaped the ongoing design of the JoyPop app and associated research projects.

Conflicts of Interest

The majority of the authors have no conflicts of interest to declare. The principal investigator (ARM) recently acquired intellectual property ownership rights for the JoyPop app (in June 2024). Prior to this time, intellectual property rights were owned by another researcher or institution. ARM did not own any intellectual property rights when applying for funding for this study, when creating the protocol, or when initiating the study. To mitigate any risk related to ARM's new intellectual property ownership rights, ARM will not be involved in collecting or analyzing the data, will be blinded to participant condition assignment, and will consult with coinvestigators throughout the study.

Abstract

Background: Physical activity (PA) has been recommended in multiple sclerosis (MS) to maintain good physical fitness and mental health, reduce the severity of symptoms and risk of relapse, and improve quality of life. Pilates has been suggested as an ideal PA to manage physical, cognitive, and psychological symptoms of MS and a useful method to maintain and improve balance and gait.

Objective: This paper presents the protocol for a study that aims to evaluate the efficacy on the physical domain (specifically balance and gait) of a home-based, self-managed PA intervention delivered through the MS-FIT exergame (HELAGLOBE Società a responsabilità limitata). In addition, measures of cognitive performance, quality of life, and well-being will be considered.

Methods: This is a 2-arm, multicenter, randomized controlled trial with 3 assessment points (baseline, 12 weeks postintervention, and 6 weeks follow-up). People with MS with mild disability, low risk of falling, preserved cognitive functions, and low anxiety and depression are potential eligible participants. The experimental group (MS-FIT) will self-administer the MS-FIT exergame at home in addition to their leisure-time physical activities. MS-FIT is an internet- and Pilates-based tool that uses the Microsoft Kinect Sensor V2. Participants in the control group will only have access to their leisure-time physical activities. Participants in the MS-FIT group will train at home with MS-FIT for 12 weeks and will be required to perform the exercises for a total of 30 minutes/day for at least 3 days/week. The primary outcome is the Timed Up and Go, a test designed to assess walking. We will also administer additional tests for motor function (visual analog scale 0-10, Timed 25-Foot Walk, Ambulation Index, 2-minute walk test, Twelve Item Multiple Sclerosis Walking Scale, Nine-Hole Peg Test), cognition (Brief International Cognitive Assessment for Multiple Sclerosis), fatigue (Modified Fatigue Impact Scale), quality of life (Multiple Sclerosis Quality of Life-54), well-being (Psychological Well-Being Scales), and PA (International Physical Activity Questionnaire and Minnesota Leisure Time Physical Activity Questionnaire). Acceptance and satisfaction with the intervention received (Client Satisfaction Questionnaire and an adapted version of the Tele-healthcare Satisfaction Questionnaire – Wearable Technology) and subjective impressions of changes in performance (Patients' Global Impression of Change) will also be assessed.

Results: Recruitment for the trial started on March 16, 2022, and the first participant was randomized the same day. Data analysis and results are expected to be published in 2025.

Conclusions: Pilates has proven beneficial in several neurological diseases such as MS. With this study, we will provide evidence for the use in clinical practice of a digital tool for self-administered Pilates exercises at home as a complement to rehabilitation and for the continuity of care in MS.

Introduction

Multiple sclerosis (MS) is a chronic inflammatory neurodegenerative disease with autoimmune demyelinating lesions of the central nervous system and one of the most common causes of neurological disability in young adults. Clinically, MS progressively worsens over time, leading to cumulative physical disability, cognitive deficits, and neuropsychiatric and behavioral symptoms [1]. Physical impairments lead up to 85% of people with MS to complain of ambulation difficulties after typically 10-15 years of disease, and, after 20 years, over 66% of people with MS do not retain the ability to walk [1]. Several factors, such as weakness, spasticity, cerebellar ataxia, fatigue, and impaired attention, can cause imbalance and gait disorders [2,3]. They prevent people from performing daily activities properly and regularly, with negative effects on work status and social relationships. Rehabilitation is the main option to enhance recovery from disabling symptoms such as spasticity, ataxia, sensory loss, fatigue, pain, mood, and cognitive disorders [4]. More recently, people with MS have been recommended to engage in regular physical activity (PA).

PA, including leisure-time physical activity and exercise, comprises any bodily movement produced by skeletal muscles' contraction that results in a substantial increase in energy expenditure over resting levels [5]. Increasing PA and reducing sedentary behavior are general recommendations to improve health outcomes for all people with chronic diseases [6]. For people with MS, PA maintains good physical fitness and mental health, prevents or reduces the severity of symptoms and the risk of relapses, and improves quality of life [7-9]. Based on current evidence and experts' opinions, recent MS guidelines recommend "at least 150 minutes/week of exercise and/or 150 minutes/week of lifestyle PA" throughout the disease course [10]. However, Klaren et al [11] report that people with MS do not engage in sufficient PA amounts, with only approximately 20% of people with MS meeting recommended levels of moderate or vigorous daily activity compared with 40% of healthy participants. Although a recent survey study reported higher rates among people with MS, only 60% of the total sample met recommendations, with the lowest rate shown in the severely disabled group [12]. Furthermore, the benefits of PA may be limited if not incorporated into a structured, personalized, and supervised program.

Various mind-body fitness modalities, such as Pilates, yoga, Tai chi, and Qigong, are widely used by people who seek to achieve physical and mental health outcomes [13,14].

Pilates has been suggested as an ideal approach to managing physical, cognitive, and psychological symptoms of MS [15] and a popular alternative method for maintaining and improving balance and gait performance [16], as in other neurological conditions [17-19]. Indeed, it is a precise and controlled form

of exercise that uses the body's stabilizing muscles and is based on the principles of concentration, control, centering, flowing movement, precision, and breathing. If followed correctly, they can improve flexibility, strength, core stability, muscle control, breathing, and posture, and increase body awareness with less ground impact and joint stress [20,21]. The research findings support the therapeutic use of Pilates in the management of MS because it is a safe, active treatment method (few adverse effects) with high adherence (low dropout rate), and it can improve important meaningful functions (eg, balance, gait, physical-functional capacities, and cognition) [22].

A possible perspective for delivering Pilates interventions could benefit significantly from the proliferation of exergames and new technologies for telerehabilitation [23]. Playing exergames is a form of whole-body physical exercise [24] that requires users to complete assigned tasks aimed at improving physical fitness and promoting an active lifestyle [25]. Furthermore, exergames have been demonstrated to be comparable with traditional therapies, may be more enjoyable and acceptable, and may improve the engagement of people with MS in PA [26]. Exergame-based telerehabilitation solutions represent an efficient alternative method to overcome barriers that prevent people with MS from accessing regular long-term rehabilitation interventions (ie, transportation and working time) and to provide effective treatments in a setting, matching the patient's circumstances (eg, at home), priorities (eg, during lunch break), and capabilities (eg, physical impairment) [27].

Recently, MS-FIT (HELAGLOBE Società a Relazioni Limitate), a Kinect-based playable exergame implementing Pilates exercises, has been developed by an Italian network of experts in the field of MS rehabilitation for future use in research and clinics [28]. It has been customized for people with MS, allows tailoring the intervention in order to potentiate the effects of an ongoing program, and has been conceived to be developed for asynchronous telerehabilitation purposes.

The aim of this study, promoted by the Italian Multiple Sclerosis Foundation, is to test in people with MS the efficacy on the mobility domain measured with the Timed Up and Go (TUG) test of a self-managed home intervention delivered through MS-FIT in addition to leisure-time physical activities, in comparison with leisure-time physical activities alone. Measures of balance, gait, upper limb functioning, PA, cognition, quality of life (QoL), well-being, acceptability, satisfaction with use, and adherence to the intervention will also be considered. In addition, a blood sample will be collected to investigate if genetic polymorphisms that are considered potential regulators of neural plasticity could influence the response to the proposed intervention [29].

Based on previous findings [30], we expect that the intervention, in addition to leisure-time physical activities, will be associated with a primary outcome of mobility (TUG) compared with leisure-time physical activities alone that are expected to worsen due to disease progression. Similar changes between groups are expected in secondary outcomes; furthermore, based on our previous findings [28], we expect high acceptability, satisfaction-to-use, and adherence to the MS-FIT intervention.

If results are positive, MS-FIT could be proposed in combination with rehabilitation to potentiate the effect of the rehabilitation intervention and ensure continuity of care for people with MS.

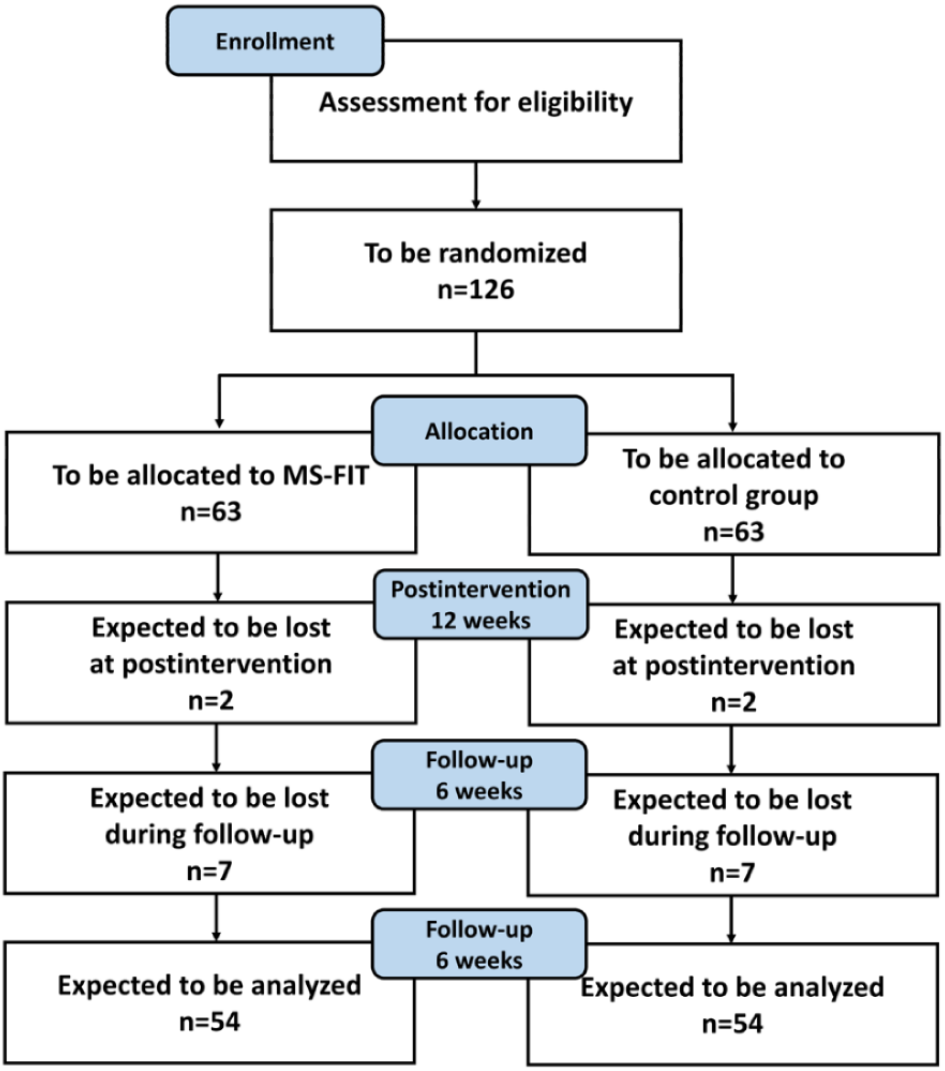
Methods

Study Design

We are conducting a multicenter 2-arm, superiority randomized controlled trial (RCT) with 3 assessment points (baseline, T0; postintervention at 12 weeks, T1; and follow-up at 6 weeks, T2). Participants will be allocated to the intervention (MS-FIT) or control group in a 1:1 ratio by simple randomization.

Participants in the MS-FIT group will have access to the MS-FIT exergame for at-home self-administration [28] (Multimedia Appendix 1) in addition to their leisure-time physical activities. Participants in the control group will have the possibility to perform only their leisure-time physical activities. Exercise will not be allowed and rehabilitation treatments, except for speech therapy, sphincter rehabilitation, and psychological support, must be suspended. The study design is illustrated in Figure 1.

Figure 1. Study design.



Setting

Participants will be recruited among those followed by 14 Italian neurorehabilitation centers; specifically, at the Italian Multiple Sclerosis Society Rehabilitation Services of Genoa and Padua, the Multiple Sclerosis Center of IRCCS (Istituto di Ricovero e Cura a Carattere Scientifico) Foundation "Carlo Besta" Neurological Institute (Milan), the Vita-Salute San Raffaele University (Milan), the Department of Neuroscience, Rehabilitation, Ophthalmology, Genetics, Maternal and Child Health (DINOGMI) of the University of Genoa, the Neurology Unit of IRCCS Neuromed (Pozzilli), the Department of Medical Science and Public health of the University of Cagliari, Department of Translational Biomedicine and Neurosciences (DiBraiN) of the University A. Moro (Bari), the IRCCS Fondazione Don Carlo Gnocchi ONLUS (Milan), the Uosi Multiple Sclerosis Rehabilitation of the IRCCS Istituto delle Scienze Neurologiche of Bologna, Department of Advanced Medical and Surgical Sciences (DAMSS) of the University of Campania Luigi Vanvitelli (Naples), the Department of Neurosciences of the S. Camillo-Forlanini Hospital (Rome), the Department of Medical and Surgical Sciences and Advanced Technologies "G.F. Ingrassia" (DGFI) of the University of Catania, and the IRCCS Centro Neurolesi "Bonino-Pulejo" (Messina).

The assessments will be carried out in person at the several centers. The intervention with MS-FIT will be performed at home.

Recruitment, Enrollment, and Randomization

People with MS along with mild disability, low risk of falling, preserved cognitive functions, and low anxiety and depression as reported in medical records are potential eligible participants. They will be contacted by telephone by the study manager of the related center (Multimedia Appendix 1), who will explain the study process in detail to ensure that patients understand the entire clinical trial; they will receive detailed information, including the purpose, procedures, follow-up content, data storage, benefits, and risks of the study, and will be given adequate time to consider participation. They will be informed that for the entire period of participation in the study, only leisure-time physical activities will be allowed, but not exercise and rehabilitation. They will also be informed verbally that their participation is voluntary and that they can withdraw their consent at any time without giving reasons and without depriving themselves of any treatment and care or other disadvantages.

Patients who agree to participate will be scheduled for a screening visit with a therapist (Multimedia Appendix 1). First, they will be asked to sign the written informed consent (Multimedia Appendix 2) after carefully reading and understanding the information about the study procedures and data security measures (including information on how to contact the study team in case of questions) provided to them. This approach is compliant with the General Data Protection Regulation and has been approved by the ethics committees.

After consent, recruited patients will proceed to the screening evaluation, where inclusion and exclusion criteria are assessed, and they will immediately receive feedback on whether or not they can participate in the study. Enrolled patients will be randomized by the study manager through the electronic case record form (eCRF) (Multimedia Appendix 1) into one of the 2 groups (ie, MS-FIT and control) and informed of the result of the assignment.

Eligibility Criteria

Eligibility criteria were selected to ensure optimal fitness of the study sample with respect to the subsequent implementation of the MS-FIT intervention in the health care setting, to minimize the impact of confounding variables (eg, rehabilitation outcomes), and to ensure comparability with other studies on similar interventions.

Inclusion Criteria

The study includes people with a diagnosis of MS according to McDonald's criteria [31] and aged ≥18 years; all disease courses are eligible (relapsing-remitting, primary progressive, and secondary progressive) [32]. Patients will be included if their disability level based on the Expanded Disability Status Scale (EDSS) [33] is between 2 and 4. Indeed, we expect that in people with MS with a lower EDSS, the proposed intervention might not be effective and other forms of PA based mainly on exercise should be considered. For people with MS with a higher EDSS, Pilates could be recommended as a complement but not as a replacement for rehabilitation; also, for this reason, we considered it unethical to include patients who should suspend their treatments for the aims of the study. Furthermore, asynchronous telerehabilitation tools for self-administered balance training should be proposed when the patient's ability to maintain balance safely is preserved (eg, pregnant women will be excluded until after giving birth). In any case, we included patients with preserved balance evaluated with the Berg Balance Scale score >46 [34].

To ensure the ability to use the MS-FIT exergame, normal cognitive functioning determined by a Mini-Mental Status Examination score >24 [35] is required; a Hospital Anxiety and Depression Scale score <10 in the 2 subsets of anxiety and depression [36] could prevent a loss of adherence due to mood disorders.

Exclusion Criteria

The study excludes individuals who have received at least 1 rehabilitation treatment (except speech therapy, sphincter rehabilitation, and psychological support) in the last month before being contacted. Other exclusion criteria are visual deficits that could compromise the use of the MS-FIT exergame and relapses in the last 3 months. Participants with relapses during the period of involvement in the study will be considered dropouts.

All hardware and software components will be provided to the participants in the MS-FIT group; training provided by the study manager will ensure ease of use. For this reason, technology will not be an exclusion criterion.

Intervention

All participants will be allowed to continue their leisure-time physical activities.

Participants in the MS-FIT group will receive the MS-FIT exergame [28]. They will be required to train at home with MS-FIT for 12 weeks by performing the exercises for a total of 30 minutes/day for at least 3 days/week.

While gaming, participants will choose their favorite and most useful exercises; the difficulty of the exercise will increase based on the user's performance. In this way, the exercise selection and the reward structure will ensure the personalization of the intervention.

Before starting the intervention, each participant will be trained in the use of the tool by the study manager.

Participants in the control group will not receive MS-FIT; however, as a reward for their participation, we will offer them the MS-FIT intervention at the end of their study involvement.

All participants will be assessed at T0, T1, and T2.

Assessment

The assessment will consist of clinical tests measuring the domains most relevant to MS. The primary outcome will always be administered first; the order of the secondary outcomes will be randomized across participants; however, the same order will be maintained for the individual participant. We assume that the administration of all tests will take, on average, about 60 minutes.

Multimedia Appendix 3 summarizes when the different outcome measures should be collected.

Primary Outcome

The primary outcome of the study is TUG [37], commonly used to measure dynamic balance and to assess activity limitations by examining the patient's ability to ambulate and perform transfers. The TUG was originally created to predict the risk of falling in geriatric patients.

At the "go" signal, the participant must rise from a chair, walk 3 m, turn around, return to the chair, and sit down as quickly but safely as possible. The participant starts with the back against the chair and the arms resting on the armrests and is timed from the moment he or she lifts the pelvis from the chair until he returns with the pelvis on the chair [34]. The participant wears his or her regular footwear and uses his or her customary walking aid (none, cane, or walker); however, due to the eligibility criteria adopted in this study, participants will not

use assistive devices for walking. No physical assistance is given.

Secondary Outcomes

Secondary outcomes will evaluate the effects of the intervention on the following:

1. Motor function: visual analog scale (VAS; 0-10) for balance subjective disability improvement [38], Timed 25-Foot Walk (T25FW) [39], Ambulation Index [40], 2-minute walk test (2MWT) [41], Twelve Item Multiple Sclerosis Walking Scale (MSWS-12) [42,43], and Nine-Hole Peg Test (9HPT) [44].
2. Cognition: Brief International Cognitive Assessment for Brief International Cognitive Assessment for Multiple Sclerosis (BICAMS), which consists of the Symbol Digit Modalities Test (SDMT), the California Verbal Learning Test-II (CVLT-II), and the Brief Visuospatial Memory Test-Revised (BVMT-R) [45].
3. Fatigue: Modified Fatigue Impact Scale (MFIS) [46,47].
4. QoL: Multiple Sclerosis Quality of Life-54 (MSQoL-54) [48,49].
5. Well-being: Psychological Well-Being Scales (PWB) [50,51].
6. PA: International Physical Activity Questionnaire (IPAQ) [52,53], the Minnesota Leisure-Time Physical Activity Questionnaire [54] which provides a general evaluation of the total energy expenditure in leisure time physical activity.
7. Perceived intervention effect: 7-point Patients' Global Impression of Change (PGIC; from 1="no change or worse" to 7="a great deal better") scale.

Technology

Furthermore, acceptance of the used technology will be evaluated with an ad-hoc questionnaire on patients' expectations; satisfaction with the intervention will be evaluated with the Client Satisfaction Questionnaire (CSQ-8) [55,56] and the Tele-healthcare Satisfaction Questionnaire (TSQ-WT) [57].

Blood Sample

If the participant consents, a peripheral blood sample will be collected at T0 in vacutainer tubes containing ethylenediaminetetraacetic acid. According to previous studies [29], participants will be divided into subgroups with respect to polymorphism. All blood samples will be genotyped for a total of 55 genetic polymorphisms of 23 potential regulators, such as Homer1, AKT1, RAPTOR, D2R, GAPD, CHAT, p53, BRCA2, LIG4, XRCC5, CYP3A4, NBS1, MDM2, CNR1, ATTn, CNR2, GRIN1, GRIN2B, TRPV1, FAAH, COMPT, and BDNF.

For example, CNR1 region containing AAT repetitions will be amplified by polymerase chain reaction from genomic DNA; sequencing products will be purified using a rapid, high-performance dye-terminator removal kit and will be subjected to electrophoresis; AAT repetitions will be counted on the resulting electropherograms (short AAT: homozygous or heterozygous for an allele with ≤11 repeats of AAT triplets; long AAT: homozygous for an allele with ≥12 repeats of AAT triplets). For the TRPV1 and FAAH, the iPLEX Gold technology and MassARRAY high-throughput DNA analysis will be performed.

The blood sample will be collected early in the morning after awakening (8:00 AM). To synchronize the sample with lifestyle variables, participants were requested to avoid excessive physical activity in the last 3 days before blood sampling, to sleep for 7-8 hours the night before the study, to avoid starvation, and to have a normal breakfast in the morning [29]. The samples will be analyzed in the center of DC.

Other Measures

Adherence to the intervention will be provided by the number of sessions actually performed as automatically recorded by the MS-FIT tool and the number of dropouts.

Safety will be assessed by the number of potential issues (ie, number of falls). The severity of adverse events will be graded according to the Common Terminology Criteria for Adverse Events v 4.0 on a 5-point scale (grade 1, mild discomfort; grade 2, moderate discomfort; grade 3, severe inability; grade 4, life-threatening or disabling; grade 5, death) and reported in detail on the eCRF. A grade higher than grade 2 will be considered as a condition for dropout.

We will also collect information on the pharmacological treatments (specific and nonspecific for MS) followed by participants, comorbidities, and the type of PA practiced during participation in the study.

Criteria for Premature Withdrawal

In addition to withdrawal of consent at any time, the study manager at each site may also consider as criteria for premature withdrawal any medical conditions that could jeopardize the safety of the patient if she or he continues the study, changes in the disease treatment during the study, and noncompliance of the participants to the study procedures.

Sample Size

The sample size was calculated by referring to the TUG change after a Pilates intervention found by Kalron et al [30] in a group of people with MS. The authors found no difference between the group receiving the Pilates intervention and the control group receiving an intervention of physical therapy. The Pilates group improved the TUG performance by about 1.8 seconds, which is clinically relevant for people with MS. Considering a variability of about 3.4 seconds, a power of 80%, a significance level (2-sided) of 5%, and a potential loss of 15% of patients at follow-up, the estimation of the necessary sample size consists of approximately 63 participants for the experimental group (a total of 126).

Data Collection and Management

Data entry, including quality checks and double entry validation, will be performed through eCRF (Multimedia Appendix 1). Missing data from the unit record will be compared with the corresponding handwriting case record form and corrected accordingly.

Statistical Analysis

Descriptive statistics will be used to evaluate differences between the 2 groups of participants. The study hypotheses will be tested using an intention-to-treat analysis, where all consenting patients who were randomized during the accrual period will be included in the analysis.

Continuous data will be summarized using count, mean, median, SD, and IQRs, whereas categorical measures will be described using frequencies. The assumption of normality will be tested with the Shapiro-Wilk test. Pre-post effects within groups will be investigated using the paired *t* test or the Wilcoxon matched-pairs signed-rank test. Between-group proportions will be compared by chi-square or Fisher exact test, while between-group comparisons for continuous variables will be done using either the unpaired 2-sided *t* test or the 2-sided Wilcoxon 2-sample test for nonnormal data. Correlations will be computed using Pearson or Spearman coefficients.

The primary analysis will be performed by comparing mean changes from T0 to T1 in the primary and secondary study outcomes. In particular, the MS-FIT group will be compared with the control group with analyses of covariance. The model includes change as the dependent variable, with the intervention group as the main effect and baseline and number of sessions as additional covariates. Finally, generalized estimating equation models will be performed to assess the persistence of the intervention effect; here the mean effect of the intervention at the time points T0, T1, and T2 on all outcomes, adjusted for the baseline value, will be evaluated between the 2 groups.

Differences in the outcome measures between subgroups defined by different polymorphisms will be analyzed using the analysis of variance or the Kruskal-Wallis test, as appropriate.

Statistical analysis will be performed using STATISTICA 7.1 software (StatSoft GmbH). Significance will be recognized for $P<.05$.

Ethical Considerations

This trial is conducted in accordance with the protocol (version 1, July 27, 2018), the Declaration of Helsinki, and good clinical practice. It has been approved by the Ethics Committee of San Martino Hospital (134/2018) and registered before patient enrollment at ClinicalTrials.gov (NCT04011579).

Any change to this protocol must be agreed upon by all the study investigators. Each amendment must be signed by the principal investigator at each site, and amendment forms will be submitted to the local Ethics Committee for approval. The amendment will be updated in the clinical trial registry.

Participants will be asked to sign the written informed consent, and their data will be deidentified. Participants will not receive any compensation for participating in the study.

A formal audit process at the end of the study is proposed for this trial.

Patient and Public Involvement

Patients and the public were not involved in the design, conduct, reporting, or dissemination plans of our research, although patient feedback was an important source for the development and improvement of the MS-FIT tool investigated in this trial [28]. Published results will be disseminated to study participants upon request.

Dissemination

The results of this RCT study will be disseminated. Dissemination includes communication and promotion of the project activities and results to participants, people with MS, and their stakeholders (eg, caregivers, health care professionals, and the scientific community). Dissemination activities will begin at launch and will continue throughout the duration of the study. Specific activities include dissemination through materials such as flyers and videos to be distributed through the internet, social networks, forums, or at local, national, and international events, and specific meetings with end users; dissemination through presentation of results in national and international peer-reviewed scientific journals; dissemination through presentation of research results at major national and international health care conferences and annual meetings; and dissemination through the ClinicalTrials website registry.

Results

Recruitment for the trial started on March 16, 2022, and the first participant was randomized on the same day. As of March 2022, we enrolled 126 participants who received a T0 visit; up to now, 108 received a T1 visit and 103 received a T2 visit. Data analysis and results will be published in early 2025.

Discussion

Summary

Cumulative data suggest that the Pilates method has proven beneficial in several neurological diseases and may be a PA tool for people with MS. A recent review [22] in MS showed that Pilates improves balance, gait, physical-functional conditions (muscle strength, core stability, aerobic capacity, and body composition), and cognitive functions; in contrast, fatigue, QoL, and psychological function did not show a clear improvement. Furthermore, high adherence (average adherence ≥80%) and few adverse effects were reported. For these reasons, future research is needed to develop clinical protocols that can maximize the therapeutic effects of Pilates for people with MS. In this context, novel devices and technologies for home-based interventions could provide solutions to overcome limitations due to urban barriers (eg, transportation), daily activities (eg, working time), and clinical conditions (eg, level of disability) and to ensure continuity of care. Therefore, practicing Pilates at home through eHealth tools could help people with MS to regularly engage in PA and to successfully maintain their physical, cognitive, and emotional status.

Here, we describe the RCT protocol designed to test the efficacy of a home-based PA intervention delivered through the MS-FIT exergame on balance and gait. In addition, we will also assess the effects on cognition, QoL, and well-being.

The present RCT protocol was designed taking into account previous studies in the MS scientific literature in terms of the

number of weeks of intervention, weekly frequency, session duration, outcomes, setting, and control group [22]. Because only one study evaluated long-term monitoring after the intervention [58] and it is unclear whether the obtained results are maintained, as an additional element of novelty, we propose to schedule a follow-up assessment in order to define whether the effects of Pilates persist.

Limitations

The first limitation of this study is that we will only have evidence of the effectiveness of a Pilates exergame for people with MS with mild disability. However, even people with MS at more advanced disease stages benefit from regular PA to maintain fitness, prevent pain and secondary complications of inactivity, and treat or reduce symptoms. Thus, as specific prescriptions should be tailored to clinical conditions, a dedicated trial for patients with a higher level of disability should be considered. Second, due to the discontinuation of the Kinect Sensor V2 adopted in MS-FIT, for the successful translation of the exergame into clinical practice, a new compatible commercial sensor will be identified, and the app will be adapted; Microsoft Azure Kinect and Mentor Age (Wita Società a responabilità limitata) are valid and comparable systems already taken into account by other researchers [28,59,60]. Third, although the MS-FIT tool was not developed to pursue rehabilitation purposes, it would be helpful to analyze the MS-FIT intervention as a complement to the work of health care professionals and evaluate if it is able to potentiate the effect of a rehabilitation intervention, possibly also in people with MS with a higher level of disability. Finally, direct evidence, such as MRI acquisition, will not be considered to reveal which microstructural changes are due to the MS-FIT intervention.

Future Directions and Conclusions

MS-FIT is a usable and accepted digital health tool for telerehabilitation implementing Pilates exercises and aims at supporting the self-administration of Pilates training at home. This study will provide evidence for the use of the MS-FIT tool in clinical practice as a complement to rehabilitation and for the continuity of care of people with MS. However, a feasibility protocol involving patients with moderate disability (EDSS between 4 and 6) should be designed and tested, followed by a multicenter trial that assesses the effectiveness of the tool and paves the way for more extensive use in MS.

Acknowledgments

The authors would like to thank the Italian Multiple Sclerosis Foundation and Roche Società per Azioni (Società per azioni) for supporting this study.

Data Availability

The data sets generated and analyzed during this study will be available from the corresponding author on reasonable request.

Conflicts of Interest

AT, MP, PC, LL, EC, MR, LS, GT, LP, FP, ES, EP, MAB, and GB have no conflicts of interest to disclose. MI is coeditor for MSJ; she has received honoraria for participation in advisory boards from Biogen, Bristol Myers Squibb, Merck, Novartis, Roche, Sanofi, and Janssen. DC is an advisory board member of Almirall, Bayer Schering, Biogen, GW Pharmaceuticals, Merck Serono, Novartis, Roche, Sanofi-Genzyme, and Teva and received honoraria for speaking or consultation fees from Almirall, Bayer Schering, Biogen, GW Pharmaceuticals, Merck Serono, Novartis, Roche, Sanofi-Genzyme, and Teva; he is also the principal investigator in clinical trials for Bayer Schering, Biogen, Merck Serono, Mitsubishi, Novartis, Roche, Sanofi-Genzyme, and Teva; his preclinical and clinical research was supported by grants from Bayer Schering, Biogen Idec, Celgene, Merck Serono, Novartis, Roche, Sanofi-Genzyme, and Teva. DP received advisory board membership, speaker's honoraria, travel support, research grants, consulting fees, or clinical trial support from Almirall, Biogen, BMS-Celgene, Sanofi-Genzyme, Merck Serono, Novartis, Roche, and Alexion. PG is an advisory board member of Biogen, Bayer-Shering, Roche, Merck-Serono, Novartis Pharma, Sanofi-Genzyme, Teva; he received honoraria for speaking or consultation fees from Biogen, Bayer-Shering, Roche, Merck-Serono, Novartis Pharma, Sanofi-Genzyme, Teva, Almirall, Sandoz; he is the principal investigator in Phase I, II and III clinical trials for Biogen, Bayer-Shering, Roche, Merck-Serono, Novartis Pharma, Sanofi-Genzyme, Teva; he received research funds from Biogen, Bayer-Shering, Roche, Merck-Serono, Novartis Pharma, Sanofi-Genzyme.

Abstract

Background: Noncommunicable diseases (NCDs) require a longer period of care, for which health care systems must acquire technologically advanced solutions to enhance patient care. Swasthya Pahal (health for all) is an innovative, interactive, multilingual, stand-alone, internet-enabled computer-based program that aims to improve the self-management of NCDs.

Objective: This study aims to enhance the self-management of chronic NCDs (diabetes, hypertension, high cholesterol, and obesity) by determining the usefulness, acceptance, and effectiveness of the Swasthya Pahal program in hospital and community settings in both rural and urban areas of Chennai, Tamil Nadu. This objective can be met by generating risk factor profiles of individuals enrolled and enhancing their self-management of NCDs using a portable health information kiosk that uses the Sustainable, Multisector, Accessible, Affordable, Reimbursable, and Tailored (SMAART) model.

Methods: A quantitative study will be conducted on a convenient sample of 2800 individuals from selected hospital and community settings in rural (n=1400) and urban areas (n=1400) in Chennai, Tamil Nadu. Data will be collected on sociodemographics, health behaviors, and clinical status, as well as knowledge, attitudes, and practices. Objective assessments such as weight, blood pressure, and random blood sugar levels will be measured. In addition, the usefulness, acceptance, and effectiveness of the Swasthya Pahal program will be determined.

Results: Results will be summarized using descriptive analysis. Appropriate bivariate and multivariate regression analysis will be performed to determine the predictors of the outcome variables of usefulness, acceptance, and effectiveness of Swasthya Pahal in wider settings. All analyses will be performed using SAS (version 9.1; SAS Institute), and the results will be reported as 95% CI values and $P<.05$.

Conclusions: The study proposes to enhance the self-management of NCDs in both rural and urban community settings through the implementation of the Swasthya Pahal program based on the SMAART informatics framework. The study aims to understand the implementation, acceptability, and usability of Swasthya Pahal among a diverse sample of people in urban and rural settings.

Introduction

Background

Noncommunicable diseases (NCDs), which include heart disease, stroke, cancer, diabetes, and chronic lung disease, are the leading causes of illness worldwide. This has been identified as one of the most significant challenges to sustainable development in the 21st century [1]. According to the World Health Organization, NCDs account for approximately 38 million (68%) of all deaths worldwide and approximately 5.87 million (60%) of all deaths in India [2]. The Sustainable Development Goal target 3.4 is to reduce premature mortality from NCDs by one-third by 2030 relative to 2015, as well as to promote mental health and well-being [3]. India faces a significant burden of NCDs, which poses a challenge in achieving Sustainable Development Goal 3 Good Health and Well-Being. In recent years, India has experienced demographic and epidemiological shifts, resulting in a shift from infectious diseases to NCDs. The World Health Organization reports that 1 in every 4 Indians is at risk of dying from an NCD before the age of 70 years [4]. If timely NCD prevention and control measures are not implemented, the total annual number of NCD deaths will rise to 55 million by 2030 [5].

In the current era, information and communication technologies (ICTs) serve as health systems, promoting, restoring, or maintaining health. They should be used for the prevention and control of both communicable and NCDs at multiple levels and in a variety of ways [4]. The use of ICT in a health-promoting lifestyle behavior program improves health behaviors that are crucial in the prevention of both communicable and noncommunicable diseases. eHealth is defined as the application of ICT in the world of health care. It includes mobile health, telemedicine, health information systems, electronic health records, and many more [6]. These technologies can be presented and accessed in a variety of ways, including web-based applications, mobile phone and alert systems, and phone and videoconferencing. They have been identified as effective measures for improving patient skills and knowledge, increasing the likelihood of healthy behavior [7]. It can provide both low-cost and high-quality services. Health information products can be designed to suit the needs of the community by incorporating high levels of interaction and accessibility. Technological solutions play an important role in health care systems by assisting individuals in self-checking their health status and providing low-cost, accessible, and affordable solutions to meet the demands of local communities across geographical locations, particularly those in resource-poor settings [8]. Studies have shown that the use of ICT through mobile health in India has benefitted both urban and rural healthy and unhealthy (“disease”) population groups. [9-11] Health kiosks will continue to play an important role in the digital health scene for the foreseeable future. One of the advantages of telehealth kiosks is that they bring medical and expert care to remote locations that medical practitioners rarely visit. In nations such as India, these locations could be distant rural areas with inadequate infrastructure [12]. A pilot study of the Swasthya Pahal (health for all) program, which is an advanced community-based program facilitated by an interactive, multilingual, standalone, and internet-enabled program, has highlighted the improvement of self-management of NCDs among police personnel [13]. The program was implemented through a digital, interactive touch screen platform Sustainable, Multisector, Accessible, Affordable, Reimbursable, and Tailored (SMAART) model. The potential outcome of the SMAART platform is that it is a personalized self-management action plan that enables easier self-management and that is backed up by continuous monitoring, interactive health information, and collaborative decision-making [8]. The pilot study had significant findings: the applicability of the study and its use beyond a purposive population group needed to be further studied. The program is based on the Population Health Informatics framework; to the best of our knowledge, this framework is now used to address the burden of NCDs in both urban and rural economic groups. This study aims to evaluate the usability of a portable health information kiosk that uses the SMAART framework to address the burden of NCDs by determining the usefulness, acceptance, and effectiveness of Swasthya Pahal in hospital and community settings of both rural and urban areas of Chennai, Tamil Nadu.

Objectives

The objectives of the research are as follows:

1. To use the digital health intervention Swasthya Pahal to assess the risk factor profile of NCDs in individuals from hospital and community settings in rural and urban areas of Chennai, Tamil Nadu.
2. To assess individuals’ Knowledge, Attitudes, and Practices (KAP) of their health status and self-management of chronic NCDs (diabetes, hypertension, high cholesterol, and obesity) through the Swasthya Pahal program among individuals from hospitals and community settings in rural and urban areas of Chennai, Tamil Nadu.
3. To investigate the usefulness and acceptance of the Swasthya Pahal program among individuals from the hospital and community settings in rural and urban areas of Chennai to enhance self-management of NCDs.

Methods

Study Design

The quantitative pre-post study will recruit 2800 study participants from the community and hospital settings in urban and rural areas of Chennai, Tamil Nadu. Individuals will have access to a touch screen device to register their health data in their respective languages. Subjective data on sociodemographic details, health behaviors, clinical status, and KAP will be gathered. Objective data will include measurements of height, weight, blood pressure, and blood glucose levels. Individuals will be randomly assigned to the intervention and control group. A total of 20% of the rural and urban samples will be assigned

to the control group (total N=560; n=280 from each urban and rural area) and intervention group (total N=560; n=280 from each urban and rural area). Those in the intervention group will have access to tailored messages through the use of multiple interactive digital formats using podcasts and SMS. Those in the control group will have access to standard of care and will be provided with a booklet in English and in the local dialect to self-manage the burden of NCDs. Individuals will receive interactive messages for 3 months on a daily or weekly basis. The message content and delivery will be tailored (based on sociodemographics, KAP, user preferences, and disease conditions) to meet the specific needs of the individuals. Monthly assessments will be done at month(s) 1, 2, and 3. At 6 months, retention analysis will be done for Knowledge. In addition, the usefulness, acceptance, and effectiveness of Swasthya Pahal will be assessed postintervention.

Study Setting and Study Population

The study population will be from hospital and community settings of selected rural and urban areas of Chennai, Tamil Nadu, namely Kannur, Pannur, Thirumanikuppam, Thodukadu, Kottaiyur, Nemili, Mannur, Kiloy, Ulundai, Narasamangalam, Karanai, Panimalar Medical College Hospital and the Research Institute and Rural Health Training Centre Chennai, and Maligaipattu village.

Sampling and Recruitment

Participants will be recruited using the nonprobability convenience sampling method from selected urban and rural sites of Chennai, Tamil Nadu. Data will be gathered from 2800 participants (1400 each from urban and rural sites).

Inclusion criteria were participants above the age of 18 years and those consenting to participate and exclusion criteria were individuals below the age of 18 years and those who would not give their consent.

Data Collection—Structured and Semistructured Questionnaire

Overview

A structured questionnaire will be used to determine the risk factor profile of NCDs in individuals from selected rural and urban areas of Chennai, Tamil Nadu. For objectives 1 and 2, data will be collected on the portable health information kiosk. Individuals will be enrolled in the Swasthya Pahal program with a unique code that will generate a SMAART health card. Information will be recorded electronically, that is, subjective data that captures sociodemographic profile, clinical status, information on health behavior, KAP of individuals, and objective data such as BMI, blood pressure, and blood glucose levels will be measured. After 3 months of intervention, a posttest will be conducted on KAP, and then a crossover of intervention mode is done. For objective 3, after the dual intervention, KAP will be conducted and the acceptance and usability of the program will be assessed by 2 tools: the Client Satisfaction Questionnaire and System Usability Scale (annexures 2 and 3 in Multimedia Appendix 1). The tool will be translated into the local language (Tamil). A small group of respondents will pilot test the study tool in the local language to ensure the clarity of the questions asked.

Variables Assessed

The following variables will be assessed in the study: variables A1, A2, A3, and A4 will be assessed with respect to objectives 1 and 2, and variables B1 and B2 will be assessed with respect to objective 3.

A1—Sociodemographic Details

Data will be gathered on the study participant's age, gender, region of residence, and education level.

A2—Health Behavior

Data on history and current smoking and alcohol consumption will be compiled. Data on the family history of consumption will also be collected.

A3—Clinical Status Details

This will include information on anthropometric measurements such as height (as measured by a Stadiometer), weight (as measured by a standard technique), and BMI. A sphygmomanometer will be used to take blood pressure readings. A glucometer will be used to measure blood glucose levels.

A4—Knowledge, Attitudes, and Practices

These data will collect information on an individual's understanding of their BMI, blood pressure, and blood sugar level. The information gathered will determine whether the individual is currently receiving treatment for any disease risks and what treatments have already been followed (eg, diet, medicine, and physical activity). The tool also captures the individual's level of understanding of obesity, hypertension, and diabetic risk factors. It also acquires information on individuals receiving treatment for any of the illness risks and information on individuals' understanding of their family's health history.

B1—Tool for Acceptance: Client Satisfaction Questionnaire

This questionnaire includes a total of 8 questions on a 4-point Likert scale that contains questions related to the accessibility of the computer-based software Swasthya Pahal.

B2—Tool for Usability: System Usability Scale

The System Usability Scale consists of 10 questions on which individuals rate the system on a 5-point Likert scale based on their opinion of the system's usefulness.

Data Collection, Data Entry, and Quality Assurance

To ensure efficient and high-quality data collection and processing, the following data management protocol will be followed: a well-defined study manual will be prepared, and a well-trained data collection team will be in charge of data collection, data entry, and data security procedures. Each question will be explained clearly by the data collector, and any doubt or confusion regarding the question will be addressed immediately. The data will be electronically recorded using the Swasthya Pahal (Health for All) software.

Data Security and Privacy

Regular backups will ensure data security by storing data files in one password-protected computer or laptop and deleted from other systems. The data files will have a unique password that only the concerned research team will be able to access. Data will be kept for 15 years after the study is completed in case it is needed to validate research findings, set priorities, or be re-analyzed by another researcher [14].

Data Analysis

The collected information will be entered in SAS (version 9.1; SAS Institute) and the results were reported as 95% CI values and $P<.05$. The data will be summarized by using frequency, percentage, mean, and SD values. Appropriate bivariate and multivariate analyses will be done. A *t* test to compare means between the continuous variables and a categorical dependent variable will be conducted. A chi-square analysis will be performed to determine whether the two independent variables are related.

Project Timeline and Milestones

A detailed research plan and schedule timeline of the tasks involved in the study are presented in Table 1.

Table 1. Scheduled timeline of the tasks in the Swasthya Pahal.

Task	Months									
	1	2	3	4	5-7	8-10	11-13	13-15	16-19	20-24

Informed Consent

The research team will provide the informed consent form approved by the Institutional Review Board (IRB) to all eligible participants in the study (Multimedia Appendix 1). The team will explain the study details, the time commitment, and the benefits of the study results to the participants. Those who are willing to participate and provide consent will be enrolled in the study. If any participant is uneducated, ethical consent will be audio recorded. Furthermore, uneducated participants will be instructed on how to complete the questionnaire in the local Indian dialect, increasing the study's usefulness and generalizability. Data privacy and patient confidentiality will be assured. The study participants will have the right to withdraw from the study at any time.

Ethical Considerations

The study with protocol number PMCHRI-IHEC-058 gained approval from the Panimalar Medical College Hospital and Research Institute Institutional Human Ethics Committee (Central Drugs Standard Control Organization Registration number ECR/1399/Inst/TN/2020) in February 2022 with approval number PMCH&RI/IHEC/20221/021 dated February 18, 2022. The study will be conducted according to the Declaration of Helsinki, as it involves human participants [15].

Results

The program Swasthya Pahal aims to enhance the self-management of NCDs, including diabetes, hypertension, and obesity, in the rural and urban setting of Tamil Nadu, which will help in examining the individual's perception of NCDs and also help in behavioral changes among the general population. The data collected will determine the predictors of the outcome variables of usefulness, acceptance, and effectiveness of Swasthya Pahal and broaden the applicability of the Swasthya Pahal program among individuals from rural and urban settings.

Discussion

Overview

NCDs claim the lives of 40 million people worldwide each year, accounting for 70% of all fatalities. Cardiovascular illnesses (17.7 million deaths), malignancies (8.8 million deaths), respiratory diseases (3.9 million deaths), and diabetes (1.6 million deaths) account for 81% of these deaths [16,17]. NCDs have become a serious public health problem in developing nations like India. NCD imposes financial consequences for India's poorer households, as well as high out-of-pocket costs for the acute and long-term impacts of NCDs. This results in catastrophic health expenditure for households [18]. As a result, it is critical to screen individuals for NCDs and provide health education. Tailored ICT-supported NCD management programs such as Swasthya Pahal (Health for All) can make a difference by ascertaining an individual's risk factor profile, as well as their perspective on NCDs and their health status. The critical need of the hour is the applicability of tailored NCD management interventions that can enhance knowledge and prognosis of the disease to the patient while also influencing policy decisions among low- and middle-income countries [19]. This digital platform intervention across a wider population group cannot only enhance the self-management or prevention of NCDs in individuals but its usefulness and acceptance may assist researchers and policymakers in health education and communication across the country.

The limitation of the study is that it is cross-sectional, needs to evaluate the long-term impact of the Swasthya Pahal program, and covers a large population group in the self-management of NCDs.

Conclusions

Swasthya Pahal offers a personalized self-management plan that is supported by continuous monitoring, interactive health data, and collaborative decision-making. It focuses on an individual's risk factor profile and helps us understand how they perceive NCDs and their health status. The research will help us understand the acceptability and usefulness of Swasthya Pahal among a large sample from urban and rural settings. It can be used to raise awareness and address the burden of NCDs. The program can be used for developing cost-effective interventions that can be used to educate populations from remote or unreached areas.

Abstract

Background: Postoperative rehabilitation following total knee arthroplasty (TKA) varies worldwide. In Finland, patients receive guidance on safe walking and home exercises from a physiotherapist both before and after TKA. These are performed independently after surgery. However, a sedentary lifestyle is rather common among patients who have undergone TKA, with pain often limiting postoperative walking, training, and activities of daily living.

Objective: This randomized controlled trial aimed to investigate the effectiveness of anti-gravity exercise, precisely the AlterG anti-gravity treadmill, on postoperative rehabilitation following TKA and to obtain new knowledge on this form of rehabilitation to better use it in the future.

Methods: This randomized controlled trial study divided the patients into two groups: the intervention group and the control group. The follow-up period was 12 months. Research data were collected through questionnaires and functional tests. All patients in both groups responded to the questionnaires and participated in functional tests before surgery as well as 4 and 12 months after surgery. Patients in the intervention group exercised on the AlterG treadmill 10 times after the surgery. All the patients in this study performed the exercises as instructed when they were in the hospital. The primary outcomes were perceived pain, walking ability, and quality of life.

Results: The data collection process began in 2018 and concluded in 2022, intending to obtain valuable information regarding the effect of AlterG training after TKA and determine whether it, along with traditional exercises, could be an effective form of rehabilitation that can be performed at home. We hypothesized that AlterG training would lead to faster rehabilitation, better walking quality, improved quality of life, improved physical activity, and improved overall functioning. The results of this study will be analyzed in 2025 and 2026.

Conclusions: This study provides information on how AlterG training can be used in rehabilitation after TKA, further enhancing the rehabilitation program for patients undergoing TKA in general.

KEYWORDS

total knee arthroplasty; AlterG; anti-gravity treadmill; postoperative rehabilitation; walking ability; quality of life; pain

Introduction

Overview

Pre- and postoperative rehabilitation for total knee arthroplasty (TKA) varies worldwide [1-3]. There are guidelines for postoperative physiotherapy after TKA [4], and physiotherapy guidance for self-directed home exercises is recommended [5]. In Finland, the current care guidelines provide guidance for pre- and postoperative rehabilitation [6], but the practices associated with the rehabilitation vary among different hospitals. Previous studies have shown that both inpatient and home-based rehabilitation are effective after TKA [7] and that resistance training in water is a feasible mode of rehabilitation with a wide range of positive effects on patients undergoing TKA [8]. Reportedly, a sedentary lifestyle is rather common among patients who have undergone TKA, with pain or discomfort while standing being the greatest barrier to increasing physical activity [9]. Pain limits postoperative walking training and activities of daily living [10].

Anti-gravity exercises could help address these challenges. They enable a more objective analysis of walking, showing the entire picture of a patient's walking problems. AlterG (AlterG, Inc., Fremont, CA), a patented compressed air technology (NASA differential air pressure technology), can be used to lighten the user's body weight and the load of gravity with 1% accuracy, thereby enabling a less painful walking exercise compared to normal land-based training [11]. While there is limited research on the effects of AlterG training, randomized controlled trials (RCTs) with small sample sizes have been reported, particularly among patients with neurological disorders, such as cerebral palsy [12] and stroke [13,14]. These studies demonstrated that AlterG training positively affected walking speed and dynamic balance and reduced the risk of falls [12-14]. Similar results were reported in studies investigating the effects of AlterG training in rehabilitation after lower limb fractures [15,16]. Precisely, it was found that AlterG training increased muscle strength in the hip area [15] and enabled better walking [16].

A pilot study on AlterG training after TKA revealed that it increased functional ability and is thus overall a safe, useful, and effective rehabilitation method after TKA [17]. Although previous researchers [17] concluded that while functional outcomes improved over time with the use of anti-gravity gait training, further studies with a larger sample size are required to define the role of this device as an alternative or adjunct to established rehabilitation protocols [17]. Furthermore, AlterG training in the acute phase of postoperative knee rehabilitation after knee surgeries, such as TKA and anterior cruciate ligament reconstruction, demonstrated a positive effect on balance in patients experiencing increased pain in weight-bearing postures [18]. AlterG training also decreased pain, enhanced joint function, improved quality of life (QoL), and maintained thigh muscle strength gains in patients with knee osteoarthritis [19]. However, as previously mentioned, not much research has been conducted on postoperative rehabilitation including AlterG training after TKA [17,18], thereby warranting further studies in the future to obtain more knowledge regarding its effects on walking and functional capacity.

Aims and Objectives

The exposures under investigation were the effects of anti-gravity treadmill training in postoperative rehabilitation following TKA and the added value it offered compared to traditional exercise. We hypothesized that AlterG training after hospitalization leads to faster rehabilitation, better walking quality, improved QoL, improved physical activity, and enhanced balance management compared to traditional rehabilitation methods with instructions, where patients perform the exercises independently at home. In addition, we hypothesized that the differences, in terms of the above factors, between the groups in the study—intervention group and control group—were larger in the early phase of the rehabilitation but became smaller over time. The study has been registered on ClinicalTrials.gov (NCT03904030).

This study aimed to determine the effectiveness of the AlterG anti-gravity treadmill in postoperative rehabilitation after TKA. Primary outcomes were perceived pain, walking ability, and QoL. To this end, AlterG rehabilitation and traditional postoperative rehabilitation with instructions were compared.

In detail, we aimed to measure the effects of AlterG training on:

- a patient's walking ability and walking distance after TKA,
- a patient's perceived QoL and functional ability after TKA,
- a patient's perceived pain, and
- lower limb and step symmetry during gait and if it normalizes the patient's stepping and walking.

Methods

Participant Selection and Sampling Strategy

Participants for this RCT study were recruited from two hospitals in the capital region of Finland: Orton Orthopaedic Hospital and Peijas Hospital, both of which are part of the HUS Helsinki University Hospital. Patients with grades 3 and 4 primary knee osteoarthritis and with a scheduled unilateral TKA were included in the study. Those with rheumatoid arthritis, who have undergone hip or knee arthroplasties within the last year, or with a BMI >40 kg/m^2 were excluded. All eligible patients who came for a knee arthroplasty surgery at Orton Orthopaedic Hospital between 2018 and 2021 and at Peijas Hospital between 2020 and 2021 were asked to participate in the study. The patients were recruited through a nurse's preoperative visit or a phone call made to the patients attending the surgery. The nurse then checked whether they met the inclusion and exclusion criteria; those who met the criteria were provided with written information regarding the study. The included patients were asked to provide signed consent forms (Multimedia Appendix 1), which they forwarded to the research assistant. When the patient had consented to participate in the trial, the randomization envelope was opened after the surgery. However, due to the nature of the intervention under study (rehabilitation intervention), it was not possible to blind the patients. The patients were randomly allocated either to the treatment group or the control group using a random number generator (StatTrek) by an expert who did not execute the study in practice. All the patients had free access to the available

health care services during the study. Overall, 62 patients (31 in each group) were recruited for the study.

Study Procedure

Patients in both groups underwent initial measurements 1-2 weeks before the surgery, which included questionnaires and functional tests performed by a physiotherapist. All the measurements were taken at Orton Orthopaedic Hospital. First, the patients were asked to complete the questionnaires, and functional tests were then performed. The questionnaires used were a visual analogue scale (measures perceived pain) [20], painDETECT [21], Tampa Scale of Kinesiophobia [22], RAND 36-item Health Survey 1.0 (RAND-36) [23], Oxford Knee Score [24,25], Western Ontario and McMaster Universities Osteoarthritis Index [26], Beck Depression Inventory [27], and State-Trait Anxiety Inventory [28] (Table 1). Functional tests performed were knee range of motion (ROM) [29], knee swelling [30], thigh circumference [31], single-leg stance test [32], Timed Up and Go test (TUG) [33,34], stair climbing test [35], and 6-minute walk test (6MWT) [36] (Table 1).

Patients were asked to complete the same questionnaires 6-8 weeks after surgery. The same questionnaires and functional tests were administered in the same order 4 and 12 months after the surgery at Orton Orthopaedic Hospital. This data can help obtain information regarding short-term (4 months) and long-term (12 months) changes. Then, 6 months after the surgery, the patients were sent a 6-month questionnaire regarding possible rehabilitation sessions, use of medication, and possible complications after TKA. The purpose of this questionnaire was to obtain information regarding their use of health care services and how their rehabilitation and recovery from the surgery have progressed.

After the surgery, the researcher informed each patient over the phone or face-to-face about their assigned group, either the intervention or control group. After that, the researcher booked training times on the AlterG for each member of the intervention group. Patients were sent a reminder through an SMS text message on the time reserved for them to ensure that the risk of forgetting was lower. If the time did not suit the patient, the physiotherapist was informed, and a new time was reserved accordingly. The patients in the intervention group exercised 10 times on the AlterG under the supervision of a registered physiotherapist. Both groups performed traditional postoperative exercises after TKA. The follow-up period was 12 months. Exercises began in the third week after surgery. In the third and fourth weeks after TKA, patients in the intervention group exercised twice a week on the AlterG and thrice a week in the fifth and sixth weeks considering individual variations. The AlterG training was recorded 3 out of 10 times—the first, fifth, and 10th training sessions. The recording began after the patient found a suitable walking speed and lightening. On average, the length of one recording was 2 minutes. The data obtained from the AlterG training was saved to a memory stick and then transferred to an electronic folder. The patient schedule of enrollment, interventions, and assessments are shown in Table 2. The study procedure is outlined in Figure 1.

The protocol has been developed using the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) checklist [37] (Multimedia Appendix 2).

Table 1. Questionnaires and functional tests.

Measurement	Explanation
Questionnaires	
Pain	
Severity of pain: VAS[a] [20]	The scale ranges from 0 to 100, where 0 indicates no pain at all and 100 indicates the worst possible pain.
Neuropathic pain: painDETECT [21]	The screening questionnaire identifies neuropathic components in patients with pain.
Fear of movement: TSK[b] [22]	The screening questionnaire detects fear of movement due to pain.
OKS[c] [24,25]	The 12-item questionnaire assesses knee pain and functionality.
WOMAC[d] [26]	The disease-specific questionnaire explores the effects of osteoarthritis treatment intervention.
Quality of life	
RAND-36[e] [23]	The questionnaire explores well-being and functional ability across eight dimensions: general health perceptions, physical functioning, emotional well-being, social functioning, energy, bodily pain, role functioning/physical, and role functioning/emotional.
Depression and anxiety	
BDI-21[f] [27]	The 21-item questionnaire measures depression.
STAI[g] [28]	The 40-item questionnaire measures trait and state anxiety.
Functional tests	
Knee ROM[h] in degrees (°) [29]	Knee ROM (flexion and extension) is measured using a goniometer.
Knee swelling (cm) [30]	Knee joint swelling is measured using a tape measure at the popliteal.
Thigh circumference (cm) [31]	The thigh circumference is measured using a tape measure 15 cm above the upper edge of the patella.
Single-leg stance (s) [32]	The balance test assesses static balance and upright posture control on a support surface narrower than a normal stance.
TUG[i] (s) [33,34]	The functional test measures an individual's mobility/ability to move.
Stair climbing test (s) [35]	The functional test measures the functionality of the lower extremities and balance control. Here, the test was systematically conducted on the same staircase, which had 11 steps. The depth of one step was 34 cm, and the height was 14.5 cm.
6MWT[j] (m) [36]	The functional test measures an individual's endurance and walking ability.

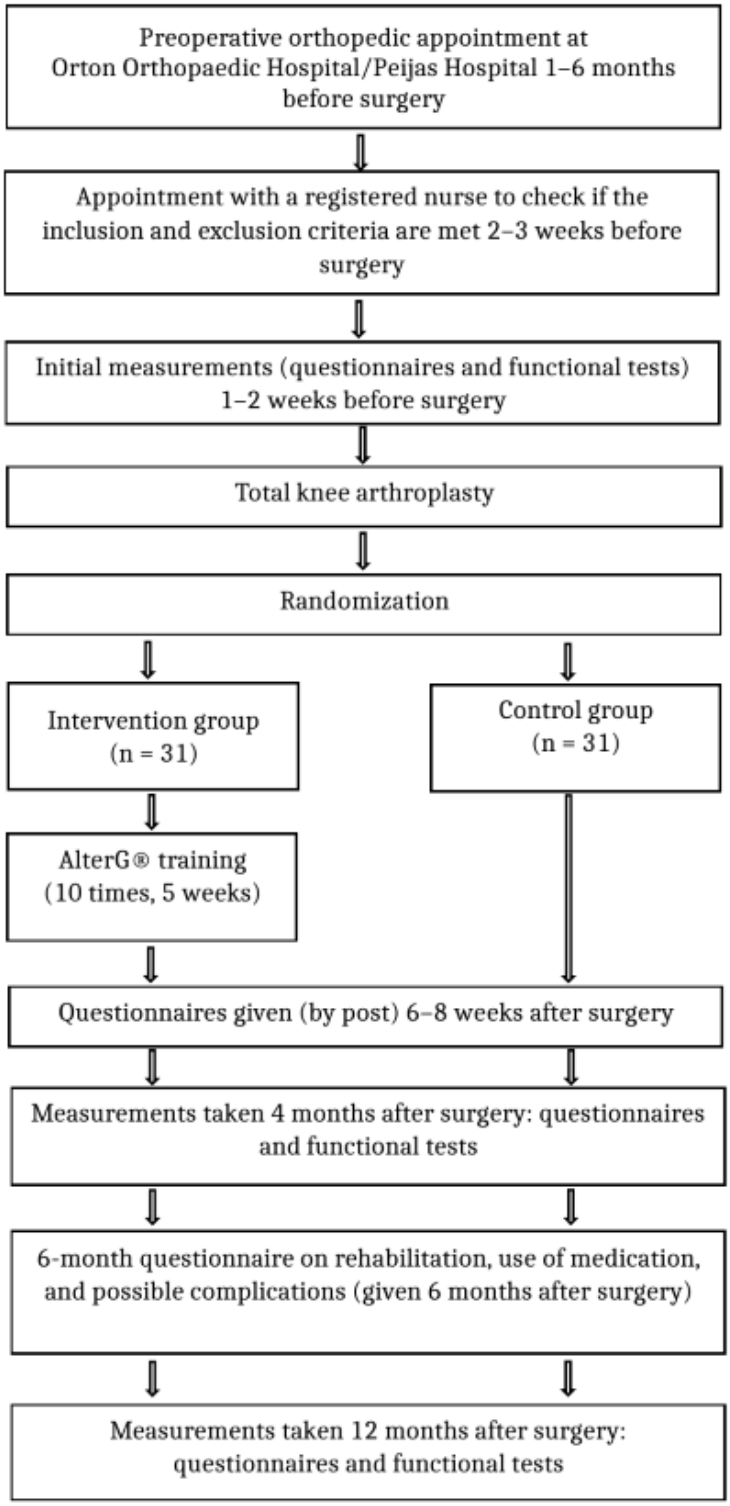
Figure 1. Study procedure.



Postoperative Exercises

Furthermore, all the patients (intervention and control groups) in the study independently performed the postoperative exercises instructed by the hospital's physiotherapists. The exercises were aimed to improve knee ROM and quadriceps and hamstring muscle strength and to stimulate venous circulation. Patients also received guidance on walking with crutches. They were instructed to perform home exercises for approximately 2 months after surgery. However, the researchers do not have information on how actively the patients were engaged with home exercises. The home exercises are described in Table 3.

Table 3. Traditional home exercises.

Exercise	Description	Aim
Knee flexion (sitting/supine position)	Sitting on a chair or in the supine position, the patient flexes the knee as much as possible, sliding the sole of the foot backward on the ground. The patient keeps the knee flexed for a while and then returns the lower limb to the starting position, sliding the sole of the foot forward.	To increase knee mobility in the direction of flexion
Knee flexion (standing position)	In the standing position, the patient brings the operated foot on a stair and shifts the weight forward, stretching the knee in the direction of flexion.	To increase knee mobility in the direction of flexion
Quadriceps strengthening (sitting/supine position)	In the sitting or supine position on a bed, the patient extends the knee and presses it against the platform or a towel roll by activating the quadriceps muscles. When performing this in the supine position, at the end of the movement, the patient can lift the straight leg off the ground. Quadriceps strengthening can also be done by sitting on a chair and lifting the straight leg off the ground.	To activate and strengthen the quadriceps muscles and the end-extension of the knee
Ankle pump movements (flexion and extension)	In the supine position, the patient flexes and extends the ankles in turns.	To stimulate and enhance venous blood circulation
Dynamic calf stretching	In the standing position, the patient performs a dynamic calf stretch, taking a step backward with the operated leg and pressing the heel on the ground while extending the knee and then lifting the heel off the ground and letting the knee flex.	To stretch the calf muscles
Hamstring stretching	In the sitting position and with the operated leg straight on the bed, the patient bends the upper body forward and stretches the hamstring muscles.	To stretch the hamstring muscles
Toe raises	In the standing position, the patient takes support from the back of the chair with their hands and rises to their toes and then returns to the starting position.	To activate the calf muscles
Walking with crutches	The patient is instructed on how to walk with crutches after the surgery, using either three-point walking or alternating walking, or with only one crutch. The patient is also instructed to walk on stairs with a crutch/crutches.	To guide the patient on how to use crutches after the surgery

Outcome Assessment and Measurements

The primary outcomes were walking ability measured with the 6MWT, health-related QoL measured with RAND-36, and perceived pain measured with VAS. All outcomes were measured before the TKA and 4 and 12 months after the TKA. In addition to this, the patients were asked to complete the same questionnaires 6-8 weeks after the TKA. The initial measurements were performed 1-2 weeks before the TKA. Depending on the patient, it took a total of 1.5-2 hours to complete the questionnaires and execute the functional tests. The same measurements were performed 4 and 12 months after the surgery, and the time required for these was the same as in the initial measurements (1.5-2 hours). Regarding the functional tests, the test scores were not calculated within the testing situation; however, the physiotherapist noted the measurement results on the test form, which were then saved in an electronic format. The results obtained from the tests were compared throughout the study between the patient's own results and between the intervention and control groups; no comparisons were made with the general reference values of the tests. The knee ROM and swelling, thigh muscle circumference, TUG, stair climbing test, and 6MWT were performed only once. The tests were performed twice only in the static balance test, and the best test result was recorded (the maximum time was 60 seconds).

All the measures of the study are presented in Table 1. During the AlterG training, the weight-bearing symmetry, step length, stance time symmetry, and cadence during walking were measured (Textbox 1).

Textbox 1. AlterG measurements.

Weight-bearing symmetry

- Weight-bearing symmetry gives information about the symmetry of the stance phase. In pathological situations, the stance phase is shorter on the weaker side [38].

Step length symmetry

- Step length is the distance from the back of one heel to the back of the other heel [38].

Stance phase symmetry

- Stance phase is the period when the foot is on the ground [38].

Cadence (steps/min)

- Cadence is the number of steps taken per minute [38].

Data Collection and Statistical Analysis

We estimated that a difference of 30 m in the 6MWT between the two groups would represent a clinically relevant difference [39,40]. To identify such a difference with 2-sided testing (α=.05 and power of 85%), the study required 31 participants in each group, with the assumption of 20% loss to follow-up.

The analysis will use the intention-to-treat principle, which will include all randomized patients. Summary statistics will be described using mean and SD, median and IQR, or numbers and percentages. Statistical comparison between the groups will be performed using the *t* test, Mann-Whitney test, χ^2 test, or Fisher-Freeman-Halton test, as appropriate. A linear mixed model or generalized estimating equation model with appropriate distribution and link function for repeated measurements will be used for analysis. In case of a violation of the test assumptions, a bootstrap-type method or Monte Carlo method will be used. Normal distributions will be graphically evaluated using the Shapiro-Wilk W test. Stata 18 (StataCorp LP) will be used for the analysis. Access to data will be granted to the research team of this study.

Ethical Considerations

The study protocol was approved by the ethics committee of the Hospital District of Helsinki and Uusimaa in 2017 (HUS/3117/2017). Helsinki University Hospital, Peijas Hospital, was also included in the study in 2020, and updated ethical permission and research permission were received from HUS (HUS 234/2020). Good research ethics practices were maintained in the study in accordance with the Declaration of Helsinki. Before participating in the study, every patient was given an information letter that would help them decide whether they wanted to participate in the study; once the decision was made, they were asked to sign a written consent form. The patients had the right to discontinue the trial whenever they wanted without giving any reason. However, the data collected before the discontinuation can be used for research purposes (Multimedia Appendix 1).

There was no inclusion of vulnerable groups such as children, prisoners, or individuals with mental disability. No participant reimbursement was provided to prevent economic factors from impacting the recruitment process.

If there were any changes to the protocol, the ethics committee and other relevant parties were informed.

Ensuring Data Quality

Anonymity and confidentiality were ensured by using numerical codes for the participants. Only the research group members had access to the participants' names. Data protection and storage security were ensured by storing the participant information and questionnaires in a locked cabinet at Orton Orthopaedic Hospital. Data were securely stored with electronic passwords on the hospital's server.

Results

The data collection began in 2018 and concluded in 2022. This study aimed to obtain valuable information on the effect of AlterG training after TKA. AlterG, along with traditional exercises, could be an effective form of rehabilitation that can be performed at home. We hypothesized that AlterG training leads to faster rehabilitation, better walking quality, improved QoL, improved physical activity, and improved overall functioning. At baseline, there were 62 participants in the study, with 31 in each group. Of these, 35 (56%) were women, and 27 (44%) were men, with a mean age of 66 (SD 7) years. The results of this study will be analyzed in 2025 and 2026. Results from this study will be submitted for publication in peer-reviewed international scientific journals and presented at scientific meetings.

Discussion

Expected Findings

The expected findings were related to walking ability, health-related QoL, and perceived pain. The expectations were that pain would decrease, walking distance would be longer, and health-related QoL would improve. In addition, we expected that the differences between the groups would be larger in the short term and eventually level out in 12 months.

Comparisons With Prior Work

Studies on postoperative rehabilitation after TKA including AlterG training are scarce [17,18]. To our knowledge, Bugbee et al [17] were the only ones who investigated the effects of AlterG training in patients who underwent TKA in an RCT. Hence, the present study was conducted to further investigate and obtain more information on the effects of AlterG training in patients who underwent TKA.

Limitations and Strengths of the Protocol

One of the limitations of this study was the risk of dropouts when patients heard that they were not included in the intervention group. Second, not all patients were committed to the 12-month follow-up. Third, the implementation of the study coincided with the COVID-19 pandemic, impacting the progress of the study and leading to dropouts.

However, this study also has some strengths. First, this is an RCT study. Second, to the best of our knowledge, there has been only one pilot and feasibility study [17] that directly focused on this issue thus far. With this relatively novel study, it is possible to collect more valuable information on how anti-gravity exercise can be used in rehabilitation after TKA. Third, it investigated aspects of a patient's physical functioning, perceived QoL, and pain rather extensively, thereby providing an opportunity to control various sources of bias such as state of depression and neuropathic pain. Lastly, the study design was planned in a multi-professional manner.

Study Significance and Feasibility

The results of this study provided information on how AlterG can be used in rehabilitation after TKA. With this knowledge, hospitals may potentially develop and enhance the rehabilitation program for patients who undergo knee arthroplasty. It is also possible to use the research results more widely with other patient groups, such as those with lower limb problems and athletes.

Conclusion

The results of this study provided information on how AlterG training can be used in rehabilitation after TKA. This information may enable the enhancement and development of a rehabilitation program for patients undergoing TKA.

Acknowledgments

We would like to thank physiotherapist Iiris Vanhanen for helping to acquire the data needed for the study. We would also like to thank research assistant Arja Mäkelä and registered nurse Leene Torri, both of whom played a key role in recruiting the patients for this study.

This work was supported by the Research Institute Orton through grants from the Ministry of Social Affairs and Health in Finland (A2500/488). The principal investigator also received a personal grant from the Finnish Arthroplasty Association (SAPLY). The funders are not involved in the collection, analysis, and interpretation of data; the writing of the report; or the decision to submit the paper for publication as contracted. This is why a data monitoring committee was not needed.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

All authors made substantial contributions to the conception or design of the study; the acquisition, analysis, or interpretation of data for the study; the drafting or critical revision of the manuscript for important intellectual content; final approval of the version to be published; and agreement to be accountable for all aspects of the study in ensuring that questions related to the accuracy or integrity of any part of the study are appropriately investigated and resolved.

Conflicts of Interest

None declared.

Abstract

Background: Combining effective eHealth programs with face-to-face consultations in general practice may help general practitioners care for survivors of cancer.

Objective: This study protocol describes a 2-armed randomized controlled trial to evaluate the cost-effectiveness of a blended intervention integrating the Cancer Aftercare Guide in general practice centers (GPCs).

Methods: A parallel-group design will compare an intervention group with a waiting list control group. Participants will be nested within GPCs and randomization will occur at the GPC level. The participants in the intervention group will receive a blended care intervention. In contrast, the participants in the waiting list control group will receive care as usual for the duration of this study and will receive the online intervention afterward. All participants will be asked to complete an online questionnaire at baseline, 6 months, and 12 months after baseline, measuring self-reported adherence to lifestyle recommendations, psychosocial well-being, and quality of life. A process evaluation and cost evaluation are also included in this study. The effects will be evaluated based on differences in residual change scores between intervention and control group participants, using multilevel linear regression analyses. Moreover, effect analyses will be supplemented with Bayes factor analyses. Finally, an economic evaluation will be conducted from a societal perspective and will include medical costs, productivity costs, and costs of the blended care intervention.

Results: This study was funded in July 2020. Data collection started in August 2022 and is likely to be completed by April 2025. As of December 2024, a total of 127 participants have been included in this study, recruited across 26 GPCs in the Netherlands. Data analysis will commence once data collection is completed. Data analysis is estimated to start in the spring of 2025. The results will likely be published in 2026.

Conclusions: The results will provide insight into the effectiveness of blended care and may be relevant to cancer aftercare, general practice, and the field of eHealth implementation in general. Potential challenges lie in recruitment due to the strain on the health care system since the COVID-19 pandemic.

Introduction

In the coming decades, the growing number of survivors of cancer will challenge health care worldwide. Global data show the increased incidence and survival rates, indicating an increase in the number of survivors of cancer worldwide [1]. Data for the Netherlands (total population of 17 million) predict that in 2032, a total of 1.4 million people will be receiving treatment for cancer or will have been successfully treated for cancer [2]. This underlines the urgency of studying the needs of survivors and finding ways to meet these needs to safeguard the quality of life (QoL) after disease and treatment.

After treatment, survivors of cancer may face physical, psychological, and psychosocial challenges that affect their transition to normal life. In addition, survivors of cancer must adhere to lifestyle recommendations regarding physical activity (PA), diet, smoking cessation, and alcohol consumption to prevent recurrence or the development of comorbidities [3]. In reality, however, many survivors of cancer find it difficult to adhere to these guidelines [4]. They seek support to help them recover and cope with the effects of their disease [5]. However, due to a shortage of health care professionals and increasing demand for care in the general population due to aging, survivors of cancer may not always receive the support they need.

Over the past decades, several eHealth interventions have been introduced to support survivors of cancer in their healthy recovery. The online Cancer Aftercare Guide (CAG) is an example of such an intervention [6,7]. The CAG is a web-based eHealth intervention that targets lifestyle and common psychological and psychosocial problems experienced by survivors by promoting self-management of these problems using evidence-based techniques, such as cognitive behavioral therapy and problem-solving therapy. Effectiveness evaluation has shown that the CAG is effective in reducing fatigue, depression, and anxiety and in increasing PA and healthy eating [8-11]. This shows that the CAG can help survivors cope with common cancer-related problems and can help reduce the risk of future disease by promoting a healthy lifestyle.

The use of eHealth for applications such as disease management and patient data sharing is encouraged [12,13], but in reality, effective eHealth interventions struggle to reach their target population [7,14,15]. For survivors of cancer in particular, it has been found that while they use the internet to search for health information, their use of eHealth self-help programs is not common [16]. One reason for this may be that many eHealth interventions are not implemented in everyday practice [17]. To improve the use of eHealth, the Dutch eHealth Monitor suggests that health care providers play an important role in informing patients about eHealth self-help programs and that health care workflows should be designed to facilitate the use of eHealth through blended care [18]. Similarly, in the case of the CAG, Willems et al [11] and Kanera [6] state that the online intervention could be offered in a blended approach, where patient-therapist interaction is provided, to promote patient engagement with the intervention.

Apart from a biyearly follow-up aimed at detecting recurrence, no structural care is currently provided for survivors of cancer in the Netherlands. For issues related to cancer survivorship, patients are referred to their general practitioner (GP) [19], resulting in on-demand care requests. In addition, GPs are responsible for tertiary prevention, which targets healthy lifestyle behaviors in survivors of cancer. With the increasing number of survivors of cancer, this demand will pose a significant challenge to general practice workflows. Therefore, a structured approach is essential for GPs to meet the needs of their patients. This is illustrated by the Dutch College of General Practitioners (in Dutch: *Nederlands Huisartsen Genootschap*), which stated that general practice could structurally provide cancer aftercare [20]. Implementing the CAG in general practice in a blended care setting could provide a solution to the growing demand for cancer aftercare by promoting healthy recovery and improving self-management of problems, ultimately reducing the care needs of survivors of cancer.

This study protocol outlines a randomized controlled trial (RCT) to investigate the cost-effectiveness and associated process evaluation of a blended care approach offering the CAG in general practice. The blended care intervention has been co-designed with GPs, practice nurses (PNs), and survivors in a separate study (MJM Smits, unpublished data, 2025) and has been tested in a pilot study before starting this RCT.

Methods

Study Design

An RCT will be conducted to compare the effectiveness of the blended CAG intervention between the intervention group and the waiting list control group. A general practice center (GPC) is usually run by at least 1 GP, supported by one or more medical assistants. In addition, many Dutch GPs are supported by PNs who are dedicated to patients with chronic disease, older adult care, and mental health care. The PNs provide additional care for identified health problems, such as asthma, chronic obstructive pulmonary disease, and diabetes (for the somatic nurse) or mental health problems (for the mental health nurse). The intervention protocol is implemented by either the GP or the PN (under the supervision of the GP). A full list of participating GPCs can be requested from the researchers.

Recruitment of GPCs

GPCs will be recruited through a variety of channels, including calls published in online primary care newsletters distributed by Regional Collaborative Care Groups or special interest groups dedicated to oncology care or lifestyle counseling in primary care. In addition, direct mail will also be sent out by the research team. If no response is received within 4 weeks, the direct mailing will be followed by telephone calls to discuss potential participation. GPCs are eligible to participate if they are located in the Netherlands. If the GPC agrees to participate in this study, an appointment will be made for the researcher to visit the GPC to give instructions on this study protocol.

Recruitment of Participants

Overview

Survivors of cancer will be recruited by general practice personnel (GPP: either GP, PN, or assistants). From the GP's

electronic medical record (in Dutch: *Huisartsen Informatie Systeem*), the GPP will select patients who meet the following inclusion criteria: (1) patients who have completed primary treatment of cancer (eg, radiotherapy, chemotherapy, or surgery), with the last treatment having been between 6 weeks and 3 years ago, or who belong to a watchful waiting condition (eg, option for prostate cancer patients); (2) patients who are 18 years of age or older; (3) patients who are able to read and speak Dutch; (4) patients without a serious medical, psychiatric, or cognitive condition that would interfere with participation; (5) patients who have access to the internet and at least minimal experience of using it; and (6) patients who have access to a computer or a tablet.

If desired, the selection of participants can be assisted by the researcher (under the supervision of the GP).

Eligible patients will be invited to participate in this study using an invitation package distributed by the GPC. The information package consists of an information letter, an informed consent form (Multimedia Appendix 1), and a prepaid return envelope. Survivors of cancer who agree to participate will need to sign the consent form and return it to the research team with the return envelope. The researchers will notify the GPC when the consent form has been received and stored. Enrolled patients will receive a welcome email from the researchers, informing them of their randomization (intervention or control group) and providing a link to the first online self-report questionnaire (baseline measurement). Awareness of randomization can lead to selection bias, but studies on survivors of cancer have shown that this effect is minimal [8-11]. Informing patients about the group to which they are assigned is required in the Netherlands by the Medical Research Involving Subjects Act.

The CAG Intervention

The online CAG program provides personalized information in 8 modules covering healthy lifestyles and common psychosocial issues related to cancer survivorship (ie, PA, diet, smoking cessation, alcohol use, fatigue, anxiety and depression, return to work, and social relationships). The CAG will use data from the baseline assessment to create the Module Referral Advice (MRA; Multimedia Appendix 2). The MRA presents personal outcomes across the 8 subtopics featured in the CAG and advises the participant to visit the module that corresponds to their greatest need, as indicated by the MRA. The modules consist of textual information and advice, video clips (in which former cancer patients share their survivorship experiences), and tasks or exercises that the participants can complete independently.

Intervention Procedure

Participants in the intervention group will receive the CAG blended care intervention. This means that after completing the baseline measurement, they will be given access to the online CAG. Participants will use the online CAG program independently at home. In addition, they will be invited to 2 consultations with their GP or PN. Within the online CAG, the intervention group participants will receive personalized advice on 8 topics related to cancer survivorship based on their results at baseline. This is represented by the MRA. Participants are asked to share their MRA results with the GP or PN at their first consultation. During the first consultation, the GP or PN and the participant will discuss the MRA results. Through shared decision-making, the GP or PN will motivate the participant to choose at least 1 of the 8 subtopics to focus on for the next 4 to 6 weeks, after which the follow-up consultation will take place. During the follow-up consultation, the GP or PN will enquire about the participant's progress with the chosen topic or topics. Any questions or problems the participant may have in interpreting the (lifestyle) advice given by the program will be addressed in the personal consultation. After the follow-up consultation, the participant will retain access to the online CAG intervention for up to 6 months after the start of the baseline measurement.

After completing the baseline measurement, participants in the control group are directed to a message thanking them for completing the questionnaire, asking them to log out and return only for the next measurement. Per GP care, participants in the control group will receive care as usual, which is mostly initiated by patient request and is usually complaint-driven. At the end of this study, the researchers will actively inform and encourage control group participants to finally use the online CAG intervention. Study groups will have full access to other interventions during the trial, but only on their initiative. The use of cointervention will be assessed by questionnaires at all time points.

Measurements

All participants will be asked to complete an online questionnaire at baseline, 6 months, and 12 months after baseline. GPs and PNs will not be present during the self-report questionnaire (participants will complete this assessment digitally at home). Therefore, no influence of the GP or PN on the Patient Reported Outcome Measures is expected. The questionnaires will measure self-reported lifestyle behaviors, behavioral determinants, and experienced psychological problems (see the *Outcomes* section).

The second questionnaire, administered 6 months after baseline, will also include items measuring health-related costs and, for intervention group participants only, a process evaluation questionnaire. In addition, biomedical measurements will be taken from all participants at 6 months after baseline. Blood pressure, total cholesterol/high-density lipoprotein cholesterol, and blood glucose were originally planned for the biomedical measurement. However, due to current circumstances in Dutch primary care (see the *Discussion* section), total cholesterol/high-density lipoprotein cholesterol and blood glucose measurements will be discontinued in consultation with the funding agency.

Nonresponse will be prevented by using previously effective protocols, including automated reminders 1 week and again 3 weeks after the distribution of questionnaires to patients [7,21] and email reminders to GPCs to ensure blood pressure measurement at 6 months. The quality control procedures ensure that there will be little nonresponse [8-11]. To improve the engagement of GPCs, relationships will be maintained through regular emails or phone calls to the designated contact person. In addition, a Christmas card will be sent each year on behalf

of the research team. In addition, the GPCs will be offered support in patient selection and patient contact by a researcher on several occasions during this study.

Outcomes

Overview

The primary outcomes of this study are changes in lifestyle behaviors, measured by validated self-report questionnaires. PA will be assessed using the self-report Short Questionnaire to Assess Health [22,23]. Smoking behavior will be assessed using a validated (self-report) abstinence scale [24,25]. Alcohol consumption will be measured using a standardized alcohol consumption scale [26]. Dietary behavior will be assessed using a food frequency questionnaire on saturated fat intake and fruit and vegetable consumption [27-29].

Secondary outcomes are changes in experienced psychosocial problems such as anxiety and depression, fatigue, health-related QoL, and health-related costs, which will be assessed using validated self-report questionnaires. Anxiety and depression will be assessed using the Hospital Anxiety and Depression Scale [30,31]. Fatigue is assessed using the Checklist Individual Strength [32,33]. Health-related QoL is measured using the abbreviated European Organisation for Research and Treatment of Cancer Quality of Life Questionnaire [34,35]. Health-related costs are considered from a societal perspective and are measured as health care consumption in the last 3 months using the Institute for Medical Technology Assessment Medical Consumption Questionnaire, productivity losses in the last 4 weeks for both paid and unpaid labor using the Institute for Medical Technology Assessment Productivity Cost Questionnaire, and quality-adjusted life years (QALY) using the EQ-5D-5L [25,36-42]. All questionnaires used are validated, we do not conduct additional validation research as part of this research project.

Secondary outcomes are also blood pressure measurements, taken from all participants at 6 months postbaseline. Blood pressure will be assessed by clinical measurements performed by GPP.

In addition to outcome measures, relevant medical data (type of cancer, time since diagnosis, type of treatment, and recurrence) and social demographics (age, sex, level of education, income, living situation, comorbidities, and BMI), as well as intention toward PA, healthy diet, reduced alcohol consumption, and smoking cessation will be assessed at baseline. Items assessing recurrence, use of cointerventions, BMI, and lifestyle behavioral intentions will be repeated at the 6-month measurement and 12-month assessments.

In addition, the process evaluation will be measured by (1) dose delivered: the number of intended modules accessed; (2) dose received: the extent to which participants actively engage with the material in the module; (3) satisfaction with the program; (4) practice-patient interaction: perceptions of the level of collaboration, satisfaction, and active engagement with the blended care program; and (5) context: aspects of the environment that influenced program implementation, impact, or outcomes. In addition to self-report measurements, log data from the online CAG (use of the website and individual CAG modules) will be automatically collected throughout the intervention.

Process evaluation will also take place with GPs and PNs. During the interview session at the end of the trial, they will be asked to report on (1) their satisfaction with the blended care program; (2) the type of patients involved; (3) the number of consultations carried out by the GP or PN; (4) the practice-patient interaction: perceptions of the level of cooperation, satisfaction, and active engagement with the program; and (5) the context: aspects of the environment that influenced the implementation/impact or outcomes of the program.

Sample Size

The effect evaluation of the online CAG intervention showed small to medium effect sizes (ES=0.20-0.40) on lifestyle behaviors at 6 months. In the current design, we expect an ES of 0.40 at 6 months follow-up [8]. Based on previous research on computer-tailored lifestyle interventions, we estimate an ES of 0.30 at 12 months [8,43-48]. Based on CAG data and other research in the primary care setting [49], we estimate an intracluster correlation of 0.03 to account for the multilevel design. Sample size calculation (ES=0.30; power=0.80; intracluster correlation=0.03, design effect 1.27) indicates that 282 participants are required for the effect study (141 in each condition). From 2 previous RCTs of online lifestyle interventions in patients or survivors of cancer, we know that dropout is 20%-25% [8,48]. Accounting for a 25% dropout, 376 survivors of cancer need to start in the RCT (188 per condition).

Furthermore, based on cancer prevalence figures, cancer survival rates, and the number of GPCs in the Netherlands, we expect that a standard GPC (consisting of 1-4 GPs and additional PNs) will have at least 20-40 survivors of cancer who meet the inclusion criteria. Therefore, to achieve a sufficient sample size, we aim to recruit approximately 40 GPCs, each of which will recruit 10 participants.

Randomization

A cluster-randomized design is used, which means that randomization to either the intervention or control condition takes place at the GPC level, and that all participants in a GPC are assigned to the same condition. Neither GPCs nor participants are blinded to their assigned condition during the trial. However, during recruitment, both GPCs and the researcher are unaware of the randomization outcome to ensure that participation is not influenced by assigned conditions. The randomization outcome will be defined by a computer-generated randomization list using simple randomization (1:1), which was generated before the start of recruitment and stored with a third person.

Statistical Methods

Overview

The first 2 steps of the analysis will test for statistical differences at baseline in lifestyle behaviors, QoL, demographics, and psychosocial and medical symptoms between the 2 study groups. Blinding of the analyst will be applied for primary outcomes.

Patterns and mechanisms of missing data will be explored. Thereby, special attention will be paid to dropouts. Randomization of the GPCs should account for an even distribution between the experimental and control conditions of socioeconomic factors or other confounding factors that may skew our results. However, in case conditions are unbalanced, these factors will be adjusted for in the analysis. If necessary, other statistical adjustment procedures will be applied to minimize the impact of any bias.

Multilevel linear regression analyses will be conducted to test for differences in residual change scores between the intervention and control groups on the primary and secondary outcomes at the 6-month follow-up and the 6- and 12-month follow-up combined. Intention-to-treat (ITT) analyses with multiple imputations will be applied. Participants will be nested within GPCs to account for potential interdependence between participants. Multilevel linear regression analyses with a random intercept for GPC level will be performed to account for possible interdependence in the effect analyses. The effects on the population will be assessed via CIs.

The primary outcome measures will be the residual change scores in lifestyle behaviors, but also differences in the secondary outcomes (anxiety and depression, fatigue, [health-related] QoL, and health-related costs). Blood pressure at 6 months will be compared between the intervention and control groups. In addition, moderation analyses will be conducted to examine different potential moderators such as age, gender, type of treatment, and level of education [8-11]. Subanalyses may be performed to explore individual differences that may be attributed to the degree of participation in the intervention. Besides factors on the level of participants, factors on the level of GPCs will be considered for further analysis. Finally, process evaluation data will be analyzed and summarized descriptively.

In addition, Bayes factor analyses will complement the primary analysis of the effects of the blended CAG intervention on the primary and secondary outcomes. A Bayes factor analysis expresses the relative strength of the evidence supporting competing hypotheses. This study examines support for the hypothesis that the blended CAG intervention has greater effects than care as usual as opposed to support for the hypothesis that the conditions do not differ or that the blended CAG intervention has a smaller effect than care as usual. In addition, the strength of support for the hypothesis that the blended CAG intervention has no smaller effects than care as usual will be compared to the support for the hypothesis that the blended CAG intervention has smaller effects than the effects found in the online-only CAG intervention, as studied in previous research [8-11]. In principle, default prior distributions will be used. It will be verified that these prior distributions are sufficiently diffuse, do not overwhelm the data, and do not destabilize the analysis.

Economic Evaluation

To calculate QALYs, utility scores will be obtained from the EQ-5D-5L scores and multiplied by the duration of follow-up (12 months). The economic evaluation will be conducted from a societal perspective and will therefore include medical costs (as measured by the Institute for Medical Technology Assessment Medical Consumption Questionnaire at T1), productivity costs (as measured by the Institute for Medical Technology Assessment Productivity Cost Questionnaire at T1), and costs of the blended care intervention. Intervention program costs include GP and PN training time, time for 2 consultations in the GPC, costs for program updates, and user licenses divided by a conservative number of potential annual users. Costs for the development of the intervention as well as research-specific costs were excluded.

Incremental cost-effectiveness ratios and incremental cost-utility ratios will be calculated by comparing the costs and effects (probability of maintaining a healthy lifestyle and QALYs) of the usual care group with those of the intervention group. Statistical differences in nonnormally distributed costs and QALYs will be tested using bootstrapped 1-tailed *t* tests. A cost-effectiveness acceptability curve will be constructed with the bootstrapped incremental cost-effectiveness ratio to visualize the probability that the blended care intervention is cost-effective at specific willingness-to-pay thresholds. The ceiling ratio for the cost-utility of the interventions will be set at €20,000 (US $20,900.80) per QALY. This is an accepted Dutch cutoff point for the willingness to pay for each QALY gained by preventive interventions and is commonly used to evaluate this type of intervention in the Netherlands [46,50-52].

Data Management

Data will be collected and handled according to the Data Management Plan that has been drafted for this project on the Data Management Plan online portal [53] and approved by ZonMw (ie, the grant provider). The progress of this study will be described in an annual report to the Medical Research Ethics Committee of Zuyderland Hospital and Zuyd University of Applied Sciences (in Dutch: *medisch-ethische toetsingscommissie van Zuyderland en Zuyd Hogeschool* [METC Z]) and the grant provider. Data will be password-protected and stored on hard disks on systems equipped with power-failure backup devices and automatic backup systems. All data will be kept confidential and anonymous. Each participant will be given a unique respondent number, not linked to a name or personal details, under which the data will be stored. Only researchers working on this project will have access to the data.

Potential Benefits and Risks

There are no risks or adverse effects associated with the trial. The participants in the intervention group can decide for themselves if, when, and how often they use the intervention. In addition, all the participants (intervention and control) can withdraw from this study at any time. It is expected that the use of the intervention will contribute to a healthier lifestyle, improve self-management, and have a positive impact on participants' QoL. During this study, the control group will only participate in the online self-report questionnaires and blood pressure measurements at the GPC. They will not be denied medical care and will be able to seek additional professional support if they wish to do so. Insurance was not compulsory for this trial, as assessed by the medical ethics committee.

Ethical Considerations

This study was approved by the METC Z before patient enrollment (NL806166.096.21, version 4.0; April 25, 2023). Informed consent (Multimedia Appendix 1) will be obtained from all the participants or legal guardians for this study. All patients will be required to provide written informed consent to participate. Participation can be discontinued at the request of the participants. Participants will receive a €10,- (10,31 USD) book voucher after completing the study. Modifications to this study protocol will be communicated to the METC Z through amendments. The METC Z has revised the informed consent materials to be given to participants and adapted them to accord with the Medical Research Involving Subjects Act. The protocol was amended to version 6.0 as of April 2023. This study conforms to the Declaration of Helsinki and is registered with the ISRCTN (International Standard Randomised Controlled Trial Number; ISRCTN12451453; registration date: December 15, 2021; last edited: September 12, 2023). All data will be kept confidential and anonymous.

Results

This study was funded in July 2020. Data collection started in August 2022 and is likely to be completed by April 2025. As of December 2024, this study is still ongoing. Data analysis is estimated to start in the spring of 2025. A total of 127 participants have been recruited across 26 GPCs in the Netherlands. The first results are expected to be published in 2026.

Discussion

Overview

This study protocol describes an RCT to evaluate the effects on self-reported lifestyle behavior, psychosocial well-being, (health-related) QoL, medical consumption, and productivity costs of the blended CAG intervention integrated into general practice.

Principal Findings

Overview

Previous research has investigated the effectiveness of the CAG in an online-only format [8-11]. This research found effects on PA, diet, fatigue, depression, and QoL, suggesting that the CAG is an appropriate eHealth intervention to support cancer survivorship. If similar results are found in this study, this would confirm that the online-only intervention has been appropriately adapted to the blended care context, maintaining its effectiveness. It would also suggest that the CAG could be integrated into the GPC workflow to facilitate the integration of cancer aftercare into general practice, as was proposed by the Dutch College of General Practitioners [20].

Comparison to Prior Work

Delivering the CAG in a blended care format improves the personalization of the care provided. This may strengthen the intervention and allow it to be better tailored to the individual recipient. Moreover, the integration of eHealth in general practice to facilitate cancer aftercare may address barriers to the uptake of cancer aftercare by general practice, as previously identified by Duineveld et al [54]. These barriers consisted of time constraints and a lack of expertise in cancer survivorship. Both of these can be complemented by effective eHealth tools such as the CAG.

Strengths and Limitations

Overview

This paper describes the study protocol for an RCT of the effectiveness of a blended care intervention for cancer aftercare in general practice. Conducting an RCT strengthens our interpretation of the results by controlling for confounding through randomization. In addition, the current research is very similar to the previous research evaluating the effectiveness of the online-only CAG intervention, which allows the results to be compared and the added value of blended care to be identified. The blended care format is being added to increase the reach of our intervention, specifically targeting a population that would not access an online-only intervention on their own. The blended care protocol has been developed in cocreation with survivors, GPs, and PNs to ensure the best fit with the general practice context and the needs of survivors (MJM Smits, unpublished data, 2025). However, some challenges cannot be foreseen. Conducting the RCT in a period following the global COVID-19 pandemic may place limitations on our study protocol. For example, it may be difficult to achieve our target sample size due to recruitment problems with both GPCs and survivors of cancer. In the aftermath of COVID-19, the health care sector is facing a workforce shortage, partly due to the retirement of a large proportion of the working population [55,56]. In primary care, this is leading to the closure of GPCs as owners are not being replaced by a new generation. Meanwhile, the COVID-19 pandemic has resulted in a high rate of delayed care, further increasing the demand for GPCs and leaving little room for trial participation and research activities such as patient recruitment. This resulted in a difference in the number of GPCs recruited compared to our target. We aimed to recruit 40 GPCs, but in reality, only 26 GPCs were recruited.

Future Directions

Future research could further investigate the implementation of eHealth for survivors of cancer in general practice or, depending on the results of this study, in different practice contexts. Emphasis should be placed on reaching survivors who are at risk of developing comorbidities or recurrence, or who have a high burden of disease that translates into medical costs or loss of productivity.

Dissemination of Research Findings

Research findings will be discussed with the consortium partners and published in academic journals. This study is the next step in disseminating the CAG in a practical context. However, to translate our findings to the real world, further research should be conducted to investigate how the intervention is sustained outside of the research protocol. Depending on our findings, the RCT will be followed by an implementation study in which survivors, GPs, and other stakeholders will be invited to share

their views on the integration of blended CAG into regular cancer care.

Implications and Relevance

The number of survivors of cancer is expected to increase in the coming decades [2]. These survivors consult their GP with issues related to cancer survivorship, resulting in a high demand for general practice [19]. To support survivors of cancer in maintaining a healthy lifestyle and managing psychosocial needs, the online CAG program was developed [57]. The program was shown to be effective in promoting healthy lifestyle behaviors and reducing fatigue, depression, and anxiety [8-11]. Structurally embedding the CAG in general practice could support GPs and PNs in caring for their patients and help reach more survivors who need support after treatment. The expected ESs are small but arguably clinically relevant given the affordability, minimal associated risks, and widespread implementability of the blended CAG intervention [58,59]. The results of this study may have implications for cancer aftercare and general practice, and may also be relevant to the wider field of eHealth implementation.

Conclusion

The research described in this study protocol will investigate the effectiveness (and cost-effectiveness) of a blended care intervention for survivors of cancer in general practice. The blended care intervention combines the use of a proven effective eHealth program (CAG) with face-to-face consultations with a GP or PN. Integrating eHealth for cancer aftercare into general practice may help GPs and PNs in caring for the growing number of survivors of cancer and may effectively improve their QoL, leading to reduced care needs in the future. The results of this study may be relevant to the field of cancer aftercare and general practice and will add to the literature on eHealth implementation.

Acknowledgments

The authors thank in advance all the patients, general practitioners, and practice nurses involved in this study. We also thank Xynthia Kavelaars, PhD, a statistician at the Open University for providing statistical advice, and the project's advisory committee for their ongoing support throughout the project: Jelle Stoffers, Silvia Evers, Brigitte Gijsen, Nederlandse Federatie Kankerpatiënten-organisaties, Centraal Ziekenfonds, Peter van Dijk, Donna Lenders, and Robert Willems. This study is supported by ZonMw: The Netherlands Organization for Health Research and Development (dossier 50-55515-98-015). The funding body played no role in the design of this study and collection, analysis, and interpretation of data and in writing this paper. Authors' Contributions

LL is the principal investigator, CAWB and IM are coapplicators, and MJMS is the PhD candidate on this research project. LL, CAWB, and IM contributed to the conceptualization, funding acquisition, and supervision. MJMS was responsible for the project administration and writing of the original draft of this paper. All authors contributed equally to the investigation, methodology, validation, and writing (review and editing) of this paper.

Abstract

Background: Health inequity is interlinked with the good health and well-being of an individual. Health inequity can be due to various socioeconomic factors like income levels or social status. Digital health interventions have the potential to reduce the existing health inequities.

Objective: This study aims to identify determinants of social, economic, and health inequity in diverse settings to enhance healthy eating and active living. It further aims to design and develop a digital health intervention HEAL (Healthy Eating Active Living) that incorporates a human-centered design framework in order to improve healthy eating and active living among rural and urban population groups in Chennai, Tamil Nadu, India.

Methods: A prospective, 3-year cohort study will be conducted. This study aims to recruit 6350 individuals across rural and urban settings of Chennai. A total of 11 sites have been selected for participation in the study. Data on sociodemographic characteristics; economic inequity; HEAL profile; depression, anxiety, and stress; well-being; sources of health information; perceived access to health care; health literacy; navigation of health literacy; and satisfaction with the health system will be gathered. This study would help to explore the determinants of social, economic, and health inequity across multiple sites. SAS (version 9.3; SAS Institute Inc) will be used for data analysis, and results will be reported as 95% CI and *P* values. This study's findings will guide the design and development of a tailored, human-centered digital health intervention to enhance the health and well-being of Chennai's population groups.

Results: As of December 2024, the literature review for the development of the intervention has been completed. The recruitment for the baseline data collection will begin shortly, followed by the development of HEAL intervention.

Conclusions: The proposed study will help in examining the role of the proposed HEAL intervention to enhance the health and well-being of the population groups of Chennai.

Introduction

Background and Rationale

The World Health Organization (WHO) identifies health inequities as "systematic differences in the health status of different population groups" [1]. Further, the WHO refers to health as "a state of complete physical, mental, and social well-being and not merely the absence of disease or infirmity" [2]. Consequently, research on health inequity is a central agenda component of the 2030 Sustainable Development Goals and various government and development dialogues [3,4]. Despite this, the WHO reports that health inequalities exist at varying degrees around the world, both within and between countries [5]. These inequalities further exacerbate health disparities between high-income and low-income, urban and rural, employed and unemployed populations, as well as between low-, middle-, and high-income countries [6] due to socioeconomic factors such as social status or income levels [7].

According to the Centers for Disease Control and Prevention, health equity can be attained when every individual can "attain his or her full health potential" and no one is "disadvantaged from achieving this potential because of social position or other socially determined circumstances" [8]. This also emphasizes the significance of measuring health inequity, promoting opportunities and monitoring the progress in health and intersectoral strategies. Additionally, measuring the interrelationship between health and its social determinants is vital to promoting effective interventions for health equity [9].

Inequalities are unfair, affect everyone, and are avoidable; however, the underlying factors causing inequality are imperfectly understood, and evidence on the effectiveness of interventions to reduce inequalities is limited [10]. Prior research has further highlighted the issue of good health for socioeconomically vulnerable groups and the need for targeted public health interventions in India [11]. A study indicated that health inequity in India is favored toward high-income populations and that despite services being available to people, there was a lack of awareness around it, especially in the rural region [12]. Considering the diversity in India and the prevalent social inequalities, the literature also emphasizes on the importance of research on health inequalities for monitoring health policies and programs [11].

Equity was also identified as one of the key principles of India's 2017 National Health Policy [13]. However, with a limited evidence base of health equity in India, there is a need to generate empirical data for the variables that create, sustain, and reinforce inequity. This would further help the policy makers to prioritize and strategize the limited resources available for the health system of the country [14].

However, the paucity of data on health inequalities in India and the subsequent research gap on critical issues related to health inequity in the country also underscore the probable impact of policies and strategies deployed to enhance the well-being of population groups. Moreover, the COVID-19 pandemic has exacerbated the health inequity worldwide [15]. In addition, eating habits are possibly determined by the socioeconomic status of the individuals [16]. Thus, this study aims to enrich the current understanding of health inequity with empirical research. The findings will also help with the design and development of digital health intervention HEAL (Healthy Eating Active Living) to improve the good health and well-being of individuals by addressing social, economic, and health inequities. Tamil Nadu, India, was the chosen region of study as it seems to be a state that has progressed in health care in recent years, and hence, this study aims to see the receptivity to digital intervention of the study population in these settings [12].

Study Objectives

This study aims (1) to identify determinants of social, economic, and health inequity to enhance healthy eating and active living among rural and urban population groups of Chennai, Tamil Nadu; (2) to design and develop a digital health intervention HEAL using the SMAART (Sustainable, Multi-Sector, Accessible, Affordable, Reimbursable, Tailored) model, targeted to enhance healthy eating and active living among rural and urban population groups of Chennai, Tamil Nadu; and (3) to evaluate impact of the proposed intervention to address burden of social, economic, and health inequity to enhance healthy eating and active living among rural and urban population groups of Chennai, Tamil Nadu.

Methods

Study Overview

The proposed research involves a multidisciplinary team with expertise in population health, epidemiology, sociobehavioral sciences, anthropology, and biochemical sciences.

Study Design and Population

The HEAL cohort study is a prospective, 3-year cohort study with the aim to recruit 6350 individuals across rural and urban settings of Chennai, Tamil Nadu. The study sample will be recruited from Kannur; Pannur; Thirumenikuppam; Thodukadu; Kottaiyur; Nemili; Mannur; Kiloy; Ulundai; Narasamangalam; Karanai; Panimalar Medical College Hospital and Research Institute; Rural Training Health Centre Chennai; and Maligaipaddu village of Chennai, Tamil Nadu. Baseline evaluation will be performed at the time of recruitment of study participants. The study participants will be recruited through convenience sampling. This will serve as cross-sectional data to estimate the prevalence of determinants of social, economic, and health inequity.

Study Intervention

The HEAL intervention will be designed based on the SMAART model to enhance healthy eating and active living for the individuals participating in the study. This intervention will ensure the coordination of social, economic, and health-related parameters to enhance the health and well-being status of the population. The SMAART model works on the principles of data, information, and knowledge; human-centered approach; information processing theory; and humanistic, behavioral, and learning theories [17]. The intervention stage will have two

parallel groups (case and control) for comparison. Individuals in the intervention group will be provided access to the informatics-based intervention for enhancing their healthy eating and active living. The participants from the intervention stage will be included in the study based on participants from the baseline stage consenting to participate in the intervention. The participants will be assigned to the intervention or control group through randomization. They would be provided information on good dietary habits and the importance of regular physical exercise for maintaining good health and well-being. Individuals in the control group will be provided an educational booklet as standard care. The intervention will be a tailored multilingual digital health intervention. Both the groups will undergo a series of baseline and follow-up assessments for estimation of change in eating patterns, physical activity, and well-being to assess the impact of intervention. The study location includes both the urban and rural areas of selected sites, and the study duration is 3 years. The study population includes all adults aged 18 years and older. The inclusion criteria are (1) individuals aged 18 years and older, (2) individuals from both urban and rural areas, and (3) individuals who consent to participate in the study.

Efforts will be made to include individuals of varied age groups, gender, location, and socioeconomic status. The exclusion criteria consist of (1) individuals younger than 18 years of age, (2) individuals who would not give their consent, and (3) individuals who have impaired cognition.

Ethical Considerations

This study (protocol PMCHRI-IHEC-067) gained approval from the Panimalar Medical College Hospital and Research Institute Institutional Human Ethics Committee (Central Drugs Standard Control Organization Registration ECR/1399/Inst/TN/2020) in March 2022, with approval PMCH&RI/IHEC/2021/078 dated March 15, 2022. The study will be conducted according to the Declaration of Helsinki, as it involves human participants [18].

The institutional review board–approved informed consent form will be administered by the research team to the eligible individuals for the study. The research team will describe the study, time required, and benefits of the study results to the participants, and those willing to participate and give their consent will be enrolled in the study. Written informed consent will be obtained in both English and local Indian dialects at the time of data collection if the participants are able to read and understand the questionnaire. In the case of participants without formal education, an audio recording of the consent will be done. Study participants will be allowed to withdraw from the study at any time [19]. No compensation will be provided.

Data security will be ensured through regular backups in password-protected computers in the locked office of the principal investigator. Data will be stored for 5 years from the point of study completion, after which it will be destroyed. All the physical data files will be stored in a locked file cabinet in the office. The information will be accessible to members of the research team only.

Data Collection, Data Entry, and Quality Assurance

Data collection and data entry will be performed by a team of trained field data collectors and data management. Data will be gathered in the field on paper and then entered on the computer. The data will be entered into the computer using Excel (Microsoft Corp). For quality assurance, a clearly defined data collection and management protocol will be in place. This will include a well-defined study manual with all the relevant instructions. For quality assurance, we will have a trained team of data collectors, weekly meetings with the research team, weekly data checks, maintenance of study participant contact, and maintenance of study participant data instrument logs.

Variable Assessment

Sociodemographic Characteristics

Information will be collected on the participant's age, gender, educational status, migration status, disability status, occupation, household size, family size, income, and number of earning members in the household.

Economic Inequity

The wealth index is a division of households into 5 wealth quintiles to show the relationship between wealth, population, and health indicators [20].

HEAL Profile

Data will be collected on the respondent's health and lifestyle profile. We will use the WHO STEPwise approach to noncommunicable diseases risk factor surveillance questionnaire. It is a simple, standardized method for collecting, analyzing, and disseminating data on key noncommunicable disease risk factors in countries. The survey instrument covers key behavioral risk factors: tobacco use, alcohol use, physical inactivity, and unhealthy diet, as well as key biological risk factors: overweight and obesity, raised blood pressure, raised blood glucose, etc [21].

Depression, Anxiety, and Stress

Data will be gathered from the respondents about their mental and well-being. We will use the Depression, Anxiety, and Stress Scale (DASS). The DASS is a set of three self-report scales designed to measure the negative emotional states of depression, anxiety, and stress. Each of the three DASS scales contains 14 items, divided into subscales of 2-5 items with similar content [22].

Well-Being

The Short Warwick Edinburgh Mental Well-Being Scale is a shortened version of the Warwick-Edinburgh Mental Well-Being Scale. It measures both mental and emotional well-being (how "good" somebody feels) and psychological functioning (how well somebody thinks they are functioning). This scale is suitable for ages 13-74 years and works well as a "before" and "after" tool to measure the change in well-being during an intervention or specific program [23].

Sources of Health Information, Social Media, Technology Access, and Familiarity

Information will be gathered about cell phone ownership in households, type of cell phone, access to the internet, and knowledge of SMS text messaging [24,25].

Perceived Access to Health Care

Information will be collected from the respondents regarding access to health care. We will use the Perceived Access to Health Care questionnaire. The questionnaire includes six dimensions: (1) availability, (2) accessibility, (3) affordability, (4) accommodation, (5) acceptability, and (6) awareness. In addition, the psychometric evaluation was conducted on the instrument's initial version with 31 items on a 5-point Likert scale (strongly agree to strongly disagree) [26].

Health Literacy

Rapid Estimate of Adult Literacy in Medicine will be used to assess the health literacy of the study participants. It is a quick screening tool to assist physicians in identifying patients with limited reading skills and in estimating patient reading levels. "At risk patients" are defined as those with a score of six or less [27].

Satisfaction With Health System

The Patient Satisfaction Questionnaire yields separate scores for each of seven different subscales: general satisfaction (2 items), technical quality (4 items), interpersonal manner (2 items), communication (2 items), financial aspects (2 items), time spent with the doctor (2 items), and accessibility and convenience (4 items). This questionnaire will be used both at baseline and postintervention [28,29].

Outcomes

The study outcomes include the identification of determinants of social, economic, and health inequity. The research would further help in identifying the key areas that need to be addressed through intervention to improve the health and well-being status of the general population. Additionally, the study would also help in developing tailored interventions targeted to reduce social, economic, and health inequities.

Data Analysis

Descriptive analysis will be conducted to report the mean and SD of the continuous variables and frequency analysis of the categorical variables. A 1-tailed *t* test will be performed to compare means between the continuous variables and a categorical dependent variable while a chi-square analysis will be performed for the categorical variables. Multivariate regression analysis will be performed to determine the determinants of social, economic, and health inequity. All analysis will be performed using SAS (version 9.1; SAS Institute Inc), and reporting of the results will be done at 95% CI and $P<.05$.

Projected Timelines and Milestones

A detailed research plan and scheduled timeline of the tasks involved in the study are presented in Table 1.

Table 1. Scheduled timeline of the tasks in the HEAL[a] study.

Variables	Month 1	Months 2-5	Months 6-7	Months 8-10	Months 11-18	Months 14-30	Months 31-33	Months 34-36
Stakeholder meeting	✓							
Baseline data collection		✓						
Design and development of human-centered intervention			✓

[a]HEAL: Healthy Eating Active Living.

[b]SMAART: Sustainable, Multi-Sector, Accessible, Affordable, Reimbursable, Tailored.

The study is in accordance with the STROBE (Strengthening the Reporting of Observational Studies in Epidemiology) guideline for case-control studies (Multimedia Appendix 1) [30].

Results

As of December 2024, the literature review for the development of the intervention has been completed. Recruitment for the baseline data collection is scheduled to begin in the upcoming months, followed by the development of HEAL intervention.

The findings of the study will be disseminated through peer-reviewed publications and national and international conference presentations.

Discussion

Expected Findings

In order to reduce the health inequity in India, it is imperative to have the requisite knowledge base. This study would help to fill the research and knowledge gap by identifying key areas that need to be addressed to improve the health status of the population. The baseline data will enable us to find the socioeconomic inequity faced by the participants, their health literacy, and their awareness regarding their health status and health care. These findings would also help to design and develop tailored population health interventions to enhance the healthy eating and active living of the population groups.

Health inequities have existed throughout time, as resonated by the concept of inverse care law (1971), which highlighted how good medical care is inversely related to people's needs in low- and middle-income countries [31]. Similarly, Cookson et al [32] recently proposed the law of disproportionate care (2021) where they argue that in high-income countries, socially disadvantaged groups receive more care but of worse quality to meet their health care needs. The available studies also reinstate the need to address health inequities by collecting and analyzing the relevant health equity data [33]. This study would therefore help in filling the requisite knowledge gaps by identifying the key determinants of health inequity. It would also help in contributing to the advancement of evidence-based strategic decisions on health inequity. The findings from this research project would also help in designing, developing, and implementing data-driven, evidence-based, and human-centered interventions to enhance the healthy eating and active living of the population groups.

Limitations

This study's limitations include that it is confined to one geographic region, and implementing it in diverse geographic and population settings would help to better understand and compare the impact of the HEAL intervention.

Conclusions

The HEAL intervention offers a model to enhance healthy eating and active living for the individuals participating in the study through the SMAART framework. The findings from the study will contribute to the understanding of the role of digital health interventions to enhance healthy eating and active living of the population groups, which will help in understanding and addressing determinants of health equity in the population.

Abstract

Background: Atrial fibrillation (AF) is a chronic cardiovascular condition with a lifetime risk of 1 in 3 and a prevalence of 3% among adults. AF's prevalence is predicted to more than double during the next 20 years due to better detection, increasing comorbidities, and an aging population. Due to increased AF prevalence, telerehabilitation has been developed to enhance patient engagement, health care accessibility, and compliance through digital technologies. A telerehabilitation program called "Future Patient—telerehabilitation of patients with AF (FP-AF)" has been developed to enhance rehabilitation for AF. The FP-AF program comprises two modules: (1) an education and monitoring module using telerehabilitation technologies (4 months) and (2) a follow-up module, where patients can measure steps and access a data and knowledge-sharing portal, HeartPortal, using their digital devices. Those patients in the FP-AF program measure their heart rhythm, pulse, blood pressure, weight, steps, and sleep. Patients also complete web-based questionnaires regarding their well-being and coping with AF. All recorded data are transmitted to the HeartPortal, accessible to patients, relatives, and health care professionals.

Objective: This paper aims to describe the research design, outcome measures, and data collection techniques in a clinical trial of the FP-AF program for patients with AF.

Methods: This is a multicenter, mixed methods, randomized controlled trial. Patients are recruited from AF clinics serving the North Jutland region of Denmark. The telerehabilitation group will participate in the FP-AF program, while the control group will follow the conventional care regime based on physical visits to the AF clinic. The primary outcome measure is AF-specific health-related quality of life, to be assessed using the Atrial Fibrillation Effect on Quality-of-Life Questionnaire. Secondary outcomes are knowledge of AF; measurement of vital parameters; level of anxiety and depression; degree of motivation; burden

of AF; use of the HeartPortal; qualitative exploration of patients', relatives', and health care professionals' experiences of participating in the FP-AF program; cost-effectiveness evaluation of the program; and analysis of multiparametric monitoring data. Outcomes are assessed through data from digital technologies, interviews, and questionnaires.

Results: Patient enrollment began in January 2023 and will be completed by December 2024, with a total of 208 patients enrolled. Qualitative interviews conducted in spring 2024 will be analyzed and published in peer-reviewed journals in 2025. Data from questionnaires and digital technologies will be analyzed upon study completion and presented at international conferences and published in peer-reviewed journals by the fall of 2025.

Conclusions: Results from the FP-AF study will determine whether the FP-AF program can increase quality of life for patients with AF and increase their knowledge of symptoms and living with AF in everyday life compared to conventional AF care. The cost-effectiveness evaluation will determine whether telerehabilitation can be a viable alternative for rehabilitation of patients with AF.

Introduction

Atrial fibrillation (AF) is a chronic cardiovascular condition occurring in 3% of the adult population, the prevalence of which is predicted to more than double over the next 20 years [1]. The increase in AF prevalence may be attributed to better opportunistic screening for silent AF, aging of the population, and an increase in conditions predisposing to AF, such as obesity, hypertension, diabetes, obstructive sleep apnea, and physical inactivity [2]. If untreated, AF is associated with a 5-fold increase in the risk of stroke; 20%-30% of all strokes are due to this type of arrhythmia [1,3].

AF imposes a substantial economic burden on the health care system, with 10%-40% of patients with AF being acutely hospitalized each year [1]. AF patients may experience a variety of symptoms, such as palpitations, fatigue, dyspnea, chest pain, sleeping difficulties, fear, and anxiety, although there is great variation in the individual symptom levels. While up to 40% of patients with AF are asymptomatic, others report severe or disabling symptoms [1]. Sleeping difficulties such as sleep apnea are also observed and may be associated with increased cardiovascular risk, further underscoring the importance of AF management [4,5]. Patients with AF trying to live with their disease can benefit from some form of effective, prolonged, and specialized cardiac rehabilitation (CR).

CR is an outpatient chronic disease management intervention that includes structured exercise. CR is based on a risk-factor assessment combined with health management interventions. Patients are educated and encouraged to quit smoking, attend vocational and nutritional counseling sessions, and seek psychosocial support. A review of CR aimed at patients with AF found gaps in the CR research, notably the need for more rigor in the reporting of intervention details, outcomes, and gender-based characteristics of CR and its effectiveness for patients with AF [6]. Many patients with AF do not feel that they have received sufficient knowledge regarding how to live with their disease [7], while other studies have shown that patients with AF often have poor knowledge about arrhythmia, its treatment, and self-management strategies [6]. In 2019, Denmark published the first national guidelines for CR for patients with AF [8], but actual rehabilitation programs have not yet been implemented. A new, innovative alternative to CR is cardiac telerehabilitation (CTR), in which certain elements of the CR program take place in the patient's home with the help of wearables and other technologies, such as a blood pressure monitor, and using remote communication between the patient and the health care professionals (HPs) [9]. Continuous monitoring, combined with the use of oral anticoagulation for stroke prevention and maintenance of normal sinus rhythm, has demonstrated benefits such as reduced hospitalization, limiting disease progression, and improving survival [10]. Reviews focusing on digital patient education for patients with AF found improvements in patient knowledge of AF [11]. For example, Desteghe et al [4] found that tailored web-based education was an effective strategy for improving AF knowledge and that patients were positive about using web-based patient education. These findings are in line with a review by Fredericks and Yau [12], who found that individualized patient education in heart surgery patients increases quality of life (QoL), improves performance of health behavior, and ameliorates psychological distress [12].

Psychological distress, such as anxiety and depressive symptoms, is prominent among patients with AF, with prevalence rates ranging from 28% to 38% [13]. Some studies have shown that AF may be a causal factor in the onset of depression, while a few studies find that depression may also cause AF [14-18]. Both anxiety and depression have been associated with recurrent AF [19], while anxiety is also described as a side effect of living with AF [15,20]. Overall, psychological distress has been associated with poorer QoL [19,21] and increased severity of AF symptoms [13,19], whereas QoL has been associated with AF severity [19]. This association highlights the importance of examining the impact of both AF

severity and psychological distress on QoL. It should be noted that psychological distress may also impair the patient's motivation for engaging in rehabilitation, thus reducing participation in rehabilitation and self-care [22,23], whereas successful alleviation of AF symptoms is often associated with reduced emotional distress [24].

The educational CTR program "Future Patient—telerehabilitation of patients with AF" (FP-AF) was developed in Denmark through a cocreation process with patients with AF, their relatives, and researchers. The program was evaluated in a pilot study [25], which showed that patients with AF and their relatives found the FP-AF useful because it created an increased sense of security, increased knowledge about mastering symptoms, and a community of practice linking patients with AF and their relatives with HPs. These findings suggest that there is a potential for increasing the QoL of patients with AF by providing educational telerehabilitation programs that can permit sufficient individualization for patients (and relatives). Following the pilot study, the intention is for the FP-AF program to be evaluated in a multicenter, mixed-methods, randomized controlled trial (RCT). The development of the program is in line with the strategies of user involvement developed by the Danish Heart Association and with national strategies promoting digital health in Denmark, as well as current recommendations for AF rehabilitation [8].

The purpose of the FP-AF program (ClinicalTrials.gov NCT06101485) is to increase the QoL of patients with AF by providing both patients and their relatives additional knowledge about AF and practical guidance on how to live with AF in everyday life. The program aims to individualize the rehabilitation process by helping patients and their relatives develop their own self-management strategies using their own clinical data and enhanced knowledge about AF. This paper describes the research design, outcome measures, and data collection techniques used in the FP-AF research project.

Methods

Research Design

The FP-AF program will be evaluated in a multicenter, mixed methods, RCT study. The telerehabilitation group will participate in the FP-AF program, while the control group will follow the conventional care regime based on physical visits to the AF clinic. Enrollment of patients began in January 2023, and the RCT is expected to end in June 2025.

Ethical Considerations

The Future Patient project has been approved by The Scientific Ethics Committee for the North Denmark Region (N-20220056). The study is listed in ClinicalTrials.gov (NCT06101485). The study is being carried out in accordance with the Helsinki Declaration, and all participants have signed an informed consent form prior to enrollment in the study. Participants have been informed that they have the right to withdraw their consent at any point in time during the study, and the reason for their withdrawal will also be documented if the participant so wishes. The participants have not received any compensation for their participation in the study. Upon the randomization, all patients have been assigned an individual identification number so their data remain anonymous. The project team will then collect the equipment upon request.

Procedure and Eligibility Criteria

All patients diagnosed with AF at the Departments of Cardiology at Central Region Hospitals in Viborg, Skive, and Silkeborg will be assessed for eligibility in the study. The inclusion criteria are as follows: patients must be diagnosed with AF; they must be adults aged 18 years or older; they must live in Skive, Viborg, or Silkeborg municipalities; they must live at home and be capable of caring for themselves; and they must possess basic computer skills or have a relative or friend with basic computer skills.

Exclusion criteria are as follows: pregnancy; refusal or inability to cooperate; patient does not speak, read, or understand Danish; and patient has a life expectancy of less than a year.

A CONSORT (Consolidated Standards of Reporting Trials) diagram will be used to document all data pertaining to the recruitment process, as well as patient withdrawal or dropout.

Power Calculation

The primary outcome of this study is AF-specific health-related QoL (HRQoL) as measured by the Atrial Fibrillation Effect on Quality-of-Life Questionnaire (AFEQT) through the use of telerehabilitation compared to conventional rehabilitation. A clinically significant mean difference of 11 points between the intervention and control groups and an SD of 23 points were used in the study power calculation, based on prior literature [26]. A sample size of 184 patients would have 90% power to demonstrate a difference between the groups. This project estimates a dropout rate of about 10%. Thus, the total number of patients required in the study is 208, with 104 patients in the intervention group and 104 in the control group.

Randomization

Randomization of the patients will be conducted according to a randomized block design using random sized blocks of 4, 6, and 8 patients. The blocks will be stratified by center and appropriate age group and sex. The randomization will be digital and blinded for the project nurses who will be recruiting patients for the study.

Theoretical Framework

The FP-AF program is based upon self-determination theory (SDT), which describes motivation as an essential part of any successful rehabilitation [27]. SDT describes human motivation as the fulfillment of 3 basic needs: autonomy, competency, and relatedness. To ensure continuous motivation, it is necessary that this motivation is intrinsic to the patient, which requires that the patient feels that all 3 of these primary needs are being supported simultaneously [27]. As such, intrinsic motivation is achieved when a patient (1) experiences autonomy, that is, identifies with the goals of rehabilitation and values these as personally important; (2) experiences competency, that is, the patient believes that he or she has the necessary knowledge and skills to achieve the goal and receives guidance and feedback; and (3) experiences relatedness, that is, the HP's and the

patient's social network create a milieu in which the patient feels respected, understood, and supported.

Future Patient Telerehabilitation Program

The FP-AF education program for patients with AF and relatives consists of two modules: (1) an education and monitoring module using telerehabilitation technologies (4 months) and (2) a follow-up module, where the patients use their own personal devices to measure steps and to access the HeartPortalen (3 months).

After enrollment, those patients randomized to the intervention group meet individually with the project nurse. At this meeting, the patient (and relatives, if necessary) are instructed in the use of the technologies (see details below), and an individual plan is formulated for the AF patient's telerehabilitation program. The project nurses at the AF clinics (Regional Hospitals in Viborg and Silkeborg) review all the patients' measured values twice a week and have continuous contact with the patients during their enrollment in the project. For each patient, the physicians at the hospital set limit values for blood pressure, pulse, and weight. If patients register values that are out of range, they are instructed to contact the project nurse or the cardiology ward. Furthermore, the patients and relatives are invited to participate in an educational module at the local health care center, where offerings include topics such as living with AF, symptoms of AF, management of own disease using digital technologies, and how you as a relative can support your spouse or partner.

The HeartPortal

The HeartPortal (version 1.0), a web-based portal used by patients, relatives, and HPs at the hospitals and health care centers, functions as a digital toolbox and learning module. Patients and relatives in the telerehabilitation group will have access to the HeartPortal, where they can read texts and watch animations about AF, have access to visualization of the patients' measured data (steps, weight, pulse, blood pressure, and sleep), and communicate in video and chat with HPs at the hospitals and health care centers. The patients can access the data from the electrocardiogram (ECG) on a separate platform. Screen captures of the HeartPortal are shown in Figure 1, and the context of the Future Patient study is shown in Figure 2.

The HeartPortal consists of 4 elements (Textbox 1).

The technologies being used in the CTR group are listed in Textbox 2.

Figure 1. Screen captures from the HeartPortal. (A) The patients front page. (B) Measurement from the sleep sensor. (C) The information platform. (D) Measurement from the pedometer.

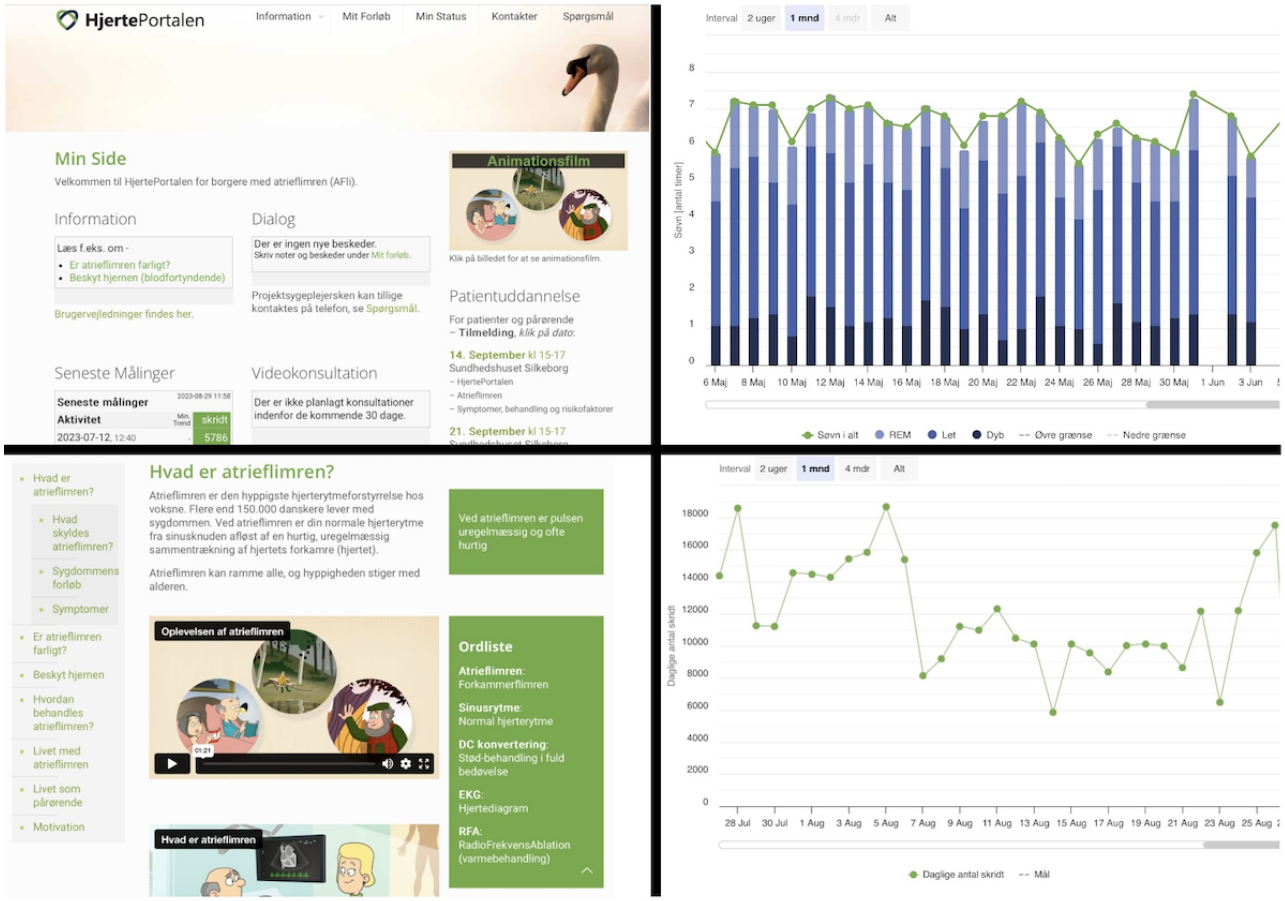

Figure 2. The context of the Future Patient program.

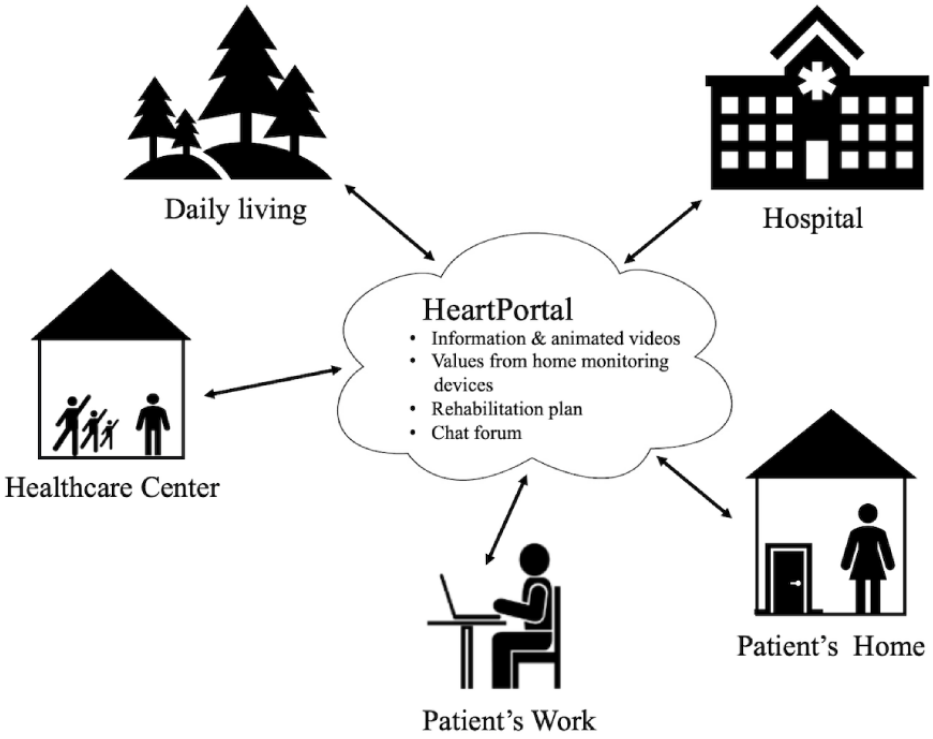

Textbox 1. Four elements of HeartPortal.

- A platform containing atrial fibrillation and rehabilitation related information pages (text, images or illustrations, animation, link to other validated sources, etc).
- Visualization of measured values (steps, weight, pulse, blood pressure, and sleep) in graphs that offer an easy overview and trends in data.
- A communication platform (video and chat) that enables patients to communicate directly with health care professionals. Video consultations will be conducted at 1 month and 4 months after enrollment in the study and additionally as needed on an individual basis.
- A rehabilitation plan. For each patient, an individualized rehabilitation plan is defined in a dialogue between the patient, the doctor, and a project nurse. The rehabilitation plan is formulated using individual parameters such as weight, physical status, pulse, and blood pressure. The patients write down their personal rehabilitation goals on the HeartPortal. The patients start the rehabilitation plan at the time of enrollment in the study. A project nurse monitors the patient's data twice a week and contacts the patients if the rehabilitation goals have not been met, data have not been transmitted to the HeartPortal, or in case data are not within the normal range set for the patient.

Textbox 2. Technologies used in the cardiac telerehabilitation group.

- Blood pressure monitor (iHealth Neo [BP5S]) [28]. Measurement of systolic and diastolic pressure and pulse. Connects to an app on the tablet to record the measurement and the tablet's internet connection to transfer the measured values. Blood pressure is measured twice a week.
- Weight scale (iHealth Lina) [29]. Allows the patient to follow his or her weight and observe weight loss or gain. Connects to an app on the tablet to record the weight, and the tablet's internet connection transfers the measured values to the HeartPortal. Weight is measured twice a week.
- Activity tracker (Fitbit Inspire 3|Health & Fitness Tracker) [30]. Measures physical activity, counted as steps and calories burned as well as pulse throughout the day. The activity tracker can also measure sleep if worn while sleeping. An app on the tablet is used for viewing and reviewing the tracked data and for data transfer. Activity, measured as steps, is measured every day and transmitted to the HeartPortal.
- Electrocardiography (ECG) monitor (KardiaMobile) [31]. Consists of a small device with touchpads, one for each hand. The monitor uses ultrasound to communicate with an app on the tablet. The app transfers the data to a General Data Protection Regulation-compliant system for clinicians, KardiaPro. ECG is carried out twice a week. The Kardia device includes an artificial intelligence–powered algorithm with an accuracy rate of 97% [31]. When patients measure their ECG, the device detects their heart rhythm. Patients have also been taught to interpret the results, such as the difference between sinus rhythm and AF.
- Sleep sensor (Emfit QS) [32]. Monitors pulse and respiration during sleep, sleep duration, stages, and sleep quality. Sleep is measured in hours every night, and the sensor data are transmitted to the HeartPortal.
- Video solution (VDX, Medcom) [33], a national video platform in Denmark within health care.

Data and Network Security

The telerehabilitation program has a strong focus on data and network security and resiliency. Security and resiliency in eHealth is a general issue that requires special measures in an environment where data are generated both from a health system (pulled data) and from the users or patients (pushed data). The format of metadata for reliable integration (source traceability), encryption, and infrastructure reliability (VPNs, VLAN, centralized vs federated storage) will be addressed by including perspectives from the different endpoints in the system (home, workplace, health center, etc), the technology used (wired, wireless, and dual technology), and the classification of information. Standardization activities, such as those from ITU-T, Continua, ENISA, etc, will be monitored and applied where possible.

Usual Care Intervention

Patients in the control care group have received AF education as usual, with the standard 45-60 minutes of orientation in AF, symptoms, treatment, and management of their own disease delivered in person at the hospital and by consultancy if needed by their general practitioner.

Baseline Characteristics

Sociodemographic data, such as civil status, level of education, work status, and IT competences, will be collected from both groups at baseline using data from the patient's electronic medical record and questionnaires.

Clinical baseline data, such as clinical status, primary and secondary diagnoses, and prescribed medicine, will also be collected for both groups using the electronic patient record.

Outcome Measures

Table 1 presents an overview of the primary and secondary outcome measures, along with the scheduled data collection dates. Except for progression in clinical data, including adverse events and dropout, all outcome measures will be collected using packages of questionnaires relevant to the specific point in time. The patients answer questionnaires in a web-based version, or on paper if they prefer.

Table 1. Primary and secondary outcome measures and data collection dates.

Outcomes	Time of measurement				End of tele- rehabilitation (at 4 months)	Follow-up at 7 months
	Baseline	Every day	Twice a week	As needed		
Primary						
Changes in AF[a]-specific quality of life	(I[b],C[c])				(I,C)	(I,C)
Secondary						
Changes in AF knowledge	(I,C)				(I,C)	(I,C)
Measurement of vital parameters

[a]AF: atrial fibrillation.

[b]I: intervention group.

[c]C: control group.

Primary Outcome

Changes in AF-Specific Health-Related Quality of Life

AF-specific HRQoL is measured using the AFEQT [34]. The AFEQT is a 20-item self-administered questionnaire designed to assess the impact of AF on the patients' HRQoL across symptoms, daily activities, treatment concerns, and treatment satisfaction. Scores range from 0 to 100, with higher scores indicating better HRQoL.

Secondary Outcomes

Changes in AF Knowledge

The Jessa Atrial Fibrillation Knowledge Questionnaire (JAKQ) is a 16-item scale used to assess the knowledge of patients' AF about the arrhythmia illness [4]. For every item, false responses or "I don't know" responses are scored as 0, and the correct responses are scored as 1. The total score of the scale is calculated by adding up all item scores.

Measurement of Vital Parameters

Clinical data on weight, blood pressure, pulse, steps, sleep, and ECG in the intervention group will be collected as specified in Table 1.

Changes in Anxiety and Depression

Symptoms of anxiety and depression are measured using the Hospital Anxiety and Depression Scale (HADS) [35]. The HADS is a 14-item self-reported questionnaire often used for screening of psychological distress in patients with cardiac conditions. Each item is scored on a 4-point Likert scale ranging from 0 to 3. The 2 subscales, anxiety and depression, each comprise 7 items, and scores on these subscales range from 0 to 21, with higher scores indicating higher levels of anxiety or depressive symptoms.

Changes in Motivation

Motivation is measured by the Health-Care Self-Determination Theory Questionnaire Packet (HC-SDTQ). The HC-SDTQ

includes 3 separate questionnaires: the Treatment Self-Regulation Questionnaire, which focuses on autonomy as stipulated by SDT [36]; the Perceived Competence Scale, which assesses patients' sense of competence about engaging in, or maintaining, a healthier behavior [37]; and the Health Care Climate Questionnaire, which assesses the patient's perception of autonomy support from their health care provider [38].

Burden of AF

The burden of AF is measured using the Arrhythmia-Specific Questionnaire in Tachycardia and Arrhythmia (ASTA) [39]. The ASTA measures symptoms and HRQoL in patients with different forms of arrhythmias, including AF. The ASTA is divided into 3 parts: Part I assesses demographic data, such as the most recent episode of arrhythmia, current medication, and the presence of arrhythmia at the time of follow-up; Part II measures the arrhythmia-specific symptom burden; and Part III measures HRQoL. Parts II and III are scored using a 4-point Likert-type scale (0="No" to 3="Yes, a lot"). The total score range is from 0 to 100, with a higher score indicating a higher symptom burden or a negative effect on HRQoL.

Use of HeartPortal

Time log files for login and logout of patients and relatives will be analyzed in order to identify which parts of the HeartPortal are being used and for how long. The patients will be asked for their consent prior to extracting their log files from the database for analysis.

Perspectives and Experiences From Participating in the FP-AF Program

Participant-observation [40,41] will be used in situations such as educating and counseling the patients and relatives in using the technologies at home and to observe how patients and relatives use the digital technologies and the HeartPortal.

Perspectives and experiences of patients, relatives, and HPs participating in the FP-AF program will be explored using semistructured qualitative interviews, inspired by Brinkmann and Kvale [42]. Interviews will be performed until data saturation is reached, with a minimum of 10 interviews conducted for each group: patients, relatives, and HPs. The interviews will be recorded, transcribed, and analyzed in themes inspired by Brinkmann and Kvale [42] and based on their phenomenological approach. The interviews will be coded by 2 researchers using NVivo (version 14.0) software [43].

Cost-Effectiveness Evaluation

Throughout the duration of the study, we will also collect information on unplanned admissions for any reason with at least 1 overnight stay, unplanned readmissions for any reason and length of stay, visits to outpatient clinics, rehabilitation activities, visits to the general practitioner, equipment used, driving distance, personnel use, and numbers of phone or video calls. The analysis will be based on the guidelines for economic evaluation elaborated by Drummond et al [44].

Data Storage

Demographic data are being stored within the Future Patient database, and the questionnaire data are stored in the REDCap (Research Electronic Data Capture; Vanderbilt University) software for quantitative analysis.

Adverse Events, Dropout, and Technical Issues

All adverse events, dropouts, and deaths, as well as any technical issues related to the equipment, will be registered. No preterm study stop criteria are planned.

Data Analysis

Statistical Analysis

Baseline characteristics will be presented as frequencies and percentages or as medians and IQRs, as appropriate, and the data will be stratified by randomization groups and by sex. Changes over time on the primary outcome will be analyzed in accordance with the intention-to-treat principle, using a mixed-effects model for repeated measures design with robust variance in order to relax the assumption of normally distributed residuals. In addition, margin plots will be produced in order to investigate the interaction of time and randomization group. A sensitivity analysis will be conducted in order to investigate the effects of missing data as a result of dropout by comparing baseline characteristics between complete cases and dropouts, followed by adjusted analyses of the primary outcome using appropriate baseline characteristics as adjustment parameters. Secondary outcomes will be analyzed in a manner similar to the primary outcome. We will also examine overlaps between and variations within groups of different sexes. In examining sex differences, we will adjust for possible confounding factors (eg, age).

Trends and Patterns in Multiparametric Clinical Data

Data will be analyzed in order to identify correlations in multiparametric data collected during the 4 months. Initial analysis of the multiparametric data will be carried out by assessing the architectural structures and complexities of the data design through basic statistical and distributive analysis. Differences in the multiparametric data between baseline and postintervention measurements will be tested with paired *t* tests. Correlations of multiparametric data will be compared with patient-reported symptoms of AF. Paired *t* tests will be performed for the multiparametric data between periods both with and without patient-reported symptoms of AF in patients experiencing symptoms. Also, *t* tests will be performed for multiparametric data between patients with and without symptoms of AF. Simplistic features will be developed based on the statistical analyses and correlations between data.

Qualitative Analysis

A research assistant will transcribe all interviews into text files. Data will be coded in NVivo (version 14.0; QSR International), drawing inspiration from the SDT theoretical framework and using methods developed by Brinkmann and Kvale [42]. Two different researchers will be responsible for conducting the interviews and analyzing the data. The data will be presented in terms of key themes and major findings.

Economic Evaluations

A cost-effectiveness analysis of the FP-AF telerehabilitation program compared to conventional care will be made at 7

months after inclusion for both groups. The analysis will be based on the guidelines for economic evaluation elaborated by Drummond et al [44].

Results

The findings of the RCT will be analyzed during the spring of 2025 and subsequently published in peer-reviewed journals in the fields of telerehabilitation, clinical cardiology, and health economics. In addition, these results will be presented at relevant international scientific conferences. A total of 208 patients will be enrolled, 104 in the telerehabilitation group and 104 in the control group.

The evaluation of the FP-AF program comprises both clinical data recorded by the patients and data gathered through interviews and questionnaires. The evaluation involves quantitative analysis of primary and secondary outcomes (questionnaires) as well as qualitative exploration of the perspectives and experiences of patients with AF, their relatives, and HPs. Finally, a health economic evaluation will be conducted. Taken together, the data and the associated analyses will provide a comprehensive perspective on the effectiveness of the FP-AF program as seen from clinical, patient, relatives, psychological, organizational, and economic perspectives.

Discussion

Telerehabilitation Program

The aim of the study is to test an individualized CTR program for patients with AF. The primary outcome measure is to assess potential changes in QoL among those patients with AF using telerehabilitation. The secondary outcome measures are changes in AF knowledge, changes in anxiety and depression, changes in motivation, the burden of AF, patients' and relatives' perspectives and experiences, patients' and relatives' use of the HeartPortal, perspectives and experiences of HPs, the development of clinical data, and a cost-effectiveness analysis.

CR for patients with AF is a fairly new initiative, and national guidelines for AF CR have only recently been published [8]. In this study, we take this initiative further by examining the potential of a CTR program for patients with AF, as telerehabilitation provides a promising and innovative alternative to conventional rehabilitation. The potential advantage of telerehabilitation is that it can provide easier access to rehabilitation assistance and activities and may therefore be a means of overcoming some of the barriers to participation in CR that have been identified in other cardiac patient groups [45]. Use of telerehabilitation may be especially relevant for patients with AF, as this group is very diverse in terms of the subjective impact of their disease; hence, some patients may not feel the need to attend physical appointments at the clinic, but they may be willing or even positive about participating through digital communication and technology. The digital option offered by telerehabilitation may thus improve their QoL.

The FP-AF program will be tested in a multicenter study in order to increase the validity of the study. The FP-AF program is based upon SDT theory and the exploration of how patients, their relatives, and HPs use the HeartPortal. We will therefore analyze the linkages between motivation and use of the digital platform. In a previous study of patients with heart failure, we have documented that telerehabilitation motivates patients with heart failure just as effectively as conventional rehabilitation and that it does not lead to higher levels of psychological distress [46].

To obtain a more in-depth understanding of how patients, relatives, and HPs perceive CTR, we also plan to conduct qualitative interviews with all groups in order to learn more about how they experience the program as part of their everyday life and work, including their evaluation of the specific modules of the program. Using interviews together with questionnaire data will allow for a more holistic understanding of the usability, effect, and acceptance of the proposed program.

Limitations

The expected limitations for the interpretations of the results are as follows. The study relies heavily on commercial tracking devices that have been chosen for their ability to automatically transmit data to the HeartPortal. Any changes in device regulations during the study could make it necessary to replace these devices, potentially leading to inconsistency in the data. In addition, the proposed intervention is complex, consisting of a chain of events and interventions and based on multiple commercially available technologies that may become outdated. This complexity, including the rapidly changing nature of technology, may pose a challenge to future replication studies.

Conclusions

Analyzing data from primary and secondary outcomes will help determine whether the FP-AF program has the potential to increase QoL for patients living with AF and give them more knowledge of how to master the disease. The cost-effectiveness analysis will provide an assessment of the health economic sustainability of the FP-AF program and shed light on whether telerehabilitation can be a viable alternative for rehabilitation of patients with AF.

Acknowledgments

The project was financed with DKK 4.3M by a grant from The Danish Heart Association and DKK 300,000 from Snedkermester Sophus Jacobsen og Hustru Astrid Jacobsens Fond through The Danish Heart Association, with DKK 1,277,097 from Aage and Johanne Louis Hansens Fond, DKK 1,223,904 from MedCom, DKK 300,000 from Viborg Municipality, DKK 864,000 from Region Midtjylland's Forskningsinnovationspulje, and DKK 40,000 from Rosa og Asta Jensens Fond. We wish to thank the project nurses Helle Mark, Cardiology Ward, Regionhospital of Viborg, and Hanne Kastbjerg, Cardiology Ward, Regionhospital

of Silkeborg. We also wish to thank health care consultants Maria Kamstrup Oeland, Skive Healthcare Center, and Susanne Engbirk Grud and Helen Skov Kjaersgaard, Silkeborg Healthcare Center.

Conflicts of Interest

None declared.

Abstract

Background: Inhibitory deficits are common in psychopathology. Emotion-related impulsivity (ERI) and rumination are general risk factors for psychiatric distress that are similarly associated with dysfunctional inhibition—particularly in affective contexts. A number of cognitive remediation procedures have been developed to improve inhibitory control; however, most remediation programs focus on "cold" cognition independent of affective processing. This pilot trial will gather preliminary evidence for a new cognitive training intervention targeting "hot" affective control (ie, inhibitory functions during elevated emotional arousal) in a transdiagnostic sample of adults who report heightened emotion dysregulation.

Objective: This manuscript describes a protocol for a pilot randomized waitlist-controlled trial to assess changes in ERI and rumination after neurobehavioral affective control training (N-ACT), an 8-week cognitive training intervention designed to improve emotional response inhibition and emotional working memory. Our primary aim is to evaluate the efficacy, feasibility, and acceptability of N-ACT in reducing rumination and ERI, which we respectively conceptualize as complementary cognitive and behavioral consequences of emotion dysregulation. Secondarily, we will examine whether N-ACT leads to improvements in inhibitory control and, more distally, psychopathology symptoms.

Methods: The final sample will comprise 80 adults who report high ERI or rumination. Participants will be randomized to (1) begin the N-ACT program without delay or (2) join a waitlist condition and then complete N-ACT. Exclusion criteria include active alcohol or substance use disorders, psychosis, and suicide risk. At the baseline and postintervention time points, participants will complete measures of emotion dysregulation and psychiatric symptoms, as well as a neuropsychological assessment of inhibitory control. Individuals assigned to the control group will undergo an identical assessment before joining the waitlist, followed by parallel assessments before and after N-ACT.

Results: This trial is funded by support from the University of California Board of Regents and the Peder Sather Foundation (funding period: October 2022-September 2025). Recruitment is scheduled to begin in spring 2025. We will begin data analysis once data collection is complete, which is planned to occur in fall 2025.

Conclusions: This pilot randomized waitlist-controlled trial is designed to assess the initial efficacy, feasibility, and acceptability of N-ACT, a novel cognitive remediation approach developed to address 2 key contributors to psychopathology: ERI and rumination. The N-ACT program uses computerized adaptive behavioral tasks to strengthen the affective control processes theoretically and empirically linked to ERI and rumination. We hope this work will help inform future studies with sufficient

statistical power to ascertain whether enhancing affective control through cognitive training (N-ACT) produces downstream reductions in psychiatric symptoms via improved emotion regulation.

Introduction

Background

Emotion dysregulation is an established risk factor for nearly all psychiatric syndromes, with particularly strong effects for anxiety and depression—the 2 most common psychological disorders [1,2].These links between emotion dysregulation and psychiatric dysfunction are well documented across ecological and laboratory studies, as well as in large-scale prospective work [3-5]. This research will evaluate a novel intervention, neurobehavioral affective control training (N-ACT), which is designed to target two trait-like facets of emotion dysregulation: (1) *rumination*, the tendency toward self-focused, past-oriented, repetitive negative thinking about the causes and consequences of negative affect [6,7]; and (2) *emotion-related impulsivity* (ERI; [8]), the tendency toward reduced behavioral control during states of high affective arousal [9], most commonly captured using measures of Urgency. These 2 aspects of emotional dysregulation reflect cognitive and behavioral responses, respectively, to negative affect. Robust associations have been documented of rumination and ERI with anxiety and depressive disorders as well as numerous other psychiatric conditions [6,7,10-18].

Inhibitory Control Deficits in Psychopathology

Rumination and ERI are both tied to problems with cognitive (inhibitory) control. Cognitive control is a multifaceted construct that includes (1) the ability to update and manipulate the contents of working memory; and (2) the inhibition of task-inappropriate behavior (ie, response inhibition), alongside closely related executive functions (eg, cognitive inhibition, set shifting or task switching). This project targets both working memory and response inhibition, which represent promising candidate mechanisms linking emotion regulation deficits to varied manifestations of psychopathology.

Cognitive difficulties associated with major depressive disorder (MDD) and other internalizing syndromes often have severe consequences for the individuals affected, likely through adverse influences on symptoms and role functioning. Systematic reviews of this literature suggest that cognitive control deficits in MDD are not simply epiphenomenal effects caused by symptoms—as some have recently suggested [19]—but rather often persist after remission, thereby exerting continued influence on everyday functioning and the likelihood of symptom recurrence [20,21]. Indeed, impaired cognitive control predicts relapse in patients with first-episode depression [22] up to 5 years after the index episode through its association with rumination [23,24]. One of the longest prospective studies of cognition in MDD revealed cognitive control impairment a full decade after symptom remission [25]. In sum, a substantial literature implicates poor cognitive control in prolonged vulnerability to depression recurrence and relapse.

Evidence for chronic neuropsychological deficits in MDD and other psychiatric disorders has generated interest in improving mental health through strengthening cognitive control and other executive functions. However, traditional psychotherapeutic interventions have limited effects on cognitive control; for example, meta-analyses indicate little to modest changes in cognitive control capacities after psychological [26] or pharmacological treatment for depression [27]. The recognition of the need for new approaches to enhancing executive functions has led to a growing focus on development of cognitive remediation or training programs that directly target inhibitory control [28-30].

However, many studies—of major depression or otherwise—rely on measures of “cold” cognitive control, in that the assessment procedures lack emotionally salient stimuli or probes. *Affective control* refers to the ability to exert inhibitory control in situations or tasks involving emotionally arousing content, often referred to as “hot” executive functions. Emotional contexts may be more likely to activate or aggravate symptoms compared to contexts without such affective components [31]. Rumination and ERI—as well as psychopathology more broadly—may be more closely linked to affective control deficits than to cold cognitive control deficits. For example, among people with remitted MDD compared to healthy controls, Ronold et al [32] observed working memory deficits (during high cognitive load) especially for negative compared to positive emotional content; moreover, in 2 independent samples, such impairment was tied to heightened rumination [33], which in turn predicted elevated risk for depressive relapse [32]. ERI is similarly associated with impaired inhibitory control, particularly during higher arousal states [34]. Moreover, poor affective control is associated with symptoms of eating disorders [35], nonsuicidal self-injury [36-40], and suicidal behaviors [31,41,42]. Thus, affective control is an empirically justified and theoretically informed target to remediate and prevent the recurrence of psychiatric symptoms.

A growing corpus of research has converged on 2 components of affective control, both of which are targeted by N-ACT: (1) *emotional working memory*, which involves the temporary

storage and manipulation of emotional information in short-term memory; and (2) *emotional response inhibition*, or the ability to regulate motor impulses driven by automatic emotional reactions. Dysfunction in working memory or response inhibition—*specifically in the context of negative emotion*—is independently tied to rumination, ERI, and internalizing symptoms, as well as self-injurious thoughts and behaviors [39,41,43-46]. Several studies have shown that emotional response inhibition, as indexed by an emotional stop-signal task (ESST), shows significant correlations with measures of ERI and psychiatric severity [37,39,43]. Negative emotional response inhibition impairment is a strong predictor of symptoms, including increased risk of future suicide attempts [41].

Cognitive Remediation in Psychiatry

The goal of cognitive remediation is to improve dysfunctional neurocognitive processes. This improvement relies on the repeated practice of specialized cognitive training exercises using computer algorithms that adjust task difficulty according to user performance. A burgeoning literature suggests that cognitive remediation may be a promising transdiagnostic intervention approach [28,47-55]. Working memory training has been found to reduce the recurrence of mood episodes among patients with remitted MDD, with stronger protective effects—apparent up to 2 years after the intervention—for those who reported reduced rumination after training [52,56]. Although accumulating evidence supports the efficacy of cognitive remediation in psychiatric disorders, meta-analytic effect sizes tend to be small to medium [28], and a substantial proportion of individuals do not respond to existing training programs for symptom reduction [57].

Numerous issues likely contribute to the relatively modest treatment effects associated with standard cognitive remediation programs. N-ACT is novel in 3 ways. First, we focus on emotion regulation rather than psychiatric symptoms as our primary outcome. Second, extant literature shows considerable variability in the delivery methods of cognitive remediation. Following consensus recommendations from an expert working group [47], we will implement scaffolding techniques to facilitate the generalization and functional impacts of N-ACT. More specifically, we will follow recommendations to provide support to facilitate translation of skills into everyday activities, so as to enhance the ecological validity and effectiveness of cognitive training programs [47-55]. Participants will accordingly complete N-ACT intervention sessions guided by a "coach," who will deliver semistructured and (partially) personalized psychoeducational content. N-ACT coaching sessions will include the identification of compensatory problem-solving strategies for emotion regulation, skills practice, motivational enhancement, discussion of the ecological relevance of the cognitive skills being trained, and procedures to promote the transfer of training effects to real-world situations. Therefore, we will be testing the effects of repeated affective control exercises, coupled with therapeutic coaching. Our hope is that this combination of techniques will support generalization to improved functional outcomes.

Third, although the stimuli and parameters in many cognitive control training tasks (eg, those using geometric shapes and letters) lack inherent salience value, our trial builds from a smaller body of work on cognitive remediation using the affective variants of inhibitory control tasks as well as traditional tasks (with neutral stimuli) that may naturally induce emotional arousal [50]. As an example of the latter, the Paced Auditory Serial Addition Test [58], which uses numerical stimuli and has been extensively implemented as an adaptive training task [29,30,59], characteristically evokes frustration [58]. To our knowledge, the only direct comparison of cold versus hot cognitive remediation was performed in a pilot trial of emotional working memory training, which yielded promising results in symptoms and cognition (but not rumination) among patients with depressive symptoms [60]. This early work is consistent with recent meta-analytic findings suggesting that hot inhibitory control training may be more effective than nonaffective cognitive remediation procedures for psychopathology [61]. Accordingly, N-ACT incorporates affective stimuli (eg, naturalistic images with standardized emotional content) into traditional training tasks designed to improve cognition such that users learn to use these mental operations in socioemotional contexts that more closely match in vivo experiences. The inclusion of affective stimuli is particularly important, given a substantial body of work suggesting that difficulties sustaining inhibitory control during states of elevated arousal are particularly relevant to emotion regulation and psychiatric symptoms.

This Study

Overview

This pilot randomized waitlist-controlled trial will enroll adult participants with high rumination or ERI scores. The primary aim of this study is to examine the acceptability, feasibility, and efficacy of N-ACT as a novel therapeutic approach to reduce rumination and ERI by improving 2 facets of affective control: emotional working memory and emotional response inhibition. Secondarily, we will test the effects of N-ACT on behavioral indices of ability transfer as well as on other subjective measures of emotion dysregulation (beyond trait rumination and ERI) and psychopathology symptom severity (refer to Multimedia Appendix 1 for details). Finally, we will conduct exploratory analyses to examine the potential mechanisms that might influence predicted changes in emotion dysregulation, informing future work to systematically test these effects in a sufficiently powered sample. In addition to performing intent-to-treat analyses, we will conduct sensitivity analyses to evaluate the extent to which program adherence predicts the hypothesized effects.

Hypotheses

We propose the following hypotheses:

- H1: Participants will rate N-ACT as an acceptable intervention to reduce emotion dysregulation.
- H2: Participants will demonstrate adherence to the N-ACT program at levels comparable to those observed in established cognitive remediation protocols [33,52,62-64].
- H3 (primary): Compared to baseline, participants assigned to complete N-ACT (without a waitlist) will report greater decreases in rumination and ERI at the postintervention

assessment than those assigned to the control condition at the postwaitlist assessment.

- H4 (secondary): Compared to baseline, participants assigned to complete N-ACT (without a waitlist) will demonstrate greater improvements in targeted affective control processes (ie, enhanced emotional working memory and emotional response inhibition) at the postintervention assessment than those assigned to the control condition at the postwaitlist assessment.
- H5 (secondary): Compared to baseline, participants assigned to complete N-ACT (without a waitlist) will demonstrate near (ie, enhanced hot affective flexibility) and far (ie, enhanced cold working memory and cold response inhibition) transfer of trained neurocognitive abilities at the postintervention assessment than those assigned to the control condition at the postwaitlist assessment.
- H6 (secondary): Compared to baseline, participants assigned to complete N-ACT (without a waitlist) will report greater decreases in self-rated psychopathology symptom severity (ie, reduced internalizing and externalizing symptoms) at the postintervention assessment than those assigned to the control condition at the postwaitlist assessment.

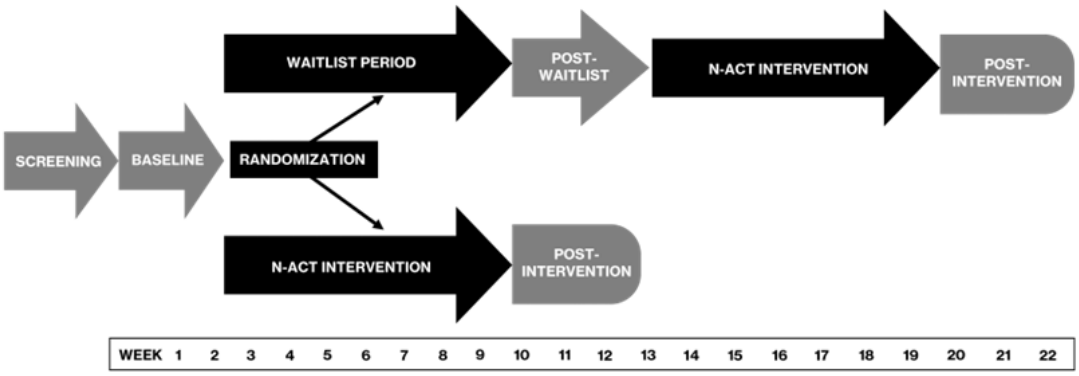
Methods

Overview

This research comprises a delayed intervention randomized waitlist-controlled trial with a mixed, 2-group (2 between-subject levels: active vs control), repeated measures (2 within-subject levels: T1=baseline or preintervention time point; T2=postwaitlist or postintervention time point) design, for which we will recruit English-speaking adults (aged 18-65 y) from the San Francisco Bay area of the United States. The inclusion criteria include high self-reported rumination or ERI. Eligible individuals will be invited to the university for an initial baseline session. At this session, they will complete informed consent procedures and an assessment battery consisting of computerized neuropsychological tasks with concurrent psychophysiological monitoring. After the baseline session, participants will complete a battery of questionnaires, followed by 1 week of baseline ecological momentary assessment (EMA) of real-world daily fluctuations in mood, rumination, and ERI.

After the baseline assessment (laboratory session, questionnaires, and EMA), we will randomly assign participants to receive active treatment (ie, N-ACT without delay) or the waitlist control condition, unblinded, using an asymptotic maximal procedure to achieve a maximally tolerated imbalance of 2, while maintaining a 1:1 allocation ratio between the 2 trial arms [63]. Participants in the active N-ACT group will begin the intervention, which consists of 8 weekly coached training sessions, within 1 week after baseline EMA. We will recontact waitlist control participants after a period equivalent to the intervention duration (ie, 2 months) to complete a second (postwaitlist) assessment session and EMA before starting the N-ACT program for the following 8 weeks. After the intervention, participants will be asked to complete a second week of EMA, and then a postintervention assessment session with comparable measures to baseline. We will recontact waitlist control participants approximately 10 weeks after their (prewaitlist) baseline assessment session to complete a second (postwaitlist) assessment and 1 week of EMA, parallel with the pre-intervention assessment procedures of the N-ACT group,. The waitlist group will then be offered 8 weeks of N-ACT, followed by a second week of postintervention EMA, and then a final assessment session. In sum, we will follow participants assigned to receive the intervention without delay for 12 weeks (3 mo) and those assigned to the waitlist control group for 22 weeks (5.5 mo). This delayed intervention randomized waitlist-controlled trial design enables us to offer all interested participants the opportunity to participate in the program and maximizes our ability to rapidly accrue a sufficiently sized sample for analyses. Figure 1 demonstrates the flow of potential participants through the study procedures.

Figure 1. Flow of participants through the trial with a delayed intervention randomized waitlist-controlled design. N-ACT: neurobehavioral affective control training. Assessments are indicated in gray.



Hypotheses and analyses were preregistered at OSF. We plan to detail any changes to this protocol in future publications and disseminate our findings to the scientific community in accordance with the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist (V 1.6.1) [64].

Ethical Considerations

The University of California Berkeley Committee for Protection of Human Subjects granted approval for this research (2023-01-15949) before data collection. All participants will complete written informed consent before commencing study procedures.

Participants will be assigned an ID number, which will be used in place of their name or other identifying information on all research materials. Data will be kept in secure, password-protected files. Although we plan to make data publicly available for reanalysis, we will carefully deidentify data before doing so. In publishing or presenting the results, we will not provide any information that could identify an individual participant.

Participants will receive course credit or monetary compensation for completing assessment procedures but will not be paid for time spent on screening or the intervention itself. Students will be able to earn credit toward required research hours in their psychology classes. We plan to increase the hourly payment rate slightly over the course of the trial to promote retention, from US $20/h for the baseline assessment to US $30/h for the postwaitlist and postintervention assessments. We will compensate participants up to US $60 (or 3 h of course credit) for completing the baseline assessment (2.5-h in-person session plus 30 min of questionnaires), a US $10 “bonus” for performance on an unrelated computer task during the baseline session, US $10 for each week of EMA if they complete at least 75% of the prompts, and US $60 for the postintervention assessment (1.5-h in-person session plus 30 min of questionnaires). Those randomized to the waitlist control condition will be eligible to receive up to an additional US $60 for completing the postwaitlist assessment (identical to the postintervention assessment).

In sum, participants assigned to complete N-ACT without the waitlist can earn up to US $150 (or 3 h of course credit plus up to US $90), while those in the waitlist control condition could earn up to US $70 in addition to those amounts. Payments will be prorated if participants complete only part of an assessment.

We will remunerate participants within 1 week of each completed assessment via digital credit cards, which will be replenished as necessary.

Study Procedures

Recruitment and Screening

We will invite up to 500 adults to complete preliminary screening procedures and an estimated 100 participants to complete the initial baseline assessment session. After accounting for 20% expected attrition, we expect 40 participants in each condition to complete all study procedures.

Study advertisements will be posted locally in public spaces and distributed by web (eg, via email listserves, Craigslist, and social media sites). We will also administer a prescreening survey to students enrolled in psychology classes at the University of California Berkeley, and we will invite students who meet the preliminary inclusion criteria based on those responses to take part in the study. Potential participants (recruited either from the community or from the student participant pool) will be directed to our website, where they can view additional details about the trial. We intend to recruit only secondarily from the student participant pool to supplement community-based recruitment, which will constitute most of the targeted sample. All questionnaires, including screening items, will be administered through REDCap (Research Electronic Data Capture; Vanderbilt University) software [65], which will also be used for the secure storage of collected data.

After providing informed consent, interested individuals will complete the brief web-based screening via REDCap to assess preliminary eligibility. The inclusion and exclusion criteria are presented in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Current California residency
- Age 18 to 65 y
- Elevated scores on self-report measures of rumination (Mn >2 on the Brooding subscale of the Ruminative Responses Scale [13]) or emotion-related impulsivity (Mn >3 on the Feelings Trigger Action factor of the Three-Factor Impulsivity Index [9])

Exclusion criteria

- Insufficient English literacy to understand study procedures (as assessed by self-report) or careless responding as indicated by the following:
- Failing ≥50% of the attention check items embedded in the screening questionnaires
- Overly rapid responding (ie, mean response time of <2 s for multiple-choice items)
- Qualitative review of long strings of identical entries
- Positive history of brain tumors, neurological disorders, or head injuries accompanied by the following:
- Loss of consciousness of >5 min
- >2 separate instances of clinically significant head trauma
- Recent alcohol or other substance use disorder (in the past 6 mo) or current psychosis (in the past 2 wk) according to the Psychiatric Diagnostic Screening Questionnaire [66]
- Past-month active suicidal ideation paired with either of the following:
  - An identified method, specific plan, or intent
  - Lifetime history of suicide attempts as assessed by the screen version of the Columbia Suicide Severity Rating Scale [67]

The exclusion criteria do not cover the presence of anxiety, depression, or other psychiatric symptoms, given our intention to target emotion dysregulation broadly and to assess the generalizability of effects across psychiatric diagnoses and severity, including participants with few or no symptoms and those without treatment history. However, the screening will include items from the self-rated screen version of the Columbia Suicide Severity Rating Scale (C-SSRS; for suicidal thoughts) as well as the alcohol, substance, and psychosis subscales from the Psychiatric Diagnostic Screening Questionnaire (PDSQ) [66]. Individuals who do not respond to the requisite screening items or do not meet eligibility requirements, including those whose responses to the psychiatric screening questions surpass established clinical thresholds, will be automatically informed that they will not be able to join the trial and will receive a list of mental health resources along with an invitation to contact our team should they desire additional referral assistance. We will provide further support for engaging with psychiatric care providers to respondents who endorse past-month active suicidal ideation with an identified method, specific plan, or intent on the C-SSRS.

Assessment

Overview

Each in-person assessment session will involve core measures expected to take 90 minutes, including a battery of computer-based behavioral tasks measuring cold and hot executive functions as well as the Positive and Negative Affect Schedule (PANAS) [68] to evaluate subjective mood before and after the neuropsychological examination. Within 24 hours of each session, participants will be asked to complete self-rated questionnaires to evaluate psychiatric symptoms and other variables of interest, which will require an additional 30 to 40 minutes. Table 1 presents key measures included at each assessment and intervention time point (refer to Multimedia Appendix 1 for a comprehensive list and additional details).

Table 1. Administration schedule of core measuresa.

Domains and measures	Format	Screening	Baseline assessment	Postwaitlist assessment	N-ACT[a] assessment	Post–N-ACT assessment
Emotion dysregulation						
Ruminative Responses Scale–Brooding	Self-report	✓		✓		✓
Three-Factor Impulsivity Index–Feelings Trigger Action	Self-report	✓		✓		✓
Three-Factor Impulsivity Index–Pervasive Influence of Feelings	Self-report		✓	✓		✓
Psychiatric symptom severity						
Columbia Suicide Severity Rating Scale	Self-report	✓				
Demographic questionnaire or mental health history survey	Self-report	✓				
Psychiatric Diagnostic Screening Questionnaire–Alcohol Use Disorder or Substance Use Disorder or Psychosis	Self-report	✓				
Externalizing Spectrum Inventory–Revised	Self-report		✓	✓		✓
Inventory of Depression and Anxiety Symptoms, Expanded Version	Self-report		✓	✓		✓
Neuropsychological assessment battery						
Digit Span Backward	Behavioral		✓	✓		✓
Stop-signal task	Behavioral		✓	✓		✓

Wechsler Adult Intelligence Scale, Fourth Edition–Vocabulary	Interview		✓	✓		✓
Emotional stop-signal task	Behavioral		✓	✓		✓
Memory and affective flexibility task	Behavioral		✓	✓		✓
Affective control training (N-ACT)						
Adaptive emotional n-back task	Behavioral				✓	
Emotional stop-signal task–adaptive	Behavioral				✓	

[a]A comprehensive list of secondary measures and additional outcomes is available in Multimedia Appendix 1.

Neuropsychological Battery

At each assessment session, participants will perform 5 computerized neuropsychological tasks (in a pseudorandom order) to index the hypothesized effects of N-ACT on emotional working memory and emotional response inhibition as well as the transfer of targeted inhibitory control processes from T1 (baseline time point) to T2 (postwaitlist or postintervention time point). The assessment battery accordingly includes 3 widely used gold standard cold executive functioning tasks that measure key components of cognitive control: (1) Digit Span Backward [69], a working memory test that requires participants to select (using the computer cursor) a series of numbers in the opposite order from which the digits were presented (in numerical strings of increasing length); (2) the stop-signal task (SST) [70], a measure of prepotent response inhibition in which participants must quickly indicate (via keypress) the direction of rapidly presented arrow stimuli, except on trials that include an unpredictable buzzer tone, which require termination of the initiated motor response; and (3) the trail-making test [71], an assay of set-shifting or task-switching ability that involves using

the computer cursor to draw a path connecting an array of alphanumeric stimuli in an alternating sequential pattern (eg, "A" to "1" to "B" to "2," and so on) as quickly as possible. The neuropsychological battery additionally includes the administration of the Vocabulary subtest from the Wechsler Adult Intelligence Scale, Fourth Edition [72], to assess crystallized intelligence, which we will examine in exploratory analyses of the specificity of intervention effects.

Participants will also complete 2 tasks to confirm the efficacy of N-ACT in augmenting 2 core facets of affective control, emotional response inhibition and emotional working memory: (1) the ESST [37,39,43], which follows procedures parallel to those of the traditional SST but differs in that participants must rapidly categorize affective pictures according to perceived valence (ie, "positive or pleasant" vs "negative or unpleasant") instead of indicating the direction of arrow stimuli, while still inhibiting prepotent motor responses on a subset of trials with an unpredictable auditory stop signal (buzzer or tone); and (2) the memory and affective flexibility task (MAFT) [73], a novel modified n-back procedure that provides indices of emotional working memory as well as affective flexibility (as captured by emotional set shifting or task switching trials) by asking participants to recall whether they have previously seen (1-3 trials earlier) serially presented images with affective content (ie, "n-level," which varies by block), with occasional interspersed "switch" trials prompting them to respond instead to perceived image valence (identical to ESST go or no-signal trials).

Psychophysiology

During the administration of the computerized cognitive assessment tasks, we will gather 2 metrics of arousal—pupil dilation, which reflects phasic norepinephrine signaling; and skin conductance, an index of autonomic sympathetic nervous system activity—to evaluate the physiological correlates of cold and hot executive functioning. We will consider incorporating physiological reactivity variables gathered during the latter set of tasks as secondary indicators in exploratory mechanistic analyses of the hypothesized treatment effects (Multimedia Appendix 1).

Pupil measurements will be recorded noninvasively with a Tobii T-120 infrared eye tracker [74] using E-Prime Extensions for Tobii [75]. We will not gather pupillometry data from participants who report a history of epilepsy or seizures triggered by arcade or video games, computer or television screens, or flickering fluorescent bulbs. Skin conductance levels will be monitored by electrodes placed (by the participant) on the inner sole of the foot. Trained research staff will calibrate physiological recording hardware (eg, by ensuring proper electrode placement and adjusting a chin rest to limit movement-related artifacts) for maximum comfort and signal.

EMA Surveys

We will use EMA to capture the temporal dynamics of real-world affect and regulation using a probes delivered via REDCap. Each EMA survey will ask participants to complete (1) PANAS items to rate current levels of anxiety, irritability, and sadness on a 7-point Likert scale; (2) the Momentary Ruminative Self-Focus Inventory–Abbreviated [76], a 3-item questionnaire evaluating state-level fluctuations in rumination, each rated on a 7-point Likert scale; and (3) the Momentary Impulsivity Scale [77], a 4-item questionnaire measuring momentary impulsivity on a 5-point Likert-type scale. Our chief EMA emotion dysregulation indices, which we predict will decline from the preintervention assessment to the postintervention assessment, include the (1a) average levels of, and (1b) variability (ie, mean square of successive difference) in, daily negative affect (derived from mean scores on the mood probes); (2) average daily levels of rumination via the Momentary Ruminative Self-Focus Inventory–Abbreviated; and (3) average daily levels of ERI, as measured by Momentary Impulsivity Scale scores during periods of elevated momentary negative affect (ie, scores above the person-level mean).

We will provide an in-person tutorial at baseline to help familiarize participants with the structure and content of EMA surveys, and to facilitate the completion of practice items. Participants will use their personal mobile phones or other internet-capable devices to submit EMA responses. Specifically, participants will receive automatic "push" notifications to complete EMA surveys 5 times per day. We will randomize notifications by binning participants' available waking hours into 5 equal windows and then randomly selecting a survey time within each bin, with an interval of at least 90 minutes between notifications. Surveys will be available for completion for 80 minutes, and reminder prompts will be sent within 40 minutes of missed survey notifications.

Questionnaires

After each in-person assessment session, we will ask participants to complete questionnaires administered via REDCap (Table 1) as promptly as possible. Each set of questionnaires includes primary and secondary outcome measures related to emotion dysregulation as well as measures of psychiatric symptom severity, perceived functional impairment in cognitive abilities and activities of daily living. The baseline assessment will also include potential moderators of treatment effects for exploratory analyses. We will ask participants who request premature withdrawal from the trial to complete an identical assessment of the major outcomes of interest (ie, self-rated emotion dysregulation, psychiatric symptom severity, cognitive deficits, quality of life, and treatment acceptability) at the time of discontinuation.

N-ACT Intervention

Overview

The N-ACT program comprises 8 in-person training sessions over 2 months. The intervention is limited to weekly 1 h sessions to maximize adherence and minimize attrition. Each N-ACT session is guided by a trained "coach" (supervised by a licensed clinician) who will explain intervention procedures and rationale, offer relevant psychoeducation, and use motivational interviewing principles to encourage and support participants. At each training session, participants will practice 2 computer-based adaptive tasks targeting affective control. Approximately half of each N-ACT session will be spent performing these exercises, and the other half will be dedicated to coaching and assessment. Coaches will discuss standard

cognitive behavioral psychoeducational content regarding emotion regulation (drawn from established therapy protocols).

Psychoeducational Content

To begin each weekly N-ACT session, a coach will review information from the previous session and discuss the implementation of learned techniques over the prior week. Coaches will then present information from 1 psychoeducational module, adapted from empirically supported interventions, on the topics presented in Textbox 2. Modules 2 to 7 will also include theoretical justification for cognitive training to enhance emotion regulation.

Textbox 2. Topics covered in coaching sessions.

Coaching session sequence

1. Introduction and orientation, which includes an overview of session procedures and program structure, rationale, and personal goal setting
2. Cognitive behavioral approaches to emotion, which introduces fundamental concepts derived from cognitive behavioral therapy to elucidate links among affect, cognition, and behavior, plus an emotion regulation strategy (“STOP”) drawn from dialectical behavior therapy (DBT)
3. Environmental influences on feelings, in which participants identify risk and resilience factors that impede or facilitate emotional self-regulation, paired with distress tolerance skill adapted from DBT (“Self-soothing”)
4. Functional analysis of behavior, which involves functional analysis of problematic patterns of thought or behavior related to personal goals for emotion regulation
5. Mindfulness, involving a guided meditation practice
6. Psychological flexibility, which introduces key elements of acceptance and commitment therapy
7. Interpersonal skills, covering 2 closely related techniques (also borrowed from DBT) to promote adaptive emotional self-regulation and communication within relationships (“DEARMAN”)
8. Review, summary, and wrap-up, involving an examination of progress toward overarching treatment goals, review of key concepts, and solicitation of participant feedback on program components via interview and self-report

After engaging with psychoeducational content in each module, participants will complete the N-ACT tasks, and coaches will end each session with an informal debriefing to help consolidate learning and identify implementation intentions (ie, interim objectives toward participants’ identified treatment goal) for the coming week. Coaches will additionally administer the PANAS before and after the training tasks. We will audio record N-ACT training sessions (with participant consent) for regular review by independent raters to evaluate coach adherence and fidelity to the intervention guidelines using session-specific standardized forms created for this study.

N-ACT Task Battery

Overview

Participants will be asked to perform the same 2 computerized training tasks each week, in counterbalanced order: (1) an adaptive emotional n-back (AEnB) task targeting emotional working memory and (2) the ESST-adaptive (ESST-A), which targets emotional response inhibition. These are adaptive versions of the affective control behavioral measures completed during assessment sessions, modified to dynamically adjust the level of difficulty according to participant performance, which we expect to improve with additional training over time. Both training tasks include gamified graphical elements (eg, user-selected avatars) to facilitate user engagement (refer to Multimedia Appendix 1 for task instructions and other details).

The AEnB Task

The AEnB training task is an adaptive variant of procedures originally described by Levens and Gotlib [78,79], in which participants are instructed to indicate (as quickly and accurately as possible via keypress) whether a *target* affective picture stimulus is a “match” or a “mismatch” to a *cue* image shown *n* trials earlier, where *n* equals the number of interim trials between the presentation of the original cue and the to-be-evaluated target stimulus (ie, the “n-level”). The AEnB task additionally draws from an adaptive version of the dual-dimension emotional (n-back) working memory training task developed by Pan et al [53], such that cue-target pairs are only considered to match if the images are identical *and* spatially congruent, as each stimulus appears in 1 of 9 positions on an invisible 3×3 grid.

All AEnB task stimuli are pseudorandomly presented and counterbalanced to ensure equivalent numbers of matched and mismatched cue-target image pairs from 3 valence categories (neutral, negative, or positive) within each of 6 blocks, resulting in 36+n trials per block, or 216+n total trials. Image stimuli are shown for 1000 milliseconds on each trial, followed by a 2500-millisecond response window and a feedback screen shown for 1000 milliseconds. Trials are separated by a jittered intertrial interval of approximately 250 milliseconds (150-350 ms) assigned pseudorandomly on each trial.

The AEnB task involves 2 orthogonal adaptive components. The first is a tracking algorithm that adjusts the number of trials per condition (ie, emotional valence of cue-target pairs) to prioritize the encoding of spatial information (over affective content) into working memory for emotionally arousing images. Specifically, independent of the current n-level, higher accuracy for emotional (negative or positive) versus nonemotional (neutral) cue-target pairs will result in 2 fewer “match” trial pairs on the subsequent block. Crucially, the emotional images on these 2 trial pairs will remain identical but will be mismatched in spatial location. The algorithm will continue to swap matched emotional pairs with identical mismatched images until the participant achieves greater accuracy for neutral cue-target pairs (that are spatially congruent throughout the

task), at which point the number of emotional trial pairs per condition returns to baseline, on a per-block basis, with 1 negative and 1 positive identical but spatially mismatched pair replaced by fully matched emotional cue-target pairs.

The second adaptive feature of the AEnB task is the n-level itself, which is adjusted after the first block either upward (n=3) or downward (n=2) at the start of each subsequent block (range: n=1-7), contingent on participants' accuracy and response times (with larger values indicating greater working memory load). Specifically, the n-level decreases if a participant is unable to achieve at least approximately 80% accuracy (ie, at least 30 correctly identified pairs out of 36+n trials) within a given block; conversely, once a participant surpasses this accuracy threshold, the n-level increases at the start of the next block but only if the mean reaction time during trials with neutral target stimuli is faster than that during trials with emotional stimuli (regardless of whether cue-target pairs are matched or mismatched, provided that responses are accurate). This training approach is intended to encourage the development of relatively more rapid—but equally accurate—evaluative responses to less arousing or salient images. In sum, the AEnB task involves multiple adaptive components designed to facilitate diminished stimulus reactivity or enhanced engagement of affective control when processing emotionally evocative stimuli (eg, via enhanced attentional focus on key perceptual features rather than affective information, per se) for immediate recall in working memory.

The ESST-A Task

The ESST-A is a training variant of the original ESST [37,39,43], with comparable design elements; however, the ESST-A is distinct in that emotional (negative or positive) image stimuli are presented exclusively on no-go or stop trials (n=60 per valence), and, conversely, neutral images are only shown on go or no-signal trials (n=90 per block over 4 blocks) without an inhibitory cue. Participants must accordingly terminate emotional reactions to the most arousing and evocative stimuli on the ESST-A. This unique design feature of the ESST-A is meant to facilitate implicit associative learning, wherein salient affective content serves as a reliable "cue" that predicts upcoming stop signals, while stimuli with neutral information are consistently delivered without accompanying inhibitory demand. Therefore, repeated training with the ESST-A is expected to promote more automatic, reflexive engagement of inhibitory control at earlier stages of emotional information processing.

Similar to the nonadaptive version, the ESST-A comprises 4 blocks of 120 trials each, with stimuli presented pseudorandomly and counterbalanced across blocks to ensure equivalent numbers of trials per condition. Each ESST-A trial spans 2000 milliseconds, which includes a fixed pretrial pause period of 500 milliseconds, followed by a central fixation cross displayed for approximately 250 milliseconds, depending on a jittered latency value assigned on a trial-by-trial basis (150-350 ms), comparable to the AEnB task. The target image stimulus replaces the fixation cross in the center of the screen, where it is displayed for 1250 milliseconds. The initial (50 ms) stop signal is presented 250 milliseconds after stimulus onset, separately for positive and negative stimuli.

The primary adaptive component of the ESST-A is identical to the assessment version of the ESST (and similar to other SSTs). Specifically, the ESST-A includes 2 independent staircase algorithms that adjust valence-specific stop-signal delay (SSD) values (ie, distinct tracking values for negative and positive images) in 50-millisecond increments depending on participant performance, such that successful inhibition results in a longer SSD on the next no-go or stop trial with the same type of image, thereby increasing inhibitory demand. By contrast, commission errors (ie, false alarms) shorten each SSD by 50 milliseconds on subsequent no-go or stop trials with images from the same emotional valence category. These 2 stepwise algorithms are programmed to maintain commission error rates at approximately 50% of the no-go or stop trials, separately for negative and positive images, which enables calculation of valence-specific indices of emotional response inhibition (ie, stop-signal reaction time).

Data Quality Assurance

The screening survey and assessment questionnaires will randomly incorporate simple "attention checks" (eg, "2 + 2 = ?" and "for our data quality checking, please answer '1' to this question") to identify patterns of careless responding, which we will supplement by manual review to confirm the validity of self-report data. As previously noted, we will exclude participants who demonstrate patterns of careless responding during the screening questionnaire. Before conducting statistical analyses, research staff will perform comprehensive data cleaning and processing procedures as needed (eg, ascertaining violations of distributional assumptions for parametric tests and comparison with published norms).

Training and Reliability

Our team has comprehensive preparation procedures for all staff members involved in data collection. Before study recruitment, N-ACT coaches will receive extensive training in each session-specific intervention module to promote protocol adherence. Coach training and group supervision will comprise regular team-based meetings led by clinically licensed investigators, with didactic instruction, role-play, the development of interrater reliability to evaluate coach fidelity, and a review of practice tapes by senior researchers. We will conduct session adherence evaluations (as a group) monthly and provide retraining as necessary to address drift.

Risk Management

Overview

Trial procedures are designed to balance respect for participants' autonomy with the need for safety. Study consent forms will provide contact information for crisis hotlines and other mental health resources. We will offer referral assistance to interested individuals. All team members with direct participant contact will receive training regarding psychiatric emergencies, suicide risk assessment, and crisis management. A detailed manual will provide assessment probes, decision rules, referral resources, and contact information for use during emergency situations. Training will emphasize procedures for providing feedback in a clinically sensitive manner, and senior investigators will use role-play to demonstrate fundamental principles related to

assessment, obtaining supervision, providing referrals, and preparing documentation according to legal and ethical guidelines. This training will cover circumstances in which staff are permitted to breach confidentiality to contact emergency services.

Research assistants and coaches will be trained to carefully monitor cues indicating participant distress or discomfort, and we will offer breaks or opportunities to reschedule as warranted for fatigue or distress. Participants who endorse significant distress or endorse active suicidal ideation will be given the opportunity to speak with clinically licensed senior investigators, who will evaluate and determine the need for further follow-up. Research staff will work with these participants to develop a plan to obtain support, which may include strategies for discussing symptoms with their current provider, removing access to lethal means, and the provision of feedback or referrals. Our team has developed relationships with local sites to facilitate referral for individuals with insurance or those without; after referral, we will follow up with these participants as warranted to ensure that they received sufficient support.

Adverse Events

We will describe the limits of confidentiality as part of informed consent procedures to minimize the likelihood of study-related adverse events. During the consent process, we will also emphasize that our team is unable to provide emergency services or review research data in real time, and it is therefore important for participants to have access to other sources of care. Consent documents will encourage participants to contact the senior investigators with any concerns.

Throughout the trial, N-ACT coaches will also informally solicit information about potential issues at each training session. We will formally assess adverse events at the postintervention session. We will follow up with participants who show apparent clinical deterioration and will attempt to determine whether emergent symptoms or concerns might be somehow connected to study procedures. Adverse events will be reported to the university's Committee for the Protection of Human Subjects within 1 week.

Measures

Screening

The screening survey will include a demographic questionnaire to assess inclusion criteria in addition to the self-report measures outlined in the following subsections.

Mental Health History Survey

The mental health history survey includes items to identify individuals whose linguistic abilities or cognitive, neurological, or psychiatric condition might interfere with completing study procedures or fully engaging in the intervention.

C-SSRS, Screen Version

The screening includes the self-report screen version of the C-SSRS [67], a well-validated and widely used instrument designed to assess suicidal thoughts and behaviors. Endorsement of the C-SSRS ideation item (Have you actually had any thoughts of killing yourself?) will trigger 3 follow-up items, to cover past-month presence of an identified method, intent, and a specific plan. Responding affirmatively to any of these 3 items will result in automatic study exclusion. Regardless of their responses, all participants will be asked an item to evaluate lifetime history of suicidal behavior; those who endorse this item in addition to past-month active suicidal ideation will also be automatically excluded from study participation.

PDSQ Prompts

The screening survey includes the Psychosis, Alcohol Use Disorder, and Substance Use Disorder scales of the PDSQ (6 *yes* or *no* items per scale) [66]. Questions regarding psychosis refer to the previous 2 weeks, and substance-related questions cover the previous 6 months. Prospective participants who respond affirmatively to at least 1 of these prompts (on any of the 3 PDSQ scales) will be automatically excluded, based on established clinical cutoffs for this measure [62].

Ruminative Responses Scale–Brooding

The Ruminative Responses Scale–Brooding (RRS-B) [13] will be used to assess study inclusion criteria. The RRS-B comprises 5 items to evaluate the dispositional propensity to engage in past-oriented patterns of repetitive negative thinking. Respondents rate prompts on a scale ranging from 1 (*almost never*) to 4 (*almost always*) based on characteristic reactions to dysphoric mood described by each item.

Three-Factor Impulsivity Index

Eligibility will be further determined using the Feelings Trigger Action (FTA) scale of the Three-Factor Impulsivity Index (TFII) [9], a 54-item multidimensional measure of trait-like impulsiveness that asks respondents to rate their agreement with each prompt on a scale of 1 (*I disagree a LOT*) to 5 (*I agree a LOT*). FTA includes 26 items describing tendencies to engage in impulsive speech and action in response to emotional states. The TFII includes 2 additional scales derived from factor analysis: Pervasive Influence of Feelings, which comprises 9 items reflecting powerful cognitive and motivational responses to emotion; and Lack of Follow Through, which captures distractibility and lack of perseverance. Pervasive Influence of Feelings is included as a secondary measure of emotion dysregulation (assessed in conjunction with FTA, at baseline).

Emotion Dysregulation

Our primary measures of emotion dysregulation will comprise self-reported rumination (RRS-B) and ERI (FTA). The secondary indices of emotion dysregulation further include EMA indices of daily negative affect, rumination, and ERI, in addition to scores on questionnaires capturing conceptually related constructs (Multimedia Appendix 1).

Psychiatric Symptom Severity

Participants will complete the following questionnaires at baseline, postwaitlist, and postintervention time points to evaluate the hypothesized clinical effects of N-ACT (refer to Multimedia Appendix 1 for the secondary symptom outcome measures).

Externalizing Spectrum Inventory–Revised

The Externalizing Spectrum Inventory–Revised (ESI-R) [80] is a 100-item questionnaire that covers 23 facets of externalizing

psychopathology, including aggression, alcohol and other substance use problems, and fraudulent behavior. Respondents rate each ESI-R item as *true*, *mostly true*, *mostly false*, or *false*. Items referring to impulsivity (ie, redundant with the TFII) will not be included in the scale totals.

Inventory of Depression and Anxiety Symptoms, Expanded Version

The 99-item Inventory of Depression and Anxiety Symptoms, Expanded Version [81], is a validated questionnaire that assesses various emotional syndromes across the internalizing spectrum of psychopathology (eg, anxiety, depression, obsessions and compulsions). This instrument produces scores on 3 major factors (distress, fear, and mania), which are each composed of multiple subfactors (18 in total).

Statistical Analysis Plan

Our final target sample size (n=80) was derived from power analysis (1-β>0.85), based on hypothesized medium between-groups effect sizes (Cohen d=0.35) for the main outcomes of interest (α=.05). Before conducting the analyses, data will be checked for errors, statistical assumptions, and potential confounding variables to examine as covariates. Missing data imputation will also be performed as appropriate; we will present the results with and without imputed values for comparison. Our primary analyses will follow the International Conference on Harmonization E9 statistical principles for clinical trials. In accordance with these principles, we will use intention-to-treat analyses to estimate the main effects of N-ACT, using the final assessment scores of all randomized participants. To augment these findings, we will conduct sensitivity analyses restricted to data from participants who complete preintervention and postintervention assessments and at least 6 of the 8 weekly N-ACT sessions.

Descriptive statistics will be calculated to address the preliminary hypotheses regarding N-ACT's acceptability and adherence. Mean scores on the Interest or Enjoyment and Value or Usefulness subscales of the adapted Intrinsic Motivation Inventory [82] will serve as our main indices of the N-ACT program's acceptability (H1); specifically, we predict that participants who complete the intervention will provide average ratings of at least 5 (out of 7) across both scales. We further hypothesize that N-ACT participant adherence and retention will be comparable to those observed in other cognitive remediation interventions (H2); specifically, we anticipate median person-level adherence levels between 70% and 75%, which we expect to decrease at the group level by approximately 5% each week [63,64], with most participants (ie, >66%) completing all 8 N-ACT training sessions [33,52]. Consistent with other cognitive remediation protocol procedures [63], we will calculate percentage adherence for each participant as a function of the number of *completed* N-ACT training task trials divided by the *total* number of trials, that is, individual differences in the "dosage" of training.

We will consider potential confounds before testing key hypothesized effects. Of particular import, we will examine whether participants differ significantly in treatment gains based on assignment to a specific training coach and control for this unintended influence as necessary. Specifically, we will use multivariate analysis of covariance (MANCOVA) to explore the effect of coach assignment (independent variable) on postintervention emotion dysregulation (ie, scores on the TFII-FTA and RRS-B; dependent variables), controlling for scores at initial screening.

The core aim of this pilot trial is to determine whether N-ACT significantly reduces ERI and rumination, as measured by the TFII-FTA and RRS-B, respectively (H3). To achieve this aim and the related objective to explore potential mechanisms, we will conduct parallel 2 (group: immediate N-ACT vs waitlist control condition; between-subjects factor)×2 (time: T1 vs T2; within-subjects factor) mixed MANCOVAs to evaluate whether N-ACT completion is associated with greater pre-postintervention improvement in these 2 primary outcomes compared to the waitlist control condition. Among all participants, T1 will represent data collected at the baseline assessment; for participants assigned to the immediate N-ACT group, T2 refers to the postintervention assessment, whereas for those assigned to the control condition, T2 refers to the postwaitlist assessment. Thus, these models will not include postintervention data for participants initially allocated to the waitlist, permitting direct comparisons of the slope of change over time associated with completing N-ACT or the waitlist period. The key index of treatment effect in all MANCOVA models will be the group×time interaction. We will also perform a parallel set of multivariate cluster-robust general linear models with time (T1: baseline time point vs T2: postintervention time point) as the sole regressor on key outcomes of interest, which will include all participants who complete N-ACT (regardless of initial group or condition assignment) to maximize statistical power.

In addition to testing the hypothesized effects on emotion dysregulation, mixed MANCOVA and multivariate cluster-robust general linear models will be used to evaluate performance changes over time on (1) 2 hot executive functioning tasks (ESST and MAFT), which will be used to assess the hypothesized effects on the targeted aspects of affective control (H4); and (2) one hot (MAFT) and 2 cold (Digit Span Backward and SST) executive functioning tasks, which will be used to ascertain transfer to the nontargeted cognitive processes (H5). We will specifically derive key dependent variables from the ESST (valence-specific indices of stop-signal reaction time) and the MAFT (valence-specific indices of accuracy) to assess intervention-related changes in emotional response inhibition and emotional working memory, respectively. We will similarly calculate summary metrics of hot affective flexibility from the MAFT (valence-specific indices of accuracy and reaction time on less frequent "switch" trials prompting emotional reactions instead of working memory recall [73]) as well as cold working memory, updating from the Digit Span Backward (mean span) and cold response inhibition from the traditional SST (stop-signal reaction time) to evaluate near and far transfer of hypothesized N-ACT training effects, respectively.

Finally, we will perform a complementary set of secondary analyses (ie, mixed MANCOVA and multivariate cluster-robust generalized linear models) to explore the hypothesized

downstream effects of N-ACT on changes in psychiatric symptom severity (H6). We will use dimension-reduction techniques (eg, confirmatory factor analysis) to extract the summary indices of internalizing and externalizing symptoms from the Inventory of Depression and Anxiety Symptoms, Expanded Version and ESI-R, respectively. Statistical models will use these latent factors as dependent variables, potentially providing preliminary evidence for the efficacy of affective control training as a transdiagnostic intervention to address psychopathology (via diminished emotion dysregulation; refer to Multimedia Appendix 1 for more information). Support for this hypothesis will motivate future work to more directly and precisely examine the effectiveness of the N-ACT program in sufficiently powered samples of patients with psychiatric conditions.

Results

This trial is funded by support from the University of California Board of Regents and the Peder Sather Foundation (funding period: October 2022-September 2025). Recruitment is scheduled to begin in spring 2025. We will begin data analysis once data collection is complete, which is planned to occur in fall 2025. We anticipate publishing the findings in 2026.

Discussion

Summary

This randomized waitlist-controlled trial extends cognitive remediation research by testing a novel intervention program focused on facets of hot cognition typically unaddressed in this body of work. The trial will also be novel in testing a transdiagnostic sample comprising individuals with emotion regulation difficulties. Drawing on a substantial theoretical and empirical literature, we aim to modulate 2 aspects of affective control (ie, emotional working memory and emotional response inhibition) putatively underlying the problems with emotional self-regulation strongly implicated in common forms of psychopathology. Given the low cost, minimal coach training requirements, and relatively simple delivery of the N-ACT program, success in this project has major implications for reducing the public health burden associated with prevalent psychiatric conditions—as well as subclinical distress or dysfunction—involving tendencies toward rumination or ERI.

If our findings align with our hypotheses, this pilot trial will provide early data to support the further refinement and larger-scale deployment of N-ACT in a fully powered randomized clinical trial of patients with psychiatric conditions. Our findings will help identify the levels of interest and adherence and may suggest components that need to be refined for greater acceptability. Beyond the results concerning change in cognitive processes, we hope to learn more about how cognitive changes generalize to psychopathological outcomes. The profile of effects may help us understand which participants would be most likely to benefit from inclusion in future trials.

Limitations

The potential impact of this work should be considered in the context of several limitations. Regarding the study sample, we will make every effort to maximize participant diversity and, accordingly, the generalizability of our findings; however, the modest target sample size (n=80) for this pilot trial will constrain our ability to ensure adequate representation of all psychiatric symptom types and severity levels. Relatedly, patients with acute symptoms of alcohol or substance use disorders and psychosis will be excluded. Additional studies will thus be necessary to elucidate the putative mechanisms identified in this work. Although our protocol incorporates a variety of well-validated multimodal measures to assess key constructs, 1 of the 2 primary behavioral outcomes will be derived from the MAFT, which is a novel task developed for this study. This limitation is somewhat lessened in that the MAFT includes design elements drawn from existing tasks that are widely used to index working memory and shifting and switching (eg, other emotional n-back procedures [73]). Finally, we see 2 core needs for enhancing the N-ACT intervention if the initial findings are promising. The current N-ACT intervention is limited in its scope of training around transfer to real-world tasks. Others have more extensively integrated ecological elements into cognitive remediation programs, including simulated work situations [83] and compensatory transfer sessions to supplement computerized training procedures [84]. Future work might help clients practice their skills in the context of mood inductions as a method to facilitate skills transfer. It will also be important to consider gamification [85,86] and other techniques to enhance the appeal of training programs.

Conclusions

In conclusion, this study represents an important step in translating knowledge from basic affective science to produce interventions (with empirically informed treatment targets) that can be widely disseminated and easily implemented. This area of research is promising, given the need for alternative approaches to improve mental health because a substantial portion of patients do not seek nor respond to traditional treatment modalities. In addition, current rapid technological advancements, such as the proliferation of accessible and affordable mobile devices capable of delivering cognitive training, support the feasibility of digital therapeutics. Therefore, N-ACT has the potential to reduce barriers to mental health treatment, particularly among people from underserved groups or cultures with persistent stigma against talk-based psychotherapy as well as those who may be more amenable to computerized interventions for various reasons (eg, youth and patients with social phobia). Crucially, we expect N-ACT to have transdiagnostic applications, given that the program's central aim is to address emotion regulation problems, which include shared features across a broad range of psychopathologies. We hope that establishing efficient and cost-effective means of modulating these common risk factors might eventually facilitate prevention among individuals considered vulnerable before diagnosable psychiatric disorders emerge.

Acknowledgments

The authors are grateful to have received funding for this project from the Peder Sather Foundation. The authors further acknowledge the support of their investigative teams' volunteer research assistants, clinicians, and coaches who collectively make this collaboration possible.

Data Availability

The datasets generated and analyzed during this study will be available in this project's Open Science Framework repository [87].

Authors' Contributions

KJDA, MVE, EHR, AH, and SLJ were responsible for conceptualization. KJDA, EHR, AH, and SLJ were responsible for funding acquisition. KJDA, MVE, EHR, LM, AH, and SLJ were responsible for methodology. KJDA, NR, and SLJ were responsible for project administration. SLJ was responsible for resources. KJDA, MVE, and SLJ were responsible for supervision. KJDA and SLJ wrote the original draft of this manuscript. All authors reviewed the final manuscript.

Conflicts of Interest

KJDA is the director of Brain Health Consulting, which provides consultation on neurocognitive approaches to mental health assessment and intervention. The neurobehavioral affective control training program is not currently being offered through Brain Health Consulting.

Protocol

Evaluation of Comparative Efficacy of Polyherbal Steam Inhalation Versus Polyherbal Nasal Fumigation (Dhoopana) in Children With Rhinitis (Pratishyaya): Protocol for an Open-Label Randomized Controlled Trial

Abstract

Background: Rhinitis is a condition characterized by inflammation of the nasal mucosa. It causes obstruction and congestion in the nasal cavity. Clinically, it resembles *pratishyaya* (rhinitis) in Ayurveda, which is caused by accumulation and downward movement of the *tridoshas* (3 elements, named *vata*, *pitta*, and *kapha*) in the nasal cavity. Rhinitis is one of the most common diseases among children. There is no role for antibiotics in rhinitis, and nasal decongestants have also not been found to be effective in its management. In Ayurveda, *dhoopana* (nasal fumigation) is mentioned in the *pratishyaya* treatment protocol. However, we have found no previous study regarding its efficacy. The efficacy of *tulsi*, *vasa*, *nirgundi*, and *nilgiri* is already proven when they are used for steam inhalation in respiratory tract infections. Therefore, in this study, a *dhoopana* of a polyherbal formulation containing *tulsi*, *vasa*, *nirgundi*, and *nilgiri* will be compared with the inhalation of steam containing *arka* (a liquid obtained by distillation) of *tulsi*, *vasa*, *nirgundi*, and *nilgiri* leaves in children with *pratishyaya.*

Objective: We aim to evaluate the efficacy of polyherbal steam inhalation as a standard control against *dhoopana* in children aged 7 to 14 years with *pratishyaya*.

Methods: A total of 70 participants fulfilling the inclusion criteria were selected and distributed into 2 groups of 35 each. The intervention group received *dhoopana* and the control group received polyherbal steam inhalation, both twice daily for 7 days. The primary outcome measure was the change in Total Nasal Symptom Score and a modified cold spatula test. At the same time, the association between *prakriti* (body constitution) and the prevalence of *pratishyaya* in children was analyzed as a secondary outcome. Assessments were performed on days 3, 5, and 7, with a follow-up time of 28 days. Appropriate descriptive and inferential statistics will be used for data analysis.

Results: As of November 2024, we have completed our enrollment of 70 patients, with 35 patients in each group. Data analysis will be completed by February 2025, and we expect results to be published in March 2025.

Conclusions: We anticipate that polyherbal nasal fumigation will be found to be equally as effective as polyherbal steam inhalation in the management of acute rhinitis in the pediatric population. This study may provide a standardized, herbal, safe, and cost-effective treatment for rhinitis in children in the form of *dhoopana*.

Introduction

Overview

Rhinitis is defined as inflammation of the nasal mucosa due to any infection, allergy, or injury. Symptoms of rhinitis are sneezing, discharge from the nose, obstruction in the nasal cavity, irritation in the nasal cavity, body ache, a feverish sensation, and headache [1]. As per Ayurveda, a clinical picture of rhinitis is seen in the disease *pratishyaya*. It is one of the *nasagata roga* (nasal disorders) in which *kaphadi tridoshas* (the 3 elements of the body) are continuously eliminated through the nose. These vitiated *doshas* accumulate in the head, and their further movement toward the nose causes *pratishyaya* [2]. According to Acharya Charaka, the definition of *pratishyaya* is "*pratikshnam shyayatiitipratishyaya*," which means the "continuous outward movement of *vata*, *pitta*, and *kapha* doshas from the nostrils." The prevalence of nonallergic rhinitis is about 40% [3]. The prevalence of allergic rhinitis in India was reported as "11.3% in children aged 6-7 years and 24.4% in children aged 13-14 years" [4]. Acharya Videha explained the clinical presentation of *pratishyaya* as excessive secretions from the nasal cavity and eyes, fever, and generalized weakness with severe headache [2]. *Pratishyaya* is classified into 5 types: *vataja*, *pittaja*, *kaphaja*, *sannipataja*, and *raktaja pratishyaya* [2,5]. The nasal mucosa has a rich blood supply, and stimulation of the sympathetic nervous system causes vasoconstriction that results in shrinkage of the nasal mucosa on the other side, while stimulation of the parasympathetic nervous system is responsible for excessive secretion from the nasal mucosa along with dilatation of local vessels. Emotional disturbance also plays a significant role, as the autonomic nervous system innervation of the nasal mucosa is under the control of the hypothalamus [3]. If no treatment is given at an early stage, the condition may become complicated and lead to comorbid conditions like chronic rhinitis, cough, or breathing difficulty and debility [2]. There is no use of antibiotics in acute rhinitis [6]. Antihistamine decongestants are frequently used in cough and cold. However, in some studies, these were not found to be effective in the management of rhinitis [7]. There are limited data regarding the safety of pseudoephedrine and phenylephrine in rhinitis [8]. In Ayurveda, various oral medications are available for the management of this condition. However, it is difficult to administer Ayurvedic medicines orally to children. So, this study has been planned to find an effective way to manage the acute stage of rhinitis that can be administered locally in the nasal cavity. Various Ayurvedic interventions are mentioned in the Ayurveda classics as protocols for the management of *pratishyaya*, including *dhoopana* (nasal fumigation), an intervention that can effectively manage the disease. In this intervention, various herbs are made into a stick known as a *varti* (wick), and its fumes are used for local fumigation of the affected area. It can be considered an Ayurvedic therapy that delivers the medicines directly into the airways, providing relief and protection to the local region [9].

Pratishyaya treatment should be aimed at relieving the *avarodha* (obstruction) created by the dosha. Drugs having *ushna* (hot) and *tikshna* (pungent) properties are indicated in *dhoopana*. The efficacy of steam inhalation of *tulsi*, *vasa*, *nirgundi*, and *nilgiri* has already been shown in respiratory tract infections [10]. So, in this study, *dhoopana* of a polyherbal formulation containing *tulsi*, *vasa*, *nirgundi*, and *nilgiri* will be compared with a steam inhalation containing *arka* of *tulsi*, *vasa*, *nirgundi*, and *nilgiri* in *pratishyaya* in children. *Kashyapa Samhita* (an Ayurveda classical text) is mainly devoted to the Kaumarbhritya branch (Ayurvedic pediatrics) of Ashtanga Ayurveda, and *dhoopana* is described in the treatment protocol of *pratishyaya* [11]. There are many studies regarding the efficacy of oral medication in *pratishyaya* but there is no previous study available regarding the efficacy of local fumigation with medicated fumes in *pratishyaya* in children. Steam inhalation has a known soothing effect on the nasal mucosa in rhinitis. Herbal steam inhalation is more effective as compared to plain water steam inhalation [12], but steam inhalation is quite difficult to administer in children. So, in this study, we plan to compare the effect of polyherbal steam inhalation with polyherbal fumigation in children with *pratishyaya*. The herbs chosen for *dhoopana* were justified in previous studies, as steam inhalation of *tulsi*, *vasa*, *nirgundi*, and *nilgiri* was found to be effective for reducing local inflammation in the nostrils. A detailed description of previous articles and a research gap analysis with justification for this study is given in Table 1.

Table 1. Previous studies and research gap analysis.

Reference	Conclusion	Remark
Memon [13]	*Vyoshadi vati* was found to be effective in reducing signs and symptoms of *pratishyaya* (rhinitis) in comparison with chlorpheniramine maleate in children aged 4-8 years.	Children tend to resist the intake of medicines orally in most cases, especially when they are sick. So, local fumes or steam inhalation could be a better choice.
Tarun and Anup [14]	*Nasya* with *tulasi swarasadi taila* and *haridrakhand* showed 100% results in objective as well as subjective parameters of *pratishyaya*. *Tulasi swarasadi taila nasya* and *haridrakhand* gave effective results in treating *pratishyaya*.	As *tulsi* has an anti-inflammatory effect and was found to be effective in the management of *pratishyaya*, and the *nasya* procedure is contraindicated in the acute stage, fume inhalation can be done with the use of *tulsi* in place of *nasya karma*. Local fume inhalation can provide instant relief for the symptoms of *pratishyaya*.
Rajput and Patni [15]	According to Acharya Charaka, any drug when instilled into the nostrils causes direct action in the brain; hence, it is highly effective in the treatment of various diseases related to the nervous system and supraclavicular region. The *nasya* procedure is indicated in *pratishyaya*. Standardization of *nasyakarma* with Ayurveda and modern scientific parameters with proper documentation is a current need.	*Nasya* is widely used in rhinitis but it is contraindicated in its acute stage. Moreover, it is quite difficult to administer to children. Direct contact with oil in the nostrils sometimes irritates children. In this study, acute cases were mentioned in the inclusion criteria, so local fumes could provide a better approach to the treatment of *pratishyaya*. Moreover, local nasal fumigation is described in the treatment protocol of *pratishyaya*, but no previous study has been done to determine its efficacy in rhinitis.
Kamble et al [16]	Steam inhalation of *tulsi* leaves was found to be more effective in reducing sign and symptoms of cough and cold in adults than steam inhalation of plain water.	*Tulsi* steam inhalation was found to be better than plain steam inhalation in the adult population. This shows that volatile herbs like *tulsi* have better efficacy when given locally in the form of vapors. Steam inhalation is also easier to administer in children. So in this study, *tulsi* was chosen as one of the herbs for fume as well as steam inhalation.
Kumar Dwibedi et al [17]	Initially, there was mild relief in symptoms. Gradually, improvement was seen in signs and symptoms at further appointments. In the last appointment, the patient felt relief and could perceive smells.	Atrophic rhinitis is a chronic stage of *pratishyaya*; hence, a combination of *nasya* and *dhoompana* was given to the patient. *Trikatu dhoompana* was found to be effective in the management of the disease in the chronic stage. Thus, *dhoopana* (nasal fumigation) should only be given to children in the acute stage of *pratishyaya*.
Gowrishankar et al [10]	Phytochemicals from selected plants were found to be effective against protein targets of COVID-19.	In an in silico study, the active components of *vasa*, *nirgundi*, and *nilgiri* were found to be effective against protein targets of SARS-CoV-2. Hence, these herbs were chosen for the intervention as well as the control group.
Swain and Sahu [18]	There was improvement in symptoms of COVID-19 after taking steam inhalation. The severity and duration of infection was reduced after steam inhalation. It was found to be a ray of hope in that pandemic.	This was a nonrandomized, nonclinical trial. The study was performed along with oral medications for COVID-19 without confirming the efficacy of steam inhalation alone. So there is a need for a study of herbs as a single therapy in children. This study is a randomized clinical trial with the use of polyherbal steam inhalation in the control group of children without oral medication.
Berger et al [19]	The intranasal formulation of azelastin and fluticasone propionate was found to be safe for administration in children, and it was well tolerated for 3 months by children with allergic rhinitis.	Epistaxis was reported as a treatment-related adverse effect in both groups, followed by headache and other adverse effects. Herbal procedures are quite safe and effective. Local polyherbal fume administration can be an alternative.
Sebastian and Sujatha [20]	The study showed that steam inhalation with *tulsi* leaves is effective in relieving symptoms of coryza compared to hot water steam inhalation in children aged 6-12 years.	The study was performed in a selected community with a small sample size, and no randomization was done. Steam inhalation was administered for only 3 days. The follow-up time was not mentioned in the article. This study is a randomized clinical trial, and *tulsi* along with *nilgiri*, *nirgundi* and *vasa* will be used for steam inhalation in the control group for 7 days with a follow-up of 28 days.
Macchi et al [21]	A statistically significant improvement was seen in ciliary motility in the first group, who received a nasal wash with sodium hyaluronate in saline solution ($P<.001$).	This was a pilot study with very small sample size. Moreover, the study included patients with recurrent upper respiratory tract infections; there was no specific disease chosen for the study. Aerosol use was indicated in lower respiratory tract infection, as there was a chance of the medicine entering the lungs. In our study, only *pratishyaya* cases will be included, rather than all patients with respiratory tract infections. Polyherbal fumes will be administered in the trial group, which could be a better alternative to aerosols.

Reference	Conclusion	Remark
Baartmans et al [22]	Annually, on average 3 people are admitted to a Dutch burn center for burns resulting from steam inhalation therapy. Most patients are children, and they need skin grafting more often than adults. At burn centers in the Netherlands, 31 patients were admitted with burns caused by steam inhalation therapy in the 1998 to 2007 period.	These data show that steam inhalation can result in burns, especially in children. So, in our study, we plan to find if *dhoopana* can be an alternative.
Murphy et al [23]	Between July 1 and December 31, 2002, 7 children were admitted to the burn unit of a children's hospital in Dublin with scalds sustained during the course of steam inhalation. The children ranged in age from 9 months to 10 years. Techniques involving kettles or bowls of boiling water should be actively discouraged.	The common technique of steam inhalation is risky in children as it may cause burns. So, in our study, we plan to find an easier way to administer herbal effects to the nasal mucosa through *dhoopana*.

Aim

We aim to study the efficacy of polyherbal steam inhalation versus *dhoopana* in children with *pratishyaya*.

Primary Objectives

There are 3 primary objectives: first, to determine the efficacy of *dhoopana* in reducing signs and symptoms of *pratishyaya* compared to polyherbal steam inhalation; second, to study the duration of alleviation of Total Nasal Symptom Score (TNSS); and third, to determine the efficacy of *dhoopana* in the reduction of nasal obstruction in a modified cold spatula test.

Secondary Objectives

There are 2 secondary objectives: first, to study the prevalence of *pratishyaya*, its origin, and its causative factors, such as viruses, bacteria, or allergies; second, to analyze the association between *prakriti* (body constitution) and the prevalence of *pratishyaya* in children.

Hypothesis

The alternate hypothesis is that *dhoopana* has equivalent efficacy to polyherbal steam inhalation in reducing the signs and symptoms of *pratishyaya* in children aged 7-14 years. The null hypothesis is that *dhoopana* does not have equivalent efficacy as polyherbal steam inhalation in reducing the signs and symptoms of *pratishyaya* in children aged 7-14 years.

Trial Design

This will be a randomized, reference, controlled, open-label equivalence clinical study. A total of 70 patients have been recruited for the study.

Methods

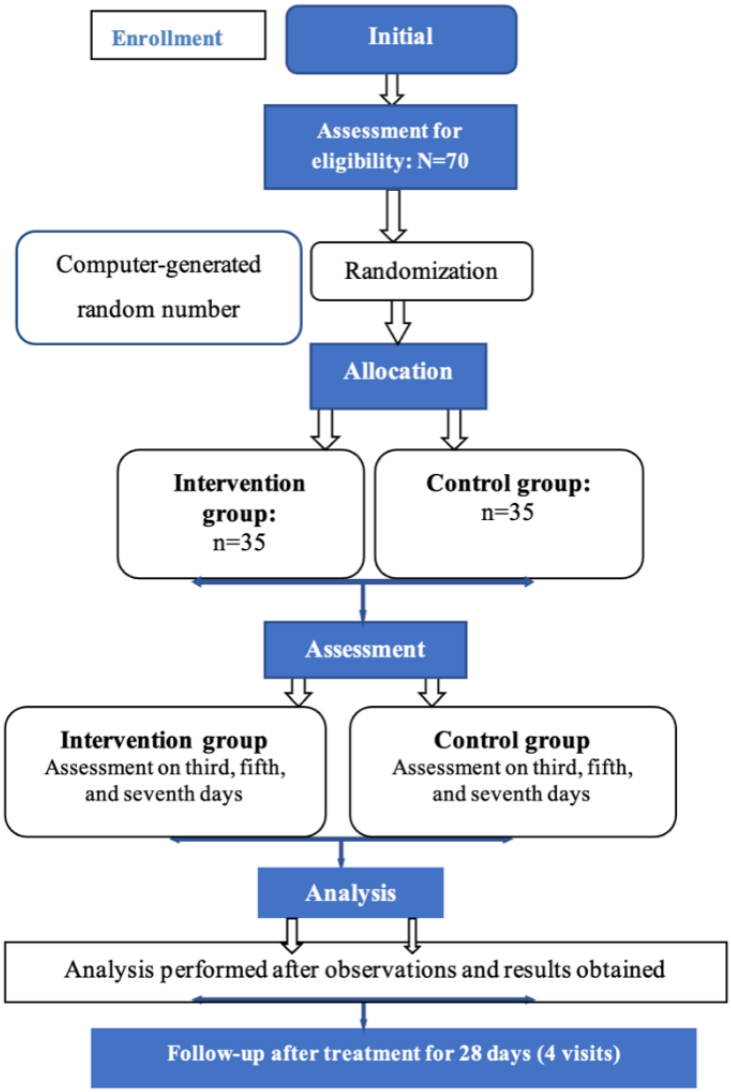
Recruitment

The patients were selected from the outpatient and inpatient departments of the Department of Kaumarabhritya (Ayurvedic pediatrics) of Mahatma Gandhi Ayurveda College, Hospital & Research Centre and from the surrounding region. After initial screening, the patients were randomized using computer-generated random numbers into 2 groups; the control group (polyherbal steam inhalation) and the intervention group (polyherbal nasal fumigation). All baseline parameters were recorded at the start of the study. Both groups underwent treatment for 7 days. All the parameters were recorded on the third, fifth, and seventh days, with a follow-up of 28 days after the treatment period. Patients were advised to drink warm water and stay away from cold and sour items. Patients were given regular counseling and reminders through calls or messages to follow the rules and regulations of the trial.

Guidelines

This study used the Consolidated Standards of Reporting Trials (CONSORT) guidelines; Figure 1 shows a flow diagram of the study.

Figure 1. Consolidated Standards of Reporting Trials (CONSORT) flow diagram.



Grouping and Dosage

Grouping and dosage are described in Table 2.

Table 2. Grouping and dosage.

	Control group (polyherbal steam inhalation)	Intervention group (*dhoopana*; polyherbal nasal fumigation)
Participants, n	35	35
Name and details of the medication	*Arka* is prepared from *tulsi*, *vasa*, *nirgundi*, and *nilgiri*. In participants with mild symptoms, 2.5 ml *arka* is added to 500 ml of water, and in those with moderate to severe symptoms, 5 ml *arka* is added to 500 ml of water for steam inhalation.	*Dhoomvarti* (polyherbal wick) prepared from dry leaves of *tulsi*, *vasa*, *nirgundi*, and *nilgiri*.
Mechanism of delivery	Steam	Fumes
Duration	1 minute for mild symptoms and 1.5 minutes for moderate to severe symptoms.	1 minute for mild symptoms and 1.5 minutes for moderate to severe symptoms.
Route/mode of administration	Nostrils	Nostrils
Frequency	Twice daily	Twice daily

Inclusion Criteria

Children of either sex aged between 7 to 14 years whose parents provide written consent for enrolling their child in the study will be included if they have had the common cold with features of *pratishyaya* for 7-10 days.

Exclusion Criteria

Patients will be excluded if they have had the common cold for more than 10 days or if they have chronic allergic rhinitis, *dushta pratishyaya* (chronic rhinitis with complications), *raktaja pratishyaya* (a type of rhinitis with dominance of the blood element), *sannipataja pratishyaya* (rhinitis with involvement of all 3 elements), or infectious diseases such as tuberculosis. Patients will also be excluded if they have a cleft palate, a deviated nasal septum, or nasal polyps, or if they are hypersensitive to the trial drug or any of its ingredients.

Drug Collection and Authentication

The raw material for the drug was purchased from a reliable source and authenticated and identified by the Department of Dravyaguna and Rasashastra. Details of the raw ingredients are provided in Table 3 and images are shown in Multimedia Appendix 1.

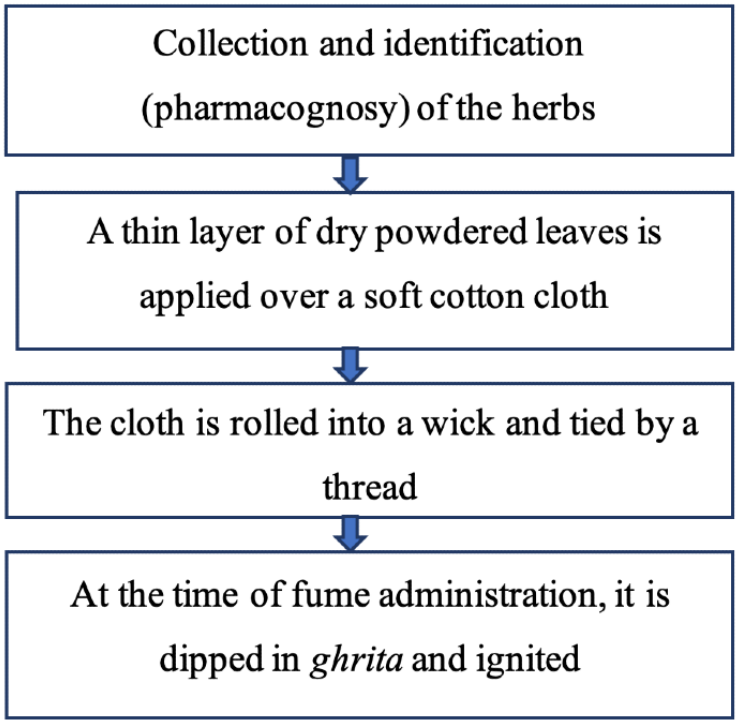
The *dhoomvarti* (polyherbal wick) for nasal fumigation and *arka* (for steam inhalation) from *tulsi*, *vasa*, *nirgundi*, and *nilgiri* leaves were prepared as per the classical methods and standard protocol at the Mahatma Gandhi Ayurveda College and Hospital and were analyzed in a pharmaceutical laboratory. The method of drug preparation is described in Figure 2.

Arka of the leaves of *tulsi*, *vasa*, *nirgundi*, and *nilgiri* was prepared by using a distillation process. Parents of the patients were counseled and trained regarding the administration of *dhoopana* and steam inhalation at their homes.

Table 3. Latin name and family name of the herbs used for nasal fumigation and steam inhalation

Serial No.	Drug	Latin name	Family
1	*Tulsi*	*Ocimum sanctum* Linn	Lamiaceae
6	*Nirgundi*	*Vitex negundo* Linn	Verbenaceae
7	*Vasa*	*Adhatoda vasica* Nees	Acanthaceae
8	*Nilgiri*	*Eucalyptus globules* Labill	Myrtaceae

Figure 2. Method of preparation of dhoomvarti.



Outcomes

The outcomes are designed to compare the efficacy of *dhoopana* and polyherbal steam inhalation on *pratishyaya* with subjective and objective parameters.

Subjective Criteria

Signs and symptoms of *pratishyaya* will be evaluated with the TNSS, illustrated in Table 4.

Table 4. Total Nasal Symptom Score (TNSS).

Symptom and domain	Score
Symptoms	
Rhinorrhoea	
No symptoms	0
Aware but not troubled (mild)	1
Troublesome but does not interfere with normal day-to-day activities or sleeping habits (moderate)	2
Interferes with normal day-to-day activities or sleeping habits (severe)	3
Nasal itching	
No symptoms	0
Aware but not troubled (mild)	1
Troublesome but does not interfere with normal day-to-day activities or sleeping habits (moderate)	2
Interferes with normal day-to-day activities or sleeping habits (severe)	3
Nasal obstruction	
No symptoms	0
Aware but not troubled (mild)	1
Troublesome but does not interfere with normal day-to-day activities or sleeping habits (moderate)	2
Interferes with normal day-to-day activities or sleeping habits (severe)	3
Sneezing	
No symptoms	0
Aware but not troubled (mild)	1
Troublesome but does not interfere with normal day-to-day activities or sleeping habits (moderate)	2
Interferes with normal day-to-day activities or sleeping habits (severe)	3
Additional symptoms as per Ayurveda texts	
Sirashoola **(headache)**	
No headache	0
Occasional headache	1
Frequent headache	2
Continuous headache	3
Aruchi **(loss of appetite)**	
Absent	0
Present	1
Kasa **(cough)**	
No cough	0
Occasional cough	1
Moderate cough	2
Continuous cough with throat and chest pain	3

Objective Criteria

The modified cold spatula test will be used to measure nasal patency in rhinitis. The test is done to study the area of fogging associated with a nasal obstruction and compare the pre- and posttreatment outcomes. The patients are asked to breathe normally over a polished stainless steel plate, and the extent of fogging is marked with a marker pen. The magnitude of fogging is then measured with a transparent graph sheet marked with a central red line at 50 mm on the x-axis, dividing the graph into 2 equal parts with corresponding right and left areas of fogging.

Sample Size

A comparative pilot study was performed with 20 patients, including 10 patients in 2 groups, to evaluate the efficacy of *dhoopana* for rhinitis in comparison with polyherbal steam

inhalation. Based on the results of that study, the minimum sample size for this study was calculated by using the following formula of proportion:

The parameters related to sample size were as follows: α=.05; β=.2; proportion in group 1=0.60; proportion in group 2=0.90; ratio (group 2/group 1)=1; minimum sample size needed for group 1=32; and minimum sample size needed for group 2=32. The minimum total sample size needed was 64, and the minimum total number of patients to be enrolled was 35 in each group (including a 10% withdrawal rate).

Data Collection Tools

This study will use the *Ayurveda Samhitas* (a textbook on Ayurveda), modern texts, and an online search of PubMed and Google Scholar. The polyherbal *dhoomvarti* will be prepared from a powder of *tulsi*, *vasa*, *nirgundi*, and *nilgiri*. The polyherbal *arka* will be prepared from *tulsi*, *vasa*, *nirgundi*, and *nilgiri*. The study will also use a case record form, patient information sheet, and written informed consent form.

Data Analysis

Data will be analyzed by using appropriate descriptive and inferential statistics. Quantitative variables will be analyzed with the Student *t* test and subjective parameters will be analyzed with the Wilcoxon signed test and Mann-Whitney *U* test. Alternate statistical methodologies may be applied if deemed necessary.

Ethical Considerations

The study obtained approval from the institutional ethics committee of Mahatma Gandhi Ayurved College Hospital and Research Centre (MGACHRC/IEC/JULY-2022/522). The committee will decide on the end point and oversee the trial as it progresses. The researchers will assess any adverse events and will report to the ethics committee. Consent from parents and assent from patients was obtained before conducting the trial in the local language while explaining every aspect of the study. The informed consent form included a patient information sheet (part 1) and a certificate of consent (part 2). Data will be anonymized and personal information of the participants will be kept confidential before, during, and after the trial. Physical data will be stored in a protected storage facility with access available only to the researchers. Computerized data will be held in a password-protected hard drive with access available only to the researchers. There was no need to provide any compensation to the patients in the trial. Identification of individual participants and users will not be possible in any images in the manuscript or supplementary files. If needed, prior consent will be obtained from identifiable individuals before the inclusion of such images.

Withdrawal Criteria and Stoppage

No adverse effects of the trial drug were noted during the treatment period. Thus, no cases were excluded from the study. A total of 4 patients, including 2 patients in each group, voluntarily stopped taking treatment during the trial and were counted as withdrawn.

Dissemination

This protocol will be published and disseminated as a thesis on *pratishyaya*. The study protocol provides a detailed overview of the study design, methodology, data collection procedures, data analysis plan, and ethical considerations. By disseminating this protocol, we hope to advance knowledge in the field and facilitate future research.

Results

As of November 2024, we completed the enrollment of 70 patients, with 35 patients in each group. A total of 4 patients voluntarily withdrew from the trial. Data analysis of 66 patients will be completed by February 2025, and we expect the results to be published in March 2025.

Discussion

Dhoopana is mentioned in the Ayurveda classics for the management of acute rhinitis, and we anticipate that it will be found to be equally effective as polyherbal steam inhalation in the management of acute rhinitis in children. Steam inhalation of the herbs that were chosen for this study has been found to be effective in the management of upper respiratory tract infections. Thus, fumes of the same ignited herbs (ie, *tulsi*, *vasa*, *nirgundi*, and *nilgiri*) should work just as well in the management of rhinitis. The disease *pratishyaya* is very common in the pediatric population, but no standardized Ayurvedic therapy is available that can be given locally in the nostrils in its acute stage. Locally given medicines are fast and effective compared to oral medication. Another classical procedure known as *nasya* (nasal instillation of oil) is recommended for rhinitis, and as per previous research, it is effective in the management of chronic and recurrent rhinitis, but as per the Ayurveda classics, it cannot be used in acute rhinitis. The herbs chosen for this study are hot and pungent in nature and can reach the minute *srotasa* (channels of the nostrils); thus, they promise to be beneficial in acute rhinitis. Polyherbal *dhoopana* is safe and easy to administer, and if it is found to be effective, it may be a better alternative to steam inhalation. Thus, it can be used in general pediatric practice for patients with acute rhinitis. A positive outcome of the study will facilitate further studies in a large population with standardization of the procedure for *dhoopana*. In this study, a polyherbal wick was prepared manually, and it takes some time to ignite the herbal powder. In the future, this can be improved by using a pocket-friendly herbal nasal fumigator that ignites the herbs in few seconds without any manual practice. This could be patented and copyrighted later and publicized for the benefit of the population.

Acknowledgments

The experts whose works are cited and discussed in the manuscript are acknowledged by the authors for their significant assistance. The authors also acknowledge the Department of Rasa Shastra (Pharmacology), as well as the staff of the Department of Research, Administration, and Management at Datta Meghe Institute of Medical Sciences for their cooperation and assistance. All authors declared that they had insufficient or no funding to support open access publication of this manuscript, including from affiliated organizations or institutions, funding agencies, or other organizations. JMIR Publications provided article processing fee (APF) support for the publication of this article.

Data Availability

The data sets generated during and/or analyzed during this study are available from the corresponding author upon reasonable request.

Conflicts of Interest

None declared.

Abstract

Background: Pediatric acquired brain injury (ABI) is frequently associated with cognitive and socioemotional alterations. Therefore, targeted rehabilitation to improve everyday functioning, particularly executive functioning (EF), is needed to limit the possible deterioration of cognitive abilities and behavior over time and the associated social and psychological costs.

Objective: In this paper, we present the protocol for a phase-2 randomized controlled trial (RCT) aimed at examining the feasibility and efficacy of a web-based intervention (ie, the Italian version of the Teen Online Problem-Solving [I-TOPS] intervention) to improve problem-solving abilities versus an active-control, web-based intervention (ie, wellness intervention) providing health and wellness content.

Methods: A double-blinded, phase-2 RCT will be conducted to guarantee controls on data quality and findings. In total, 42 adolescents will be recruited from a rehabilitation institute and individually randomly assigned in a 1:1 ratio to receive the I-TOPS intervention or the web-based wellness intervention. Both interventions will include 10 core sessions and will be delivered remotely using a web-based platform. Participants allocated to both interventions and their caregivers will independently complete the learning modules in an everyday setting using their computer. The I-TOPS intervention's core sessions will target the EF domain (eg, planning, emotion regulation, and social skills), while all the contents of the wellness intervention will be aimed at providing psychoeducation on ABI sequelae and supporting health and wellness. Participants assigned to the I-TOPS intervention will also receive bimonthly direct training in problem-solving coupled with remote support from a psychologist. Feasibility data and efficacy outcomes on both adolescents' and parents' functioning will be assessed. Cognitive abilities in the EF domain and behavioral and psychological functioning (ie, internalizing and externalizing symptoms) of the adolescents will be evaluated via performance-based measures, administered remotely using the Google Meet platform, and paper-and-pencil questionnaires; parents' well-being will be assessed through paper-and-pencil questionnaires. Efficacy will be evaluated immediately after training and at 6-month follow-up.

Results: This study started on February 26, 2021, and ended on February 28, 2023. A total of 42 adolescents were enrolled and randomly assigned to the 2 study groups, 34 (81%) completed the intervention and posttreatment evaluation (I-TOPS: n=19 and wellness intervention: n=15) and 31 performed follow-up evaluation (I-TOPS: n=18 and wellness intervention: n=13). Data analysis on feasibility and efficacy will be performed after protocol publication, and the results will be published in the form of a paper in a relevant journal in 2025.

Conclusions: This double-blinded, phase-2 RCT could extend knowledge on the best rehabilitation practices to adopt with the survivors of pediatric ABI by providing evidence-based data currently lacking for the Italian context. If this study yields positive results, a larger, multicenter, phase-3 RCT could be planned and delivered to examine program cost-effectiveness in a larger sample.

Introduction

Background

Acquired brain injury (ABI), a condition of either traumatic (eg, traumatic brain injury [TBI]) or nontraumatic origin (eg, stroke, anoxia or hypoxia, and infections or inflammation to the brain), represents one of the leading causes of lifelong disability among children and adolescents [1-4]. Together with physical disabilities, the most common consequences of a pediatric ABI include cognitive impairment, reduced academic and vocational attainment, issues with emotional and behavioral regulation, and social problems, all negatively affecting the quality of life of patients [5-15]. Research has indicated that patients with pediatric ABI may be at high risk for substance misuse, mental health problems, criminal behavior, and unemployment in adulthood [5,9,12,15]. Pediatric ABI also substantially causes stress and burden for caregivers and families because children with these conditions experience neurocognitive, behavioral, and adaptive challenges that require relatives to change their lifestyle and develop additional skills to help their children, which often generates significant physical and emotional burden [16,17]. Therefore, pediatric ABI exerts adverse long-term effects on the individual, their family, and the society [6,9,12,15-17].

Specifically, executive functioning (EF) difficulties represent one of the core deficits of ABI, affecting not only cognitive abilities but also behavioral and social functioning [6,9,13,18-24]. EF deficits have been linked with socioemotional adaptation and psychological well-being, with several patients with these deficits exhibiting externalizing behaviors and temper outbursts [6,9,13,18-24]. Thus, there is a clear need for programs designed to rehabilitate EF during the chronic phase of an ABI. However, studies indicate that many children with ABI fail to receive the recommended treatments for optimal recovery after discharge from the hospitals or rehabilitation centers [25-29]. Research has also reported that numerous children with mental health issues do not obtain adequate support [30]. Barriers to receiving treatment have different origins, ranging from intervention accessibility (eg, geographical barriers and time and economic demands to health care facilities and families), poorly designed and grossly underresourced health services, to patients' and families' readiness to work on issues [26-31]. Therefore, numerous rehabilitation interventions for this population deliverable at a distance (ie, telerehabilitation) have been developed and offered over the years [31-38]. Telerehabilitation has diminished the financial and time burden on families typically associated with traditional rehabilitation, thereby allowing patients to receive higher therapy doses [31,39-41]. In the field of psychology, telerehabilitation has also been found to reduce the stigma of therapy, to have similar clinical outcomes to traditional face-to-face interventions, and to improve treatment utility and satisfaction [31,39-41].

In the United States, in the mid-2000s, Wade et al [42] developed a technology-assisted intervention for pediatric patients with TBI and, subsequently, with ABI, with the aim to address EF in everyday settings. The program targets problem-solving within the family context, combining the problem-solving framework by D'Zurilla and Nezu [43] and D'Zurilla et al [44] with the collaborative family problem-solving model by Robin and Foster [45]. The Teen Online Problem-Solving (TOPS) program was originally designed with the specific purpose of providing a contextualized treatment that addressed EF, self-regulation, and communication challenges in everyday settings. The web-based format of the intervention had the objective of increasing patients' participation in outpatient rehabilitation and improving retention rates. The TOPS-contextualized approach is in contrast with training programs that involve only drill-based exercises, which often suffer from a lack of generalization of the effects [37].

The TOPS program includes self-guided, web-based sessions that the child and their family complete at home and bimonthly videoconferences with a psychologist with expertise in cognitive behavioral therapy [42]. The sessions provide training in the steps of problem-solving, teaching adolescents and families to apply them to everyday challenges with organization and planning, social interactions, and emotion control. Metacognitive strategies to promote self-monitoring and self-regulation are also taught. Both the child and the family are required to complete the web-based learning modules, including reading or listening to the didactic information and performing exercises to reinforce understanding of what they read.

In randomized controlled trials (RCTs) of the TOPS program conducted in the United States, families have evaluated the web-based modules of the intervention as helpful, the length and structure as feasible, and the overall program as easy to follow and useful [46,47]. In addition, the web-based program was found to be convenient and beneficial as face-to-face therapy [48]. Regarding efficacy, previous studies have demonstrated the beneficial effects of the TOPS program on children (eg, EF and psychological well-being and behavior at home, school, and other settings); parents (eg, levels of

depression and psychological well-being); and even parent-child conflicts [37,42,46,48-52]. In view of this success, recent guidelines acknowledged TOPS as an evidence-based treatment and a standard of care for executive dysfunction and behavioral issues following TBI in the United States [36].

In Italy, there is a great need to develop rehabilitation interventions accessible to large cohorts of patients with ABI, considering the substantial distance of many families from rehabilitation centers and, in some cases, the presence of geographical barriers (eg, living in remote rural areas, mountains, and islands), which make it difficult for many patients to receive treatments in the chronic phase [31,53]. At present, in Italy, telerehabilitation for cognitive and behavioral functions is still at an embryonic phase. The lack of remote interventions for young children with neurological conditions in this country has been highlighted by a review published in 2020 [53], reporting very limited research on the topic, with only one intervention for children with ABI conducted up to 2019 [54]. Importantly, no intervention focusing on everyday EF was detected. In 2020 and 2023, two papers on an RCT of our research group on the effects of a drill-based remote intervention for children with ABI were published, but also in this case, no focus on EF was given [55,56]; no other intervention delivered in Italy was found up to 2023 [57]. Nevertheless, the area of remote interventions is a matter of great interest for the Italian health care system, as suggested by the publication of 2 relatively recent documents on the following topics: the Italian State-Regions agreement on telemedicine delivery published in 2020 [58] and the guidelines for home assistance published in 2022 by the Italian Ministry of Health [59]. These documents report the national guidelines for the provision of remote services and identify the key elements required for the delivery of treatments at a distance.

To increase rehabilitation opportunities for young patients with ABI and embrace the push toward remote interventions in Italy, we translated and adapted the original American TOPS program to create an Italian version of the TOPS (I-TOPS) intervention [31]. The usability of the I-TOPS intervention and its potential positive effects on adolescents with ABI in Italy should be rigorously tested by conducting an RCT, with the aim to inform the Italian health care system on standardized methods to promote recovery and well-being among this population. A clear evaluation of the clinical impact and cost-effectiveness of the program should be provided to support recommendations for effective behavioral and neuropsychological interventions.

To this end, a single-center, double-blinded, phase-2 RCT will be conducted, comparing an experimental group receiving the I-TOPS (ie, I-TOPS intervention group) intervention with an active control group receiving a modified version of the program (ie, wellness intervention group), having the same structure but omitting problem-solving–related content. The sample size of the study was established through power analysis by considering data from a previous meta-analytic study on the effects of the original American TOPS program [37]. This paper describes the trial protocol; the steps required to conduct the study, including study procedures (ie, setting, participants' characteristics, sample size calculation, randomization and blinding, intervention and active control characteristics, and outcomes selected); and a discussion of the clinical implications of the study.

Objectives

In summary, the study objectives are to (1) examine I-TOPS intervention feasibility in a sample of adolescents with ABI aged 11 to 19 years—we will examine different feasibility outcomes taken from previous studies on remote cognitive rehabilitation interventions for pediatric patients with ABI, considering both the feasibility of the training (eg, accessibility, training adherence, technical smoothness, and training satisfaction) and the feasibility of study and procedures (eg, participation willingness, participation rates, assessment procedures, assessment timescale, and loss to follow-up) [54,60]—and (2) examine I-TOPS intervention efficacy—before training, after training, and at the 6-month follow-up, we will administer questionnaires and performance-based measures to participants and parents in the 2 study groups to assess neurocognitive and psychological or behavioral functioning of children as well as the psychological well-being of parents.

Methods

Trial Design

We will conduct a single-center, 2-arm, parallel-group RCT. The trial will apply a pre-post design, with a baseline preintervention assessment (T0), a postintervention assessment immediately after the 6-month intervention period (T1), and a long-term follow-up assessment conducted 6 months after the end of the intervention (T2). Participants will be randomly assigned to groups in a 1:1 ratio to receive the I-TOPS or the wellness intervention. The wellness intervention presents the same structure as the I-TOPS intervention but omits contents related to problem-solving. No change to the I-TOPS or wellness intervention content will be made during the trial; therefore, both interventions will be delivered in their initial Italian version. Eventual failures or system downtimes will be recorded and considered for the evaluation of the feasibility of the training, but no changes in functionality will be made. The trial was registered on ClinicalTrials.gov (NCT05169788) on December 23, 2021.

Study Setting

The I-TOPS and wellness interventions will be delivered remotely using a web-based platform including web-based learning modules. Participants will complete the intervention in an everyday setting, generally at home using a computer, as the program is not compatible with tablets and mobile phones. Every 2 weeks, a psychologist located in the rehabilitation center (ie, Scientific Institute IRCCS E. Medea in Bosisio Parini, Lecco, Italy) will contact patients and families using the Google Meet videoconference platform to provide remote monitoring, content discussion, and support on the problem-solving process for the I-TOPS intervention and remote monitoring and content discussion only for the wellness intervention.

Demographic, clinical, and outcome data will be collected and stored at the Scientific Institute IRCCS E. Medea.

Eligibility Criteria

The inclusion criteria for the study, in accordance with those of the studies on the original American TOPS program [42,46,49-52], are as follows: a diagnosis of nonprogressive ABI (eg, TBI, stroke, brain inflammation or infection, and anoxia or hypoxia) in the chronic phase (ie, at least 1 year after the event); ages between 11 and 19 years at the time of the recruitment; full-scale IQ ≥70; proper comprehension and speaking abilities in the Italian language; having a PC and access to the internet in the everyday setting, and adolescent and family familiarity with basic computer and internet literacy to manage emails, access to the internet and websites, and video calls; and at least one parent or guardian living with the adolescent available to participate in the intervention.

Exclusion criteria, in accordance with those of the studies on the original American TOPS program [37,42,46,48-52], are as follows: presence of preinjury or comorbid conditions, such as sensory impairments and global developmental delay; a history of abuse; a history of psychiatric hospitalization; and receiving concomitant psychological intervention.

Participant Recruitment

The staff members responsible for the study (AB and CC), in conjunction with the referring physicians, will identify potentially eligible participants by reviewing medical records related to pediatric ABIs at the Scientific Institute IRCCS E. Medea. Families of all potentially eligible patients or the patients themselves, if of age, will be met face-to-face in the clinic or contacted by phone by a psychologist of the research team and provided with details about the aims and methods of the study. Parents and adolescents will be given the opportunity to ask questions about the study and to confirm whether they are interested in participating. No information on group allocation, and thus, on differences between the I-TOPS and the wellness intervention will be provided to limit user expectations and biased results; only general information on the structure of the program and its duration and aims will be discussed. If families are interested in participating, eligibility criteria will be checked with the parent to confirm suitability for the research and ascertain whether both parents or which parent will participate with the adolescent during the intervention. A summary of the informed consent will also be provided. To achieve adequate participant enrollment, research assistants will contact all adolescents meeting the inclusion criteria with up-to-date contact information until the target sample size is reached.

Randomization and Blinding

After completion of the informed consent and baseline measures, participants will be randomly assigned into one of 2 groups: G1, receiving the regular I-TOPS treatment, or G2, receiving the active control training, namely, the wellness treatment. In detail, the randomization will be conducted by a researcher of the Institute, independently from the research staff responsible for recruiting participants. Randomization of patient assignment to the groups will follow a coin flip procedure using the randomization tool of Microsoft Excel: an automated number will be randomly associated with any recruited patient and determine assignment to G1 (0-0.49) or G2 (0.50-1). No stratification will be used. The independent researcher will give the staff members responsible for the study (AB and CC) a sealed envelope containing the participant's group assignment to keep it concealed from the research staff. This is to avoid selection bias and to prevent the research staff from subverting the allocation sequence. In turn, the research staff will give this envelope to the psychotherapists supervising the interventions, who will contact parents of enrolled adolescents to provide information regarding the next study steps on the basis of the group allocation. Indeed, to allow for clinical supervision, treatment fidelity, and patient interactions, the supervising psychotherapist will be required to receive group allocation information. Other research staff, participants, and testers will remain blinded to group assignment. Given these considerations, this study will constitute a double-blinded RCT. Emergency unblinding will be used only in front of reasonable request by the patient or the referring physician due to clinical reasons.

Interventions

This study will have 2 treatment arms, that is, the I-TOPS (G1) and wellness (G2) interventions, described subsequently in Textbox 1. Participants will not have to pay or will not be paid to access the allocated intervention.

For both interventions, before starting the training, a psychologist, who will follow training administration, will contact the families via telephone and discuss how to access the treatment sessions on the interventions' website and how to connect to Google Meet calls. No recommendations on timing, frequency, or intensity of use will be provided; the only requirement will be the completion of each session within a 2-week window. Prompts to use the training will be provided via emails automatically sent by the program; however, participants will choose the frequency (ie, weekly, bimonthly, or monthly) of reminders by selecting a specific option included in the program website. In addition, bimonthly meetings with the psychologist will review content and promote adherence. To this aim, the psychologist will ensure flexibility and coordinate the timing of the sessions to allow families to have time for other commitments and holidays or breaks to be built into the schedule.

No possibility to modify allocated interventions for each trial participant will be given, but each adolescent could discontinue the intervention at any study time due to personal, family, medical, or other reasons.

Textbox 1. Training sessions of the Italian version of the Teen Online Problem-Solving (I-TOPS) intervention and wellness intervention.

I-TOPS intervention

- Session 1 (*Inizio: essere positivi*; Getting started, staying positive, and handling stress): after an introduction on the I-TOPS program and its purposes, the session explains how it is important to develop and maintain a positive attitude in everyday life to better solve problems. The psychologist should review the differences between a positive versus negative approach to problems with the family, emphasizing why it is important to have a positive problem-solving orientation. The family should be encouraged to talk about how they feel when they have problems.
- Session 2 (*Problem-solving*; Problem-solving): the session introduces a 5-step strategy (ie, FAREI, which represents the corresponding acronym to the strategy ABCDE of the original version of the Teen Online Problem-Solving [TOPS] intervention) to solve practical and organizational problems; the 5 steps of problem-solving are as follows: A (ie, aim or focus on a goal), B (ie, brainstorm or analyze all the possible solutions), C (ie, choose a plan), D (ie, do or implement the plan), and E (ie, evaluate what works and what does not work). The psychologist helps the adolescent to apply the strategy by using examples.
- Session 3 (*Organizzarsi*; Getting organized): the session expounds the cognitive changes that occur following an acquired brain injury (ABI), for example, difficulties in memory and attention; the psychologist asks the teenager and the parent about problems with thinking or learning that they feel the teenager is having because of the ABI and about the strategies that they use to compensate for these difficulties. The psychologist helps the family to apply the F.A.R.E.I. strategy learned in session 2 to solve the everyday problems.
- Session 4 (*Lavorare con la scuola*; Working with the school): the session aims to provide parents with information regarding their rights as well as the rights of their adolescent in the education system, with materials and ideas to become advocates for their adolescent, and to create an optimal learning environment while respecting the school's ideas. In addition, parents are taught strategies to better communicate and work with teachers and are required to solve problems on this topic during the web-based session with the psychologist.
- Session 5 (*Mantenere il controllo*; Staying in control): the session describes the possible behavioral and emotional problems following ABI. The psychologist discusses with the adolescent and their caregivers their own problems to allow them to find a solution. During this session, the adolescent learns the 5-step SMART strategy (which is the same as the one reported in the original TOPS program) useful to empower them to manage their own behavior during social interactions. The 5 steps to stay in control are as follows: S (ie, stop and think), M (ie, monitor your behavior), A (ie, appraise and look at how others are reacting), R (ie, reflect), and T (ie, try a new or different behavior). The psychologist helps the adolescent to apply the strategy in the everyday setting.
- Session 6 (*Gestire la rabbia*; Controlling your anger): the session offers a 6-step strategy to manage anger (ie, SPACCA, which represents the corresponding acronym to the strategy STARRS of the original version of the TOPS intervention) and suggests how to become a good communicator by using *iMessages*. The 6 steps to control anger are as follows: S (ie, stop), T (ie, think about what is happening), A (ie, accept the situation), R (ie, relax), R (ie, reframe or look at the situation differently), and S (ie, solve). The psychologist discusses with the family why a person may have more problems with anger after ABI and helps the adolescent to apply the strategy in the everyday setting.
- Session 7 (*Ascoltare, parlare e leggere i segnali non verbali*; Verbal and nonverbal communication): the session helps the adolescents to focus on verbal and nonverbal communication skills and encourages them to focus on nonverbal signals from communication partners and their own nonverbal communication. The adolescent learns strategies for effective verbal communication. The psychologist supervises the exercises done by the adolescents on the web platform and helps them to identify some situations of everyday life in which the learned abilities could be implemented to improve social communication.
- Session 8 (*Comportamento sociale e di gruppo*; Social behavior and problem-solving): the session focuses on possible everyday difficulties in group settings, romantic relationships, web-based communication, and family context. The psychologist discusses with the adolescent and the family how friendships and social activities could change after an ABI and asks the adolescent to identify social situations that are challenging for them and to apply the strategies learned in sessions 5 and 6 to better deal with others.
- Session 9 (*Prendersi cura di sè*; Taking care of you): the session focuses on the relationship between sleep, nutrition, hydration, physical exercise, and cognitive functioning and wellness following an ABI; it also explains the consequences of feeling stressed and suggests different strategies to manage stress. The psychologist discusses with the family members their own habits and helps the adolescents to use the strategies presented in the session to face difficulties of everyday setting and to maintain an adequate routine to support wellness.
- Session 10 (*Conclusione: mettere insieme i pezzi*; Moving forward and planning for the future): this session recaps the 3 main strategies showed in previous sessions (FAREI, SMART, and SPACCA) and introduces a fourth strategy (FOCUS) devoted at helping adolescents to understand the possible steps to effectively ask for help whenever necessary in view of potential future problems in the everyday setting. This strategy is made of F (ie, flexibility when dealing with something), O (ie, optimism), C (ie, creativity to think about other ways to deal with something), U (ie, use your own resources), and S (ie, support or ask for help). The psychologist helps the adolescent to exercise this fourth strategy to use it in the everyday setting after the end of the training.

Wellness intervention

- Session 1 (*La strada verso il recupero*; Recovery and planning for the future): the session introduces the wellness intervention and focuses on the teenager's global difficulties and worries following an ABI. The psychologist provides psychoeducation on ABI sequelae and encourages the adolescent and their caregivers to describe their personal experience of the injury and related emotions and concerns.
- Session 2 (*Fare fatica è normale*; Acquired brain injuries: possible consequences): the session describes the cognitive changes that can occur following ABI, for example, difficulties in memory, attention, and executive functioning (EF) and includes video testimonials of adolescents with ABI discussing such difficulties. The psychologist encourages the teens and their caregivers to describe their personal experience of the injury and its consequences. The content is aimed at providing psychoeducation on ABI sequelae specifically related to the area of cognition.
- Session 3 (*Essere positivi*; Staying positive and handling stress): the session explains how it is important to hire and maintain a positive attitude in everyday life, but this is not specifically related to the problem-solving process, instead to wellness, reducing perceived stress. The psychologist investigates the family's use of humor in daily life and encourages them to talk about how they feel and how they react when problems occur.

- Session 4 (*Lavorare con la scuola*; Working with the school): the session aims at providing parents with information regarding their rights as well as the rights of their adolescent in the education system and with materials and ideas to become advocates for their adolescent and to create an optimal learning environment for their adolescent while respecting the school's ideas.
- Session 5 (*Prendersi cura di sè*; Taking care of you): the session focuses on the relationship between sleep, nutrition, hydration, exercise, and cognitive and physical functioning following ABI. The psychologist investigates with the adolescent and their caregivers their habits in these areas. The aim is to support health and wellness.
- Session 6 (*Gestire lo stress*; Managing your stress): the session explains the consequences of feeling stressed on health and suggests some strategies to manage stress. The psychologist investigates how the adolescents usually cope with stress and helps them to learn the strategies to manage stress and to experiment them in daily life. The aim is to support health and wellness.
- Session 7 (*Il sonno*; Sleep): the session shows the possible sleep changes following ABI and gives advice to improve sleep quality to support health and wellness. The psychologist investigates the adolescent's sleeping habits and, if necessary, helps them to improve sleep quality. The aim is to support health and wellness.
- Session 8 (*Dopo la scuola superiore*; After high school): the session offers the adolescent an overview on the opportunities provided by the Italian system in terms of education and work activities after high school, with a primarily psychoeducational focus. The psychologist helps the adolescents to think about what they would like to be when they grow up and what paths they could follow.
- Session 9 (*Emozioni di chi si prende cura*; For parents: family coping): the session shows the possible emotional difficulties of caregivers of adolescents with ABI and offers strategies for managing stress within the family context. The psychologist reviews with the caregivers their unique responses to the injury, acknowledging that responses are as unique as they are, with a focus on normalizing their emotional reactions.
- Session 10 (*Parlare con i vostri ragazzi*; Talking with your teenager): the session helps the parents to become good listeners and good communicators to improve their communication with the adolescents and the families to support a calm family environment and overall family wellness. The psychologist engages the parents in role-playing to allow them to improve their communication abilities.

I-TOPS Intervention (ie, Experimental Intervention Group)

The qualitative data on the process of adaptation of the original TOPS program to the Italian context (ie, I-TOPS) are extensively reported as a case study in a paper published in 2021 [31]. In summary, the adaptation process comprised focus groups with parents of adolescents with TBI to understand the needs of Italian patients and their families; after a literacy translation of the original program into the Italian language, they were asked their opinions on the relevance and clarity of the program content. The main suggestions were related to the scripted videos, with recommendations to emphasizing nonverbal aspects of communication that are integral to the Italian culture. Furthermore, a clearer depiction of the consequences of negative behaviors in the videos was required. The translation of the original TOPS program text from the English language to the Italian language was completed by 3 different psychologists with expertise in the field of brain injury and cognitive behavioral therapy. Translations were subsequently produced by 1 bilingual expert via forward-backward methods, and discrepancies were discussed and resolved. The final text was checked by adolescents with TBI, their parents, physicians, and adolescents of a local school class. Any suggested changes were accepted if they did not alter the meaning of the original sentence. This process required 5 months of work, during which further content revisions were made to improve ease of comprehension and flow in the Italian language.

The regular version of the I-TOPS intervention consists of 10 core sessions focused on problem-solving, EF, behavioral strategies, and social skills and 10 supplemental sessions. Before starting the program, the psychologist will meet with the adolescents and their family to learn about the specific issues occurring in their everyday setting with respect to organization or planning, social interactions, and emotion control that they want to work on during the intervention. Thus, although the I-TOPS program is delivered according to a defined protocol and content, the problem-solving will focus on personalized, everyday issues that the adolescents and their families have identified. The 10 core modules consist of self-guided didactic content regarding the steps of problem-solving and strategies for managing everyday challenges, brief videos modeling these skills, and exercises to support implementation. The adolescents and their families will complete a new module approximately every 15 days. Each web-based session will take 30 to 45 minutes to complete depending on the adolescent's level of attention. The parent or parents will work with the adolescent to complete each module. The program will not provide any feedback on the activities completed. After the family has completed and reviewed the contents of each session, the trained psychologist will conduct a video meeting of approximately 1 hour with the adolescent and the parent to review the web-based content and practice the problem-solving skills, focusing on a problem identified by the family related to the intervention content from the web-based learning modules (ie, organization or planning, social interactions, and emotion control). Ideally, video meetings should be provided bimonthly, but this period can be slightly adjusted according to family commitments. Completion of all 10 sessions is expected to take each family 5 months. Supplemental sessions will be recommended if their specific content is determined to be potentially beneficial in addressing the ongoing problems of the adolescent or the family identified at the baseline assessment. Therefore, considering supplemental sessions (a maximum of 2 supplemental sessions will be scheduled for each adolescent and family), we anticipate that participants will take approximately 6 months to complete the program.

Wellness Intervention (ie, Active Control Training)

The active control wellness intervention was developed by translating the original TOPS program contents related to health and wellness into the Italian language, usually included in

supplemental sessions, or contents included in original core sessions related to psychoeducation on TBI. In addition, in this case, the translation of the original TOPS program text from the English language to the Italian language was completed by 3 different psychologists having expertise in the field of brain injury and cognitive behavioral therapy. Translations were subsequently produced by 1 bilingual expert via forward-backward methods, and discrepancies were discussed and resolved.

Patients included in the wellness intervention will complete the treatment according to the same schedule as patients of the experimental group but will not receive direct intervention on EF nor support with respect to the problem-solving process. This control treatment focuses on health and wellness but omits contents on problem-solving, EF, behavioral strategies and social skills, and goal setting. The wellness intervention consists of 10 core sessions and 3 supplemental sessions to provide adolescents and their families with a program having the identical structure to the original I-TOPS intervention. The wellness intervention represents an active control training. No feedback will be automatically provided on the activities completed by the program. Bimonthly meetings of a brief duration (ie, about 15 minutes each) with the psychologist will focus on promoting knowledge regarding the consequences of ABI and on healthy lifestyle behaviors to improve wellness and will have the goal to sustain compliance. Completion of all 10 sessions and potentially supplemental ones (a maximum of 2 supplemental sessions will be scheduled for each adolescent and family) is expected to take each family a total of 6 months, similar to the experimental TOPS program. The active control group allows us to control for the placebo effects associated with being involved in a rehabilitation treatment and to isolate the effects of problem-solving training in the I-TOPS intervention.

Therapist Training

The I-TOPS intervention and the wellness treatment will be delivered by psychologists with expertise in psychotherapy. To ensure fidelity and quality assurance, all psychologists will receive training in recruitment strategies, interviewing techniques, questionnaire administration, and delivery of the I-TOPS and wellness interventions before beginning the program implementation; instructions for delivering each session are detailed in a treatment manual written by the TOPS program developer SLW and her research staff.

Treatment Fidelity

In relation to the I-TOPS intervention, psychologists will receive weekly supervision from a qualified psychotherapist with a master's in clinical psychology, a specialization in cognitive behavioral psychotherapy, and qualification in clinical neuropsychology to ensure treatment fidelity and quality assurance.

With respect to the wellness intervention, a supervising psychotherapist will conduct a random review of the sessions conducted by the psychologists every 2 weeks to ensure fidelity. The main topic of discussion will be how to focus on the ABI consequences without directly teaching problem-solving strategies to manage those consequences.

Data Collection

Following completion of the consent process, sociodemographic information (eg, age, sex, and socioeconomic status); details of past medical history; concurrent medication; the adolescent's age at the time of injury; and injury severity, measured using the Glasgow Coma Scale [61] will be collected from each patient's referring physician. Family compositions will be collected from parents via telephone for outpatients or directly in the clinic for hospitalized patients who are close to discharge.

At baseline (T0), after treatment (T1), and at 6-month follow-up (T2), adolescents and parents will be asked to complete study outcome measures, including questionnaires on cognitive and behavioral functioning of adolescents, and the psychological well-being of parents and adolescents will undergo remote cognitive performance–based evaluations. Questionnaires will be sent to adolescents and families in a sealed envelope; after completing them, adolescents and parents will be required to return them to the research staff using an envelope with a postmark included in the sealed envelope within 2 weeks. To promote participant retention, support from a member of the research team could be given for questionnaire fulfillment, if needed. In addition, performance-based measures on adolescents' cognitive functioning will be remotely administered, thus removing practical barriers to patient retention in the study, such as difficulties in transportation and reaching research centers.

Feasibility Outcomes

Outcome measures to assess study feasibility will be taken and adapted from previous studies on telerehabilitation interventions for adolescents with ABI, with the aim to use a priori–defined criteria and allow comparisons [54,60]. These measures have been developed for a previous study [60] based on the relevant literature on pilot feasibility studies [62,63]. A total of 9 measures will be used: 4 to assess the feasibility of the I-TOPS or the wellness intervention (ie, accessibility, training adherence, technical smoothness, and training motivation) and 5 to evaluate the study design and procedures (ie, participation willingness, participation rates, assessment procedures, and assessment length and loss to follow-up).

With respect to the feasibility of the I-TOPS or the wellness intervention, the outcomes outlined in Textbox 2 will be considered.

In relation to the feasibility of study design and procedures, the outcomes outlined in Textbox 3 will be considered.

Textbox 2. Outcomes to be considered regarding the feasibility of the Italian version of Teen Online Problem-Solving (I-TOPS) or wellness intervention.

- Accessibility: number and percentage of participants who ask for further instructions to understand training content and session-related tasks when at home. This criterion refers to understanding how to access the training, how to enter a session, how to perform and save exercises, and how to print specific materials. The criterion for success: 90% of families understand training content and session-related tasks when at home, after the explanation of sessions' content and activities by the psychologist. For all families, the explanation of the content of sessions will be performed during each scheduled web-based meeting (ie, at the end of each session, the psychologist will briefly explain the content of the following one, also indicating to families the web-based activities they are expected to do for the next meeting), with instructions repeated if a family asks for further clarification. If ≥3 explanations are needed, requiring other remote calls, the criterion will be considered to not have been satisfied. The criterion for success was 100% in the paper presenting the original version of the feasibility criteria [60] and in a previous study of our research group [54], both focusing on remote cognitive interventions having a drill-based format. However, for this study, it was reduced to 90%, given the complexity and multiple requirements of navigating and completing content in the I-TOPS intervention.
- Training adherence: number and percentage of the 10 core sessions completed during the scheduled training period (ie, expected time for completion of the 10 core sessions is 5 months) by each patient, including dropouts. No data on the number of log-ins or average session length will be recorded, as, for both treatments, these data do not provide significant information on better training use and are not considered to be associated with improving target abilities. The criterion for success: average 80% of treatment core sessions is completed after 5 months by each treatment group; the remaining 20% (ie, 2 core sessions) should be completed in a maximum 1 further month (ie, 2 extra weeks for each session). To be adherent, participants needing an additional month to complete the training need to have agreed in advance with the psychologist to postpone sessions due to valid reasons (such as holidays or other family plans). The average completion rate per treatment group in the scheduled time frame, calculated as the sum of the percentage of sessions completed by each participant divided per the total number of participants, is considered.
- Technical smoothness: number and percentage of participants who encounter technical issues with the training material (eg, the platform does not work) that persist for 2 or more weeks, thereby generating a training interruption and possibly influencing total training duration. The criterion for success: all participants will be able to perform the training without technical issues; dropouts are included in the calculation, considering only sessions performed.
- Training satisfaction: training satisfaction will be assessed through a satisfaction questionnaire created ad hoc for the original Teen Online Problem-Solving program and already used in previous studies on its feasibility (Multimedia Appendix 1) [46,47]. The questionnaire assesses perceived helpfulness and usability of the program and improvements as a result of treatment, and for this study, it was translated into the Italian language. Item responses include 1 (ie, strongly disagree), 2 (ie, disagree), 3 (ie, agree), and 4 (ie, strongly agree) on a Likert scale. In particular, 5 items pertain to perceived changes in one's problem-solving abilities and psychological wellness, 10 items pertain to satisfaction with the overall program (ie, program helpfulness and enjoyment and relevance of contents), and 2 items focus on the website ease of use. The questionnaire generates a total score, with higher scores indicating greater perceived satisfaction. A total score of ≥57 reflects a positive outcome in terms of satisfaction. The criterion for success: 80% of participants have a neutral or positive global score on the questionnaire.

Textbox 3. Outcomes to be considered in relation to the feasibility of the study design and procedures.

- Willingness to participate: number of participants who accept to partake in the study among those who were contacted for study enrollment. The criterion for success: 75% of eligible participants agree to take part in the study; the criterion is considered on the whole group, as referred to prerandomization data.
- Participation rates: number and percentage of enrolled participants who complete ≥1 session of the interventions, not abandoning the study after baseline measurements and before the start of the training. The criterion for success: 80% of participants who agreed to partake actually participate in the study.
- Assessment procedures: number and percentage of participants for whom outcome data are collected without any problems (eg, missing data and technical issues of assessment tools) on the 3 assessment time points (ie, baseline [T0], after treatment [T1], and 6-month follow-up [T2]). The criterion for success: 90% of the outcome measures for each participant are collected at each time point.
- Assessment timescale: number of participants whose follow-up data are collected within a week after training completion, for posttraining assessment, and within 2 weeks after the 6-month period from training end, for follow-up evaluation. The criterion for success: for all participants, the interval between training end and immediate posttraining evaluation is ≤7 days; for the 6-month follow-up, the assessment is performed in a range of 0 to 14 days from the first day of the 6 months subsequent to training end. This criterion is calculated only for participants performing posttraining and follow-up evaluations, excluding dropouts.
- Loss to follow-up: number of patients who fail to complete all outcome measures at posttraining assessment and 6-month follow-up. The criterion for success: less than 20% of participants enrolled fail to complete all outcome measures on both posttraining assessment and 6-month follow-up. This criterion does not refer to the presence of evaluations with missing data for each participant, for which the criterion "assessment procedures" already provides such information.

Efficacy Outcomes

A total of 9 outcome measures will be used to test preliminary evidence of training efficacy. Specifically, 7 self-assessed outcome measures (ie, 5 questionnaires for parents and 2 questionnaires for adolescents), 2 performance-based tasks assessing social cognition taken from a standardized neuropsychological battery, and a virtual reality–based assessment of everyday setting EF will be used. Questionnaires will be sent to patients and families in a sealed envelope; after completing them, participants will be required to return them to the research staff using an envelope with a postmark included in the sealed envelope within 2 weeks. The performance-based subtests assessing social cognition and the virtual reality–based assessment will be administered remotely using the Google Meet videoconference platform.

A detailed description of outcome measures is provided in Textbox 4. The sample of this study will include adolescents aged 11 to 19 years, but some measures and questionnaires have been standardized for populations having a lower maximum age range; however, they will be adopted for this study as no other measures with the same characteristics are available in the Italian language. The individual measures affected by this problem are clearly described in Textbox 4.

All outcome measures will be administered at T0 (ie, preintervention assessment), T1 (ie, immediately after the 6-month intervention), and T2 (ie, 6 months after the end of the intervention).

For the questionnaire outcomes, approaches to missing individual items will follow the guidelines for missing item procedures indicated in the manual for each questionnaire. If no guidelines for individual missing items are available, the mean of the completed items will be used to replace missing items if ≤10% are missing.

A summary of outcome measures to test training efficacy is presented in Textbox 5.

Textbox 4. Description of outcome measures.

- Behavior Rating Inventory of Executive Function Second Edition (BRIEF-2)−parent form [64]: the BRIEF-2–parent form questionnaire is aimed at assessing executive functioning (EF) behaviors of children and adolescents (aged 5-18 years) in everyday life by considering their parents' perspectives. The questionnaire is composed of 63 items referred to 9 different clinical scales (ie, inhibit, self-monitor, shift, emotional control, initiate, working memory, plan or organize, task-monitor, and organization of materials) and 3 validity scales (ie, inconsistency, negativity, and infrequency). BRIEF 2–parent form is administered to parents, who rate the frequency of executive problems of their children on a 3-point Likert scale. Raw scores on the global scale range from 63 to 189. The *t* scores (mean 50, SD 10) are used to evaluate the level of EF behaviors relative to normative samples. Higher scores indicate a worse outcome. As this questionnaire covers the age range of 5 to 18 years, scores of adolescents of 19 years have been standardized by considering norms for adolescents of 14 to 18 years.
- BRIEF 2–self-report form [64]: the BRIEF 2–self-report form questionnaire is aimed at assessing self-reported EF in everyday life of adolescents aged 11 to 18 years. It is composed of 55 items belonging to 7 clinical scales (ie, inhibit, self-monitor, shift, emotional control, task-monitor, working memory, and plan or organize) and 3 validity scales (ie, inconsistency, negativity, and infrequency). Raw scores on the global scale range from 55 to 165. The *t* scores (mean 50, SD 10) are used to interpret the level of EF compared to normative sample. Higher scores represent a worse outcome. As this questionnaire covers the age range 5 to 18 years, scores of adolescents of 19 years have been standardized by considering norms for adolescents of 14 to 18 years.
- Child Behavior Checklist 6 to 18 (CBCL 6-18) [65]: the CBCL 6 to 18 is aimed at assessing psychological adjustment and behavioral functioning of children and adolescents aged 6 to 18 years, as rated by parents. The questionnaire includes 113 items. The scores of this instrument considered for this study are total problems, internalizing problems, and externalizing problems. Raw scores of the Total Problems Scale range from 0 to 226 and are converted to *t* scores (mean 50, SD 10) to interpret the level of behavioral functioning compared to normative sample. Higher scores indicate a worse outcome. As this questionnaire covers the age range 6 to 18 years, scores of adolescents aged 19 years have been standardized by considering norms for adolescents aged 12 to 18 years.
- Youth Self-Report 11 to 18 (YSR 11-18) [65]: YSR 11 to 18 is aimed at assessing self-reported psychological adjustment and behavioral functioning of adolescents aged 11 to 18 years. The questionnaire includes 112 items. The scores of this instrument considered for this study are total problems, internalizing problems, and externalizing problems. Raw scores of the Total Problems Scale range from 0 to 224 and are converted to *t* scores (mean 50, SD 10) to interpret the level of behavioral functioning compared to normative sample. Higher scores represent a worse outcome. As this questionnaire covers the age range 11 to 18 years, scores of adolescents aged 19 years have been standardized by considering norms for adolescents aged 11 to 18 years.
- Beck Anxiety Inventory (BAI) [66]: the BAI is a 21-item questionnaire aimed at assessing state and trait anxiety in adults. In this study, the questionnaire is administered to parents to evaluate their psychological functioning. The total score is calculated as the sum of the 21 items (4-point Likert scale, ranging 0-3), with a minimum score of 0 and a maximum score of 108. Higher scores indicate a worse outcome. Specifically, a score of 0 to 21 indicates low levels of anxiety, a score of 22 to 35 indicates moderate levels of anxiety, and a score of 36 to 108 indicates potentially concerning levels of anxiety.
- Symptom Checklist 90 (SCL-90) [67]: the SCL-90 is a self-report questionnaire for adults aimed at measuring psychiatric symptom intensity on 9 different subscales (ie, somatization, obsessive-compulsive, interpersonal sensitivity, depression, anxiety, anger-hostility, phobic anxiety, paranoid ideation, and psychoticism). The 90 items included in the questionnaire are scored on a 5-point Likert scale (ranging 0-4), indicating the rate of occurrence of the symptoms during the last 7 days. In this study, the questionnaire is administered to parents to assess their psychological well-being. The Global Severity Index (GSI) is considered, for which the score is reported as a ratio of the sum of all items to the number of items scored. Higher scores indicate higher psychiatric symptom intensity; consistent with recommendations [65], an average score corresponding to ≥1 on the GSI enters the clinical range.
- Parenting Stress Index (PSI)–Short Form [68]: PSI–Short Form is a 36-item questionnaire aimed at assessing levels of stress associated with parenting in relation to different areas: parenting competence, restrictions on life introduced by parenting, parental conflict, depression, and social support. The 36 items of the questionnaire are scored on a 5-point Likert scale. The global score (PSI-total) is considered for this study, for which clinical cutoff is established at 90. Higher scores indicate higher distress.
- Jansari assessment of Executive Functions for Adolescents (JEF-A) [69]: JEF-A is a computerized assessment based on nonimmersive virtual reality aimed at evaluating everyday EF in adolescents aged 10 to 18 years. It is a performance-based assessment administered to adolescents. Participants are asked to plan, set up, and run a birthday party through the completion of 16 tasks resembling real-world activities. JEF-A tasks evaluate 8 constructs related to EF: planning, prioritization, selective thinking, creative thinking, adaptive thinking, action-based prospective memory, event-based prospective memory, and time-based prospective memory. All tasks are scored on a 3-point scale: 0 for failure, 1 for a partial or nonoptimal completion, and 2 for satisfactory completion. The scores for the 2 tasks for any particular construct are summed (ie, maximum of 4 possible), and this score is converted to a percentage of achievement for this construct. In addition to the 8 individual module scores, an average total percentage is computed for the whole assessment. The final raw score ranges from 0 to 32. Higher scores and percentages indicate a better EF. Although this instrument has been tested on adolescents with acquired brain injury (ABI) who are aged 10 to 18 years, in this study, we adopted it for participants aged 19 years as well to ensure comparability and a task in line with tasks related to such an age instead of administering to those adolescents the task for adults involving a multiple errand task based around a business office [70].
- A Developmental Neuropsychological Assessment-2 (NEPSY-2; Theory of Mind and Affect Recognition subscales) [71]: the Theory of Mind and Affect Recognition subscales of NEPSY-2 are performance-based subtests administered to adolescents and aimed at evaluating their social perception and emotion recognition skills. Theory of Mind subscale–part A measures understanding of mental functions and other people's perspectives, and its raw scores range from 0 to 17; Theory of Mind subscale–part B examines the ability to match basic emotions (eg, happy, sad, angry, afraid, and disgusted) to specific situations, and its raw scores range from 0 to 8. The Affect Recognition subscale tests the ability to recognize emotions in facial expressions, and its raw scores range from 0 to 35. Raw scores are converted into scaled scores (mean 10, SD 3) based on age norms ranging from 1 to 19. Higher scores indicate better outcomes. As this battery covers the age range 3 to 16 years, scores of adolescents aged 17 to 19 years have been standardized by considering norms for adolescents aged 11 to 16 years.

Textbox 5. Outcome measures to test training efficacy administered to adolescents and parents.

Cognitive outcomes

- Jansari assessment of Executive Functions for Adolescents (JEF-A; performed by the adolescent) [69]
- A Developmental Neuropsychological Assessment-2 (NEPSY-2; performed by the adolescent) [71]
- Behavior Rating Inventory of Executive function 2 (BRIEF 2-self-report form; related to self-functioning. filled by the adolescent) [64]
- Behavior Rating Inventory of Executive function 2 (BRIEF 2-parent form; related to the adolescent, filled by the parent) [64]

Behavioral or psychological outcomes

- Youth Self-Report 11 to 18 (YSR 11-18; related to self-functioning, filled by the adolescent) [65]
- Beck Anxiety Inventory (BAI; related to self-functioning; filled by the parent) [66]
- Child Behavior Checklists 6 to 18 (CBCL 6-18; related to the adolescent, filled by the parent) [65]
- Parenting Stress Index (PSI; related to self-functioning, filled by the parent) [68]
- Symptom Checklist-90 (SCL-90; related to self-functioning, filled by the parent) [67]

Sample Size and Power Calculation

A previous meta-analysis on the effects of the original American TOPS program on the various outcomes found a small-to-medium average effect size (Hedges g=0.37) [37]; however, high variability was found among the effect sizes of the different studies analyzed. This led us, to be conservative, to estimate a small effect size of f=0.2 for the evaluation of the power calculation in the present study. Power analysis was conducted using G*Power3 Software (Heinrich-Heine-Universität Düsseldorf) [72,73]. Assuming a correlation of 0.50 between repeated measures and setting the α level at P<.05, a sample size of 21 participants per group will be required to obtain 80% of power with our 2 group- and 3 time-point- design. Therefore, a whole sample of 42 participants will be required to be included in the study. Attrition was not considered in performing power calculation, as adherence rates will be a core outcome of this study, which is pioneering for the Italian context and, therefore, will be aimed at collecting data on feasibility. Therefore, any eventual dropouts will be accounted for in statistical analyses using intention-to-treat analysis procedures.

Data Analysis Plan

All randomized adolescents will be included in the analyses, irrespective of adherence to treatment in the I-TOPS or wellness intervention. No imputation of a missing baseline or follow-up data will be performed. The t tests and chi-square analyses will be performed to compare the I-TOPS (ie, experimental) and wellness (ie, control) intervention groups on continuous and dichotomous variables, respectively. Similar analyses will be performed to examine baseline differences between patients who will complete the study and those who will drop out. Frequencies and means related to feasibility outcomes will be calculated. Analyses will be performed using SPSS (version 29.0.1.0; IBM Corp) [74].

Efficacy outcome measures will be separately entered into linear mixed effect models with “time” (baseline vs immediately after treatment vs 6-month follow-up) and “treatment” (regular I-TOPS vs wellness intervention) and their interaction as fixed factors and “intercepts” and “participants” as random factors. In case of differences in any clinical or demographic variables between groups at baseline, those measures will be included in the analyses as covariates. Mixed model analysis allows flexible modeling of the pattern of change over time and uses all the data for a given participant, even if that participant is not seen at all assessments, allowing us to retain participants with missing assessments. Significant interaction effects (ie, time and group) or group effects will be analyzed by post hoc tests. The significance threshold will be set at <.05. No interim analysis will be planned.

Safety Reporting

The risks associated with participating in this trial are considered minimal. The exclusion of adolescents with photosensitive epilepsy reduces the possible risks associated with the prolonged use of a technological device. The interventions, both the original I-TOPS and the wellness interventions, could raise awareness of injury-related cognitive or behavioral problems, which could contribute to conflict between family members. Family communication and problem-solving in the I-TOPS group might increase family burden. Nevertheless, the purpose of the original I-TOPS program is ultimately to help families cope with these difficulties by teaching problem-solving and communication strategies. In addition, the psychologist supporting the web-based interventions (ie, both original I-TOPS and wellness intervention) is trained to handle any emerging problems. Should any issues arise, the psychologist will have the opportunity to discuss the situation during weekly group supervision meetings with the supervising psychotherapist who is qualified in psychotherapy (a minimum of 2 psychologists is scheduled to deliver the treatments). Thus, there is no requirement to report nonserious adverse events (SAEs) in this study; nevertheless, a monitoring of SAEs will be performed. SAEs may be reported by referring physicians of each patient or researchers, the I-TOPS intervention coaches, participants themselves, or any other informant. Adverse event data will be monitored by the Ethics Committee of the Scientific Institute, IRCCS E. Medea to ensure safety. All suspected SAEs will be reported within 24 hours of discovery to the chief investigator, who will be asked to inform the ethics committee contact person at our Institute. All SAEs will be followed up until resolution.

Ethical Considerations

This study has been approved by the Ethics Committee of Scientific Institute, IRCCS E. Medea (08/21-CE, January 21, 2021). The trial will be conducted in accordance with the protocol and the principles of the 1964 Declaration of Helsinki. Any eventual amendments to the protocol will be submitted to the Ethics Committee of Scientific Institute, IRCCS E. Medea for approval. The principal investigator should make available, on request, relevant trial-related documents for monitoring and audit by the sponsor (Scientific Institute, IRCCS E. Medea) or the relevant research ethics committee.

The informed consent will be obtained face-to-face by staff members responsible for the study (AB and CC) when the adolescents and parents come to the clinic or remotely by using a sealed envelope for those families not able to reach the Institute. The consent process depends on the age of the participants; for participants aged 11 to 17 years, the parents or guardians will provide consent, while participants aged 18 or 19 years will provide their own signed consent. Families will be required to sign the "participant information sheet and informed consent for research participation." Participants will be given the opportunity to express their concerns and declare barriers to participating in the study at the time of enrollment. Participants will have the ability to opt out at any time during the study.

Parents of participants below the age of consent or participants of age will be required to sign a "privacy policy statement and consent." An Institute Data Protection Officer (DPO) will be available, representing a contact point between the Italian Data Protection Authority and the concerned parties. DPO email address is reported on the "privacy policy statement and consent" signed by the parents or the participants. In addition, using the email address of the DPO reported on the "privacy policy statement and consent," participants will have the possibility to provide feedback and express any concerns about the project.

Participants' personal data will be pseudonymized. A unique trial number will be provided to each participant consenting to participate in the study. Each participant will be identified in all study-related documentation by the trial number and initials. A record of names and addresses linked to participants' trial numbers will be maintained by the research team and stored securely. All data will be entered into a password-protected database and encrypted using a stored procedure. Data will be stored for 50 years, except in the case of extension by law, in accordance with information reported in the document on data management for scientific research.

To prevent problems with mislaid usernames and passwords, participants will access the web pages of the allocated training program through links emailed to them by the research team members. Once the program has been completed by the participant, it will be locked to prevent further data entry or change.

The trial database will be designed and maintained by 2 members of the research team responsible for data management (AB and CC); access to the database will be given to eventual research assistants involved in the research project by signaling their name to the specific privacy office of the Institute. Database access by researchers will be password protected.

All data will be collected and managed in accordance with Regulation (European Union) 2016/679 of the European Parliament and of the Council of April 27, 2016, on the protection of natural persons with regard to the processing of personal data and on the free movement of such data and repealing Directive 95/46/EC.

No compensation related to study participation will be provided.

Results

After the approval of the ethics committee, the study started on February 26, 2021, and ended on February 28, 2023. Recruitment started on December 27, 2021, and ended on February 25, 2022. The last patient evaluation was performed on February 22, 2023. A secular event, namely the COVID-19 emergency, fell into the first part of the study period, which could have increased the interest of adolescents and families in participating in a remotely delivered treatment. However, due to the need of the target population to receive neurocognitive treatment in the chronic phase, we consider this fact marginal and not influencing the adherence rate. At study protocol submission in *JMIR Research Protocols*, the study has been concluded; the expected 42 participants were randomly assigned into the 2 treatment groups, and 34 (81%) of them concluded the assigned intervention and underwent posttraining and 6-month follow-up evaluations. The total attrition rate was 19% (8/42).

Figure 1 depicts the CONSORT (Consolidated Standards of Reporting Trials) flow diagram.

After the publication of the protocol, data analysis to test feasibility and efficacy will be performed, and final results are expected to be published in the form of a paper in a relevant scientific journal in 2025. In this paper, demographics associated with digital divide issues such as age, education, gender, family socioeconomic status, and computer or internet literacy will be reported.

Discussion

Principal Findings

This RCT will evaluate the feasibility and efficacy of a web-based training aimed at improving EF and problem-solving abilities (ie, I-TOPS intervention) versus an active control web-based intervention providing health and wellness content (ie, wellness intervention) in adolescents with ABI. Substantial evidence on the feasibility and efficacy of the original TOPS program developed and delivered in the United States has been collected, while this RCT will be the first study providing data for the Italian context using the adapted Italian version of the intervention (ie, I-TOPS).

EF rehabilitation is highly recommended for pediatric patients with ABI to limit the progressive deterioration of behavior over time and to reduce associated social and psychological costs [31,75]. Telerehabilitation represents a new form of service that mitigates issues associated with face-to-face rehabilitation, such as limitations in access or elevated costs for families and hospitals, creating more care opportunities for patients. Until now, in Italy, no specific remote intervention for EF for this population is available [57]. Therefore, the TOPS program, originally developed in the United States to help teenagers with TBI and, subsequently, other types of ABI to improve problem-solving in the everyday setting, has been translated and adapted to the Italian cultural context with the name "I-TOPS." The I-TOPS intervention urgently needs to be administered in a rigorous RCT in Italy, allowing a test of its feasibility, clinical efficacy, and cost-effectiveness. Our research team has already conducted pilot trials on telerehabilitation treatments for children with ABI in recent years and has also concluded and published a phase-2 RCT on the effects of a drill-based cognitive training [55,56]. However, data on the efficacy of the program were promising only for visual-spatial working memory and not for other cognitive domains, including EF or behavioral and psychological measures [55,56]. Therefore, at a clinical level, the need remains to provide patients with a rehabilitation program to improve EF in everyday settings. This research is the first Italian study that will focus on this topic.

We will conduct a phase-2 RCT to guarantee adequate controls on data quality and findings, consistent with recommendations proposed for studies on rehabilitation interventions [75]. This RCT protocol is reported in accordance with the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist (version 1.6.1) [76] (Multimedia Appendix 2), which allows for improving the quality of reports of web-based intervention evaluations. Data from this RCT will help inform future directions for investments in the field of telerehabilitation in Italy.

Strengths and Limitations

The planned study possesses a number of strengths, including the use of an active control group (ie, wellness intervention) instead of a passive one, which allows controlling for placebo effects. Furthermore, although the I-TOPS program involves self-directed, web-based learning modules, the provision of active problem-solving therapy by a trained cognitive behavioral psychologist constitutes a key aspect for the success of this RCT. In support of this, a recent study highlighted the fundamental role of patient-therapist engagement in obtaining good results during the rehabilitation therapy [77]. Finally, the use of the computer, rather than a smartphone, for treatment delivery should allow adolescents to maintain an adequate level of commitment and concentration while performing the I-TOPS intervention, requiring them and their families to carry out the program in a quiet place at home and not in random places (eg, on the beach and means of transportation). However, at the same time, this requirement may restrict treatment access and preclude participation by families who do not have the financial means to buy a computer and the necessary equipment for the

videoconferences. Furthermore, families who go on vacation during the 6-month intervention period will have to plan to bring a computer to continue the program or postpone appointments if they are unable to access a computer, which may cause problems with respect to the treatment schedule. At the same time, the long study duration could cause study adherence issues. Nevertheless, it will be the responsibility of our research team to indicate whether the postponement of the sessions is agreed in advance (ie, for holidays or other justified or warranted engagements of the family) or it is instead linked to other factors associated with feasibility issues (eg, forgetfulness, lack of desire or motivation, and failure to carry out tasks). An accurate examination of the feasibility associated with both the training and study design and procedures will be reported.

To limit the issues related to potential biases associated with subjective measures [37], this study examines efficacy as well by using performance-based measures. Furthermore, it adopts a virtual reality–based assessment [69] requiring adolescents with ABI to do errands typical of the everyday setting, which could provide important information on their actual functioning in activities similar to those of real life. Inclusion of these measures will provide further evidence regarding the utility of the intervention in improving various neuropsychological consequences, and thus, this information could be useful to provide the National Health Care System with recommendations for survivors of pediatric ABI.

In addition, the examination of training and study procedure feasibility will allow investigating the usability of the training and the adequateness and potential replicability of the study design, which could help addressing potential issues to intervention delivery in the clinical context and study replication by future research teams. This could also favor the evaluation of the generalizability of trial findings to the general patient population of adolescents with brain injury, addressing sources of potential bias and imprecision. In the clinical context outside of an RCT setting, the I-TOPS intervention would be delivered in the same exact way as in this study, in terms of content, prompts to use the training and human involvement, which increases the relevance of findings of this study to inform the clinical practice.

Conclusions

If this phase-2 RCT yields positive results, a larger, multicenter, phase-3 RCT could be planned and delivered to examine I-TOPS intervention efficacy and cost-effectiveness in a larger sample. Since 2020, Italy has a network for sharing the best practices related to rehabilitation for pediatric neurological children—Rete Pediatrica degli IRCCS [78]—with an important focus on telerehabilitation. This network could enroll in the phase-3 RCT, particularly given that the institute conducting the phase-2 RCT is part of this network.

If the phase-3 RCT demonstrates efficacy, future work will focus on broader implementation within the Italian health system. Beyond providing clinical benefits to adolescents with ABI and their families, the I-TOPS intervention might reduce longer-term health care service use, thus limiting rehabilitation costs. The program might also have broader societal benefits through improvements in educational and vocational outcomes and reductions in criminal behavior frequently associated with EF impairments following ABI [6,9,13,18-24]. Considering local policy making and treatment delivery, the I-TOPS intervention requires limited economic resources to be implemented due to its web-based format and allows for a centralized psychologist, with expertise in the program and pediatric ABI, to provide treatment throughout the country rather than limited to a single region. Therefore, I-TOPS intervention delivery does not necessarily need individuals with this expertise throughout Italy, especially in rural areas or islands, but could allow clinicians of specialized rehabilitation centers to take charge of a wide range of patients, also reaching those living in remote regions. In addition, with the program being accessible at any time that is convenient for the adolescents and their families, it could be less burdensome than traditional clinic appointments, which often require children to miss school lessons or parents to modify their work schedules. Using I-TOPS intervention materials, the National Healthcare System might routinely provide the program to adolescents with ABI and their families throughout the country using a single central therapist to support the needs of multiple families in disparate locations. The findings from this RCT will be disseminated through publications in peer-reviewed and popular science journals and presentations at scientific conferences with the aim to reach relevant research, clinical, health service, and patient communities.

Acknowledgments

This study was supported by the Italian Ministry of Health (Ricerca Corrente 2022-2024 to SS) and “5 per mille” funds for biomedical research. Study sponsors and funders had no role in study design; collection, management, analysis, and interpretation of data; writing of the report; and the decision to submit the report for publication. The authors would like to thank the principal, teachers, and students of Scuola Superiore Maria Ausiliatrice, Lecco, Italy, for their precious contribution in realizing the videos included in the Italian version of the Teen Online Problem-Solving (I-TOPS) program.

Authors' Contributions

CC, AB, CU, RB, and SLW defined the study design and method. CC, MP, and SLW wrote the manuscript. AB, AJ, FAS, GP, CU, RB, RR, and SS significantly revised the manuscript. CC, MP, and SLW prepared the tables and figures. All authors read and approved the final manuscript.

Conflicts of Interest

SLW is the developer of the original Teen Online Problem-Solving program, which was adapted for the Italian context (Italian version of Teen Online Problem-Solving) by the first author, CC. In this regard, we declare that no conflict of interest exists in data reporting: CC was not responsible for patient enrollment and allocation and was masked with respect to participants' group allocation; SLW did not have access to any information on patients nor to the database. All other authors declare no other conflicts of interest.

Abstract

Background: The coverage of influenza vaccination among older adults in Norway is insufficient, especially in some immigrant groups. To improve public health, there is a need for an intervention that can increase influenza vaccination coverage. Further, interventions tailored to reduce potential barriers among immigrants can reduce health inequities.

Objective: InfluSMS aims to determine if SMS nudging increases vaccination coverage among those aged 65 years or older (1) in Norway's general population; (2) among immigrants born in Poland; and (3) among immigrants born in Ukraine; and evaluate the impact of SMS nudging in Norwegian versus in the official language of the native country of immigrants born in Poland or Ukraine.

Methods: InfluSMS is a pragmatic randomized controlled trial conducted among people aged 65 years or older residing in Norway. Influenza vaccination coverage is the main outcome, measured in control and intervention arms for each of the 3 populations listed earlier. In all 3 populations, the control arm is standard care, that is, no individual reminder for influenza vaccination. All populations have an intervention arm that will receive an SMS nudge in the Norwegian language. In addition, the Polish and Ukrainian immigrant populations include a second intervention arm that will receive an SMS nudge in Polish or Ukrainian, respectively. In the general population, at least 23,485 individuals will be randomized to the SMS intervention arm while the rest of the population constitutes the control arm. In each of the 2 immigrant populations, we will randomize all eligible individuals 1:1:1 into the 3 arms. The intervention will take place at the start of the 2025-2026 influenza season. All eligible individuals will be passively followed up through the National Immunisation Registry, SYSVAK, from which individual influenza vaccination status 3 months after the SMS nudge will be collected. Coverage rates between arms within each population and effect sizes between the populations will be compared. The cost-effectiveness of SMS nudging will also be assessed.

Results: The inclusion of participants will start in the third quarter of 2025, and the registry data will be available in the first quarter of 2026. Coverage rates of each strategy and coverage differences between strategies will be presented.

Conclusions: SMS nudging is a scalable, inexpensive, and nonintrusive intervention that could be integrated into the national influenza vaccination program if the trial shows it effectively increases influenza vaccination coverage among older adults.

Further, the trial will establish whether language is a barrier to influenza vaccination uptake among recent immigrant groups that have low influenza vaccination coverage, and to what extent this potential barrier can be diminished by SMS nudging in the official language of their native country.

Introduction

Background

Seasonal influenza has a high disease burden worldwide and may cause up to 5 million severe cases and 645,000 deaths annually [1]. Vaccination against influenza is generally safe and may be effective in reducing influenza-like illness and associated conditions [2-4]. It is a widely recommended public health intervention [5,6], especially for groups experiencing a disproportionately high influenza burden such as older adults, who have a higher risk of severe disease, hospitalization, and mortality [7,8]. However, influenza vaccination coverage generally falls far below the 75% target set by the World Health Organization [9], thus many older adults that could have benefitted from vaccination remain unprotected. Furthermore, vaccine hesitancy, defined as a "delay in acceptance or refusal of vaccination despite availability of vaccination services" [10], is widespread for influenza vaccination [11]. The World Health Organization has defined vaccine hesitancy as one of the 10 current threats to global health [12].

Several immigrant groups have shown a relatively low vaccination coverage in their adopted country and a relatively high burden of vaccine-preventable disease [13,14]. This may partly be related to differences in vaccine hesitancy, which may differ between countries [15,16]. It may also be associated with more limited access to vaccination among some immigrant groups, for instance, if immigrants do not understand the language in their adopted country. Whatever the reason, efforts are needed to narrow the gap in vaccination coverage and to promote public health as well as health equity. Tailored interventions addressing acceptability and access barriers faced by immigrants may be useful to achieve this end [14,17].

Vaccine hesitancy is a complex phenomenon that has several psychological components [18,19] that may be influenced by public health interventions that facilitate action and reduce barriers to uptake [20,21]. Behavioral nudges may improve compliance with the use of primary health care services [22], including influenza vaccination uptake among older adults [23]. However, the effectiveness of nudging varies substantially by mode, content, and population [24]. Nudging by reminding older adults to vaccinate against influenza has proven effective in increasing coverage but with far higher effectiveness for reminders sent by ordinary mail [25] than by a governmental electronic letter system [26]. SMS text message nudging may improve childhood vaccination [27], COVID-19 vaccination among health system employees [28], and influenza vaccination among patients due for a routine primary care visit [29]. However, a recent systematic review of randomized control trials (RCTs) on text messaging for improving vaccine uptake shows that very few trials have addressed influenza vaccination among older adults [30].

Norway's influenza vaccination program recommends vaccination to people aged 65 years or older, as well as to other risk groups and health care personnel. Each municipality organizes local vaccination of risk groups. Vaccination is typically available at general practitioner's offices, health clinics, and pharmacies, and is currently offered at an out-of-pocket cost ranging from NOK 150 to 500 (US $14 to $47). In general, vaccination at general practitioners requires the vaccinee to schedule an appointment, while vaccination at pharmacies can be drop-in or scheduled. There is no individual invitation, reminder, or scheduling for vaccination organized by the influenza vaccination program. COVID-19 vaccination is also recommended to the same age group at the same time of year. The same vaccination conditions apply to all residents of Norway, regardless of their citizenship or legal residency status.

InfluSMS is designed as a pragmatic, multiarmed, superiority RCT embedded in the Norwegian influenza vaccination program. In this trial, we aim to determine if sending a smartphone SMS nudge to be vaccinated against influenza can improve vaccination coverage in the general population aged 65 years or older in Norway, and further, to determine the impacts on vaccination coverage associated with providing an SMS nudge in the official language of the native countries of immigrants born in Poland or Ukraine. The Norwegian setting is well suited to conduct an RCT on SMS nudging among older adults, including in selected immigrant groups because there are nationwide administrative and health registries that can be used for this purpose.

An RCT on SMS nudging for influenza vaccination among older adults is warranted because the coverage is insufficient and because evidence on the effectiveness of this intervention is lacking [23,30]. Moreover, most older adults in Norway have a smartphone, thus an SMS intervention is likely to reach most of the eligible population. It is also a relatively nonintrusive and inexpensive intervention that is highly scalable, which thus could function as part of a national influenza vaccination program.

On average the influenza vaccination coverage among older individuals in Norway is 64%. However, the coverage among

some immigrant groups is much lower. Immigrants born in Poland and Ukraine have especially low coverage rates with only 19% and 3% vaccinated in the 2023-2024 influenza season, respectively (Table 1). Poles and Ukrainians are the 2 largest immigrant groups in Norway. As of March 2024, there were 110,000 and 66,000 immigrants from Poland or Ukraine, respectively, accounting for 2.0% and 1.2%, of the entire Norwegian population. Even though the age profile of immigrants from Poland and Ukraine is younger than for some other country backgrounds, they still account for many older adult individuals (Table 1), and this demography is likely to increase in the coming years. Furthermore, Poles and Ukrainians are relatively recent immigrants and may as such have a limited proficiency in Norwegian. If this language barrier hinders their uptake of services, it could potentially be reduced by providing nudges in the official language of their native country.

Table 1. Nationwide coverage[a] of influenza and COVID-19 vaccine among individuals aged 65 years or older[b] during the 2023-2024 influenza season in Norway, stratified by country background[c].

	Total population	Influenza vaccine[d], n (%)	COVID-19 vaccine[e], n (%)
All	1,020,728	656,990 (64.4)	555,745 (54.4)
Born in Norway	941,657	623,598 (66.2)	530,923 (56.4)
Born in Sweden	7129	4520 (63.4)	3976 (55.8)
Born in Denmark	5966	3820 (64.0)	3372 (56.5)
Born in United Kingdom	4606	2888 (62.7)	2594 (56.3)
Born in Germany	3991	2000 (50.1)	1783 (44.7)
Born in Poland	3888	740 (19.0)	520 (13.4)
Born in Ukraine	3843	119 (3.1)	72 (1.9)

[a]Norwegian Immunisation Registry SYSVAK [31] data, extracted May 31, 2024.

[b]Age on December 31, 2023 (born 1958 or earlier).

[c]The most common country backgrounds among individuals aged 65 years or older.

[d]Received at least 1 dose of influenza vaccine between September 1, 2023, and May 29, 2024.

[e]Received at least 1 dose of COVID-19 vaccine between September 1, 2023, and May 29, 2024.

Poles and Ukrainians in Norway also had a very low uptake of the COVID-19 vaccine, both during [32] and after (Table 1) the pandemic, showing that low uptake of adult vaccines in these populations is not limited to influenza vaccination. Thus, interventions that may overcome vaccine hesitancy, which is prominent in Ukraine and Poland [15,16], as well as potential access barriers such as language, are likely to have a general relevance for vaccine uptake.

A recent systematic review highlighted language and tailored text message nudges for improving vaccine uptake as understudied [30]. We are not aware of any studies that have investigated the effectiveness of SMS nudging for influenza vaccination in several languages among immigrant populations.

Objectives

The primary objectives of the InfluSMS trial are to establish whether (1) influenza vaccination nudging by SMS in the Norwegian language increases influenza vaccine coverage compared to standard care, among the Norwegian population aged 65 years and older; (2) influenza vaccination nudging by SMS in Polish or Ukrainian language increases influenza vaccine coverage compared to standard care, among older adults of Polish or Ukrainian background, respectively; (3) influenza vaccination nudging by SMS in Norwegian language increases influenza vaccine coverage compared to standard care, among older adults of Polish or Ukrainian background, respectively; and (4) influenza vaccination nudging by SMS in Polish or Ukrainian language increases influenza vaccine coverage more than nudging by SMS in Norwegian language among older adults of Polish or Ukrainian background, respectively.

For primary objectives 1-3, we hypothesize that SMS nudging will increase coverage. If this hypothesis is not confirmed, the interventions investigated here are futile from a public health perspective, and the remaining study objectives will not be investigated. For primary objective 4, we hypothesize that an SMS in the official language of the native country of each immigrant population will be more effective in increasing coverage than an SMS in Norwegian.

The secondary objectives are to establish whether (1) the effect of SMS nudging in the Norwegian language differs by country background; (2) the effect of SMS nudging in the official language of their native country differs between older adults of Polish or Ukrainian background; (3) SMS nudging for influenza vaccination is cost-effective compared to standard care; (4) SMS nudging for influenza vaccination influences coverage of COVID-19 vaccination; and (5) the time to vaccination differs by the comparisons described in the primary objectives.

Secondary objectives 1-4 are exploratory and have no hypotheses. For secondary objective 5, we hypothesize that SMS nudging will shorten the time elapsed to vaccination.

Methods

Participants

Overview

All Norwegian residents have a unique personal identification number, which is used in health and administrative national registries and can be used to merge data across different registries. In this study, we identify all eligible individuals based on information available from the National Population Register and the Norwegian Immunisation Registry SYSVAK.

The trial has 3 separate populations of individuals who are aged 65 years or older and who reside in Norway, namely (1) the entire Norwegian population (except immigrants born in Poland or Ukraine); (2) immigrants born in Poland; and (3) immigrants born in Ukraine.

Inclusion Criteria

- Aged 65 years and older (age at the end of 2025, ie, born in 1960 or earlier).
- Resident in Norway and have a valid ID number on September 1, 2025.
- Have a smartphone number in the common contact register.

Exclusion Criteria

- Have received the 2025 influenza vaccine prior to the SMS nudge dispatch date.
- Have emigrated or died before SMS nudge dispatch date.

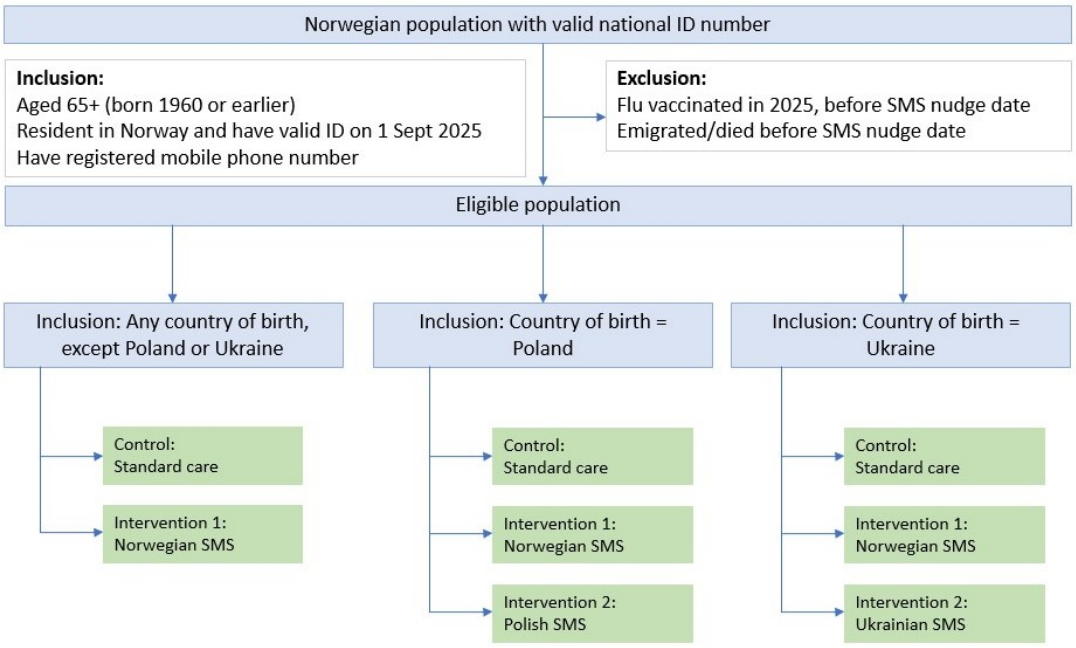
Interventions

Participants in the intervention arms receive an SMS reminder for influenza vaccination in Norwegian, Polish, or Ukrainian. Participants in the control arm do not receive an SMS reminder for influenza vaccination, which is “standard care” in Norway. A description and overview of the InfluSMS study arms and participant flow are shown in Table 2 and Figure 1.

Table 2. InfluSMS study arms.

Study arm	Description	Population
Control	Standard care: Individuals do not receive an SMS reminder for influenza vaccination.	• General population • Immigrants born in Poland • Immigrants born in Ukraine
Intervention 1	Norwegian nudge: Individuals receive an SMS in Norwegian language at the start of the influenza season; to remind them they are recommended to get the influenza vaccine	• General population • Immigrants born in Poland • Immigrants born in Ukraine
Intervention 2	Polish or Ukrainian nudge: Individuals receive an SMS in the official language of their native country (ie, Polish or Ukrainian) at the start of the influenza season, to remind them they are recommended to get the influenza vaccine	• Immigrants born in Poland • Immigrants born in Ukraine

Figure 1. InfluSMS participant flowchart.



Outcomes

The primary outcome measure is having been vaccinated against influenza during the 3 months following the SMS dispatch date in the 2025-2026 influenza season (yes or no, for each individual), as registered in the Norwegian Immunisation Registry SYSVAK [31]. Notification of influenza vaccination to SYSVAK is obligatory for vaccine administrators and does not require patient consent. Follow-up during this trial is passive and does not require any effort from the participants.

Effects will be assessed by influenza vaccination coverage, that is, percent uptake, which will be compared between strategies. SMS nudging will take place at the earliest timepoint at which vaccines for the upcoming influenza season become widely available across the country, which usually is around week 42. All SMS nudges will be dispatched within 1 week. Each individual will be followed up through SYSVAK for 3 months after their SMS dispatch date. We end follow-up at 3 months because we expect that the potential effect of an SMS nudge will be exhausted by then, and because most vaccinations in the influenza vaccination program will have occurred by the end of this period.

Time to influenza vaccination, that is, the number of days elapsed between the SMS dispatch date and the influenza vaccination date (as registered in SYSVAK), is a secondary outcome measure.

We will also address coverage of COVID-19 vaccination as an outcome in the exploratory analyses.

Sample Size

Primary Objective 1: General Population in Norway

We will identify all individuals in the National Population Register that fulfill the eligibility criteria, and among those, make a random selection to receive the Norwegian nudge (intervention 1). We power for a 1% point minimal detectable increase in uptake in the SMS arm compared to the control arm in the general population because the intervention is relatively inexpensive and might be cost-effective even with low effectiveness on coverage. To achieve this minimal detectable increase with a baseline uptake rate of 60%, a power of 0.8, and a 1-sided α of .05, we need to randomize 18,788 individuals to intervention 1. However, based on available statistics, some 20% of individuals may have received the influenza vaccine before the scheduled trial start date and will be excluded from the trial after randomization. We thus need to randomly sample at least 23,485 individuals aged 65 years or older from the entire Norwegian population (except those born in Poland or Ukraine) to be allocated to intervention 1 to be able to detect an increase of 1 percentage point (23,485×80/100=18,788). The control group will be the rest of the Norwegian population that fulfills the eligibility criteria. Currently, there are circa 1.1 million persons aged 65 years or older who reside in Norway. We use this large group as a control because it gives the study high power, the inclusion of individuals receiving standard care carries no cost, and it will provide real-world data on the entire older adult population in Norway.

Primary Objectives 2-4: Immigrants Born in Poland or Ukraine

To maximize power among individuals born in Poland or Ukraine, we will include all eligible individuals and randomly assign them 1:1:1 to each of the 3 study arms. The number we will be able to include in the trial will most likely be higher in 2025 than in 2023 (Table 1) due to the age structure in these immigrant populations and due to new migration. Based on current national demographic statistics, we anticipate there will be some 6000 individuals aged 65 years or older from each immigrant group at the start of the trial. However, some 10% may be excluded due to not having a registered phone number, and a further 1% and 6% (Table 1) may be excluded due to influenza vaccination before the scheduled SMS dispatch date among the Ukrainian and Polish immigrant populations, respectively. Thus, we expect to be able to randomize 5346 Ukrainian immigrants, giving 1782 individuals in each study arm. With a baseline uptake rate of 3% (Table 1), a power of 0.8, and a 1-sided α of .05, this gives a minimal detectable coverage increase of 2 percentage points, adjusted for 3 pairwise comparisons. Similarly, we expect to be able to randomize 5076 Polish immigrants, giving 1692 individuals in each study arm. With a baseline uptake rate of 19% (Table 1), a power of 0.8, and a 1-sided α of .05, this gives a minimal detectable coverage increase of 4% points, adjusted for 3 pairwise comparisons.

In conclusion, the minimal detectable coverage increases of this trial fall within the range of effect sizes reported for other modes of nudging investigated in neighboring countries that share a similar influenza vaccination policy. Specifically, a recent study from Denmark reported that nudging by electronic letters increased coverage by approximately 1% points [26], while a recent study from Finland reported that nudging by ordinary mail on average increased coverage by approximately 6% points [25].

Stratified Analyses

We will also perform analyses stratified by sex, broad categories of age, years of residency in Norway, and household composition. These analyses will have lower power to detect the differences indicated earlier because the sample size in each stratum will be lower than for the overall population.

Recruitment

The study uses data from all residents in Norway who meet the eligibility criteria. The data is retrieved from complete nationwide registries that contain routinely collected information. Therefore, recruitment and follow-up are entirely registry-based and do not require any action by the participants.

Assignment of Interventions

Assignment of treatment arm (control, intervention 1, and intervention 2) will be randomized, automated, and concealed. The identities of the participants will not be decipherable by the data managers.

We will use an external service provider to identify the eligible study population, perform the random selection and randomization procedures, and dispatch the SMS. The provider will be selected through a tendering process. All data

management by the service provider will be done in close collaboration with and under the supervision of the project group. Data management, random selection, and randomization procedures will be performed with reproducible code that includes documented and adequate software functions, preferentially in R programming (R Foundation for Statistical Computing). For the Norwegian population, individuals in intervention arm 1 will be randomly selected from the whole eligible population, while the remainder of the eligible population will serve as the control arm. Similarly, we will use complete random assignment to treatment arm for the Polish and Ukrainian populations. Examples of R functions that serve these purposes are sample_n (from the *dplyr* package) and complete_ra (from the *randomizr* package). Random selection and randomization procedures will be performed after the assessment of the exclusion criteria. The project group will inspect the randomization code before dispatching the SMS.

Blinding

The outcome measure of the trial is based solely on routinely collected data and those reporting or registering this information will not be aware of whether a vaccinated individual has received an SMS nudge. Thus, the trial is blinded to the outcomes assessor. Moreover, treatment allocation is randomized and computer-generated, there is no interaction between the InfluSMS project team and study participants, and the InfluSMS researchers work with deidentified data and do not know the identity of any participant in the dataset. Due to the inherent characteristics of the intervention, treatment allocation cannot be blinded for participants.

Data Collection

The external service provider will be asked to prepare a key file that includes all individuals born in 1960 or earlier in the Norwegian population, with associated individual information including the individual national ID number, the household ID, a randomly generated study ID unique for each individual, and categorical variables indicating treatment arm and exclusion status. This key file will be shared with the National Population Register and SYSVAK. All registries involved will merge requested variables from their registry to this file by the national ID number, and forward the resulting file, excluding the national ID number, to the InfluSMS team. Using the study ID, InfluSMS researchers will then merge the deidentified files from the registries. The key linking the national ID numbers and the study ID numbers will be kept by the service provider and will never be accessible to the InfluSMS team. The procedure is illustrated in Figure 2.

Table 3 lists the variables that will be used in the trial. Note that the national ID will only be used to generate the dataset.

Figure 2. InfluSMS data flow and deidentification of registry data.

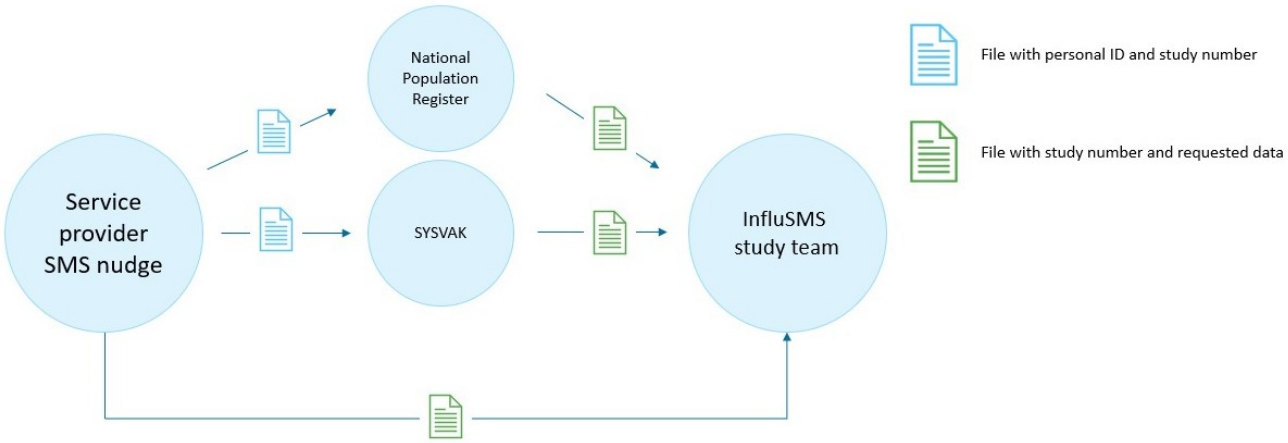


Table 3. List of variables collected or generated in the trial.

Variable	Reason for inclusion
National Population Register	
National ID	Used to identify eligible individuals and link to study ID. Not shared with InfluSMS project group
Household composition	Variable identifying whether eligible individuals live in the same household, to enable sensitivity analyses
Year of birth	Potential confounder (age)
Sex	Potential confounder
Vital status, with date	Exclusion of individuals who died or emigrated
Country of birth	Determine if born in Poland or Ukraine
Immigration date	Determine time living in Norway (potential confounder)
SYSVAK	
National ID	Used to identify eligible individuals and link to study ID. Not shared with InfluSMS project group
Date of vaccination	Determine if date of vaccine was before/after nudge, and impact of vaccination
Disease against which the vaccine protects: • Influenza • COVID-19	Determine who received each vaccine, to calculate vaccination coverages
External service provider	
National ID	Used to identify eligible individuals and link to study ID. Not shared with InfluSMS project group
Demography: • General population • Born in Poland • Born in Ukraine	Study populations
Randomized, and received intervention (SMS): • Yes • No	Identify control or intervention groups
Date SMS was sent	Start of intervention
SMS language: • Norwegian • Polish • Ukrainian	Type of intervention
Excluded from study: • No • Yes, with code for reason	Quantify exclusions
SMS sending errors: • Yes: error in sending • No: no known error	Quantify errors with intervention or infrastructure

Data Management

All data management and analyses will be scripted in R code so that each step can be reproduced and quality assured. Range and other logical data checks will be performed for quality assurance. Programming will be validated by several team members. Data and scripts will be used and stored in a high-security data zone that will be accessible only to team members via login.

Statistical Methods

All individuals randomized will be analyzed, except individuals who die or emigrate during follow-up, who will be excluded from the analyses. We expect exclusions to be evenly distributed between treatment arms due to the randomized design.

Additionally, we anticipate a low proportion of excluded individuals given the relatively short follow-up time of the trial. According to official statistics [33], we can expect approximately 2800 deaths and 100 emigrations per month among the nearly 1.1 million persons aged 65 years or older residing in Norway, which accounts for 0.3% of this population.

As recommended for binary RCT outcomes [34], coverage differences between treatment arms will be expressed on absolute and relative scales, that is, as percentage point differences and as relative risks, with associated 95% Wald CIs. The primary focus will be on absolute scale analyses because they may be most informative for public health decision-making. Absolute estimates will be derived from linear regressions [35], while relative estimates will be derived from generalized linear models with a log-binomial link function [36]. Overall interactions (specifically secondary objectives 1 and 2, where differences between treatment arms will be compared between country backgrounds) will be assessed by likelihood ratio tests and, if significant, further analyzed by the participation differences between factor levels of the variables that interact.

We will compare the time to vaccination (ie, the number of days elapsed between the SMS dispatch date and the influenza vaccination date) between trial arms by the Kaplan-Meier method and the log-rank test.

We assume the registry data for randomized individuals to be close to complete and thus will not impute missing values.

As sensitivity analyses, we will exclude households consisting of at least two or more people aged 65 or older. Comparing the results of these analyses with the main results will indicate whether there may be spillover effects of the SMS interventions within households. Moreover, it will exclude persons living in nursing homes, who may experience easier access and less autonomy regarding influenza vaccination. In exploratory analyses, we will also address the potential effects of SMS nudging for influenza vaccination on the coverage of COVID-19 vaccination. We will use the same statistical methods for these sensitivity and exploratory analyses as described for the main analyses.

We will develop a decision analytic model that can evaluate the potential cost-utility of each nudge compared to standard care and each other. The model will be based on coverage differences observed in the trial and will incorporate implications of increased coverage on the spread of influenza and its consequences for the use of health care resources. Data on reduced influenza from increased uptake will be based on effect estimates of vaccination from the best available scientific evidence. Costs associated with the intervention as well as with increased uptake of the vaccine will be recorded in detail during the project phase. Direct medical costs related to the downstream use of health care services will also be incorporated into the model. The cost-utility analysis will be based on Norwegian guidelines [37], conducted according to standard principles for health economic evaluation [38], and reported according to current guidelines [39].

Data Monitoring

The trial does not pose any harm to participants; thus, the project does not have a data monitoring committee or plans for auditing of trial conduct. Similarly, there will be no interim analyses before the end date of follow-up and no stopping guidelines for the trial.

Ethical Considerations

We have submitted the project for initial evaluation to the Regional Committees for Medical and Health Research Ethics, who recently determined that the project does not fall under the jurisdiction of the Health Research Act [40] (reference #787321). We will thus apply for exemption from the duty of confidentiality from the Health Directorate. The rationale for this decision was that the objective of the research is not to gain new knowledge on health and disease as such, with reference to paragraphs 2 and 4a of the Health Research Act. The application was considered by the REK sør-øst B committee.

This study cannot be performed based on informed consent. Exemption from the duty of confidentiality gives a permit to access and merge the personal registry data without obtaining informed consent. We have conducted several similar registry-based studies. It is our experience that exemption for the duty of confidentiality is granted for studies of this nature, that have large potential public health benefits and no direct consequence for participants [41-44]. The registries own their data and will grant the project data access based on the permits we supply in our data application (ie, exemption from the duty of confidentiality).

Smartphone numbers will be accessed through the Contact and Reservation Register, in which every Norwegian citizen who has logged into a Norwegian public service using an electronic ID is registered. Individuals can opt out of the register, and those who have done so will not receive an SMS as part of this study. About 95% of the adult Norwegian population is part of the Contact and Reservation Register. Opting out will not be considered in the analyses in this pragmatic trial because access to smartphone numbers would be through the same register if SMS reminders were part of the influenza vaccination program. We expect that the drop-out rate will be similar across treatment arms due to the randomized design.

We will submit the protocol and approvals together with a dedicated data protection impact assessment for assessment by the data protection officer at the National Institute of Public Health. The data protection officer oversees data processing in research projects to ensure it is in accordance with applicable data protection laws. The main principles regarding data protection and confidentiality in the project are described in the Data Collection and Data Management sections.

In case of protocol amendments, all stakeholders that have granted approvals to the project, as well as Clinicaltrials.gov, will be notified. None of the project members have any financial or other conflicting interests to declare.

Data access is contingent on the specific permits described above. Thus, data are only accessible to project members. To advise the project, users of Polish, Ukrainian, and Norwegian

origin will be part of the project group. We will also have focus groups with users from each nationality to help formulate acceptable and adequate SMS nudges.

Dissemination

We plan to publish the protocol and the findings of the trial in international peer-reviewed scientific journals. Authorship will be granted according to the Vancouver Convention. Professional writers will not be used.

The findings will also be presented at national and international conferences. To inform the public, we will publish information about the trial on a project web page. Information aimed at the public will mainly be in Norwegian. Further, we will present the project to various stakeholder groups, notably the main user groups of the study (organizations for older adults and immigrant groups) and public health organizations.

Results

As of July 3, 2024, the project has received funding for protocol development from Foundation Dam (grant SDAM_FOR-558766) and we are in the process of obtaining permits, agreements, and access to the infrastructure needed to conduct the trial. Inclusion of participants will start in the third quarter of 2025 and the outcome registry data will be available in the first quarter of 2026. We plan to publish the results during the fourth quarter of 2026.

The results will be reported according to the Consolidated Standards of Reporting Trials (CONSORT) statement on eHealth [45,46]. We will present the baseline characteristics of the 3 study populations, and describe the coverage by treatment arm and population, for strata of age, sex, and duration of residency. We will present the absolute and relative coverage differences between the treatment arms as described in objectives 1-4. In addition, we present comparisons of effect sizes between populations as described in secondary objectives 1 and 2, on absolute and relative scales. The primary focus will be on absolute scale analyses for the coverage analyses (primary outcome measure). We also compare the time to vaccination between treatment arms (the secondary outcome measure). All effects are presented with 95% CIs. We also present the likelihood ratio test *P* value for interaction terms. Table shells for the analyses described earlier can be found in Multimedia Appendix 1. The main findings may also be illustrated in the figures.

Discussion

This pragmatic RCT will provide insights into the effectiveness of SMS reminders in improving influenza vaccination coverage among older adults, which was specifically mentioned as a knowledge gap in a recent review on this topic [23]. The trial will estimate the effectiveness in the older adult population in Norway at large, and among older adult immigrants from Poland or Ukraine, which are large immigrant populations that have a particularly low influenza vaccination coverage in Norway. For the immigrant populations, the trial will also address whether the language of their adopted country may represent a barrier to influenza vaccination uptake that can be reduced by SMS nudging in the official language of their native country. If SMS nudging is effective, it is a strategy that may be feasible for implementation in a nationwide influenza vaccination program because it is scalable, inexpensive, and non-intrusive. Since influenza vaccination protects against influenza and its sequelae, a higher influenza vaccination coverage will benefit society through lower health care costs, as well as the individuals who get vaccinated through direct protection against influenza.

Strengths of this trial include the use of data on nearly all individuals aged 65 years or older residing in Norway, whose health and administrative data are captured in nationwide registries without any loss to follow-up. This eliminates selection and response biases associated with surveys, ensures high quality of the main outcome measure of the trial, that is, influenza vaccination coverage, and yields results that are valid at the national level. Further characteristics that contribute to the high internal validity of this study include the randomized design, no experimenter bias, and standardized procedures for all participants. This trial also has high external validity since it is conducted in real life and will thus yield data that will be entirely representative of how these interventions would work should they become part of an adult vaccination program. Moreover, the results are likely to be of relevance internationally, both as a proof of concept of whether SMS interventions might be effective in increasing adult vaccination coverage and more directly for the immigrant groups addressed here, which likely experience similarly low coverage, for similar reasons, in other adopted countries. The trial will also establish the feasibility of implementing an SMS nudging intervention using the infrastructure available in Norway, for instance in terms of timely access to the necessary health and administrative registry data. Novelty is another strength of the study since we are not aware of other trials with similar interventions and objectives. The trial will also be informed by users, which may enhance its relevance to the populations targeted by the interventions.

The trial also has several limitations, most of which relate to the number of Polish and Ukrainian immigrants we will be able to randomize. First, the number of persons in the immigrant groups who are aged 65 years or older in the 2025-2026 influenza season is a moving target that will be influenced by the influx and outflux of people by that time, as well as the exact underlying age distribution of these immigrant populations. Second, our estimates of the fraction of people missing a registered smartphone number are based on statistics for the whole Norwegian population, and we do not know whether this fraction may be different for the Polish and Ukrainian sub-populations. Third, the minimum detectable effect size for the Polish and Ukrainian populations is approximately 4% and 2% points, respectively. This may be a limitation because even smaller effect sizes might be of public health interest for an inexpensive intervention. Finally, even though we will initiate the trial at the very start of the influenza season, some people will already have been vaccinated by this point, and they will be excluded from participation in the trial. The number of excluded individuals will depend on national vaccine distribution logistics and the epidemiology of influenza in the trial season, which are beyond our control.

The current influenza vaccination program lacks an individual cue to action, which could potentially be more effective than a general recommendation that lacks personalization or direct communication. Sending SMS nudges for influenza vaccination is one way to make individual contact that is likely to reach a very large proportion of the eligible population. If sending SMS reminders is effective, even small effect sizes may benefit public health and be cost-effective. Furthermore, nudges tailored to immigrant groups that have very low uptake of influenza vaccine may reduce inequalities in the use of this preventive health care service and, thus, in health. Insights from the interventions investigated in the current trial can extend to other vaccination contexts and be of international relevance.

Acknowledgments

The authors wish to thank Suzanne Campbell from the National Immunisation Registry SYSVAK for providing background coverage estimates, and Folkehelseforeningen for administrative support and endorsement for project funding. The project was funded by Foundation Dam (grant SDAM_FOR-558766). The funder did not have any role or authority in the study design; collection, management, analysis, and interpretation of data; writing of the report; or decision to submit the report for publication.

Data Availability

The datasets generated in this study are not publicly available because the participants have not consented to it. The data are available from the corresponding author upon reasonable request with permission from the relevant Norwegian authorities.

Authors' Contributions

BTH, LEØ, and HM conceived the study. BTH acquired funding for the study and is the principal investigator. BTH and HM wrote the original draft of the manuscript. All authors contributed to the development of the methodology of the study, critically reviewed manuscript drafts, and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Mood and anxiety disorders are prevalent mental health diagnoses. Numerous studies have shown that measurement-based care, which is used to monitor patient symptoms, functioning, and treatment progress and help guide clinical decisions and collaboration on treatment goals, can improve outcomes in patients with these disorders. Including digital information regarding patients' electronic communications and social media activity is an innovative approach to augmenting measurement-based care. Recent data indicate interest and willingness from both mental health clinicians and patients to share this type of digital information in treatment sessions. However, the clinical benefit of systematically doing this has been minimally evaluated.

Objective: This study aims to develop an electronic dashboard for tracking patients' digital social activity and a protocol for a pragmatic randomized trial to test the feasibility and efficacy of using the dashboard in real-world clinical care of patients with depression or anxiety disorders.

Methods: We developed a personalized electronic dashboard that tracks patients' electronic communications and social media activity, visualizes data on these interactions through key graphics and figures, and provides a tool that can be readily integrated into routine clinical care for use by clinicians and patients during treatment sessions. We then designed a randomized trial to evaluate the feasibility and effectiveness of using the electronic dashboard in real-world care compared to treatment as usual. The trial included patients aged ≥12 years with a mood or anxiety disorder who were receiving treatment in outpatient psychiatry clinics in the Johns Hopkins Health System and the Kennedy Krieger Institute. The primary outcome includes changes in patient-rated depression symptoms. Secondary outcomes include changes in patient-rated anxiety symptoms and overall functioning. Exploratory analyses examine the impact of the intervention on measures of therapeutic alliance and the detection of clinically actionable targets.

Results: We successfully developed an electronic dashboard for tracking patients' electronic communications and social media activity, and we implemented a protocol for evaluating the feasibility and efficacy of using the dashboard in routine care for mood

or anxiety disorders. The protocol was approved by the Johns Hopkins University School of Medicine Institutional Review Board. In this study, we report the technological, ethical, and pragmatic considerations in developing the dashboard and testing it in a real-world setting.

Conclusions: The integration of an electronic dashboard to monitor digital social activity in mental health care treatment is novel. This study examines the feasibility and effectiveness of the dashboard and the challenges in implementing this protocol. The lessons learned from developing and implementing the study will inform ongoing discussions about the value of gathering collateral information on patients' digital social activity and how to do so in a way that is acceptable and clinically effective.

Introduction

Background

Mood and anxiety disorders are among the most common mental health disorders in the United States, and they are associated with significant morbidity, mortality, and overall impairment in functioning [1]. These disorders are prevalent across the lifetime, with an onset often in adolescence, and evidence suggests that their rates are increasing in this age group in the United States [2]. A tragic outcome of depression and anxiety is suicide, which has increased by 30% since 2000 and is a leading cause of death in individuals aged between 10 and 34 years [3].

There are treatments for mood and anxiety disorders, but these are not always effective. In a meta-analysis of 38 studies of patients with depression and anxiety receiving outpatient mental health therapy, >40% did not show a reliable change in symptom improvement [4]. Barriers to effective treatment include patient adherence to the treatment model, session attendance, and the alignment between patients' needs and clinicians' therapeutic modalities [5]. There is clearly an urgent need to provide improved mental health care and develop new approaches to treat patients with mood and anxiety disorders.

Measurement-based care (MBC) is a promising but underused approach to providing more effective care for patients with mood and anxiety disorders [6]. MBC refers to the systematic use of measurement tools to monitor patient symptoms, functioning, and treatment effects in care to guide clinical decision-making and promote collaborative treatment planning [7]. A wealth of evidence shows that, when properly implemented, MBC can significantly improve patient outcomes; however, clinicians have been slow to adopt MBC in routine practice [8]. MBC traditionally entails the regular collection of patient-rated or, less frequently, clinician-rated outcome measures during treatment. A significant barrier to adopting MBC is the burden on both patients and clinicians to collect the outcome measures during busy clinical encounters [7]. The emergence of digital technologies, such as smartphones and wearables, has the potential to dramatically broaden the scope of MBC by offering new sources of collateral information that can be more readily leveraged to achieve the goals of MBC [9]. Digital information from these devices can provide valuable insights into a patient's course of illness in real time beyond the point of care [10], and the information can be "passively" collected, which reduces the burden on patients and providers and facilitates downstream use as part of a more expansive approach to MBC [9].

A variety of information relevant to mental health can be gleaned from digital devices [9]. A particularly rich source of digital information is available from social media [10] and other forms of electronic communication, such as SMS text messages [11], collectively referred to as digital social activity in this study. Our social activity is crucial in shaping our mental health, and electronic communication and social media platforms have transformed the way people communicate and interact with one another daily. Indeed, they are typically the predominant form of communication, especially among adolescents and young adults [12,13].

A growing body of research has examined the potential for obtaining useful clinical insights into mental health from digital social activity. Multiple studies have shown that quantifiable signals derived from the language used and activity on different social media platforms are associated with and can be used to develop computational models that distinguish individuals with depression [14-17], postpartum depression [17], schizophrenia [18-20], posttraumatic stress disorder [21], and other serious mental illnesses [22,23]. Other studies have developed models that can predict clinically salient changes in the trajectories of mental illness, such as relapse leading to hospitalization in patients with psychotic disorders [22], the emergence of suicidal ideation or attempts [24,25], the occurrence of binge drinking [26], and clinical responses to antidepressant treatments [27]. Many earlier studies were limited by a reliance on self-report or inferences drawn from data available on social media platforms to establish "ground truth" about mental health end points. In addition, these studies typically analyzed data from only 1 social media platform, while individuals regularly engage with multiple platforms [28]. More recent studies have validated models using clinically documented samples with data from electronic health records [16,20], and another recent study specifically addressed the challenges of developing generalizable models based on diverse social media data sources [29].

Together, these studies suggest that it is possible to reliably monitor digital social activity for actionable collateral information, sparking interest in using such information to improve clinical care for patients with mental illnesses.

Several recent surveys have found that clinicians ask about their patients' electronic communications and social media activity [30-32], and they believe that using this information is helpful in providing more effective treatment [32]. Both clinicians and patients have reported that they are comfortable with using and discussing social media and digital data in mental health therapy [31,33,34]. However, one study found that adult patients were less willing to share more personal data, such as their location or private communications, compared to less personal data, such as screen state (ie, phone screen on or off) and motion data [34]. Another study found that therapists were concerned about whether patients' online posts would accurately reflect their mood, while patients did not want their use of social media and content to be the sole focus of their therapy sessions [31]. In a different study, adolescent patients at risk of suicide, whose social media activity was being monitored by their therapists, expressed concern about the balance between privacy and safety, with some reporting that they may be less likely to seek peer online support [35].

Despite the promise, it remains unclear whether systematic monitoring of digital social activity in routine care of patients with mood or anxiety disorders is acceptable and feasible. Moreover, it has not been shown whether doing so is effective in improving patient outcomes. One group has reported on the design and development of an electronic dashboard for displaying the results of computational analyses of patients' digital social activity that can be used by clinicians and patients [36,37]; however, the use of this dashboard has not been formally tested in clinical practice. Another group has taken a simpler approach to incorporating collateral information from patients' digital social activity and tested this approach in an unblinded randomized trial [38]. They found that integrating insights about patients' social media use in clinical care is feasible; however, there was no significant difference in mental health outcomes between the intervention and treatment as usual (TAU) arms [38]. More research is needed to better understand the appropriate role of systematically monitoring digital social activity in routine clinical care of patients with mental illness.

Objectives

This study was initiated to address the aforementioned need. In this study, we report on the development of an electronic dashboard for tracking patients' digital social activity and a protocol for a pragmatic randomized trial to test the feasibility and efficacy of using the dashboard in real-world clinical care of patients with depression or anxiety disorders. We describe our guiding conceptual model and the decisions we made in designing the dashboard and protocol to test the dashboard, and we discuss the challenges we confronted and the solutions we implemented to launch the trial. The systematic monitoring of patients' digital social activity in clinical care is not only novel and promising but also presents several important challenges. This study informs discussions about translating the promise into clinical reality and sets the stage for reporting trial results in a subsequent paper, which will ultimately contribute to the evidence base on whether monitoring digital social activity in clinical care is warranted.

Methods

Conceptual Model

The conceptual model that guided our development and testing of a digital social media intervention in patients with depression or anxiety is shown in Figure 1.

It is grounded in the principles of MBC. We have an expansive view of MBC, which posits that systematically monitoring multiple sources of collateral information, in addition to patient- and clinician-rated outcomes measures, throughout the course of treatment can significantly improve clinical outcomes. In this case, the intervention is designed to gather collateral information about the patient's digital social activity, which growing evidence suggests can provide important real-time insights into the patient's mental health status. We hypothesize that such an intervention may improve downstream clinical outcomes through 2 mediating pathways. In the first pathway, routinely gathering collateral information on the patient's digital social activity may lead to better detection of clinically actionable targets. Clinically actionable targets may include the early detection of signals that the patient's course of illness is starting to worsen or of interpersonal struggles that may precipitate declines in the course of illness. Earlier detection of these clinically actionable targets can lead to more rapid treatment adjustments to address emerging issues before they become more intractable problems. The treatment adjustments may involve a wide variety of interventions, including changes in medication; frequency and duration of clinical visits; the focus of psychotherapy; and outreach to parents, the school, or other responsible parties in the patient's social support network. In the second pathway, the digital social media intervention may improve the therapeutic alliance by fostering more informed and open communication between the patient and clinician, and a substantial body of evidence indicates that a strong therapeutic alliance is crucial to the success of psychiatric treatment [39]. The conceptual model hypothesizes that through these 2 mediating pathways, the intervention may improve more proximal clinical outcomes on clinical symptomatology, which, in turn, leads to improvements in more distal outcomes, such as overall functioning. It is possible that routinely collecting information about the patient's digital social activity may lead to the false positive detection of clinically actionable targets, leading to unnecessary and perhaps harmful changes in treatment. Another possibility is that data collection may disrupt the therapeutic alliance between the patient and clinician by raising concerns over privacy and engendering distrust, which together could ultimately lead to worse clinical outcomes. These are empirical questions about the impact of the proposed intervention that need to be tested and are the focus of our randomized pragmatic trial.

Electronic Dashboard

Overview

We developed an electronic dashboard to present information about our patient participants' digital social activity for review by their treating clinician in collaboration with the participants during routine clinical encounters. The creation of each personalized dashboard involves 4 steps. First, data from different social media and electronic communication platforms used by the participants, which they have identified for release, were collected using a commercially available app called Bark. Second, the gathered data were transferred to and processed at Johns Hopkins University. Third, the data were analyzed and translated into a set of key graphs and figures that can be rendered in an electronic dashboard format. Fourth, a patient-specific dashboard was delivered to the treating clinician. For each of these components, we implemented steps to ensure the privacy and security of the data as they were gathered and processed, which are detailed in the Data Collection and Data Processing sections.

Data Collection

Data from the patient participants' digital social activity were collected using Bark [40]. Bark is a commercially available app that is designed for use by parents or caregivers to monitor and manage their children's online activity by scanning >30 social apps, web browsers, emails, and SMS text messages. It provides alerts based on algorithms trained to detect online threats, such as cyberbullying, and offers personalized insights and recommendations regarding how to address these alerts. The app works with both iOS and Android mobile devices, but differences exist in how the app accesses certain communication platforms. Apple has stricter controls to prevent third-party apps' direct access to monitor iOS devices. Therefore, to access text messages on iOS devices, users install an app on a desktop computer, and text messages from the iOS device are "manually" transferred to the desktop via a cord connection and uploaded to Bark when the desktop is connected to the internet.

In partnership with Bark leadership, we modified the app for use in this research project by shutting down all features, including alerts, except those related to gathering data from participant activity on SMS text messages, email, and various social media platforms. As a result, the Bark app was used in our study as a data collection tool rather than an analytic tool. Textbox 1 shows the data types and platforms that are monitored by the app.

Textbox 1. Overview of data types and platforms monitored by Bark.

Data type and data sources

- Email: AOL, Comcast, Gmail, iCloud, Outlook, and Yahoo
- Search engine: Microsoft Edge (Android), Firefox (Android), Google Chrome (Android), and Safari (iOS)
- Social media: Instagram, Twitter, Snapchat, Facebook, Pinterest, Reddit, Tumblr, and TikTok
- Text messaging: GroupMe, SMS text messages (Android and iOS), iMessage (iOS), Gmail Chat, WhatsApp, Discord, and Kik
- Miscellaneous: Google Drive (documents and comment or reply), iCloud Notes (iOS), YouTube (comment), and OneNote

Data Processing

Bark executes queries to their internal database at regular intervals (approximately every 30 min) that identify newly captured digital traces from all active participants in the study. These queries generated JSON-formatted data files, which were then automatically uploaded to a password-protected access point on Amazon Web Services Simple Storage Service (AWS S3). Data files were transferred through an encrypted https or transport layer security connection from AWS S3 to a remote network drive hosted at Johns Hopkins University using a scheduled job that executes hourly on a remote server. Microsoft Active Directory was used to restrict network drive access to a subset of study team members on a need-to-have basis. The study team did not provide Bark with any information about patient participants except for the unique signup codes. Data collected by Bark were not shared with guardians in the case of minor participants.

Bark does not apply any exclusion criteria to preemptively filter data uploaded to AWS S3. Instead, the study team used an intermediate processing stage to discard data that lacked natural language text, were unlikely to contain clinically relevant information (eg, promotional emails), or were of a nature that would be likely deemed too invasive by study participants. Images, videos, geolocation tags, and internet use (not including search engine queries) fell into the latter group. Text from the remaining data was passed through a toolkit, which replaced personally identifiable information (ie, phone numbers, social security numbers, zip codes, email addresses, and names) with grammatically appropriate synthetic alternatives [41].

Dashboard Generation

The research team developed several algorithms to analyze the electronic communication data (ie, messages) gathered via the Bark app and, in turn, created a patient participant–specific dashboard that highlighted patterns of patient electronic communication use relevant to their mental health. The choice of the information displayed on the dashboard was primarily based on previous empirical observations recorded in the literature regarding relationships among digital activity, language use, and mental health status (ie, anxiety and depression), and certain visual elements (ie, distribution of platforms used by the participant and the total number of messages sent) were included to contextualize the analyses. Some measures of use were included on the dashboard to facilitate clinician engagement with patient participants (eg, use by platform). Broadly, the type of information displayed to clinician participants about patient participants fell into the following 3 general categories: use statistics, content, and measures of content.

Use Statistics

The dashboard presented information regarding the frequency at which the patient participant had recently used electronic communication. To contextualize the information contained within the dashboard, digital cards located at the top of the dashboard indicated the number of messages a patient participant sent and received during the past week (with comparisons to a running weekly average), a list of platforms (eg, SMS text messages and Discord) used to send messages, and an indicator of the platform most frequently used to send messages [42,43]. To identify possible sleep disturbances or irregularities, a bar graph presented the daily distribution of messages sent during the daytime (6 AM to midnight) and late at night (midnight to 6 AM) over the past 7 days [44,45]. To provide an indication of social connectedness, a second bar graph displayed a weekly distribution of messages sent and received during the past 90 days [46]. A final bar graph displayed the weekly distribution of platforms used to send messages during the past 90 days, which was included primarily to engage participants and provide grounding to existing digital measurement tools (eg, iOS Screen Time).

Content

Language from messages sent by the patient participant during the past 7 days was displayed in multiple forms throughout the dashboard. First, to provide a general summary of the patient participant's communication patterns over the previous week, a word cloud displayed the 40 most frequently used words across all digital platforms, with the size of each word dependent on its use frequency. Second, to capture recent thoughts, interests, and personal challenges, search engine queries were semantically clustered using an external knowledge base derived from Wikipedia and then listed within a table [47,48]. To highlight specific psychologically relevant themes, all messages were processed by the Linguistic Inquiry and Word Count (version 2007) toolkit [49]. The most frequently used words for a set of predefined themes were identified as psychologically relevant in previous literature [16,50-54] and representative messages for those themes were displayed. These themes included the following: positive emotion, negative emotion, anxiety, anger, sadness, family, friendship, work, health, achievement, leisure, home, money, and death. Representative messages for each theme were those that contained the highest number of thematically relevant words. Importantly, as a privacy measure, representative messages were hidden behind a pop-up window until patient participants granted their clinician verbal

permission to view them. In all the aforementioned cases, common "stop words," such as articles and pronouns, were excluded from consideration.

Measures of Content

Several numeric measures were also extracted from the content described earlier and visualized in the dashboard. A bar graph showed the proportion of messages sent over the previous 7 days that contained each theme from the Linguistic Inquiry and Word Count toolkit. To facilitate temporal comparisons, a heat map displayed this same measure computed weekly over the previous 90 days. A second heat map displayed the proportion of messages, aggregated weekly over the previous 90 days, containing different forms of pronouns (eg, personal vs impersonal and first person vs third person). The inclusion of the pronoun measures was based on multiple previous studies identifying correlations between the use of certain pronoun forms and mental health status [55-57].

Dashboard Delivery

Electronic dashboards for each patient participant were updated nightly using an automated script and stored as HTML in a password-protected relational database. Code hosted on a web server behind the Johns Hopkins University firewall was used to retrieve and display dashboards to the clinicians treating patient participants. Multiple guardrails were in place to control access to patient participant dashboards by the treating clinicians. The clinicians were allotted permission in our study's Microsoft Active Directory group and connected to the Johns Hopkins University virtual private network to access the dashboard's landing page. Upon reaching the dashboard's landing page, treating clinicians were prompted to authenticate themselves using Johns Hopkins single sign-on (with 2-factor authentication). A cookie generated by the single sign-on authentication procedure was used throughout the dashboard to ensure that clinicians could only access dashboards for their own patient participants. The list of appropriate patient participants (including a participant ID and name) was shown to the clinician to facilitate navigation around the dashboard.

Data Privacy

We worked closely with our technology team to implement several solutions that helped preserve the privacy of the data collected through the Bark app. We developed a coding system for patients to log into the Bark app so that Bark would not have direct access to any personally identifying information about the patients who were under our care and participating in the study. In addition, we transferred and processed all the collected data to servers behind the Johns Hopkins University firewall that could only be accessed by approved study team members using Johns Hopkins University's standard 2-factor authentication procedures. To further protect the privacy of the data collected through the app, we implemented a pipeline that minimized manual review of the data to only what was necessary to process the data and use it clinically. In addition, we instructed clinicians to review the appropriate dashboards only when they met with their patients, and at that time they could address any potential concerns that emerged from the collected data. We informed patients that the collected data would not be monitored in real time, so they were aware of the procedures.

Randomized Trial

Overview

Motivated by our conceptual model, we hypothesized that providing clinicians with an electronic dashboard of their patients' digital social activity before routine clinical encounters would aid the dialogue and exchange of relevant collateral information during those encounters and thereby improve patient outcomes. The goal was to test this hypothesis in a randomized pragmatic trial comparing patients who received care augmented by the electronic dashboard versus patients who received TAU. The primary research questions to be addressed by the trial were as follows: (1) Is the use of the electronic dashboard in routine care feasible and acceptable to both patients and their clinicians? and (2) Does the use of the electronic dashboard in routine care improve outcomes for patients with depression or anxiety disorders? The outcomes to be examined are described subsequently.

Study Sample

The study was carried out in outpatient psychiatry clinics across the Johns Hopkins Medical Institution and the Kennedy Krieger Institute, which is affiliated with but separate from the Johns Hopkins Medical Institution. We focused on clinics that use a collaborative care model in which patients see a psychiatrist for medication-assisted care as well as a master's level therapist or doctoral-level psychologist for ongoing psychotherapy. Both clinicians and patients were recruited to participate in the study. We first recruited clinicians in the selected clinics to participate in the study and then sought to enroll patients on their case rolls. Patients aged ≥12 years with a mood or anxiety disorder receiving ongoing care were eligible. To be pragmatic and stay as close to the real world as possible, there were no exclusion criteria other than if the treating clinician determined the patient was not able to provide informed consent. In addition, all patients who met the inclusion criteria were eligible, regardless of their current mental health status and scores on patient or clinician rating scales.

Study Procedures

All patient participants downloaded the Bark app and went through the process of connecting their social media and electronic communication platforms to the app. To promote trust and participation in the study, we allowed patients to decide which platforms to connect to the Bark app. While patients retained final control of the decision, we explained to them that their most frequently used apps would provide the most relevant information. Patients were randomized within strata formed by treating clinicians in a 1:1 ratio with blocks of size 2 to either the dashboard intervention or TAU. The purpose of stratified randomization in blocks was to promote balance in the number of patient participants in the 2 treatment arms seen by each clinician, thereby reducing the impact of differences between treating clinicians on comparisons of patient outcomes between the 2 arms. For patients in the intervention arm, the electronic dashboard was delivered to the treating clinician before scheduled clinical visits. The clinician and patient

collaboratively decided when and how to use the dashboard in the session during each clinical encounter. For patients in the TAU arm, the clinician did not receive a clinical dashboard for review. After the initial visit to download the Bark app, there were no more study-specific research visits. To be pragmatic and stay as close to the real-world setting as possible, patients continued to be seen by their clinician as clinically indicated. The first regularly scheduled clinic visit with their clinician after the patient consented and downloaded the Bark app was considered the study's baseline visit. Patients were then followed through their clinical care for up to 6 months, and all study measures were completed during their regularly scheduled clinic visits.

Study Measures

Both the patient and clinician participants completed measures throughout the study follow-up. The measures were selected to address the primary research questions and (based on our conceptual model) to tap into potential mediating constructs. Table 1 provides the schedule of measures during the study follow-up.

Table 1. Schedule of participant measures.

[a]These measures were collected every 3 months, coinciding with the nearest regularly scheduled clinic visit.

[b]CSQ: Client Satisfaction Questionnaire.

[c]SF-36 MHC: 36-Item Short Form Health Survey Mental Health Component.

[d]WAI-SR: Working Alliance Inventory-Short Revised.

[e]SES: Session Experience Scale.

[f]PHQ-9: Patient Health Questionnaire-9.

[g]GAD-7: Generalized Anxiety Disorder-7.

[h]MFAS: Monitoring and Feedback Attitudes Scale.

[i]M-CICAS: McLean Collateral Information and Clinical Actionability Scale.

[j]EDMH: Electronic Data and Mental Health.

[k]WAI-SRT: Working Alliance Inventory-Short Revised-Therapist.

Patient Measures

To measure proximal outcomes on mental health symptoms, participants completed the Patient Health Questionnaire-9 (PHQ-9) [58] and Generalized Anxiety Disorder-7 (GAD-7) [59] at the baseline and every subsequent clinic visit during follow-up. The PHQ-9 is a 9-item measure of current depressive symptoms ranging from 0 to 27, with higher scores representing greater levels of depression. The GAD-7 is a 7-item measure of current anxiety symptoms that ranges from 0 to 21, with higher scores representing greater levels of anxiety. In addition, to measure more distal outcomes on overall mental health–related quality of life, participants completed the Short Form-36 Health Survey Mental Health Component (SF-36 MHC) at baseline and every 3 months, coinciding with their nearest regularly scheduled clinic visit. This 13-item mental

health component scoring ranges from 0 to 100, with higher scores indicating higher mental health–related quality of life [60]. We selected these measures as our primary (PHQ-9) and secondary (GAD-7 and SF-36 MHC) outcomes because they are brief, making them pragmatic to collect, and they are widely used with well-established psychometric properties for measuring important clinical outcomes that, based on the conceptual model we hypothesized, will improve with the proposed intervention.

To measure the overlapping constructs of therapeutic alliance and patient satisfaction, participants completed the Working Alliance Inventory-Short Revised (WAI-SR) and Client Satisfaction Questionnaire at baseline and every 3 months, coinciding with their nearest regularly scheduled clinic visit. The WAI-SR is a 12-item measure of the goal, task, and bond aspects of the therapeutic alliance, and each item ranges from 1 to 5, with higher scores indicating greater alliance [61]. The Client Satisfaction Questionnaire is an abbreviated 8-item measure of patient satisfaction with clinical therapy sessions, and each item ranges from 1 to 4, with higher scores reflecting greater satisfaction [62]. In addition, to further measure therapeutic alliance after every clinic visit, patients completed the Session Experience Scale. This is a 4-item scale that assesses key dimensions of effective therapeutic relationships [63]. Finally, at the end of the study follow-up, patients completed the patient questionnaire, which was a 4-item open-ended measure of the patient-clinician relationship that we developed to assess patient perception of the therapeutic relationship with their clinician and whether discussions about electronic communication had occurred and whether this was helpful.

Clinician Measures

At baseline, clinicians completed the Monitoring and Feedback Attitudes Scale. This is an 18-item measure of clinician attitudes toward treatment tracking and the usefulness of incorporating individualized progress measures. It is scored on a 5-point Likert scale, with higher scores indicating more positive attitudes [64]. To measure clinician perspectives on the therapeutic alliance, they completed the WAI-SR-Therapist at baseline and every 3 months, coinciding with the patient's nearest regularly scheduled clinic visit. This is a 10-item version of the WAI-SR, and each item is rated on a 0 to 5 scale, where higher scores represent a higher alliance [65]. In addition, at every clinic visit, clinicians completed the McLean Collateral Information and Clinical Actionability Scale (M-CICAS) and the Electronic Data and Mental Health (EDMH) Questionnaire. The M-CICAS [66] collects information on the collateral sources of information reviewed, clinical actions taken, and shared decisions made between a clinician and a patient in a clinical session. The EDMH Questionnaire is a 6-item assessment of electronic communication that was completed by clinicians after sessions with patients randomized to the dashboard arm. It includes three Likert-rated questions: (1) Did review of electronic communications affect topics discussed in sessions? (2) How helpful was the review of this information to patient care? and (3) How likely is the clinician to recommend reviewing electronic communication to other clinicians? The questionnaire also includes 3 open-ended questions to gather more context about responses to the first 3 questions. Finally, at the end of the study, clinicians completed the clinician questionnaire, which is a 2-item open-ended survey to measure the use of dashboard-prompted electronic communication in discussion and the usefulness of the dashboard on patient care. We developed the EDMH Questionnaire and clinician questionnaire, but these have not been validated. They were included to gather additional qualitative data on the experience of using the dashboard in clinical care for exploratory analyses.

Data Management

The PHQ-9 and GAD-7 were collected as part of an MBC program that has been implemented in our clinics. As part of this program, patients completed the PHQ-9 and GAD-7 before every clinic visit through the Epic electronic health record as part of routine care. All other measures were collected remotely at the scheduled times via text with a link to questionnaire forms developed in a REDCap (Research Electronic Data Capture; Vanderbilt University) database that is maintained by approved study team members at Johns Hopkins University. These data are to be joined and processed for downstream analyses after removing all patient identifiers except for dates of service.

Statistical Analysis

The primary outcome of the trial is the difference in depressive symptoms measured by the PHQ-9 total score over the course of follow-up between the dashboard intervention and TAU arms. Secondary outcomes include differences in anxiety symptoms measured by the GAD-7 total score and in the more distal outcome of functioning, as measured by the SF-36 MHC. Because the PHQ-9 and GAD-7 were collected at each clinic visit and the SF-36 MHC at baseline and end of the study, there are repeated measures over time for each scale within individual patients. We plan to use random effects linear regression models to test for differences in scores on these measures between the 2 treatment arms. We will include fixed effects terms for the treatment arm as well as for time. Furthermore, we will consider including fixed effects terms for potential confounders, such as demographics (eg, age, sex, and race), and clinical factors, such as primary diagnosis and the number of clinic visits as an indicator of clinical severity. We will also include random effects for individuals to account for the correlation in outcome measures within repeated measures of the same individual as well as for clinicians, if indicated, to account for the potential clustering effects of treatment within clinicians. The primary statistical test of interest will focus on the fixed effects term for treatment, which will provide an estimate of the mean differences in the outcome measures between the 2 treatment arms, controlling for time. We will consider different functional forms of the time covariate and use the one that provides the best fit to the data on changes in score over time. Given that patients will be enrolled in the study regardless of their current mental health status and scores on these outcome measures, we consider the model in which we control for time to be the most appropriate test of differences between the treatment arms. However, we may consider examining interactions between treatment and time to see whether changes in the scores over time differ between the 2 treatment arms. We will use the conventional threshold of $P<.05$ to declare differences statistically significant.

In additional exploratory analyses, we will examine whether there are differences between the 2 treatment arms in measures of therapeutic alliance and detection of clinically actionable targets, both of which we hypothesize, based on our conceptual model, may mediate the therapeutic effect of the intervention. These analyses will provide important evidence as to whether the proposed intervention actually engages the targeted mechanisms of action. In particular, we will test whether there are differences between the 2 treatment arms on scores on the WAI-SR (which measures therapeutic alliance for both patients and clinicians) and the M-CICAS (which captures information about the detection of clinically actionable targets and whether subsequent treatment adjustments were made). For the WAI-SR score, which is a quantitative measure and was captured every 3 months, we will use the same modeling approach as statistical modeling for the primary and secondary outcomes. For the M-CICAS, which was captured after every clinic visit, we will tally the number of times issues related to the patient's social media activity or electronic communications were discussed in the clinical encounter and the number of times treatment adjustments were made. We will again use the same modeling approach as described earlier, except that we will use random effects logistic regression models to carry out separate tests of differences in the probability of these events occurring over time between the 2 treatment arms. Furthermore, we will use $P<.05$ as the threshold to declare findings significant even though multiple tests will be carried out because these analyses will be exploratory.

Finally, we will conduct a series of analyses to assess the feasibility and acceptability of the intervention. We will use several different approaches to do this. First, we will provide descriptive statistics on how many clinicians and patients whom we approached agreed to participate and the reasons why some declined. We are particularly interested in learning whether clinicians and patients decline due to concerns about privacy in sharing personal information obtained from their social media and electronic communication activity or due to the burden of collecting and sharing this information during busy clinical encounters. Second, we will examine descriptive statistics regarding which social media and electronic communications platforms patients agreed to share to assess whether patients were selective about what information they voluntarily provided. Third, we collected a qualitative survey from clinicians to describe the main themes on whether they found systematically discussing social media and electronic communications during treatment helpful, and, if so, what they found most useful.

Sample Size

We estimate that the study has 80% power to detect differences in the primary outcome measure described earlier between the 2 treatment arms with a Cohen *d* effect size of at least 0.5, given the prespecified sample size of 100 and at least 3 repeated outcome measures. We selected a planned sample size of 100 to balance pragmatics and novel treatment intervention, while ensuring a large enough sample size to detect clinically meaningful differences.

Ethical Considerations

The study protocol was approved by the Johns Hopkins University School of Medicine Institutional Review Board (#00184638). We obtained informed consent from both patients and clinicians who participated in the study, ensuring voluntary participation and understanding of objectives, procedures, and potential risks of the study. We obtained assent from patients who were aged <18 years and consent from their guardians. All personal data collected were anonymized and stored in encrypted electronic databases, accessible only to the research team members. To compensate participants for their time and effort, patients received US $100 at randomization and another US $100 at the completion of the study. Participants who shared iOS text data were compensated US $50 because of the extra work required from the participants to share these data. Therapists received US $100 for enrolling 5 patients, US $200 for enrolling 10 patients, and US $250 for enrolling ≥15 patients.

Results

The study was initiated in April 2019, but progress was delayed due to the onset of the COVID-19 pandemic. Data collection has been completed, and the study results will be reported in a separate manuscript. The study is registered on ClinicalTrials.gov (NCT03925038).

Discussion

Challenges

Overview

The goals of this study were to create an electronic communication dashboard and evaluate its use in routine mental health treatment for patients aged ≥12 years with mood or anxiety disorders. The integration of a dashboard to monitor social media use in routine mental health care is novel and promising. With the explosion in the use of electronic communications, it is increasingly relevant to consider social media activity in the therapy setting to aid in treatment planning. However, there are important challenges that merit consideration in deciding how to best achieve this and testing whether doing so is acceptable and effective. In this study, we report the decisions we made to address these challenges in designing and testing such an intervention. The challenges generally fall into 3 categories: technological, ethical, and pragmatic.

Technical Challenges

The most immediate questions to tackle are technological, including how to monitor social media and electronic communications and how to extract and present the information from these data for routine use in clinical care. Regarding the first question, we decided to collaborate with a private start-up company and use the Bark app as a tool for monitoring patients' digital social activity. Our patients typically use several social media and electronic communications platforms, and we wanted to simultaneously track as many as possible to obtain a more comprehensive picture of their digital social activity. The Bark app offers the best out-of-the-box solution that meets our needs for monitoring the widest array of platforms and working with

both the iOS and Android operating systems, which are widely used by our patients. However, there are challenges in working with Bark. The app was not designed for our use case; therefore, we worked with the company to make certain modifications, to make it suitable for our purposes. To give an illustrative example, we had to shut down all alerts from the app, especially ones that promoted the product, because we did not want to be seen as endorsing it commercially. In addition, there are unavoidable challenges to making connections with the different social media and electronic communication platforms through the Bark app that are beyond its control. The iOS and Android operating systems each present their own challenges to work with, but Apple devices, in general, have stricter controls in place. Bark has implemented certain workarounds to these controls, such as for capturing SMS text messages; however, these solutions can add extra burden to patients in using the app, and it is important to learn whether this impacted their willingness to engage with the intervention. Moreover, different social media and electronic communications platforms are constantly evolving their rules and application programming interfaces for third-party access to their data, which could potentially disrupt the connections made by our patients through the Bark app. We will learn what impact, if any, this had on fidelity to the intervention throughout the course of the study. Finally, our incentives are not always aligned when working with Bark. They are a commercial enterprise and understandably motivated to focus on developing a product that will appeal to their target customers, which are parents. By contrast, we wanted to use a tool that can be seamlessly integrated into clinical care and would appeal to both our patients and their clinicians. There is clearly some but not complete overlap in our interests, and it is an open question whether working with the Bark app is sustainable beyond the life of this study.

Regarding a solution to digest and present information about the patient's digital social activity, we decided to develop a custom electronic dashboard. Bark has developed its own algorithms to analyze social media activity data and present alerts of concerning behavior to parents. However, we chose not to use Bark's alerts because their algorithms are proprietary, and we could not clinically validate them. As there were no other options that met our needs at the time, we decided to develop our own approach. As part of future work, we will conduct a qualitative assessment to gather stakeholder feedback on the dashboard, which can inform the next generation of development.

Ethical Challenges

The next set of challenges to consider are ethical challenges. A major concern is how to ethically manage personal information often exchanged on social media and other electronic communication platforms. This concern is especially heightened because we were dealing with patients as young as 12 years, and we were processing potentially sensitive information about their mental health through a third-party commercial app. We worked closely with our technology team to develop several solutions to securely gather and store data in a way that protected the privacy and confidentiality of our patients. However, these solutions raised competing concerns about how to manage scenarios where collected data might contain information that a patient was at risk of harming themselves or others. In weighing the competing concerns about privacy against responding to actionable findings revealed by the collected data, we decided to err on the side of privacy. We sought to inform patients when they joined the study that the information gathered through the Bark app was not monitored in real time and would be reviewed when they met with their clinicians. The clinicians were able to directly address any concerns about the risk of harm to the patient or others that emerged from reviewing their digital social activity during clinical sessions.

Furthermore, there was concern that social media and electronic communications may reveal information about third parties who did not consent to be in the study, such as friends, families, or acquaintances. To address this concern, we used automated procedures to anonymize the content by replacing identified names with fictitious substitutes. While no procedures for scrubbing identifiers in text are 100% effective, this step helps to minimize the chances of inadvertently revealing third-party identities. Consistent with this thinking, we also opted not to analyze data from videos or pictures. The videos and pictures are likely a rich source of information about a patient's mental health status; however, we decided to forgo such information again in favor of caution in protecting the patient's privacy.

Pragmatic Challenges

The final set of challenges to consider are pragmatic challenges. It is one thing to implement procedures that ensure the intervention is ethically sound, but it is another thing to ensure patients and providers are comfortable using those procedures. We anticipate that trust is an important factor in the adoption and success of the intervention. To respect the patient's choice and promote trust, we chose to let participants select which social media and electronic communications platforms they connected to the Bark app. We recognize that some patients may have decided not to connect to certain platforms they regularly use because they were uncomfortable sharing their activity on these platforms, and, as a result, we may have missed important information that is highly relevant to their mental health. However, we reasoned the potential risk was worth the benefit of giving patients control over participation in the study and building trust with the intervention. We sought to explain to the patients during the log-in process the value of sharing their commonly used platforms to encourage more complete engagement. Similar reasoning motivated our decision to mask any specific content (ie, SMS text messaging) that was extracted from the social media and electronic communication platforms and displayed on the dashboard. Moreover, we wanted to give patients a measure of control over how the intervention was used and allow them to decide when clinicians could review the content. Finally, we decided to let the clinicians and patients decide collaboratively whether and when to use the dashboard during the clinical encounter. We trained the clinicians on how to interpret and use the information on the dashboard, but we let them make the decisions with their patients on how it was used in actual care. We understand that this may result in variability across clinicians on how the intervention was used, but we opted to be pragmatic and give the clinicians and patients control over the use of the intervention to foster greater buy-in.

Limitations

In addition to the challenges detailed earlier, there are several limitations to the study that will be important to consider when interpreting the findings that come from it. First, the dashboard we developed and tested is a first-generation product, which may have important limitations in functionality. For example, it is unable to distinguish sarcasm or specific kinds of speech, such as slang, that may be important to correctly interpret social interactions. In addition, it does not include nontext forms of communication, including images or emojis, which can be rich sources of information. It is possible that the functional limitations may negatively impact the efficacy of the intervention. It will be important in future work to continue improving the dashboard to address these functional limitations and achieve the full potential of its clinical utility. Second, there is potential for selection bias in the study participants and their sharing of social media and electronic communication data. Moreover, for those who agreed to participate, their use of social media may have been influenced if they knew it was being regularly monitored. These considerations may skew the findings and limit their generalizability. Information gathered during the conduct of the study from those who do and do not agree to participate may help inform the extent to which these biases influence the results.

Conclusions

We anticipate that this study will be an important step in advancing the use of novel tools for monitoring digital social activity in routine clinical care to improve outcomes for patients with mood or anxiety disorders. We will learn whether using such tools is acceptable and feasible and whether there is evidence that doing so provides clinical benefits. In addition, we will learn what works and what does not work when using this intervention approach, which will crucially inform how to improve upon it for real-world implementation.

Acknowledgments

This work was supported by a generous grant from the Once Upon a Time Foundation. The authors would like to thank Dr Raina Merchant and her team at the University of Pennsylvania and Dr Ipsit Vahia and his team at McLean Hospital for the many productive discussions about the conceptual model and design considerations for this intervention study.

Data Availability

The datasets generated and analyzed during this study as well as the code for the dashboard will be available from the corresponding author upon reasonable request.

Abstract

Background: Breast cancer is the second most common cancer in women worldwide. Treatments for this disease often result in side effects such as pain, fatigue, loss of muscle mass, and reduced quality of life. Physical exercise has been shown to effectively mitigate these side effects and improve the quality of life in patients with breast cancer.

Objective: This randomized clinical trial aims to evaluate the efficacy of a 12-week supervised exercise program on pain, physical function, and quality of life in female patients with cancer.

Methods: This randomized, double-blind clinical trial will recruit 325 participants, divided into an intervention group receiving the exercise program and a control group receiving standard care recommendations. Outcome measures, including pain (assessed via the Brief Pain Inventory), physical function (Disability of the Arm, Shoulder, and Hand Questionnaire), and quality of life (European Organization for Research and Treatment of Cancer QLQ-C30 and European Organization for Research and Treatment of Cancer QLQ-BR23), will be evaluated at baseline, immediately post intervention, and 12 weeks post intervention. Statistical analysis will involve repeated measures of ANOVA and MANOVA to determine the significance of the intervention's effects across time points.

Results: Recruitment and data collection will commence in February of 2025, and data analysis is scheduled for completion at the end of 2025. No results are currently available

Conclusions: Physical exercise is anticipated to play a significant role in alleviating pain, enhancing physical function, and improving the quality of life in female patients with cancer. This study will provide robust evidence to support the integration of supervised exercise into standard care protocols for this population.

Introduction

Background

The World Health Organization (WHO) defines breast cancer as a pathology in which cells present in the breast reproduce uncontrollably and form tumors [1]. It is the second most common type of cancer worldwide, with an incidence in 2022 of 2.3 million. Similarly, in 2022, its mortality rate ranked fourth in the world with a rate of 669,418 [2]. Women are the most affected by this disease, with only 0.5% to 1% of cases in men [1].

Genetic mutations play a key role in cancer development. Mutations in *BRCA1* and *BRCA2* increase the risk of breast [3], ovarian, and prostate cancers, while *TP53* is linked to multiple cancers like breast and colon due to its role in cell cycle regulation [4]. *PTEN* mutations are found in breast and thyroid cancers [5], and APC is associated with colorectal cancer [6]. *MLH1* and *MSH2* mutations cause Lynch syndrome, increasing colorectal cancer risk [7]. *KRAS* mutations are common in lung, colon, and pancreatic cancers [8].

Other causes of the disease are diverse: on the one hand, advanced age at motherhood and late menopause are also considered risk factors. On the other hand, breastfeeding, physical exercise and not consuming alcohol are considered protective factors against the disease [9,10].

Treatment will be selected according to the characteristics of the tumor. Generally, it is based on neoadjuvant or adjuvant chemotherapy, radiotherapy, surgery, and hormonal therapy [11].

The prognosis of the disease has improved due to early diagnosis and therapeutic advances. The mortality rate, in turn, has decreased significantly [12,13]. Because of this increase in survival, scientific society is becoming interested in the treatment of the side effects that these patients may suffer, which include both physical and psychological symptoms [14]. Associated physical symptoms that may appear include lymphedema, decreased movement and strength of the upper limb, decreased mobility and strength of the upper limb [15], pain [16], bone loss [17], and sarcopenia [18].

These side effects have a direct impact on the health-related quality of life of patients with cancer [14]. The WHO defines quality of life as the individual's perception of his or her social and cultural way of life, as well as his or her expectations and goals. This is a very open concept that encompasses different aspects of the person from physical health, psychological state, level of independence, social relationships, and personal beliefs [19]. Quality of life measurement is frequently used in breast cancer studies to evaluate the effectiveness and outcomes of treatments [20].

Exercise and Breast Cancer

It has been observed that patients with breast cancer present atrophy of the skeletal muscle apparatus, which is associated with the mitotoxic effects of chemotherapy. Anthracyclines, substances that play a leading role in chemotherapy against breast cancer, have an affinity for the inner membrane of the mitochondria, the place where the body's energy is produced; therefore, this mechanism explains fatigue, atrophy, and muscle pain [21,22].

Various treatments are currently being studied to alleviate these side effects, including therapeutic exercise. Exercise provides short- and long-term benefits to reduce the symptoms that may appear during treatment in each patient. Here, therapeutic exercise specialists play an important role in helping patients overcome their fear and improve their physical abilities [23]. The American College of Sports Medicine says exercise is associated with improved survival after developing cancer [24].

The health professionals in charge of applying this type of therapy must evaluate each patient individually and adapt the exercise prescription to each one of them. The ideal type of exercise for these patients is one that includes a combination of aerobic and resistance exercise, the intensity of each of these parts will be determined by the characteristics of the patient [25,26].

There is evidence that professionally supervised physical exercise has positive results compared to unsupervised exercise. Research has shown evidence that it positively influences decreases anxiety, depressive symptoms, and fatigue, improves quality of life and physical function, and there is no risk of exacerbating upper limb lymphedema. Even people who have already developed lymphedema can perform resistance exercises. In 2000, Harris and Niesen-Vertommen [27] were the first to start strength studies with people with lymphedema, as the existing recommendations so far were the rest of the affected limb [27-30].

The objective of this project is to develop a randomized clinical trial to determine the efficacy of a supervised exercise program on pain, physical function, and quality of life in female patients with cancer.

Methods

Hypothesis

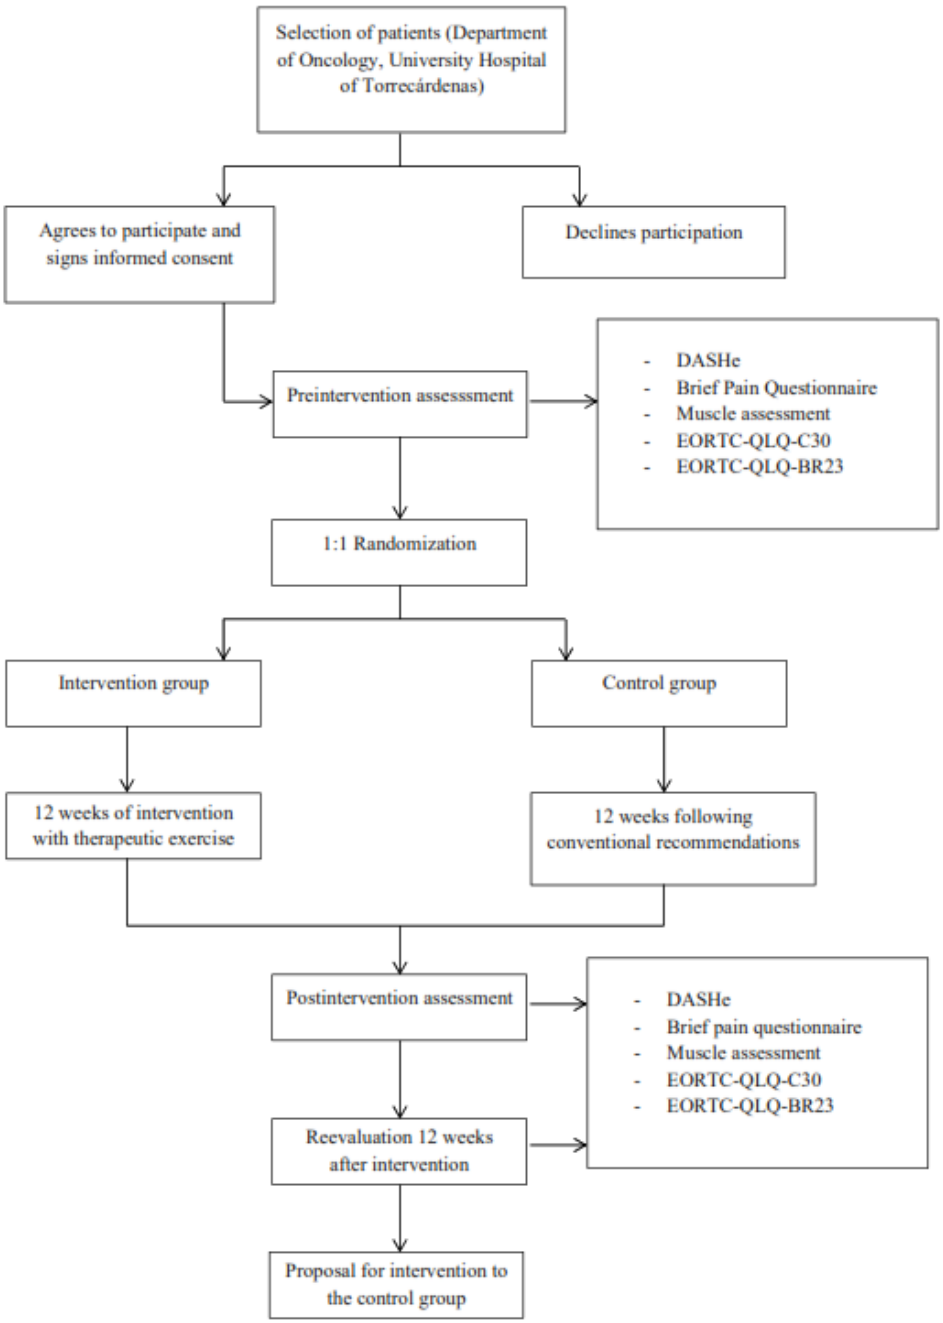
- A supervised exercise program reduces pain and improves physical function and quality of life in female patients with cancer compared to a control group not receiving the exercise program.
- The beneficial effects of the supervised exercise program are maintained over time at least 12 weeks after the end of the program.

Study Design

This study will be a single-blind, randomized clinical trial. To determine the efficacy of a therapeutic exercise program on the different dimensions of quality of life, physical function, and pain in patients with cancer. Once the participants have been recruited, they will be randomly assigned to 2 groups (intervention group and control group). Three assessments will be made: initial assessment, assessment after the end of the intervention, and assessment 12 weeks after the end of treatment. The intervention group will follow a 12-week therapeutic exercise plan, and the control group will follow the usual recommendations for this type of patient. After this last

assessment, the participants in the control group will be offered the intervention. (Figure 1). Approval will be sought from the ethics committee of the University Hospital of Torrecárdenas.

Figure 1. Untitled.



Study Population

The participants will be recruited through the oncologists of the University Hospital of Torrecárdenas. The inclusion criteria will be the following: women aged between 45 and 65 years (age range with the highest incidence in Spain), with oncologic treatment completed less than 3 months ago, without metastasis, without pathologies that contraindicate exercise, and who have agreed to sign the informed consent form. The exclusion criteria will include: not attending scheduled sessions to instruct on the exercises to be performed, being part of other studies, undergoing another type of therapy, and pregnant patients.

The selected age range of 45 to 65 years for participants is based on epidemiological data indicating that this demographic encompasses the highest incidence of breast cancer in Spain. This range ensures a representative sample for evaluating the intervention's efficacy while excluding populations less likely to face similar diseases and treatment dynamics. Additionally, menopause is included as an independent variable in the analysis due to its significant influence on both physiological and psychological responses to breast cancer treatment and exercise interventions. Hormonal changes associated with menopause can affect musculoskeletal health, fatigue levels, and overall quality of life, making it a critical factor to consider when evaluating the intervention’s outcomes on pain, physical

function, and quality of life [31]. By accounting for these variables, the study aims to provide a nuanced understanding of how menopausal status may modulate the benefits of supervised exercise in patients with cancer.

Sample

To calculate the sample size, the QuestionPro software (QuestionPro Inc) was used [32]. It consists of software that, among other functions, incorporates a sample calculator for research.

Based on breast cancer morbidity data in the province of Almeria for 2022, published by the National Institute of Statistics [33], the calculation assumed a moderate effect size of 0.5, based on prior research on exercise interventions in similar populations. To ensure sufficient sensitivity to detect meaningful differences, the significance level (α) was set at .05 (2-tailed), and the study power (1–β) was set at 80%. Considering these assumptions, an initial sample size of 280 participants was determined. However, recognizing the potential for participant dropout, which is common in exercise-based trials, we accounted for an estimated attrition rate of 15%. To compensate for this and maintain statistical power, the final sample size was adjusted to 325 participants.

This approach ensures that the study is adequately powered to detect significant differences between the intervention and control groups for the primary outcomes. If further specifics or expanded parameters are required, we are happy to provide additional details. This explanation aims to address editorial concerns and clarify the robustness of our calculation methodology.

In the beginning, an attempt will be made to recruit the estimated size of participants; if this cannot be done, a smaller sample size will be used, assuming a decrease in the confidence level of the results.

Randomization

All participants have the same probability of belonging to either group. Assignments will be randomized with a 1:1 ratio using the OxMaR software (OxMaR Inc) in its Spanish version [34].

Measuring Tools for Evaluation

Disability of the Arm, Shoulder, and Hand Questionnaire

Self-administered and validated questionnaire in Spanish, the original questionnaire was first published in 1996 [35]. This measuring instrument assesses the impact of processes occurring in the upper limb. This questionnaire consists of 30 items and 2 optional modules. The score obtained is transformed to a scale from 0 to 100, where higher scores show a worse result. It shows a high internal consistency (Cronbach α=0.96) [36].

Brief Pain Questionnaire

This questionnaire is a pain assessment instrument used to measure pain intensity and its impact on the patient's daily life; the original questionnaire was developed at McGill University in 1971, with an internal consistency of 0.7 [37]. The questionnaire used in the study was validated in Spanish in patients with neoplastic pain. It consists of 11 items on a Likert-type scale from 0 to 10 (where 0=no pain and 10=worst possible pain) and 15 additional items that assess the impact of treatment on pain relief. It presents a high internal consistency, with Cronbach α being higher than 0.7 in all dimensions (0.89 for pain intensity and 0.87 for impact on daily life) [38].

Muscle Assessment

Muscle strength will be assessed using a 1 maximum repetition (MR) protocol for the chest press in the horizontal plane and the leg press, as this is the most commonly used muscle assessment test in similar studies, according to the meta-analysis by Hasenoehrl et al [39]. One RM is defined as the maximum weight at which only 1 repetition can be performed [40].

For the evaluation, we will start with an initial warm-up series with 6 repetitions, the initial weight will be 2.5 kg and 18 kg for the upper and lower limbs, respectively. According to the perceived effort of each participant, we will start with an approximate weight for the one RM test, until it increases according to tolerance to find out the 1 RM weight of each participant. This is the strategy followed by Brown and Schmitz [41]. The assessment of the upper limb will be performed unilaterally in order to objectively evaluate the difference between the affected and healthy upper limb, as was done by Hagstrom et al [42]. Thus, we will start with 1.25 kg for each upper limb.

EORTC-QLQ-C30 Quality of Life Questionnaire

A questionnaire was created by the European Organization for Research and Treatment of Cancer (EORTC) to assess the quality of life in patients with cancer. The organization provides the questionnaire translated into several languages, including Spanish. It consists of 30 Likert-type questions that assess various aspects of quality of life, including the ability to perform activities, symptom control, general perception of health, and other relevant aspects such as difficulty breathing, insomnia, anorexia, constipation, diarrhea, and economic impact [43].

The EORTC-QLQ-C30 presents in most of the studies performed a good internal consistency (Cronbach α=0.7 for most of the scales). This questionnaire, based on a specific formula, obtains results on a scale from 0 to 100, where a higher score indicates a better quality of life. The scores for each question within each dimension (physical, emotional, and social functioning) are summed [44]. Within this questionnaire, there are specific modules that complement it for some types of cancer, for breast cancer they have created the EORTC QLQ-BR23 [44].

EORTC Quality of Life Questionnaire, QLQ-BR23

This questionnaire is a specific module for breast cancer that complements the previous questionnaire. Two main aspects are assessed here: functional scale (body image, sexuality, and concern for the future) and symptom scale (breast symptoms, arm, and side effects of treatment). It presents in most of the studies carried out a good internal consistency (Cronbach α=0.7) [44]. Like the general module, this questionnaire has a score from 0 to 100, where they are transformed according to a formula by specific dimensions.

Ethical Considerations

In this study, clinical investigations involving medical devices are conducted on human participants. In order to safeguard the integrity, well-being, and privacy rights of the participants, the study is carried out in accordance with the guidelines set forth by the Declaration of Helsinki of the World Medical Association (64th General Assembly, Fortaleza, Brazil, October 2013), the Council of Europe Convention on Human Rights and Biomedicine, Good Clinical Practice standards, Royal Decree 1090/2015 of December 4, which regulates clinical trials with medicinal products, the Research Ethics Committees for Medicinal Products and the Spanish Registry of Clinical Studies, and Royal Decree 1591/2009 of October 16th, which regulates medical devices [45,46].

The study protocol will be submitted to the Bioethics Committee at the University Hospital of Torrecárdenas for review and approval in February 2025, during the preparatory phase. Ethical approval will be obtained before the initiation of any participant recruitment or data collection activities, in compliance with ethical standards. Recruitment is scheduled to begin in February 2025, contingent on receiving ethical approval. The ethical approval number will be provided in the final manuscript once it is obtained.

Before the study commences, explicit informed consent will be requested from participants via a digital form, clearly explaining the study's objectives and participation details (Multimedia Appendix 1). Participants will have the ability to opt out at any stage without consequences. For any secondary data analyses, it will be confirmed that prior institutional review board–approved consent covers reuse without requiring additional consent. Compliance with Spanish Organic Law 3/2018 of December 5, 2018, on the Protection of Personal Data and the guarantee of digital rights [47], will also be ensured. Participant privacy will be rigorously protected, and all collected data will be anonymized or deidentified to prevent the disclosure of personal information. The data will be securely stored and used exclusively for this research project and any resulting publications. If any identifiable data is included in images or supplementary materials, explicit consent will be obtained and the necessary documentation will be submitted as supplementary files.

Participants will not receive any financial compensation for their participation in the study. However, they will be provided with detailed information about the study's objectives, potential benefits, and their rights as participants to ensure transparency and fairness in the research process. These measures ensure that the study adheres to the highest ethical standards and prioritizes participant safety, confidentiality, and informed consent in compliance with national and international research ethical regulations.

Intervention

The proposal will be carried out in the intervention group (group 1), while the control group (group 2) will undergo the conventional recommendations indicated for this type of patient.

A supervised training plan will be carried out for 12 weeks with a frequency of 3 sessions per week with a duration of 60 minutes, an ideal estimate according to the meta-analysis of Montaño-Rojas et al [48]. In first 2 weeks, the group exercises will be performed to familiarize the participants with the exercises and then each participant will perform them at home with a review every 2 weeks to assess the increase of the load.

The exercises and loads included in this treatment plan have been designed and modified based on previous clinical trials [39,49-51]. The training plan will work the upper limbs, lower limbs, and trunk. All sessions begin with a general warm-up, which will be previously instructed to the participants, in which the heart rate will be increased (Multimedia Appendix 2). After a 2-minute break, the specific block of each session will begin (Textbox 1 and Multimedia Appendix 2). All exercises will be performed with dumbbells, elastic bands, and a ball. We will consider the age of each participant, making minor adjustments to the initial exercise program as needed.

Three sets of all exercises will be performed with 10-12 repetitions at 50%-60% 1 MR (previously calculated for each participant in each of the exercises) with 1 minute of rest between sets. Finally, we will conclude with general stretching previously instructed (Multimedia Appendix 2). The control group will participate in a general education and wellness program designed to promote overall well-being and maintain a basic level of activity. This program, matched in duration to the experimental group, will include regular counseling sessions covering topics such as nutrition, stress management, sleep quality, and relapse prevention. In addition, participants will be encouraged to engage in low-impact physical activities, such as short walks and gentle mobility exercises. For the experimental group, the supervised exercise program aims to improve pain, physical function, and quality of life through a variety of carefully selected exercises tailored to each participant's needs. These include stretching exercises, such as pectoral stretches for chest mobility and shoulder and arm stretch to enhance the range of motion and relieve tension. Strength training exercises using resistance bands or light weights will focus on improving upper limb and core strength to enhance posture and stability. Aerobic activities like walking or stationary cycling will be incorporated to boost cardiovascular endurance and mobility. Flexibility exercises, including range-of-motion activities, will help maintain and improve overall flexibility, while balance and coordination exercises will enhance stability and prevent falls. Muscle endurance will also be developed through lightweight or resistance band exercises. The program's design emphasizes a personalized approach, guided by physiotherapists or exercise specialists, to ensure safety and maximize benefits for patients with cancer.

Textbox 1. Strength exercises included in the training plan.

Session 1

- Squats
- Biceps curl
- Superman in quadruped
- Dumbbell chest press in horizontal plane
- Shoulder rotators with elastic band
- Dumbbell rowing

Session 2

- Proprioceptive shoulder exercises with ball on wall
- Static stride
- Upper limb flexion with ball on wall
- Isometric abduction with ball (elbow 90º)
- Prone spine extension
- Quadruped hip abduction

Session 3

- Dumbbell triceps extension
- Quadruped gluteal kick
- Triceps kick with dumbbell
- Lateral shoulder raises with dumbbells
- Dead weight with dumbbells
- Rowing with elastic band

Data Management and Analysis

Once all the measurements included in the measuring instruments section have been taken, they will be recorded and analyzed using SPSS (version 28.0; IBM Corp) [52].

The quantitative data of the sample will be described by number, mean, and SD.

A result is understood to be significant when $P \leq .05$. In statistics, significance or internal consistency indicates that there is congruence between the different results obtained [53].

For the statistical analysis of the results of this test, 2 tests will be performed as follows.

- Repeated measures ANOVA: This analysis allows us to evaluate whether the differences between the results of the same test in a participant are statistically significant. If so, it also determines what percentage of the effect is attributable to the intervention and not to other factors [53]. Two ANOVA analyses will be performed: one comparing the preintervention assessment with the postintervention assessment, and the other comparing the postintervention with the assessment 12 weeks later. This test will check if there is a significant improvement in the different measures of pain, physical function, and quality of life. Finally, the paired comparison table will tell us in which measurement periods the differences are found [53].
- ANOVA of differences: In this case, the differences between the results of the intervention group and the control group will be compared [53]. With the results obtained from this statistical analysis, it will be possible to verify whether the differences between groups in terms of pain, physical function, and quality of life are significant between the participants receiving the intervention and those belonging to the control group.
- MANOVA: To assess the overall effect of the intervention and determine whether the hypotheses can be accepted or refuted, the following hypotheses will be tested [53].

These statistical analyses described the significance between the test results of the same individual and the significance between the different results of both groups of the test that will be tested.

Results

Recruitment and data collection will begin in the third quarter of 2024. Data analysis will be conducted between the first and second quarters of 2025. No results are available at the time of this intervention protocol.

Discussion

Principal Findings

This randomized clinical trial is intended to test the efficacy of an exercise program applied to patients with cancer.

Most of the patients present a deterioration of their quality of life and physical function after suffering breast cancer, physical exercise can be a great ally to counteract these negative effects [23-30]. Therefore, the results obtained in the intervention group are expected to be significantly better than those of the control group. It is likely that there will be benefits to the intervention in some aspects and not in all the variables measured in the study. In addition, the benefits provided are expected to be maintained in the long term, hence the reassessment 12 weeks after the end of the intervention.

A compelling finding emerges from the systematic review by Montaño-Rojas et al [48], which demonstrates significant muscle strengthening benefits, even with low-intensity and short-duration exercise programs. Participants in these programs showed notable improvements in muscle strength compared to those who did not engage in physical activity. This aligns with the meta-analysis by Shen et al [54], which reported improvements in pain and joint amplitude of the upper limb following physical exercise after radiotherapy in breast cancer. These findings complement international guidelines, such as those from the Clinical Oncology Society of Australia (COSA), which recommend at least 150 minutes of moderate aerobic exercise and 2 resistance training sessions per week, tailored to the individual's health and treatment phase. Like the protocol in this study, COSA highlights the benefits of exercise in reducing fatigue, improving musculoskeletal health, and enhancing quality of life [30]. However, COSA also emphasizes the routine integration of exercise into oncology care, a practice that remains inconsistently implemented across European health care systems. This comparison underscores the universal importance of exercise in patients with cancer and highlights the need for tailored adaptations to local health care systems and cultural contexts to maximize accessibility and impact [29].

In line with the aforementioned, Zengin Alpozgen et al [55] obtained positive results in their clinical trials for pain relief. In contrast, the results of Loudon et al [56] are not significant in terms of pain reduction. This difference may be due to the fact that the first two use exercises that involve greater resistance and dosage; in contrast, the latter performs an intervention of a single session per week based exclusively on yoga exercises.

On the one hand, Aydin et al [57] in their clinical trial, show that physical exercise not only has a positive influence on the physical condition of the participants but is also strongly related to the improvement of mental health. In her study with 48 participants, she used the EORTC-QLQ-C30 and WHO Quality of Life–Brief Version scales to measure the quality of life of the sample. On the other hand, Koevoets et al [58] used the EORTC-QLQ-C30 scale to measure the impact of exercise on cognitive function in patients with breast cancer after chemotherapy. Reporting positive results in the participants of the intervention group. On the contrary, Bruce et al [59] in a clinical trial with 392 participants, found no significant differences in the improvement of mental health in participants who had performed physical exercise and those who had followed the usual recommendations. These differences may be due to the sample size as the latter study presents a significantly larger sample than the previous ones. They may also be due to the dosage and type of exercises proposed in the intervention; since Aydin et al [57] and Koevoets et al [58] perform aerobic and general strength exercises of all muscle groups, while Bruce et al [59] only perform a shoulder strengthening program in flexion, abduction, and external rotation.

Regarding when to start the exercise program, authors such as Carayol et al [60] recommend starting a supervised exercise program during chemotherapy or radiotherapy treatment, combined with an adequate diet to improve health status and the consequences of these treatments.

Vincent et al [61] compared in a randomized clinical trial the results obtained in a group that started the intervention with exercise during chemotherapy and in another group that started it after the end of chemotherapy, not observing significant differences between the two and highlighting the importance of performing them either during or after.

From another point of view, not only is the impact of physical exercise after breast cancer being investigated but there is already research that is beginning to show positive results in the prevention of breast cancer through exercise in populations with risk factors. An example of this is the studies by Coletta et al [62] and Khosravi et al [63] where they performed interventions with physical exercise in postmenopausal participants and with various other risk factors to see the impact of this training with leptin and myokine levels. Prevention of both first-time disease onset and recurrence, aided by physical exercise could be a future line of research that will gain more momentum.

The strengths of this study are randomization, as well as the use of previously validated assessment tools, some of them specific to breast cancer, such as the EORTC QLQ-BR23. The variables analyzed range from pain to physical function and quality of life. In addition, it is based on a protocol of resistance exercises, which, according to previously cited research, provides better benefits.

The main limitation of this study is that the intervention will be carried out through patients recruited from a single referral hospital, although a large sample is achieved, it would be interesting for future studies to have a variety of more heterogeneous participants and better generalize the results. In addition to making longer-term measurements to see how the possible improvements acquired are maintained. Furthermore, the study's results may be influenced by factors like hormonal variables, age, and treatment responses. Hormonal changes, such as menopause, can affect treatment effectiveness and side effects. Additionally, younger patients may experience different side effects or treatment responses due to metabolism, health, and comorbid conditions.

Conclusions

Oncology research is advancing at a very fast pace. Therefore, addressing the side effects of the disease is a great success for these patients, who today have a high survival rate. Therapeutic exercise is a great ally in improving strength, pain, and joint mobility after breast cancer, as well as positively influencing the improvement of quality of life.

Acknowledgments

This study received grants aimed at supporting recognized research groups from public universities of Castilla y León starting in 2024 (BU043G24). All authors have approved the final version of the manuscript and agree to be accountable for all aspects of the work. Generative artificial intelligence and artificial intelligence–assisted technologies were not used in the writing process. The study has been conducted with resources available to the authors and their affiliated institutions.

Data Availability

The data that will support the findings of this study will be derived from patient medical record data. The datasets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

JGM was responsible for conceptualization, formal analysis, investigation, methodology, software, visualization, and drafting as well as reviewing and editing the manuscript. OSV contributed to conceptualization, data curation, formal analysis, investigation, methodology, project administration, resource management, supervision, validation, visualization, and both drafting and revising the manuscript. MSV took charge of the methodology and the preparation and review of the manuscript. JHOH played a role in conceptualization, data curation, formal analysis, investigation, methodology, project administration, supervision, validation, visualization, and manuscript preparation, including drafting and revisions. All authors reviewed and approved the final manuscript and took full accountability for all aspects of the work.

Conflicts of Interest

None declared.

Abstract

Background: The Telemedicine & Advanced Technology Research Center (TATRC) commenced a new research portfolio specifically addressing Autonomous Casualty Care (AC2) in 2023. The first project within this portfolio addresses the current and historical challenges of capturing tactical combat casualty care (TCCC) data in operational settings.

Objective: The initial autonomous casualty care effort, the Passive Data Collection using Autonomous Documentation research project, conducts systematic, simulated patient and casualty care scenarios, leveraging suites of passive sensor inputs to populate a data repository that will automate future combat care.

Methods: To obtain the required datasets, TATRC will engage care provider participants who provided consent in one of 6 randomized simulated TCCC scenarios leveraging an institutional review board–approved office protocol (#M-11057). These simulations will leverage mannikins (low and high fidelity) and live simulated patients (eg, human actors who provided consent). All consenting participants (eg, both the care providers and live simulated patients) will be equipped with suites of sensors that will passively collect data on care delivery actions and patient physiology. Simulated data is being collected at Fort Detrick, Maryland; Fort Sam Houston, Texas; Fort Indiantown Gap, Pennsylvania; Fort Liberty, North Carolina; and a commercial site in Greenville, North Carolina.

Results: Across all research locations, TATRC will collect and annotate approximately 2500 simulation procedures tasks by March 2025. These study data will generate the first machine learning and artificial intelligence algorithms to populate Department of Defense (DD) Form 1380 fields accurately and reliably. Additional data collected past March 2025 will be used to continue to refine and mature the algorithm.

Conclusions: The military health care system (MHS) lacks real-world datasets for TCCC care at the point of injury. Developing a data repository of simulated TCCC data is required as an essential step toward automating TCCC care. If TATRC's research efforts result in the ability to automate care delivery documentation, this will alleviate the cognitive burden of TCCC care providers in austere, chaotic environments. By generating a TCCC data repository through this Autonomous Documentation research project, TATRC will have opportunities to leverage this research data to create machine learning and artificial intelligence models to advance passive, automated medical documentation across the health care continuum.

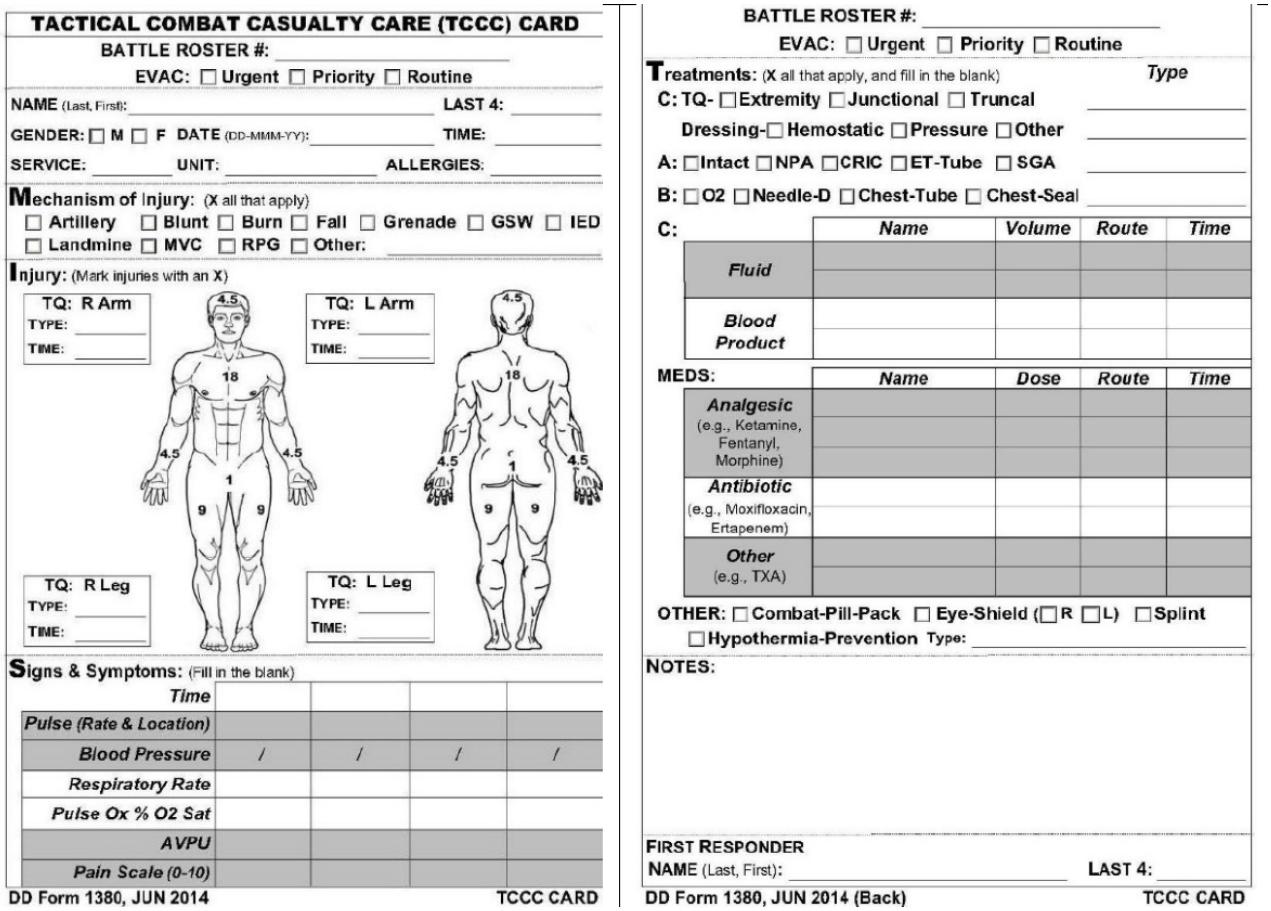
Introduction

The military health care system (MHS) is a Joint Service health care system that operates under the Defense Health Agency (DHA) [1]. Within this health care system, there is a diversified set of health care data ranging from routine preventative services for service members (SMs) and their families to battlefield casualty statuses. Due to the nature of its complexity, the MHS thrives in stable connected environments and languishes in operational settings where network communications are compromised or insecure. Thus, when our SMs are located in various tactical environments in multidomain operations, the MHS lacks a robust, accurate, and reliable methodology to collect, store, and track health data, often referred to as tactical combat casualty care (TCCC) data.

Historically, TCCC data has been manually collected using the DD Form 1380, also known as the TCCC card (Figure 1). The TCCC card is intended to be filled out by combat medics at point-of-injury (POI) and Role 1 and attached to the casualty's uniform.

Figure 1. DD Form 1380, the TCCC card.



The intent is for this DD Form 1380 to travel with the casualty until they reach their final treatment destination where its contents will be populated into the electronic medical record in the MHS. Current assumptions, which constrain the success of the manual TCCC data capture process, include the following: (1) the DD Form 1380 will be present at the time of the SM's final treatment destination, (2) the DD Form 1380 will be undamaged and legible to transcribe into the medical record, and (3) there will be abundant resources to transcribe all DD Form 1380 data entries or fields into that record.

Due to the chaotic nature of conflict environments, most of the DD Form 1380s are either incorrectly or inadequately completed. Capturing the medical care provided in these austere venues is secondary to saving lives; however, the need for timely, accurate medical documentation remains for acute care and long-term care management [2-4]. In the near term, this data generates valuable information for higher echelons of care, medical resupply, and logistics systems, and command situational awareness. The long-term benefit is the ability to provide a basis for evaluating quality of care and benchmarking key metrics for quality improvement efforts and to leverage machine learning (ML) and artificial intelligence (AI) to enhance future care delivery in the tactical environment, as well as to inform clinical decision support systems and algorithms deployed in these settings [5].

In May of 2023, the telemedicine and advanced Technology Research Center (TATRC) commenced a new Autonomous Casualty Care (AC2) research portfolio with the initial objective of creating an innovative, trustworthy, reliable solution to enhance TCCC and improve medical documentation in the MHS. TATRC intends to develop a passive (ie, with minimal human effort and distraction), autonomous documentation (AutoDoc) solution of medical care in operational environments comprising a system of sensor suites that passively collect accurate and reliable data about casualty status, care provider actions, and real-time resource usage.

The goal will be for the sensor suites to passively and autonomously document data for a digital DD Form 1380. To accomplish this, TATRC will (1) identify which commercial off-the-shelf (COTS) sensors are most suitable to collect TCCC data elements required to populate the DD Form 1380; (2) conduct human subjects research using participants who perform TCCC skills in controlled, simulated environments; and (3) annotate all sensor suite data collected to build a TCCC dataset for current and future ML and AI algorithms to leverage.

Methods

Overview

Since the AC2 mission realignment in May 2023, TATRC has worked in partnership with the United States Army Medical Research and Development Command (USAMRDC) Institutional Review Board Office (IRBO) to ensure optimal human participant protections can be achieved within the scope of our research study. The novelty of developing a study design that leverages sensor suites and simulated data across multiple locations and includes iterative improvements in the technology configuration features due to the agile development process is groundbreaking for the organization. TATRC received its initial human subjects research protocol approval (#M-11057) from the USAMRDC IRBO in February 2024 to conduct this research and will continue to amend the protocol as new collaborators onboard and new methodologies are adapted, as required. Study personnel will follow the protocol requirements including consenting mandates as directed by the IRBO.

Passive data collection using AutoDoc is a research, development, test, and evaluation (RDT and E) project that will be conducted in three separate stages: (1) selection and procurement of sensor suite components, (2) data collection via live human actor simulations, and (3) data annotation.

Sensor Suites

Individual COTS sensors were bundled into synchronized technology suites designed to capture both patient physiological data and care provider interventions. These passive sensor suites generate data that can be used to generate an electronic DD Form 1380. The categories of sensors used in this research project are listed in Table 1. The COTS sensors selected for the research project's suite were based on technology maturity level, National Defense Authorization Act compliance, suitability for the operational environment (eg, durability and ruggedization), and ability to extract data from the sensors (eg, nonproprietary data formats). Before leveraging the passive sensor suites in the AC2 research project, the technologies were systematically evaluated through a series of assessments. The sensor suites are worn by consented participants (eg, both the care providers and live simulated patients) in the simulated TCCC scenarios for data collection.

Table 1. Categories of commercial off-the-shelf sensors integrated into sensor suites.

Sensor category	Sensor type
Primary care providers	
Audio	Microphone clipped to a collar, lapel, or helmet
Identification readers	Near field Communication cards attached to items in the care provider's bag
Inertial measurement unit	Wrist-worn inertial measurement units to track hand movements
Mounted video	Traditional video and infrared video
Simulated Patients	
Vital signs monitor	Velcro blood pressure cuff and skin safe adhesive electrocardiogram electrodes leads, adhesive vitals monitoring patch (blood pressure, heart rate, respiration rate, temperature, and SpO_2[a]), and finger pulse oximeter

[a]SpO_2: oxygen saturation.

Data Collection

Live, controlled, simulated scenarios will be used for all passive sensor suite data collection activities. The purpose of conducting live simulation events is to observe participants performing TCCC-related activities. These structured data collection events allow the research team to obtain relevant data for future algorithm development. The purpose of the data collection events is research-specific, and not to educate, assess, or help caregivers self-identify knowledge gaps.

TATRC has identified Department of Defense (DoD) affiliated collaborators to generate the volume of data needed to train the ML and AI. TATRC personnel are currently collecting data at 5 different locations at Fort Detrick, Maryland; Fort Sam Houston, Texas; Fort Indiantown Gap, Pennsylvania; Fort Liberty, North Carolina; and a commercial site in Greenville, North Carolina.

Settings

Live simulation data collection events are conducted at the 5 approved research locations. At each location, a series of physical spaces are dedicated to simulating the prehospital roles of care: POI (casualty collection point or equivalent), Role 1 (battalion aid station or equivalent), Evacuation to Role 2, and Role 2 (Forward Surgical Team or equivalent). In addition, the equipment and medical supplies that are available at each prehospital venue are accessible to the research participants. Data collection locations can create immersive virtual environments, sounds, or other environmental characteristics (smoke, smells, etc) to create a realistic combat environment. In addition, an audiovisual system (AVS) is leveraged to record and archive activities conducted during the data collection events. When data are collected in a formal laboratory venue, the AVS is fixed, but in other locations, a portable AVS is leveraged (Figure 2).

Figure 2. Staged simulation scenario of primary care provider triaging simulated patient (Mannikin).

Study Participants

Participants will be split into two groups: (1) care provider and embedded participant or (2) simulated patient, based on inclusion criteria. The research team is using video, audio, and kinematic recording equipment to collect first-person data from care providers and embedded participants during the TCCC scenarios. The first-person sensors will record casualty injury patterns, care and tasks provided by the care providers, equipment and supplies used, and other environmental factors. In addition, vital signs monitors, such as finger pulse oximeters, blood pressure cuffs, adhesive electrocardiography patches, and so on, will be placed on the simulated patient participants to record physiological data.

Inclusion Criteria

Care provider and embedded participants specific inclusion criteria. This research population group must be a certified provider, as defined below, to participate, ensuring that the simulated data collected reflects data that would be collected by a care provider in a real battle space (Textbox 1). Care provider participants will be split into 2 separate roles during a scenario:

1. Primary care provider (PCP): The PCP is the person providing care to the patient in the scenario and will be required to wear the system of sensors during the simulation.
2. Embedded participant (EP): The EP assists the PCP throughout the scenario by updating vitals, holding items, injecting added pressure onto the PCP, prompting the next steps, and so on.

Textbox 1. Inclusion criteria and exclusion criteria by participant role.

Inclusion criteria

- Primary care provider or embedded participant
- Are between the ages of 18 and 65 years
- Must have one or more of the following:
  - Active tactical combat casualty care certifications for All Service Members, the Tier 1 course
  - Working knowledge of combat casualty care skills through medically related training (eg, combat medic or equivalent training)
  - Deployment with medical experience in the last 36 months
- There are no preexisting conditions that would negatively impact their ability to provide care for a 20-minute simulated trauma care scenario or work outside for prolonged periods of time (eg, extreme allergies or extreme reactions to sun exposure, etc)
- Simulated Patient
- Age 18 years or older
- Must have the ability to act injured and unconscious for the duration of a 20-minute patient care scenario. The range of injury acting will vary from a state of unconsciousness (ie, lying still) to yelling and writhing in pain

Exclusion criteria

- All participants
- Younger than 18 years
- Currently pregnant
- History of abnormal heart rate (eg, arrhythmias)
- Internal electric medical devices (eg, pacemakers)
- Uncontrolled high blood pressure disorders
- Uncontrolled breathing disorders
- Severe allergies
- Epilepsy
- Primary care provider or embedded participant
- Younger than 18 years or older than 65 years
- Do not hold an active certification for tactical combat casualty care Tier 1
- Simulated Patient
- Younger than 18 years
- Unable to meet the physical requirements of acting as an injured or unconscious patient, such as an inability to act in a predetermined way for up to 20 consecutive minutes or having an adverse response to prolonged time outdoors

Exclusion Criteria

For generalized and participant-specific exclusion criteria, please see Textbox 1.

Procedures

After recruitment, enrollment, and consent, each participant will be placed into one of 6 simulated scenarios that were scripted for this project. Participants will be paired based on similar levels of expertise described in Bloom's Taxonomy and then randomized into provider type groups [6].

A total of 6 combat casualty care scenarios were designed and written by TATRC's combat medic subject matter experts. The injury patterns were developed using common battlefield mechanisms of injury and real-world scenarios. The majority of the TCCC tasks in the scenario correspond to an Individual Critical Task List item for the 68W Combat Medical Specialist, with only a few exceptions. The severity of the casualties differs to capture all triage categories and levels of difficulty. Baseline simulations were developed for each scenario by selecting the appropriate patient mannikin, applying relevant moulage (medical makeup), and by selecting the applicable scene location for POI care. The six scenarios are as follows:

> *26-year-old male infantryman injured by small arms fire during dismounted patrol. Patient is unresponsive and has a massive hemorrhage from the face or neck and left inguinal area. Enemy threat has been eliminated, and combat lifesaver (CLS) has been attempting to control bleeding for several minutes unsuccessfully.*
>
> *29-year-old male SM involved in improvised explosive device (IED) explosion. Patient alert to verbal stimuli,*

and complains of 10/10 pain all over. Obvious right leg below knee amputation. Bleeding from right chest and forehead.

23-year-old male SM injured by small arms fire during key leader engagement. Patient suffered multiple gunshot wounds to the left shoulder, left arm, and left leg. Patient presents with moderate bleeding but alert.

25-year-old male platoon leader injured by mounted IED explosion. Patient has shrapnel and burns to the left arm, leg, and torso with minimal bleeding. Patient is alert and complaining of 10/10 pain. Enemy threat in the area has been eliminated and CLS has been attempting to control bleeding for several minutes unsuccessfully.

35-year-old male platoon sergeant injured by mortar strike. Patient is alert and has right arm amputation below elbow and shrapnel wounds to the right side with moderate bleeding. Patient is alert and complaining of 10/10 pain.

31-year-old male involved in an IED explosion. Patient alert to verbal stimuli with complaints of 10/10 pain on left side of body. Patient has burns to neck and face with stridor. Left side "peppered" with minor shrapnel injuries. Patient is found extricated from vehicle and burning process has been stopped. Scene is absent of enemy activity and no percutaneous transluminal angioplasty treatment has been provided.

Before the simulation commences, the PCP is trained on how to use the sensor suite and if using a simulated patient, the appropriate moulage is applied. The participants are then taken to one of two locations, depending on their assigned scenario: (1) indoor laboratory or training facility: fully controlled environment; and (2) outdoor training facility: partially controlled environment, used for scenes with potential for care under fire.

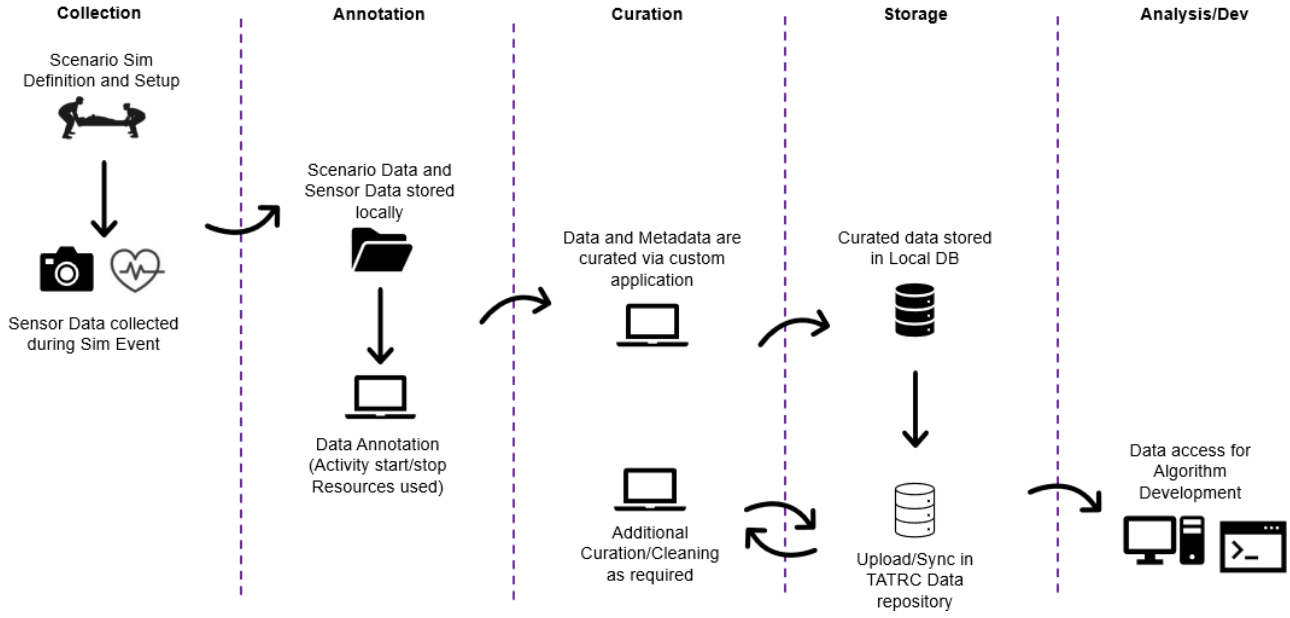
After arriving at their assigned location, each participant is given a scenario brief. The scenario brief contains information on simulation tasks, conditions, and standards, and allows time for the participants to prep their equipment and supplies or ask any last-minute questions.

The data collected from each scripted scenario will differ based on each PCP. Each caregiver will manage the problem set differently based on their personal experiences and knowledge base resulting in individualized outcomes (Figure 3). Only one PCP will manage the simulated patient. The generalized process of how each scripted scenario occurs is as follows:

1. The simulated patient, PCP, and EP are all present at their assigned location.
2. The PCP is trained on the sensor suite technology while the simulated patient is reviewing the script and having moulage applied.
3. The simulated patient, PCP, and EP are given a scenario brief.
4. The start cue is given, and the scenario commences.
5. The simulated patient begins to act out their injuries.
6. The PCP begins performing care to treat the simulated patient, while the EP is standing by. The EP only intervenes if the PCP requests their assistance (eg, to hold equipment or to provide updated patient information), to troubleshoot equipment, or to prompt the PCP.
7. After a determined amount of time, the PCP is notified that evac has arrived.
8. The scenario ends.

From the beginning of the scenario brief to after action reporting, each participant will be engaged in the study for a maximum of 2.5 hours, where 50 minutes is the maximum amount of time a participant can participate in a simulation run.

Figure 3. Autonomous documentation flow diagram from simulation data collection to algorithm development. TATRC: Telemedicine & Advanced Technology Research Center.



Data Annotation

Following the simulation, all simulated TCCC data collected on the sensor suites will be uploaded into TATRC's secure, PIA-approved data repository. The data are considered "unlabeled" and will require annotation with "labels" for future use in algorithm development.

Unlabeled sensor data must be annotated with labels defining a specific action necessary for algorithm development or "training." In this case, the object is to build algorithms that, based on sensor data collected in each scenario (input), infer a specific treatment or procedure was performed by providers (output). For example, if a combat medic is placing a tourniquet, then the algorithm must be able to correctly label this specific act using sensor-generated data including start and stop times. Task start and stop times are recorded relative to the simulation start time. The annotation process can be summarized as follows: annotations are applied to each simulation, and 2 annotators review the video and audio resulting from the simulation.

Individually, the annotators record start and stop times for standardized TCCC tasks of interest. Start and stop time identification is guided by pre-established start and stop time markers specific to each task. Examples of the annotations and descriptions of the time points can be visualized in Table 2 below.

1. Comparison and review: task periods (bounded by start and stop times) are compared between the 2 annotators. Any task with less than 80% overlapping between the annotators must be discussed and reannotated by each annotator. If an 80% overlap is still not achieved, another annotator will annotate and review the data. This process will continue until >80% overlap is achieved.
2. Label combination: the final bounds for each task are defined as the outermost stop and start times between the 2 annotators (ie, the union of A and B). The original start and stop times each annotator records, will also be maintained for transparency.

All annotations will be stored in a spreadsheet linked to simulation metadata via a unique simulation ID. The goal of this project is to develop a cloud-based dataset that will enable ongoing and future ML and AI algorithm development for automatic, passive documentation of DD Form 1380 data fields.

Table 2. Examples of annotations and descriptions of time points.

Task	Start time (s)	Stop time (s)	Duration (s)
Start of scenario	0	76	76
Tourniquet application	85	142	57
Chest seal application	167	253	86
Nasopharyngeal airway	195	214	19
Treat a casualty for a cold injury	270	346	76
Uses sensor	355	465	110
Documentation	404	579	175
Administer medication	542	579	37
Chest needle decompression	583	612	29
Initiate an intravenous	652	717	65
Uses sensor	681	708	27
Uses sensor	715	738	23
Initiate an intravenous	739	848	109
Administer medication	854	917	63
Administer fluids through an infusion	884	980	96
Documentation	923	954	31
Administer tranexamic acid	956	1048	92
Uses sensor	1010	1050	40
Documentation	1053	1116	63
Bag-valve-mask assisted ventilation	1125	1294	169
Chest needle decompression	1143	1164	21
Documentation	1209	1294	85
End of scenario	1293	1303	10

Ethical Considerations

Ethics Review Approvals or Exemption

This protocol was reviewed and approved by the USAMRDC IRBO, which included human subjects' ethics review. The approved protocol (#M-11057) was classified a minimal risk to human participants and undergoes annual continuing reviews by IRBO to ensure the safety and ethical considerations of research on all human participants in our research.

Informed Consent

Within 48 hours before the simulation scenarios are conducted, one of the research team members will provide the individual with a mailed hard copy or emailed electronic copy of the consent to review and contact them over either a secure telecommunication software or face-to-face, whichever is most convenient for the potential study participant. In either form of meeting, the ombudsperson is also present to explain that participation is voluntary and that the information provided about the research is consistent with the institutional review board (IRB)–approved materials. If over telecommunication software, the research staff member ensures the participant is in a private space and can adequately hear all explanations. If the consent process is in-person, the process takes place in a private area. The trained research effort staff members are completely trained on providing all necessary information to the potential participants and go through the consent form with them. This consent form explains the activities, potential risks, and data collection that the Principal Investigator would like to conduct. The consent form highlights that the data collected in this effort contains footage of the participant's faces or participants' voices. As the research team member reviews the consent form with the potential participants, they encourage the participants to ask questions about the data collection specifics.

After the review is complete, the participants are told they may review the consent information up until the day data are collected as the consent form describes and their decision to participate or does not negatively or positively affect their job. The potential participant also is given an opportunity to speak with the ombudsperson alone to discuss any concerns of participation they may have. If the potential participant agrees to participate, she is asked to sign the consent form. Participants will also be asked to sign an optional image release form for use in presentation, promotional, and marketing materials. The participants either sign in person or sign a virtual copy of the consent form and send this back to the research staff member, via methods such as DocuSign or in person. After signing, a copy of the signed consent form is provided to the study participant. The original consent forms are printed and stored in study files in a locked filing cabinet in the TATRC research office. Before leaving the consenting meeting, the volunteers will be reminded that they can reach out to the ombudsperson at any time if they have concerns about participating in this research effort.

Privacy and Confidentiality

Care providers and simulated patient participants are assigned a participant ID to be associated with collected demographics, video, and physiological signal recordings. All data are stored in DoD- and HIPAA (Health Insurance Portability and Accountability Act)-compliant safety and security compliant e-storage facilities. All hard copy documents including completed consent forms are stored in locked filing cabinets at TATRC.

The research team collects all video and physiological signal recordings. Following data collection sessions, all recordings are checked within 1-7 days and before media is removed to ensure no nonconsented individual's identifiable information was not recorded. If any inadvertent recordings were made, the PI or a study team member deletes these segments of recordings. All recordings are stored securely in a DoD-approved, TATRC maintained server or repository including a NAS at Fort Detrick, Maryland. The procedure for consent occurs prior to participants engaging in simulation scenarios. If a person does not consent to data collection, they will not participate in research activities.

One of the main aspects of the data that is collected is that the faces and physiological signatures of the simulated patients are included in the footage of the data. This is needed to be able to accurately train the algorithms and technology that is developing from this effort. This is made abundantly clear to the participants in the consenting process. If they do not consent to their faces being included in this data, they are not allowed to move forward with participating in the collection. Photo Release Waivers for image use in nonresearch activities accompany the consent forms at the start of participation but are entirely optional for participation in the study.

Compensation Details

Military volunteers who meet the eligibility requirements and consent to participate in the study have the opportunity to participate in volunteer hours as a participation incentive. After completion of their participation in the study, the participant may request a letter of participation from the research team. The eligibility for volunteer hours toward service recognition will be determined by the units or offices who grant the volunteer hours. The research team will provide the letter of participation in an electronic format to the participant's email address. This process will be mirrored at all data collection locations. There are no monetary incentives or compensation for this research effort for volunteers.

Results

TATRC is on track to collect and annotate approximately 2500 simulation procedures (or tasks) by March 2025. In addition to the data recorded at each TATRC-hosted simulation event, TATRC intends to continue to expand its data repository by acquiring data from similar recorded simulated events at other military and civilian organizations and creating or obtaining augmented or synthetic TCCC data through synthetic modeling environments (ie, digital twin systems). Synthetic modeling environments can generate novel TCCC data to increase the variety and complexity of the datasets. To furthermore diversify the datasets, TATRC plans to collect simulation data from non–TATRC sponsored events (ie, research conferences, operational exercises, etc). Combining both physical and augmented simulation data, TATRC's aspirational goal is to

accumulate approximately 100,000 TCCC simulated procedure or task recordings to populate and generate DD Form 1380 elements by the end of September 2025 (Figure 4). As the annotated simulation procedures are aggregated into TATRC's data repository, contracted extramural partners will commence algorithm and software development to support TATRC's goal if automating combat casualty care scene interpretation and patient encounter documentation to significantly reduce manual data entry and enhance the capabilities of combat medics. By September 2025, the extramural algorithm partners intend to complete the machine perception algorithms and associated software to leverage data collected by the AutoDoc suite of sensors to auto-populate all DD Form 1380 elements into a digital XML or JSON format.

Discussion

TATRC's AC2 mission focuses on addressing and improving the current reality for combat medics:

> *A distracted, stressed combat medic managing their way through a chaotic battlefield with multiple casualties surrounds them, with only a bag full of supplies, including one permanent marker and several DD Form 1380 cards.*

There are minimal improvements in how the Joint Forces have documented health data beyond our borders, specifically in operational settings in times of conflict, despite the large advancements in data science and technology in the last decade. TATRC's goal is to replace the current, paper-based process, with modern, passive data collection and automated documentation. The aim is not only to create a more reliable, accurate method for collecting casualty care data but to alleviate the care provider's cognitive burden in the battle space of this strenuous additional duty.

The methodology for collecting TCCC data may raise questions on why our research team is not leveraging existing or available datasets from historical conflicts. The simple answer is that they do not exist. During the Afghanistan and Iraq conflicts, there were approximately 30,000 documented casualties but only 10% of those casualties had any documentation of prehospital care, and 1% or less had sufficient information to inform care at the next echelon [7]. Similarly, an unpublished 15-month review by the Joint Trauma System (JTS) found that from 172 submitted DD 1380 Forms from the field, more than 50% of them did not meet the criteria for completeness as measured by a quality checklist developed by the JTS. Furthermore, there is a lack of data granularity necessary in medical documentation from the POI based on an analysis of the JTS DOD Trauma Registry database in 2011 by Therien et al [8]. How, when, and where this data was stored remains unknown. These previous publications have illustrated the extreme, nearly impossible, expectation of documenting TCCC while in the battle space. Limiting TCCC data collection to just 1 form and expecting this 1 form to travel with the casualty from the POI to their final treatment destination, without being damaged or lost, is the reason why only less than 1% of DD Form 1380 during the Afghanistan and Iraq conflicts were sufficient to inform the next echelon of care. The result is that there are no existing combat casualty care datasets within the MHS.

TATRC's solution to this data limitation is using scripted, simulated TCCC scenarios to capture the data. TATRC has partnered with other DoD entities to provide an environment emulating specific battlefield conditions generating realistic TCCC data outcomes. Together, TATRC and partners, are testing and refining the sensor suites while simultaneously diversifying the TCCC dataset and generating the volume of

data needed to create trustworthy solutions for care providers across the echelons of care. Although the AutoDoc project primarily focuses on building DD 1380 Forms, the data obtained across all research locations could be used to create an abundance of tools and capabilities, such as algorithms to automate personal health information documentation into an existing electronic health record (eg, MHS). The possibilities to use this data to benefit the warfighter are limitless as long as you can find a way. TATRC is devoted to having this data serve as a foundation for future research, development, test, and evaluation projects across the DoD to improve our understanding of TCCC and allow organizations across the DoD to build upon our work and create innovative tools to automate future healthcare and improve the current standard of care.

Acknowledgments

The authors would like to acknowledge the contributions of COL Jeremy Pamplin and COL Sharon Rosser for their leadership and encouragement during the initiation and execution of our new research journey.

In addition, the authors would like to acknowledge the contributions of the TATRC staff members in the development of this research protocol, including Carl Ducummon, SSG Lam Bui, Jonathan Chambers, Evan Feuer, Nathan Fisher, Sharon Garlena, Wesley Huff, Courtney Kentrus, Benjamin Knisely, Zack Lattimore, Jaeyeon Lee, Carl Manemeit, Moriah Newman, Keo Pich, Matt Quinn, Mark Spears, Jesse Steffens, Ann Trout, SPC Dustin Turner, and Kerri Virtz.

Finally, the authors would like to thank the United States Army Research Institute of Environmental Medicine for assurance and adverse effect reporting.

The funding for this project (#CO23004) is under the Joint Program Committee-6 Combat Casualty Care Research Program. The funder did not influence the design of the study or strategies related to its collection, analysis, or interpretation of data.

Abstract

Background: The obesity rate among women in Côte d'Ivoire is rising, particularly in urban areas. Merchantry is the leading occupation for women in the country, and merchant women face a high risk of obesity owing to their sedentary lifestyle. A previous survey indicated that the obesity rate among merchant women was 30%, double the national average. Furthermore, 82.2% of merchant women with obesity were unaware of their condition, and 40.1% expressed no interest in losing weight. While most weight loss programs target individuals ready to lose weight, community interventions should also address those with minimal readiness. Additionally, low-cost weight-loss interventions that do not require health professionals are needed in countries with limited medical resources. Smartphones could offer a cost-effective solution as they enable self-monitoring and remote communication.

Objective: This study will evaluate a low-cost smartphone-based intervention that targets individuals who are not ready to lose weight without the involvement of health professionals.

Methods: The intervention will run for 6 months, and its efficacy will be assessed in an unblinded, parallel-group, randomized controlled trial with 108 participants per group. All direct interventions for participants in this study will be carried out by staff without medical qualifications. The intervention group will receive weighing scales and be encouraged to record their weight with a smartphone app. Health education will be provided via weekly group messages and monthly phone calls. The evaluation will be conducted face-to-face. The primary outcome will be the weight change, and the secondary outcome will be differences in body fat percentage, abdominal circumference, and stage of behavioral change in weight loss behaviors from baseline to 3, 6, and 12 months.

Results: In accordance with this protocol, the recruitment of participants started on August 26, 2024. A total of 216 participants were allocated, with 108 in the intervention group and 108 in the control group. The baseline survey began on November 15, 2024, and is currently ongoing as of the end of November 2024.

Conclusions: This study will be the first in sub-Saharan African countries to implement a smartphone app-based weight loss program in sub-Saharan Africa that does not require direct intervention by health care professionals but specifically targets communities. Furthermore, if the effectiveness of this program is confirmed, it has the potential to serve as a low-cost sustainable weight loss model at the policy level.

Introduction

Background

Obesity caused an estimated 5 million deaths associated with noncommunicable diseases (NCDs) such as cardiovascular diseases, diabetes, cancers, and chronic respiratory diseases [1]. Additionally, its high prevalence in people 18 years and older is a critical issue, at 17.9% for women and 13.6% for men in 2022. In Africa, the obesity rate was 17% in women and 6.8% in men in 2022 [2]. This difference is particularly significant, making obesity among women an urgent issue. The percentage of women with obesity in Côte d'Ivoire has doubled compared to 20 years ago (7.3% in 2002 and 15.7% in 2022) [2].

The characteristics of the occupational style of African market traders indicate that these traders are at high risk of obesity due to long sedentary hours and easy access to food [3-5]. In Abidjan, the largest city in Côte d'Ivoire, 64.3% of working women are merchants [6], and merchant is a common occupation among women from lower- and middle-income groups. A survey of medical facilities in Abidjan also showed that merchantry was the most common occupation among patients with overweight and obesity [7]. Furthermore, our all-inclusive market survey showed that the obesity rate among merchant women is 30% [8], double the national average of 15.3%. This indicates an urgent need to address obesity among individuals in the merchant community.

Obesity is a substantial cause of NCDs such as heart disease and type 2 diabetes [9,10], and weight loss can reduce the risk of NCDs. However, in Côte d'Ivoire, there is no community-targeted weight loss program. In general, weight loss programs often target those who wish to lose weight. However, in African countries such as Côte d'Ivoire, where being plump is a symbol of wealth and power, many individuals with obesity have no desire to lose weight. Notably, 82.2% of merchant women with obesity who work at the targeted market were unaware that they had obesity, and 40.1% did not wish to lose weight (38.6% wished to maintain their current weight and 1.5% wished to gain weight) [8]. Thus, in an environment such as that in Côte d'Ivoire, developing measures to address obesity in communities that include those with minimal readiness for weight loss is necessary.

To increase the willingness of individuals with obesity to undergo weight loss, we must educate them on their condition and reasons to lose weight. Weighing is key to this; however, in our study, 53.3% of merchant women with obesity did not weigh themselves once a year, and 95.5% of them did not own a scale. Regular weighing is effective for weight loss even without interventions such as weight loss programs [11] and is one of the most cost-effective and easiest weight loss methods to implement. In this study, we aim to increase the awareness of one's own weight through regular weighing, promote awareness of health risks, and increase readiness for weight loss.

Noninvasive exercise and diet are the cornerstones of behavioral therapy as a treatment method for obesity [12]; overweight and obesity management guidelines [13] that include behavior change programs have been established in the United States. However, these are primarily conducted by primary care physicians in medical institutions and require advanced medical personnel and resources such as frequent counseling and elaborate individualized behavioral strategy planning. Therefore, implementing these behavior change programs as is in resource-limited countries such as Côte d'Ivoire is challenging [14,15].

Mobile health is cost-effective and impactful in supporting diet and exercise regimens [16-20]. Self-monitoring using smartphones is more effective than other methods of weight management [20]. Enhanced social support through online social networking services (SNSs) can also be effective. For example, Facebook groups have shown weight loss benefits [21]. In Côte d'Ivoire, WhatsApp is a popular private communication tool; however, studies on implementing behavior change using WhatsApp are limited [22]. Most studies that use smartphone apps and SNSs have been conducted in high-income countries. Such studies are limited in sub-Saharan Africa because sociocultural backgrounds and the use of smartphones and SNSs are different.

The prevalence of smartphones in sub-Saharan Africa was 45% in 2019 and is expected to steadily increase [23]. In our previous study, 77% of female traders in the target markets used smartphones [8], suggesting that interventions using smartphones are feasible. Smartphone use is important in areas requiring low-cost interventions.

Community-based weight loss interventions in sub-Saharan Africa include a group session intervention in South Africa [24] and a program initiated in Burkina Faso that includes multiple in-person dietary counseling sessions with experts [25]. These include multiple in-person sessions with health professionals, counseling, and health education.

Considering their feasibility in areas where medical resources are scarce, smartphone use that allows for remote intervention and methods that require less intervention by health care workers are required.

In this study, we aim to examine the effectiveness of a low-cost versatile weight loss intervention that can be implemented without intervention by health professionals in a community that comprises those with minimal readiness for weight loss. Specifically, this study will examine the effectiveness of a weight loss intervention that incorporates weight measurement promotion, the use of a smartphone app, and communication with non–health professionals among female merchants with

obesity in Côte d'Ivoire. This will be an unblinded, parallel-group, randomized controlled trial.

This paper outlines the study protocol of a randomized controlled trial, describing the intervention and examining its effectiveness.

Hypothesis

This study hypothesizes that the intervention group will achieve a weight loss of at least 2% [13] from baseline to 6 months, significantly differing from the control group. We will consider 2% weight loss as a clinically meaningful value; since the average weight of women with obesity in the target market is 85.6 kg [8], the equivalent of 2% is –1.7 kg. Based on the results of previous studies [19], this goal was deemed feasible.

Methods

Research Design

This study will focus on market A in Abidjan, Côte d'Ivoire. The effectiveness of the weight loss intervention will be tested in a parallel-group (1:1) randomized controlled trial among Merchant women with obesity within this market. As standard treatment, the control group will be weighed and provided with their BMI based on physical measurements, whereas the intervention group will receive a scale and the weight loss intervention using a smartphone app, and the differences will be compared. The study will be unblinded, and the effectiveness of the program will be evaluated after 6 months. In addition, a follow-up evaluation will be conducted 12 months later to assess sustained changes after the intervention is complete. We followed the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) 2013 statement and CONSORT-eHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist (V 1.6.1).

Eligibility Criteria

The target population will be female merchants between 18 and 65 years of age working in market A with a BMI ≥30 who own a smartphone for personal use and who can use WhatsApp. The exclusion criteria included those who are pregnant or lactating, those who are found pregnant during the intervention period, those for whom weight loss is contraindicated (due to a cancer diagnosis, eating disorders, poorly controlled hypertension, diabetes, etc), and those using physician-prescribed weight loss medication. If they have medical records, we will review them for the eligibility assessment. If they do not, we will ask about their conditions in detail and make a judgment.

Recruitment

Four interviewers and supporters will visit the target market, approach potential participants, and screen them to see if they satisfy the inclusion criteria by asking a few questions and taking physical measurements (weight and height measurements). If the participants were eligible, we explained the purpose of the study, the intervention and procedures, and the eligibility and exclusion criteria in detail and returned at least half a day later to obtain their signatures on a consent form. We also explained that the participants would be randomly assigned to either the intervention or control group and would not be able to self-select. We explained that all participants would be weighed regularly at the beginning of the intervention as well as 3, 6, and 12 months later, and that their height would be measured at the beginning of the study so that their BMI would be known each time. We further explained that the control group will have access to free scales placed at several locations in market A 12 months after the end of the entire study, which they can use at their leisure. We also informed them that smartphone apps and other devices would be introduced to them at the end of the study.

Participants could withdraw from the study at any time before data collection at 6 months by submitting a consent withdrawal form to a member of the research team.

Intervention

The weight loss intervention implemented in this study will target communities, including those who have no desire to lose weight, and will be low-cost without direct intervention by health professionals. The basic framework will be based on the American Heart Association (AHA)/American College of Cardiology (ACC)/The Obesity Society (TOS) guidelines for the management of overweight and obesity in adults [13] and the Burkina Faso program [25], which is implemented in the sociocultural context of West Africa. However, since both of these programs include direct intervention by health professionals, which differs from the purpose of this study, the content of the intervention is adapted to the situation in Abidjan in this study (Table 1). The weight loss intervention will be conducted for 6 months. The intervention will be based on self-weighing [11], which has been shown to be beneficial for weight loss, and will include the use of a low-cost personalized support smartphone app [16]. In addition, direct contact with the intervention group will be conducted by Ivorian non–medical professional supporters who were selected based on their research experience within Côte d'Ivoire and have received training for this study.

The intervention consisted of the following three components: (1) promoting weight measurement and encouraging self-monitoring through a smartphone app; (2) health education using a messaging app; and (3) in-person or telephone health education based on the stage of behavior change [26]. Lose it! (FitNow, Inc.) is a weight management app that will be used for weight self-monitoring [27], which has been used in weight loss programs in previous studies [20,28] and is available for free. WhatsApp, which is widely used in Côte d'Ivoire [29], can send and receive images, videos, audio, and text [30], and can deliver a variety of health education messages at low cost [31,32]. In addition, a step-counting app, such as Google Fit (Google Inc) for Android users and Health Care (Apple Inc) for iPhone users, can be installed for weight change and step-count monitoring. These apps will be installed on the smartphones of the intervention group, and participants will receive an orientation on their use. Additionally, they will be able to contact their supporters via WhatsApp to inquire about the use of Lose It! and another app at any time.

Health education should include recommendations for and emphasize the importance of a healthy diet, exercise, and weight

measurement. Diet and exercise content should be in line with the "Diet and Exercise" described in the "Obesity" chapter of the Côte d'Ivoire National Disease-Specific Cookbook Guidelines [33]. In-person or telephonic health education will be conducted once a month and tailored to the stages of behavioral change [26] (precontemplation, contemplation, preparation, action, and maintenance) of the target population. Interventions corresponding to the change process [34-36] of each stage are provided. The intervention stimulates interest in weight loss during the precontemplation stage, motivates implementation during the contemplation stage, supports implementation during the preparation stage, supports continuation during the action stage, and supports maintenance during the maintenance stage to maintain confidence in behavior. The intervention and evaluation schedules are shown in Table 2.

To maintain consistency among supporters in the intervention, a manual was developed on how to send health education material via WhatsApp. A manual for telephone interviews was developed, and supporters will conduct telephone interviews according to the manual and provide a report on the content of the interviews. Supporters will be trained on the content of the intervention and the survey to ensure the quality of the intervention and the survey.

No interventions are administered in the control group. For the control group, height and weight are measured at baseline and at data collection at 3, 6, and 12 months, and BMI is calculated and reported on the spot by the supporter. This allows participants in the control group to know their weight and BMI regularly. In addition, after the 12-month survey is completed, scales will be installed in the target markets free of charge so that participants can continue to measure their weights. In addition, we will introduce the app to those who wish to use it.

Table 1. Adaptations of the weight loss program following the American Heart Association (AHA)/American College of Cardiology (ACC)/The Obesity Society (TOS) guidelines for the management of overweight and obesity in adults.

Variable	AHA/ACC/TOS guidelines [13]	Intervention adapted to this study	Reason for adaptation
Participants and setting	Individual with obesity who contacted with general practitioner or another medical organization	Community recruitment	Many individuals with obesity are unaware of their obesity risk and do not feel the need to lose weight, making them less likely to visit a health care facility voluntarily.
Intervention method and frequency	In-person, high-intensity (≥14 sessions in 6 months) sessions and counseling for feedback (face-to-face or telephonic)	6 phone calls and 3 face-to-face health education sessions (focused on behavior change stages, not full medical counseling)	For nonmedical interventions, feasibility was considered.
Intervention duration	6 months	6 months	No change
Interventionist	Health professionals (registered dietitians, psychologists, exercise specialists, health counselors, or professionals in training) who adhered to formal protocols in weight management	Trained non–medical professionals over 3 days, covering coaching, intervention methods by behavior change stage, and diet/exercise per Côte d'Ivoire obesity guidelines	Côte d'Ivoire's limited medical personnel and resources were taken into consideration.
Weight loss goal	Loss of 5%-10% of baseline weight within 6 months	Loss of 2% of baseline weight within 6 months	It is a clinically meaningful minimum value and is feasible according to previous studies [8,19].
Physical activity	Advice by health professionals; increased aerobic physical activity (such as brisk walking) for ≥150 min	Recommend increasing the number of steps in one's daily routine and establish a step count goal	With limited facilities and resources for fitness programs, the plan recommends daily walking and using a smartphone app for exercise.
Dietary intervention	Advice by health professionals; daily energy deficit of 500 kcal typically achieved with dietary intake of 1200-1500 kcal/d for women	Advice from trained non–health professionals based on the National Recipe Guidelines: offer recommended local dishes and cooking tips	The method is feasible for non–health professionals, using guidelines adapted to local eating habits without calorie calculations, which are difficult for participants and interventionists.

[a]The intervention lasted from months 0 to 6.

Outcome

The primary end point of the study is to compare weight changes from baseline to the end of the intervention (6 months later) between the intervention and control groups.

Secondary end points include the differences in body fat percentage, abdominal circumference, stage of behavioral change in weight loss behaviors such as diet and exercise, percentage of individuals with correct weight perception, degree of body pain (with visual analog scale [VAS]), and self-rated health at the end of the intervention (6 months later) compared to baseline. Simultaneously, the intervention group will be evaluated in terms of the frequency of inputs to the self-monitoring apps, degree of participation in WhatsApp groups, average number of steps taken, and degree of weight loss during the intervention period.

To evaluate the interim process of the intervention, the intervention and control groups will be compared and analyzed in the same manner as described above, 3 months after the start of the intervention. In addition, the intervention group will be evaluated for weight change at 1, 2, 4, and 5 months and for changes in the behavioral change stage of weight loss behaviors such as diet and exercise.

As a follow-up evaluation after the intervention, both groups will be evaluated at 12 months (6 months after the end of the intervention) in the same way.

Sample Size Calculation

For the sample size calculation, we relied on a meta-analysis [19] of a smartphone app–based weight loss intervention. We applied –1.5 (95% CI –2.09 to –1.09) kg as the clinically meaningful difference between the 6-month smartphone-only intervention without face-to-face motivational interviewing and the control group, as indicated in the meta-analysis. However, the meta-analysis did not provide SD values, so we used the SD (–1.8, SD 3.7) [37] value of the smartphone self-monitoring–only intervention results as a reference and set the expected value at –1.5 (SD 3.7) kg. Furthermore, the α error was set at 5% (95% CI=1.96), power (1 – β error) at 80% (0.842), and the dropout rate at 10%. Based on the above values and after consulting a statistical expert, the sample size was calculated to be 108 individuals for each group (N=216 in total).

Assignment, Allocation Concealment, and Blinding

The random assignment will be performed using the permuted block method. Stratification will be conducted based on BMI (threshold: 32 kg/m^2) and age (threshold: 45 years), which represent the median values reported in a previous study. The four resulting strata will be as follows: (1) BMI ≥32 and age ≥45 years, (2) BMI ≥32 and age <45 years, (3) BMI <32 and age ≥45 years, and (4) BMI <32 and age <45 years.

The list of potential participants recruited was sent to study member allocator 1 in Japan. Allocator 1 prepares a provisional ID list that does not contain attributes other than BMI and age to ensure concealment and sends it to allocator 2. Allocator 2 creates an allocation table with an allocation ratio of 1:1 and BMI and age as adjustment factors using software for randomized controlled trial–stratified substitution blocks and allocates the provisional IDs to each stratum in descending order of provisional ID numbers, from top to bottom.

This study will be conducted in an unblinded manner. This is because the intervention group will be given a scale and an app to be installed; therefore, blinding of the participants will not be possible. In addition, the content of the questions asked during each evaluation differs between the intervention and control groups, making blinding difficult for supporters and research team members.

Data Collection Methods

Data will be obtained from supporters visiting the market to conduct face-to-face structured interviews (Multimedia Appendix 1) and anthropometric measurements. Body measurements will be taken at the time of recruitment to measure height and weight, and BMI will be calculated immediately. Subsequent data collection will include weight measurements, body fat percentage, and abdominal circumference. Height will be measured using a hardware SHUREMAN Lock Convex measuring tape (Kenoh Co, Ltd, Japan, model LC-5525) with a locking function, and an InBody (InBody Japan Inc, model H20N) will be used as the body composition scale. Structured interviews will be conducted using a questionnaire asking about sociodemographics, weight perception, behavioral change stages related to weight loss, behaviors related to weight management, body pain level (using the VAS scale), and the use of smartphone apps for weight management.

In addition, the intervention group will be asked about the weight and behavioral change stages of exercise and diet during the monthly telephone intervention.

Statistical Methods

The primary outcome will be evaluated by comparing the difference in weight change between the intervention and control groups 6 months after the intervention ended. In addition, the effectiveness of the weight loss intervention will be estimated using a linear regression model with weight change at 6 months as the dependent variable and the affiliation group, stratification variables, and other sociodemographic attributes as covariates.

Among the secondary outcomes, weight, body fat percentage, abdominal circumference, and degree of body pain (VAS scale) will be measured and compared in the same way as the primary outcome at all evaluation periods (3, 6, and 12 months). Other secondary outcomes will be compared to differences in rates at baseline and 3, 6, and 12 months. These analyses will follow the intention-to-treat principles. Additionally, intention-to-treat and per-protocol analyses will be performed and compared to address cases of protocol noncompliance.

Within the intervention groups, weight loss will be used as the dependent variable, and linear regression model analyses will be performed to estimate the impact of self-monitoring input frequency, WhatsApp group participation, and sociodemographic characteristics as covariates.

Data Management and Monitoring

All data will be collected on paper, entered into an Excel data entry format, and stored as digital data. The reason for this is that the intervention in this study involved self-monitoring of weight by app and encouraging behavioral change, so no significant safety issues are foreseen [38,39].

The research team will create a participant management sheet and continuously monitor the participants' health and weight loss status during the supporters' calls to identify any problems. During the study period, supporters will hold web-based meetings with the research team 1-6 times a month to share the participants' situation, which will facilitate the detection of unexpected adverse events.

Ethical Considerations

This protocol (version 6) and all related materials for this study were reviewed and approved by the Ethics Committee for Research on Life Sciences and Medicine Involving Human Subjects of Yokohama City University, Japan (approval General 2024-020) and by the National Ethics Committee in Health and Life Sciences of Côte d'Ivoire (RefNo 218-23/MSHPCMU/CNESVS-km). In the event of a protocol change, the ethics committee and UMIN Clinical Trials Registry will be notified.

After receiving a full explanation face-to-face, the participant will be asked to sign an informed consent form. At the same time, the participant will be informed that she can withdraw her consent (Multimedia Appendix 2). The collected digital data will be password-protected, and the paper-based data will be stored in a locked cabinet. Additionally, the data for this research will only be accessible to the research team members who have been instructed to maintain strict confidentiality. The results of this research will be published in a peer-reviewed international scientific journal.

The study was registered in the UMIN Clinical Trials Registry (ID 000055142) (Multimedia Appendix 3).

Results

In accordance with this protocol, the recruitment of participants started on August 26, 2024; by September 8, 2024, a total of 231 people were recruited. After reconfirming eligibility, one participant was excluded, and from 230 people, 108 were allocated to the intervention group and 108 were allocated to the control group. The baseline survey began on November 15, 2024, and is currently ongoing as of the end of November 2024.

Discussion

Expected Findings

The expected outcomes will analyze body weight, body fat percentage, and abdominal circumference. It is anticipated that the intervention group will achieve greater reductions in these three indicators compared to the control group. Additionally, the difference between the intervention and control groups is expected to be greater at 6 months and remain stable at 12 months.

Comparisons With Prior Work

There are fewer community-based weight loss programs in sub-Saharan Africa than those conducted within health care facilities. One such program is that of Herrmann et al [25];

however, it primarily involves interventions led by health care professionals with specialized knowledge and does not use smartphones or web-based media.

In our study, we deliberately chose to use nonmedical staff as direct interventionists to evaluate the feasibility of implementing a weight loss program by those staff in sub-Saharan African countries where human resources in health care are particularly scarce.

Additionally, weight loss programs that use smartphone apps often recruit participants via web-based media, thereby primarily attracting individuals who are already motivated to lose weight [20]. Our study differs from previous research in that it targets communities with cultural norms that view being plump as a virtue, includes individuals who may not be aware of the need to lose weight, and recruits participants through face-to-face interactions.

To our knowledge, this is the first study to implement a smartphone app–based weight loss program in sub-Saharan Africa that does not require direct intervention by health care professionals and targets specific communities.

Study Significance and Feasibility

The findings of this study will provide information on the effectiveness and feasibility of a smartphone app–based weight loss program for communities in sub-Saharan Africa. Additionally, it will offer evidence on the extent to which interventions led by nonmedical individuals can be effective.

In Côte d'Ivoire and neighboring countries, the most common occupation among women is merchant [40-43]. If the feasibility of using smartphone apps within this community is demonstrated, it could pave the way for applying it to other health programs. Furthermore, if the effectiveness of this program is confirmed, it has the potential to serve as a low-cost, sustainable weight loss model at the policy level.

Limitations

First, the intervention cannot be blinded to the participants because those in the intervention group will receive a weighing scale. It is also difficult to make the supporters blinded because the questionnaires are different between the two groups. Second, it is not possible to perfectly prevent the participants from exchanging information with each other. However, we will try to understand the status of communications between the two groups by including a related question in the questionnaire. Third, the target population of the study may not represent all female merchants in Côte d'Ivoire as we only included those who have smartphones. However, as the smartphone ownership rate among female merchants in the market in the previous study was 77% [8], we judged this to be feasible.

Acknowledgments

Abstract

Background: While cognitive behavioral therapy has shown efficacy in treating stress-related disorders, such as adjustment disorder and exhaustion disorder, knowledge about factors contributing to treatment response is limited. Improved identification of such factors could enhance assessment procedures and treatment strategies. In addition, evaluating how traditional prediction methods and machine learning can complement each other may help bridge gaps in understanding and predicting treatment response.

Objective: This study aims to (1) evaluate putative predictors of treatment response in patients with stress-related disorders using traditional prediction methods and (2) model treatment outcomes using a machine learning approach. This design combines the interpretability of traditional methods with the ability of machine learning to identify complex patterns.

Methods: We will analyze data from a randomized controlled trial comparing 2 internet-delivered treatments, cognitive behavioral therapy versus an active control treatment, for patients diagnosed with adjustment disorder or exhaustion disorder (N=300). Prediction models will be based on pooled data from both treatment arms due to the limited sample size and lack of knowledge on predictors of treatment effects. Putative predictors include sociodemographic and clinical information, clinician-assessed data, self-rated symptoms, and cognitive test scores. The primary outcome of interest is responder status on the Perceived Stress Scale-10, evaluated based on the reliable change index posttreatment. For the traditional approach, univariate logistic regressions will be conducted for each predictor, followed by an ablation study for significant predictors. For the machine learning approach, 4 classifiers (logistic regression with elastic net, random forest, support vector machine, and AdaBoost) will be trained and evaluated. The dataset will be split into training (70%) and testing (30%) sets. Hyperparameter tuning will be conducted using 5-fold cross-validation with randomized search. Model performance will be assessed using balanced accuracy, precision, recall, and area under the curve.

Results: All data were collected between April 2021 and September 2022. We hypothesize that key predictors will include younger age, education level, baseline symptom severity, treatment credibility, and history of sickness absence. We anticipate that the machine learning models will outperform a dummy model predicting the majority class and achieve a balanced accuracy of ≥67%, thus indicating clinical usefulness.

Conclusions: This study will contribute to the limited research on predictors of treatment outcome in stress-related disorders. The findings could support the development of more personalized and effective treatments for individuals diagnosed with adjustment disorder or exhaustion disorder, potentially improving clinical practice and patient outcomes. If successful, this dual approach may encourage future studies with larger datasets and the implementation of machine learning models in clinical settings, ultimately enhancing precision in mental health care.

Introduction

Background

Mental disorders have a negative effect on quality of life, often precipitating personal suffering and work disability [1]. Around 23% of all who receive a psychiatric diagnosis in Swedish primary care receive a stress-related diagnosis [2], and these account for most psychiatric long-term sickness absences [3]. In Sweden, disorders believed to stem from persistent or overwhelming subtraumatic life events are often categorized using the diagnostic labels adjustment disorder (AD) or exhaustion disorder (ED). Even though ED is only recognized as a medical diagnosis in the Swedish version of the *International Classification of Diseases, Tenth Revision*, the clinical picture of ED is similar to the internationally acknowledged burnout construct [4], a condition that is often associated with significant suffering and work disability [5].

According to diagnostic definitions of AD and ED, these conditions develop in the context of one or several subtraumatic life events (stressors), resulting in mixed symptoms of anxiety, depressed mood, disturbed sleep, fatigue, and impaired memory and concentration. They share symptomatology with other mental disorders, and their diagnostic validity is debated [6,7]. Despite evidence indicating the efficacy of cognitive behavioral therapy (CBT) [8-10] and problem-solving interventions [11] on symptoms of stress, many studies have suffered from significant attrition, and knowledge regarding the factors that contribute to treatment response is still limited [8,12]. Improved identification of such factors could facilitate development of improved assessment procedures and adaptive treatment strategies that might improve outcomes [13].

Research on predictors of psychiatric treatment outcomes is limited [14,15] but demographic factors (eg, age and education level) [16,17], clinical characteristics (eg, use of medication and symptom severity) [17-19], treatment-related factors (eg, treatment credibility and adherence) [16,18] and cognitive functioning [20] have been associated with treatment outcomes.

When it comes to studies investigating predictors of treatment for stress-related disorders, Kocalevent et al [15] found that symptoms of anxiety but not perceived stress, depressive symptoms, or demographic variables predicted self-rated mental health following treatment for patients diagnosed with AD. In a study investigating burnout, Pallich et al [21] identified emotional competence, but not demographic characteristics, as a predictor of treatment response. However, both of these studies suffer from limited generalizability due to their inadequate description of the treatment offered, the fact that the interventions were conducted in an inpatient setting, and the lack of control groups. In ED patients, one study identified several predictors of treatment outcome following multimodal rehabilitation, including younger age, baseline symptom severity (insomnia, anxiety, and depression), perfectionism, physical activity level, treatment credibility, and a history of sickness absence due to ED [22]. However, the effects of demographics and pretreatment symptoms were so small that they offered limited clinical utility. In sum, at the current stage of research, it is a challenge for clinicians to determine who will benefit from treatment, underscoring the imperative for more sophisticated predictive studies.

Traditionally, prediction in psychiatry has relied on interpretable linear or logistic regression models. The aim has been to identify variables explaining a statistically significant portion of the variance in outcome, under the premise that such variables should inform researchers and clinicians. For example, the presence of previous sickness absence and earlier unsuccessful treatment attempts might lead a psychologist to conclude that a patient requires additional support, possibly extending the treatment duration. Although this approach of identifying predictors has offered some clinical utility, it often falls short in practice; the predictive power of specific variables in isolation is typically inadequate to inform assessment, treatment selection, and adaptations of interventions. Given the inherent complexity of mental disorders, the likelihood of pinpointing strong predictors with clinical utility is small, thus limiting the practical value of this approach [23,24].

Machine learning (ML) represents a promising methodological shift in psychiatric prediction modeling, transitioning from the identification of statistically significant predictors to an emphasis on quantifiable model performance, characterized by ensemble methods and adaptability to new datasets. This approach often sacrifices explainability in favor of enhanced predictive performance but offers unique value in handling the complex, nonlinear, high-dimensional data characteristic of mental disorders [25]. With this approach, a model generates a prediction (eg, remission, yes or no) intended to be actionable for a clinician. For example, patients predicted to have low probability of treatment success could be offered additional psychological support or an alternative intervention, thus increasing the likelihood of remission [26,27].

Forsell et al [28] have proposed a balanced accuracy (BACC) threshold of 67% as a benchmark for clinical utility in psychiatric applications, offering a tangible goal for ML implementation. However, the efficacy of ML in this domain remains an ongoing area of inquiry, and its capacity to surpass conventional methods in clinical usefulness is yet to be established [29].

Given the high prevalence and substantial societal costs associated with stress-related disorders, it is imperative to critically evaluate both the applicability and the limitations of ML within this specific context. Such an assessment will not only contribute to the broader understanding of the role of ML in precision psychiatry but also inform the development of more effective diagnostic and treatment strategies for stress-related disorders.

Objective of the Study

The overall objective of this study is to predict treatment outcomes in patients with stress-related disorders. Due to limitations in existing methods for prediction analyses, this study aims to first evaluate putative predictors using a traditional prediction paradigm, and second to model treatment outcomes using an ML approach. Our primary outcome of interest is responder status after treatment on the Perceived Stress Scale-10 (PSS-10), evaluated using the reliable change index (RCI; further described in the Planned Statistical Analysis and Data Cleaning and Preparation sections). On the basis of earlier research on predictors of treatment outcome, we hypothesize that key predictors will include younger age, education level, baseline symptom severity, treatment credibility, and history of sickness absence. Furthermore, we anticipate that the ML models will outperform a dummy model predicting the majority class and achieve a BACC of ≥67%, thus being indicated clinically useful [28].

Methods

Study Design

We will use collected data from a randomized controlled trial (RCT; N=300) of internet-delivered CBT for patients diagnosed with AD or ED compared to an active, internet-delivered control condition consisting of general health-promoting advice. A priori power analysis conducted for the main outcome in the RCT indicated that 300 study participants would be needed for a 90% power to detect a between-group effect size of Cohen *d*=0.4 with a significance level of .05 and an expected attrition rate of 10%. Due to the limited sample size and general lack of knowledge on predictors of treatment effect, prediction models in this study will be based on pooled data from both treatment arms. The study design is prospective, and predictors will include sociodemographic and clinical information, clinician-assessed data, self-rated symptoms, and results from cognitive test scores. The results will be reported in line with the TRIPOD+AI (Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis or Diagnosis+Artificial Intelligence) statement [30].

Ethical Considerations

The study was approved by the Swedish Ethical Review Authority (registration 2020–03198; 2023–06857-02) and was preregistered on ClinicalTrials.gov (NCT04797273). All participants provided written informed consent before inclusion, and their data are pseudonymized and securely stored on an encrypted server. Participants received no monetary compensation but accessed study interventions free of charge. No identifying information of participants will be included in the manuscript or supplementary materials.

Procedure

Participants

In total, 300 nationally recruited individuals were diagnosed with a primary diagnosis of AD (n=142, 47.3%) or ED (n=158, 52.7%) and were included in the RCT. Participant recruitment was carried out through social media, newspaper advertisements, and information provided to health care clinics. Participants self-referred to the study web page, where they signed digital informed consent and completed a screening battery consisting of sociodemographic and clinical background questions as well as self-report symptom questionnaires. Participants were subsequently clinically assessed by a psychologist using a structured diagnostic interview, including Mini International Neuropsychiatric Interview [31], self-rated ED [32], and the Adjustment Disorder New Module-8 (ADNM-8) [33]. For inclusion, participants needed to (1) fulfill the criteria for a primary diagnosis of AD or ED, (2) be aged between 18 and 65 years, (3) have regular access to a computer with internet access, and (4) be able to read and write in the Swedish language. Exclusion criteria included (1) drug use or addiction during the past 6 months, (2) current or past psychosis or bipolar disorder, (3) current risk of suicide, (4) changed psychopharmacological treatment in the past month, (5) other ongoing psychological treatment, and (6) previous experience of CBT for AD or ED in the past year.

Treatment

Patients were randomized to one out of two 12-week internet-delivered treatments (CBT and general health-promoting advice). They both consisted of web-based text-based modules with related exercises and assignments. Patients were guided sequentially through the modules by a therapist via a secure web-based platform. The therapists' primary role was to provide feedback on exercises, support in problem-solving, and to give emotional and technical support via weekly asynchronous text messages. Therapists were licensed clinical psychologists or clinical psychology students in their final year of training. Because this study will not evaluate the individual treatments, they will not be further described here. A full description of the treatments is described in the study by Sennerstam et al [34].

Outcomes

The primary outcome in this study and the original RCT is PSS-10 [35]. The PSS-10 is a self-report questionnaire developed to evaluate an individual's perception of life as unpredictable, uncontrollable, and overwhelming. Responses are recorded on an ordinal scale ranging from 0 n*ever* to 4 *very often*, reflecting the individual's feelings and thoughts over the

past month. It contains statements, such as '*In the last month, how often have you been upset because of something that happened unexpectedly?*' and sum scores range from 0 to 40. The PSS is the most commonly used outcome measure of stress-management interventions globally [8,36,37]. For this study, a Swedish version of the PSS-10 was used. The PSS-10 has been found to exhibit high internal consistency (Cronbach α=0.84) and adequate construct validity [38]. The PSS-10 was administered digitally through the web-based study platform before randomization to treatment, every 3 weeks during the treatment phase, and at treatment completion (12 weeks). During treatment, the instructions for the PSS-10 were modified to have patients consider the last week instead of the last month. For this study, the sum score of the PSS-10 will be dichotomized into responder or nonresponder after treatment based on the RCI criteria [39] to differentiate between statistically significant change and those attributable to measurement error or natural variability. The PSS-10 baseline and 3-week measurement will also be used as predictors.

Putative Predictors

Overview

Predictors were gathered through self-report measures that were administered in the web-based study platform, clinical assessment conducted before inclusion to the study, and remote cognitive testing. Table 1 presents all predictors included in the study.

Table 1. Putative predictors of treatment outcome in stress-related disorders

Predictor	Construct measured	Type	Clinician-rated	Scoring range
Sociodemographics				
Age (y)	—[a]	Interval		18-65
Sex	—	Categorical		Male or female
Relationship status	—	Categorical		3 categories
Number of children	—	Interval		0-∞
Educational attainment	—	Ordinal		9 categories
Employment status	—	Categorical		8 categories
Employment type	—	Categorical		11 categories
Self-rated computer skills	—	Ordinal		5 categories
Self-rated reading skills	—	Ordinal		5 categories
Swedish native speaker	—	Categorical		Yes or no
Clinical characteristics				
Number of medications	Medication	Interval	✓	0-4
Antidepressants	Medication	Categorical	✓	Yes or no
Sleep medication	Medication	Categorical	✓	Yes or no
Pain medication	Medication	Categorical	✓	Yes or no
Anxiolytics	Medication	Categorical	✓	Yes or no

Sociodemographic Variables

Information on age (interval), sex (male, female, other, or prefer not to disclose), relationship status (in relationship, single, or widowed), number of children, educational attainment (in 9 categories between <9 years of school to PhD), employment status (eg, student, unemployed, or full-time work), and employment type (in 11 categories, eg, employed in the private sector, by the municipality, or other) was gathered before the start of treatment using the web-based study platform. Self-rated reading and computer skills were rated separately on a 5-step ordinal scale from *poor* to *very good*. Patients also reported if they were Swedish native speakers.

Clinical Characteristics

During the clinical interview, patients reported their medication regimen, specifying both the number (0-4) and type of medication (antidepressants, anxiolytics, sleep medication, and pain medication and yes or no). Primary diagnosis (AD or ED), and possible secondary psychiatric diagnosis (eg, anxiety or depressive disorder) was assessed by the clinician using Mini International Neuropsychiatric Interview, self-rated ED (ordinal categories ranging from *no* to *yes—to a high degree*) [32], and the ADNM-8 [33]. Using ADNM-8, the patient was asked about which specific stressors had been present in the past 2 years (in 16 options, eg, *too much or too little work* or *financial difficulties*). The clinician assessed the length of the current episode (in months), and the age of the patients first episode (in years). Sick-leave status upon inclusion in the study (0%-100% in 5 steps), length of current sick-leave episode (*0-1 months* to *>12 months* in 5 categories) was self-reported.

Self-Rated Symptoms

Alcohol use was assessed using the Alcohol Use Disorder Identification Test [40,41]. This 10-item screening instrument evaluates alcohol consumption, drinking behavior, and alcohol-related problems over the past year. It contains items, such as *How often do you have six or more drinks on one occasion*? rated on various ordinal scales, typically ranging from 0 to 4.

Symptoms of anxiety were measured using the Generalized Anxiety Disorder-7 scale [42]. This screening tool assesses generalized anxiety symptoms over the past 2 weeks. It comprises 7 items, such as *not being able to stop or control worrying* rated on a 4-point ordinal scale ranging from 0 *not at all* to 3 *nearly every day*.

Symptoms of burnout were measured using the Shirom-Melamed Burnout Questionnaire [43,44]. It aims to measure 3 components of burnout; emotional and physical fatigue, cognitive weariness, and listlessness and contains statements such as *I have difficulty concentrating* rated on a 7-point scale ranging from 1 *never or almost never* to 7 *always or almost always* with some items using reversed scoring.

Symptoms of depression were measured using Montgomery-Åsberg Depression Rating Scale [45]. It is a 9-item questionnaire used to measure different aspects of depression such as concentration difficulties, suicidal thoughts, sadness, and affected appetite with answers rated on a 7-point ordinal scale from 0 to 6.

Symptoms of exhaustion disorder were measured using the 9-item Karolinska Exhaustion Disorder Scale [46]. Measuring different aspects of exhaustion such as fatigue, endurance, and sleep impairment, answers are rated on an ordinal scale from 0 to 6 (eg, ability to concentrate; ranging from 0 “I do not have any difficulty concentrating, and can read, watch TV and converse normally” to 6 “I cannot concentrate on anything at all.”)

Functional disability was measured using The World Health Organization Disability Assessment Schedule (2.0) [47], developed to assess functioning in the last 30 days in 6 different life domains, including cognition, mobility, self-care, relationships, life activities, and societal participation. It contains statements, such as “I have difficulty standing for longer periods such as 30 minutes.” Answers are rated on a 5-point ordinal scale ranging from 0 *never* to 4 *extreme or unable*. A 12-item version was used.

Quality of life was assessed using the EQ-5D-5L [48,49] and the Brunnsviken Brief Quality of Life Scale [50]. The EQ-5D-5L contains 5 dimensions: mobility, self-care, usual activities, pain or discomfort, and anxiety or depression each rated on 5 levels of severity from *no problems* to *extreme problems*. The Brunnsviken Brief Quality of Life Scale is a 12-item questionnaire that assesses 6 life areas (leisure time, view on life, learning, creativity, view of self, and friends and friendship). Ratings range from 0 *strongly disagree*, to 4 *strongly agree*, on statements of the importance and satisfaction of each area.

Insomnia severity was measured using the Insomnia Severity Index [51]. The Insomnia Severity Index is a 7-item questionnaire designed to assess aspects of insomnia, including difficulty falling asleep, difficulty staying asleep, and satisfaction with sleep. Ratings are given using an ordinal scale ranging from 0 to 4.

Self-rated health was assessed using Self-Rated Health 5 asking patients to rate their general health on a scale of 1, *very bad* to 5 *very good* [52].

Somatoform symptoms were assessed using the Patient Health Questionnaire [53]. It consists of 15 questions covering somatic symptoms commonly seen in primary care, such as back pain, headache, and nausea. Answers are rated on a 3-point ordinal scale ranging from *not at all bothered* to *bothered a lot.*

Subjective memory impairment was measured using the 6-item Questionnaire of Everyday Memory Problems (6-QEMP) [54]. A 5-item version has previously been used to assess subjective memory problems in this patient population [55,56]. The present version was adapted by Stigsdotter Neely for use in patients with stress-related disorders with statements, such as “How do you think your memory functions now compared to before your stress-related mental health problems?.” The answers are rated on a 5-point ordinal scale.

Treatment-Related Predictors

Clinician Treatment Expectancy was judged after patient assessment, upon inclusion in the study, by clinicians rating the probability of the patient improving after treatment on a scale of 0 *no improvement* to 10 *full remission*.

The *Treatment Credibility Scale* was administered 3 weeks after the start of treatment [57]. Patients were asked questions about their impression of the treatment and if they thought they would improve. It included statements such as "How logical do you think this treatment is?" and "How confidently would you recommend this treatment to a friend with the same problems as you?" on a scale of 0 *not at all* to 10 *very logical*, *very confidently.*

Cognitive Functioning

Attention and processing speed were measured using the Symbol Digit Modality Test. A test originally developed by Smith [58,59] that measures visual detection, attention, and processing speed. A key with 9 different symbols and matching numbers is shown on the upper part of the display. At the center one of these 9 symbols are shown and the task of the participant is to choose the corresponding number using the key as guidance. The test score is the number of correct entries in 90 seconds. Comparable substitution tasks are considered sensitive to treatment effects for patients with multiple sclerosis [60] and depression [61], and it has been used in patients with stress-related disorders [62].

Executive functioning was measured using the Verbal Fluency Test (FAS) Word Fluency Test and the Stroop test. FAS was first described by Spreen and Benton [63], and it measures spontaneous verbal fluency and selective attention and shifting. The participant is tasked with producing words beginning with a certain alphabet letter (F, A, and S). Names, numbers, or repeated words are not allowed. The test score is the number of correct words beginning with the letter. FAS and similar word fluency tasks have been shown to be impaired in patients with stress-related exhaustion [62].

The Stroop test, originally developed by Stroop [64] and described by Jensen and Rohwer [65], measures executive functioning, inhibition, as well as updating and processing speed [66]. The test has 2 parts, (1) 20 color words are presented (green, yellow, blue, or red) and they are colored congruent to their meaning (eg, the word red colored in red). In the bottom part of the display, the color words are displayed on 4 buttons. The task is to, as quickly and thoroughly as possible, click the correct button. (2) Twenty color words are presented but displayed in an incongruent color (eg, the word red colored in green). The task of the participant is to click the button containing the color of the word as quickly and thoroughly as possible. Test score is calculated as an index (number of correct answers in part 2 divided by average time in seconds from part 2) and for interference (average time in part one–average time in part one). Performance of Stroop in patients with stress-related disorders has been shown to be impaired in 2 studies [62,67], but not in others [68,69].

Memory and learning were assessed using the Consortium to Establish a Registry for Alzheimer's Disease (CERAD) Word List Learning Test and Corsi block-tapping test forward. CERAD was originally developed for use with Alzheimer disease [70] but is similar to other word-list tasks used in this patient population. It measures verbal learning and episodic memory. In the learning part of the test, a word list containing 10 words is presented over 3 trials and the task after every trial is to recall the words from the list. For every presentation the order is mixed. In the delayed recall part of the test (trial 4) that occurs after 5 to 10 minutes, the participant is asked to recall the words. Test score for the learning time is number of correct words in trial 1 to 3, and in the delayed recall part, number of correct words in trial 4. Similar word-list tasks have been used previously to assess memory functioning in patients with stress-related disorders [62,69].

Corsi block-tapping test forward gives information about visual ability of attention, short-term memory and working memory [71]. It contains 2 parts, but in this test battery, only the first part of the test is used. Nine blocks are displayed, and the testing platform starts by lighting up a sequence of blocks. The task is to repeat the sequence of blocks that the platform has displayed. The task starts out easy with only 2 blocks, but the difficulty increases by adding a longer sequence of blocks until the participant enters the incorrect sequence twice at the same number of blocks. The test score is the maximum number of correct repeated blocks. A cross-sectional study comparing patients with stress-related disorders to a healthy normative group found impaired performance on this test [62].

Planned Statistical Analysis

All data will be prepared and analyzed using the latest version of Python [72] and the libraries NumPy [73], Pandas [74], and scikit-learn [75] or equivalent statistical packages. A notebook containing the analysis in documented code will be made available on Open Science Framework [76] for research transparency following the analysis.

Data Cleaning and Preparation

We will transform categorical variables into a format suitable for numerical analysis. For binary categorical variables, we will use label encoding. For multinomial variables, we will apply one-hot encoding. In addition, for ordinal data, which have a natural order, we will transform the categories into integers.

Predictor variables with over 20% missing data will be excluded from the analysis. Categorical variables exhibiting low variance, as determined by predictors with <5% of a certain response will be removed. For instance, by removing the variable "Sleep medication" if it only occurs in 3 out of 300 patients. This approach aims to reduce unnecessary complexity in the predictions and to minimize the risk of overfitting. To control for multicollinearity, variables with a correlation coefficient ≥0.8 will be removed from the traditional prediction analysis but will be retained for the ML model development. Data that are highly skewed will be transformed if deemed appropriate.

Cognitive test results will be manually reviewed before model fitting to validate a proper result. Comments pertaining to technical difficulties and disturbances that may have affected the test result will be assessed by two of the authors and lead to exclusion if so judged. Participants who have noted during

screening that Swedish is not their native language will be excluded from the analysis for CERAD and FAS. We will standardize the raw scores from the cognitive tests using normative regression models with age, education and sex as covariates. This standardization process will convert raw scores into *Z* scores, as previously described by Franke Foyen et al [62] and for a full overview of the multiple linear regression models used and how they were calculated, see the studies by Mindmore [77] and van den Hurk et al [78].

Patients who have missing data for the posttreatment PSS-10, ie, the missing outcome variable for the primary aim, will be replaced by a PSS-10 process measurement at week 10 if available; If not, the patient will be excluded from the analysis. The number of participants excluded from the final models will be described.

To prepare our primary outcome, RCI for the PSS-10 before to after treatment will be computed using the following formula [39]:

Cronbach α=0.83 from normative data will be used [38]. Patients exhibiting an RCI of −1.96 will be classified as responders.

Descriptive Statistics

Descriptive statistics will be used to summarize the sample characteristics and pretreatment variables, including mean or median, SDs and IQR for continuous variables, and proportions for categorical variables.

Predictor Analysis

For the traditional regression analysis, data will be imputed using the KNN imputer. The imputer, a nonparametric imputation method, works by imputing missing values based on the k-nearest neighbors; in this study *k* will be determined by cross-validation. It uses the Euclidean distance metric to find the nearest neighbors and can be used for both numerical and categorical data. Each missing value is imputed using values from its k-nearest neighbors. After imputation, we will run univariate logistic regressions for each predictor listed in Table 1 using RCI as a target variable. Predictors that are statistically significant in the univariate analyses will then be included in an ablation study, a systematic approach to evaluate feature importance. This method involves iteratively removing each significant predictor from a full model, measuring the change in explained variance, and then reinserting it, thereby quantifying each predictor's unique contribution to the model's explanatory power in the context of all other features.

ML Model Development

For an introduction on the technical terms introduced in this section, see the review article by Bzdok and Meyer-Lindenberg [13].

Train Test Split

As the ultimate goal of any model is to predict an outcome in unseen data, the ML models will be developed using a training set, and then evaluated on a test set stratified on main diagnosis (AD or ED) and responder status. In total, 70% of the data will be used for selecting predictor variables and training the models, and 30% for testing the prediction accuracy of the models. The choice of 70 to 30 was due to the limited size of our sample, as fewer observations in the testing data makes it difficult to use uncommon predictors. No external validation set is currently available at the time of writing.

Standardization and Imputation

Standardization and imputation will be applied on the training and test data separately to avoid data leakage. Numerical data will be standardized and all missing data will be imputed using the KNN imputer.

Model Descriptions

We will train and evaluate 4 different ML classifiers, a multiple logistic regression (LogReg) classifier using elastic net, a random forest (RF) classifier, a support vector machine (SVM) classifier, and an AdaBoost classifier. For a review of the models used, see the textbook by Geron [79]. In short, the LogReg classifier works by modeling the probability of a binary outcome based on one or more predictor variables, using the logistic function to ensure the output is between 0 and 1. We will use elastic net regularization to facilitate feature selection and prevent overfitting. Elastic net combines L1 (lasso) and L2 (ridge) penalties, encouraging sparsity and maintaining stability in the model. The RF classifier works by building multiple decision trees on random subsets of data and predictors. Each tree's prediction is based on splits that minimize variance in the target variable, with the final model ensembling these predictions. The SVM classifier works by finding the hyperplane that maximizes the margin between different classes in the feature space. SVM is particularly effective in high-dimensional spaces and when the number of dimensions exceeds the number of samples. AdaBoost, the final classifier, works by combining multiple weak classifiers, typically decision trees, into a single strong classifier. It sequentially fits these weak learners on repeatedly modified versions of the data, focusing more on misclassified instances to improve overall accuracy.

Hyperparameter Tuning

We will conduct 5-fold cross-validation using randomized search for hyperparameter tuning and training evaluation to enhance the external generalizability and robustness of the results. This process involves defining a hyperparameter space, then randomly selecting a predetermined number of samples—in this case, 10—from this space, and conducting 5-fold cross-validation for each selected set of hyperparameters. Fivefold cross-validation is done by partitioning the data into 5 subsets, training the model on 4 subsets, and validating it on the remaining subset. This process is repeated 5 times, with each subset used exactly once as the validation data. The best performing hyperparameters will be chosen for the final models that are trained and then evaluated on the test set.

The hyperparameter ranges for the LogReg will include C values from 0.01 to 100 and l1_ratio values from 0 to 1. For RF, the parameter ranges will include the number of estimators from 5 to 1200, minimum samples required to split a node from 10 to 200, maximum depths from 5 to 750, and a binary indicator for bootstrapping. For SVM, the parameter range for the randomized search will include regularization parameter C values from 0.01 to 1 and for AdaBoost, the parameter ranges for the randomized search will include the number of estimators, ranging from 1 to 1500, and learning rates from 0.001 to 2.5.

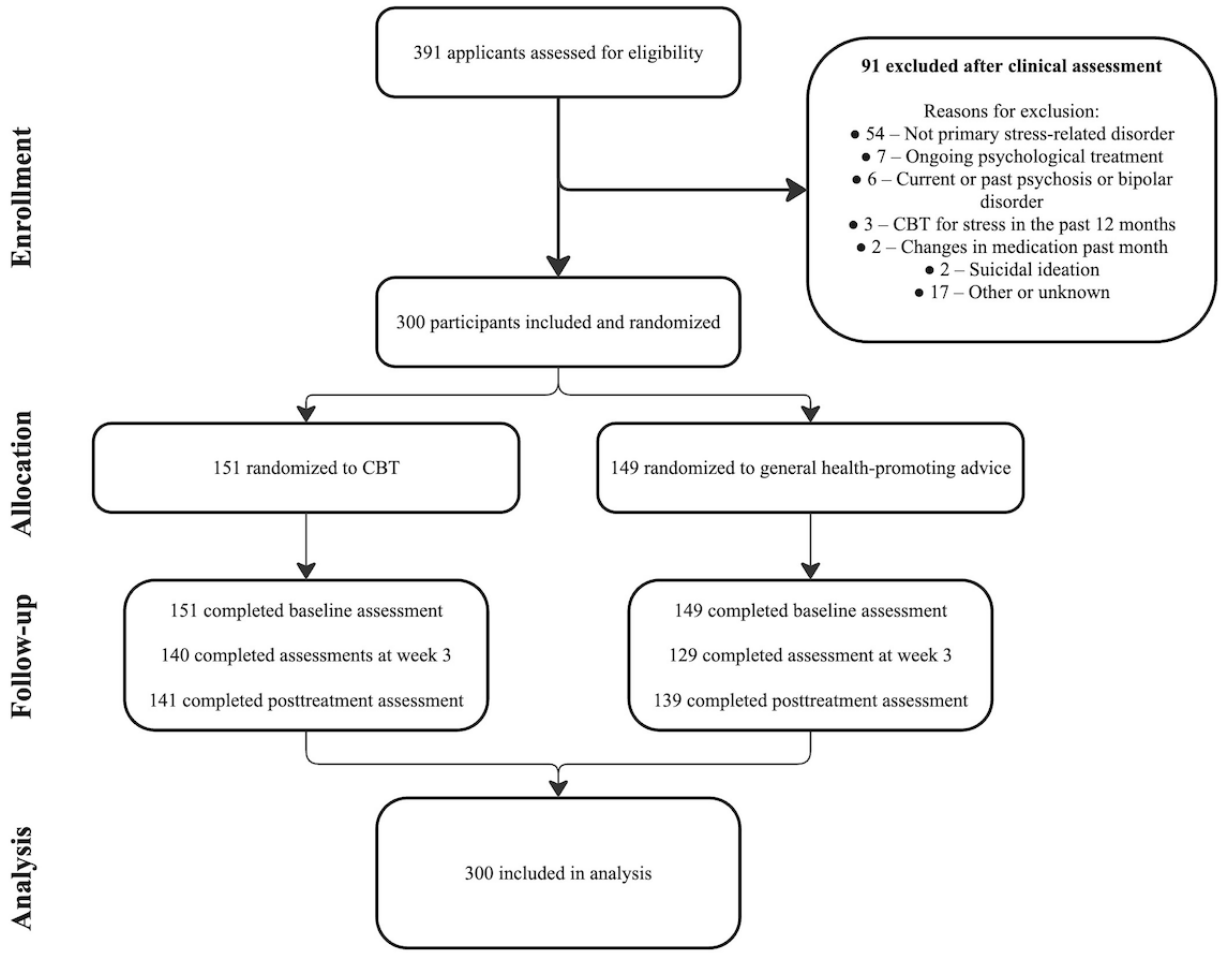
Model Interpretation

The models developed to identify the responder status will be evaluated using BACC, precision and recall, both in the training set obtained through k-fold cross-validation and in the test set. Predictor importance in the RF model will be determined using Scikit-learn's Feature importance function, which quantifies each predictor's contribution to the model's balanced classification accuracy. Area under the curve will be used to assess the models' capability to distinguish between classes accurately. The approach will aim to provide a clear understanding of the models' effectiveness and the role of various predictors. Our primary outcome of interest for comparison will be BACC in each model in the test set with the aim that (1) the model should perform better than a dummy model that simply predicts the most common responder status, and (2) that the model should perform 67% BACC or above to be deemed clinically useful [28]. Furthermore, the models will be statistically compared using bootstrap sampling. Specifically, we will generate 5000 bootstrap samples from the test set, calculating the BACC for each model on each sample. The distributions of these bootstrap BACCs will be compared and we will conclude that there is a statistically significant difference between models if the CIs do not overlap.

Results

This study was funded by ALF medicin (20190148), Region Stockholm (SLSO 2022–1278; SLSO 2022–1276), and Region Stockholm in collaboration with Stockholm university (FoUI-939533). OF is supported by the Swedish innovation agency (No. 2022-00549). All data were collected (N=300) between April 2021 and September 2022. For a participant flow diagram throughout the study, see Figure 1.

Figure 1. CONSORT (Consolidated Standards of Reporting Trials) diagram showing participant flow through enrollment, allocation, follow-up, and analysis. CBT: cognitive behavioral therapy.



A cross-sectional study investigating baseline cognitive functioning as compared with a healthy reference group has been published indicating small-to-moderate objective cognitive impairments [62], raising the question of whether objective cognitive function serves as a predictor of treatment response. In addition, an interim analysis of pre- and postcomparisons was presented at a conference in September 2022. These earlier analyses addressed separate research questions and did not influence the design, methods, or objectives of the current protocol. As of March 2025, data have not been analyzed for this study.

Discussion

Overview

This study will use a high-quality dataset from an RCT to investigate potential treatment predictors using both traditional prediction methods and an ML paradigm. This dual approach will enable the identification of predictors of treatment response in a patient population where prior research is limited. In addition, it will facilitate comparisons between different methodological approaches to prediction research.

Comparison to Prior Work

To the best of our knowledge, this is the first study to apply an ML approach to study predictors of treatment outcome in patients diagnosed with AD or ED. In line with previous traditional prediction research of treatment outcomes in stress-related disorders, we hypothesize that younger age, education level, symptom severity, treatment credibility, and history of sickness absence will predict treatment response [15,22]. Furthermore, we anticipate that the ML models will outperform a dummy model and achieve a BACC of 67% or higher, surpassing the benchmark indicated by Forsell and others [28]. If confirmed, our findings would support the notion that predictive models using sociodemographic, clinical, self-rated, treatment-related, and potentially cognitive variables are valuable when predicting therapy outcomes, as have been suggested in other patient populations [17,18,80]. In subsequent research, these models should be externally validated and tested in implementation trials to assess their utility as decision support tools. Such trials could evaluate whether integrating predictions into treatment planning improves outcomes and supports personalized care.

Strengths and Limitations

The study's strengths include the use of a multimodal dataset from an RCT, including objective cognitive functioning. By comparing traditional prediction methods with advanced ML models and employing techniques, such as cross-validation and hyperparameter tuning, the study has the potential to generate robust and generalizable insights into treatment outcomes, contributing to methodological advancements in prediction research.

A limitation is the modest sample size (N=300) which may increase the risk of overfitting. While smaller sample sizes have been used in previous ML studies [80-82], it is well established that limited sample sizes can hinder generalization [23]. The minimal sample size required for ML prediction in mental health research depends on the explanatory power of the predictors, with some researchers advocating for at least 300 observations [83], while others recommend a larger sample of 500 to 1500 for studies involving predictors with low explanatory power [84]. External validation is widely regarded as the gold standard to ensure model generalizability [85], but such data are not currently available for this study. However, ongoing data collection by the research group may enable external validation in the near future. In the meantime, k-fold cross-validation on the training set and validation on a separate test set will be used to estimate and mitigate overfitting, providing a basis for model evaluation within the study's constraints.

In addition, the recruitment strategy, which relied on social media, newspaper advertisements, and health care clinic referrals, may introduce selection bias and limit the generalizability of the findings. Participants recruited through these channels may not fully represent the broader population of individuals with stress-related disorders, potentially overrepresenting individuals with higher internet access, health literacy, or willingness to participate in internet-delivered interventions. These factors should be considered when interpreting the applicability of the study's results to other settings or populations.

Finally, ML models, such as RF, while effective at handling complex datasets, often prioritize predictive performance at the expense of interpretability. Unlike traditional statistical methods, their inclusion of numerous variables can make it challenging to understand the relationships between predictors and outcomes, limiting their integration into clinical practice where transparency is essential. Efforts to address this, such as using feature importance metrics, will be necessary to bridge this gap moving forward.

Implications for Clinical Practice

The study's findings could significantly impact clinical practice by contributing to the limited research on predictors of treatment outcome for stress-related disorders. Given the current lack of a gold standard treatment for AD and ED, this research is particularly timely and relevant. The investigation into ML models for treatment outcome prediction may encourage future larger-scale studies and, potentially, the implementation of these models in clinical settings as decision support tools. These could help clinicians tailor treatments by integrating complex data, such as patient demographics, symptom severity, and treatment history, to recommend evidence-based options, guiding therapy selection, and monitoring progress in real time. By operationalizing predictive insights, decision support tools could enhance clinical precision, reduce trial-and-error in treatment, and improve patient outcomes for individuals with stress-related disorders.

Acknowledgments

The research team gratefully acknowledges the contributions of all study patients, without whom this work would not have been possible.

Data Availability

The data referenced in this study protocol are not yet available, as the study has not yet been conducted. Once the study is completed, data may be made available on reasonable request, subject to compliance with Swedish law (the Swedish Ethical Review Act: 2003:460). For such requests, please contact the corresponding author.

Conflicts of Interest

LFF was previously employed by the cognitive testing company Mindmore until 2023 and runs a small-scale clinical psychology practice. All other authors declare no other conflicts of interest or financial involvement.

Abstract

Background: Individuals taking oral anticancer agents (OAAs) often face important challenges, requiring more timely informational support, ongoing monitoring, and side effect management.

Objective: This study, guided by the Self-Efficacy Theory, aims to assess the feasibility, acceptability, and potential effects of a comprehensive, digital OAA intervention.

Methods: A 2-arm, mixed methods, pilot randomized controlled trial took place at a large university-affiliated cancer center in Montreal, Quebec, Canada. Participants (N=52) completed baseline self-report e-questionnaires and subsequently were randomly assigned to the experimental group (intervention plus usual care, n=26) or control group (usual care only, n=26). The study intervention, designed to increase medication adherence via medication adherence self-efficacy and decreased symptom distress, included (1) OAA informational videos, (2) OAA-related e-handouts and other supportive resources, (3) nurse-led follow-up calls, and (4) e-reminders to take OAAs. The e-questionnaires were completed once a week for the first month and every 2 weeks for the subsequent 4 months, or until OAA treatment was completed. A subset from both groups (n=20) participated in semistructured interviews once they completed the study requirements. Study feasibility is assessed using recruitment, retention, and response rates, as well as intervention uptake. Through e-questionnaires and exit interviews, intervention acceptability is to be assessed prospectively at baseline and retrospectively upon study completion. Potential effects are then assessed via medication adherence self-efficacy, medication adherence self-report, and symptom distress.

Results: Data collection was completed by December 2023 with a final sample size of 41. Results are expected to be published in 2025.

Conclusions: This study relies on a theoretically based, OAA digital intervention with modalities tailored to the needs and preferences of participants. The use of quantitative and qualitative methods enriches our understanding of the potential contributions of the intervention. In addition, following participants over the course of treatment captures potential changes in oral treatment–related processes and outcomes.

Introduction

Background

It is estimated that 18.1 million new cancer diagnoses occur globally every year [1,2]. Whereas survival rates vary among cancer diagnoses and countries, mortality rates for the most prevalent cancers in high-income countries continue to decrease [2,3]. Individuals with cancer are living longer and with higher quality of life due to improvements in prevention, detection, and advancements in treatment [4]. More specifically, driven by cost-effectiveness, patient convenience, and the potential for improved patient outcomes, the use of orally administered anticancer drugs continues to grow. It is now estimated that 60% of all new cancer medications currently in development are oral, across all cancer types and stages [5].

Oral anticancer agents (OAAs), having grown in popularity in the past few years, demonstrate equivalent efficacy, safety, and outcomes as intravenous chemotherapy, while being less invasive and easier to administer [6]. As OAAs are taken at home rather than in cancer centers or hospitals, medication management resides with patients- requiring them to be active in their care [7]. For OAAs to be as effective as possible and demonstrate outcomes equivalent to those seen in clinical trials, patients must follow best practices for their treatment, resulting in added responsibilities for medication management [8]. These include attention to treatment adherence, as well as monitoring and management of side effects and adverse events, especially at OAA treatment onset when side effects and toxicity may be high [9,10]. However, the literature to date suggests that patients often report having unmet OAA-related needs, feeling helpless at home, receiving insufficient knowledge and support to manage their treatment, and having suboptimal medication adherence [10-13].

A Canadian survey conducted among individuals treated for cancer in the last 6 months (N=3300), for instance, found that only 62% of individuals on OAAs reported receiving information and guidance on potential side effects and how to manage them, compared to 74% for radiation and 76% for intravenous chemotherapy. In the same sample, only 67% of individuals on OAAs felt their care provider did everything they could to help with side effects, compared to 73% for radiation and 76% for intravenous chemotherapy [14]. Elsewhere, the lack of OAA information and monitoring for side effects were found to be significantly related to fatigue, nausea and vomiting; change of taste; and poorly managed mouth sores [15].

Medication adherence, the extent to which a person's medication-related "behavior corresponds with agreed-upon recommendations from their health care provider" [16], denotes a collaborative relationship between the health care provider and patient where the patient plays an active role in taking their prescribed treatment [17]. Medication adherence is construed as one of the primary determinants of treatment success, as unwanted alterations in dose and timing affect treatment-related outcomes [18,19]. However, medication adherence rates for OAAs vary significantly, with a systematic review across 63 studies reporting adherence rates ranging from 46% to 100% [20]. Lower OAA adherence is found to be related to decreased treatment effectiveness, increased health care utilization, and increased costs due to more physician visits, higher hospitalization rates, longer hospital stays, and in some cases, decreased survival [21-24].

As OAA development and use expands, medication adherence issues related to OAAs are increasingly of interest to multiple stakeholders, including policy makers, insurance companies, drug makers, health care providers, and researchers [25]. A systematic review of factors influencing adherence to oral anticancer drugs identified three potentially modifiable factors that interventions should address: (1) side effects and toxicities, (2) forgetfulness, and (3) the lack of timely information [26]. The American Society of Clinical Oncology and the Oncology Nursing Society jointly released evidence-based guidelines and OAA management standards. These emphasize patient education at OAA initiation and ongoing monitoring throughout treatment to enable early identification of side effects and toxicities, thus preventing complications [27,28]. Consequently, there is a need for more timely and more accessible patient support for individuals taking OAAs [28].

A comprehensive, personalized, digital OAA intervention was developed based on Bandura's [29] "Self-Efficacy Theory." One of the intervention goals is to increase medication adherence by increasing medication adherence self-efficacy (SE) and symptom distress. SE refers to individuals' beliefs in their own ability to successfully perform a specific task related to specific behavior, for instance, remembering to take medication on time to adhere to treatment, or effectively self-managing fatigue experienced from treatment [29,30]. A systematic review of the relationship between SE and medication adherence found a positive link between these two variables in 59 out of the 66 studies reviewed [31]. Behavior is influenced by the interaction between perceived SE and expectations surrounding the outcome of the behavior; thus, medication adherence is affected by a patient's belief in their capacity to consistently remember to take medication and the belief that consistently taking the medication, as prescribed, will be an effective treatment to kill cancer cells in their body. Knowledge and self-management skills of disease care can enhance SE through expectations [32]. In support of this, a standardized patient education and follow-up intervention for oral chemotherapy by Tokdemir and Kav [33] successfully increased medication adherence SE after the intervention (66.39 vs 71.04; $P<.05$). Herein, we tested a broader multimodal intervention that went beyond patient education.

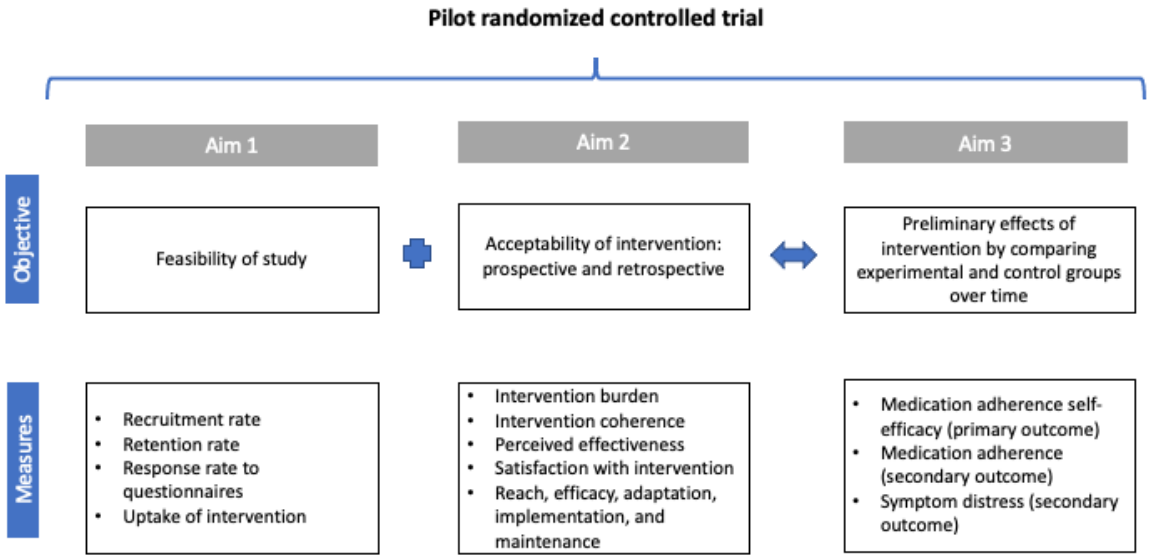
Purpose of Study

The aim of this pilot randomized controlled trial (RCT) was to document the feasibility and acceptability of the experimental

intervention. Pilot studies are critically important as a first step to address practical, logistical, and methodological issues that may arise. In addition, this pilot RCT seeks to determine whether study components can be executed and delivered to participants as planned and the intervention's potential impact on medication adherence SE, adherence, and symptom distress among participants on OAAs.

More specifically, the study's first aim was to establish feasibility, defined as "whether the intervention, study design, and procedures can be successfully executed by the researcher and delivered to the participants as planned" [34]. The constructs of feasibility herein include participant recruitment, retention, self-report questionnaire response, and uptake of the intervention. Predetermined objectives and measures of success for each are reviewed in the *Methods* section while Figure 1 provides an overview.

Figure 1. Study aims, objectives, and measures.



The second aim is to determine the acceptability of the intervention. The definition and measures of acceptability are based upon theoretical framework of acceptability of health care interventions by Sekhon et al [35], which defines acceptability as a multifaceted construct reflecting the appropriateness of the intervention. A key feature of this framework is the distinction between prospective, concurrent, and retrospective acceptability, emphasizing that acceptability can be assessed before, during, and after the intervention as all 3 can have an impact on participant use and access to the intervention. Although Sekhon et al [35] propose 7 concepts of intervention acceptability, only the 3 most relevant are included herein, namely intervention burden, coherence, and perceived effectiveness.

The third aim of the study focuses on documenting the potential effects of the intervention: As stated in the CONSORT (Consolidated Standards of Reporting Trials) on randomized pilot and feasibility trials [36], pilot trials may assess potential effectiveness using surrogate outcomes—substitute measures used as alternatives to clinical outcomes that may be challenging to assess directly [36]. Herein, potential intervention effects are assessed by comparing experimental and control groups over time, from baseline, every 2 weeks (depending on the outcome), and after the intervention. It is hypothesized that over time, compared to the control group, the experimental group will report higher medication adherence SE, higher medication adherence, and lower overall symptom distress.

Methods

Design

A prospective, mixed methods, 2-arm, pilot RCT is being conducted to address the study aims and hypothesis.

Setting

The study takes place at a large academic cancer center in a university-affiliated hospital in Montreal, Quebec, Canada.

Ethical Considerations

The study received approval from the Psychosocial Research Ethics Committee of CIUSSS West-Central Montreal Research Ethics Board (Project 2021-2861). Participants provided written informed consent. A randomly generated unique number (combination of numbers containing no identifiers) was generated and assigned to each participant such that all data collected were deidentified. As a token of appreciation for the time spent completing study e-questionnaires at baseline and follow-ups, participants received a CAD $10 (a currency exchange rate of CAD $1=US $0.69 is applicable) gift card at baseline as well as an additional one for each set of e-questionnaire completed. In sum, each participant could receive a maximum of CAD $120 in gift cards over the 5-month study period. If they withdrew from the study at any time, they receive a minimum of CAD $10 for the baseline e-questionnaire with an additional CAD $10 for each follow-up e-questionnaire completed.

Sample

A sample of 52 participants (26 per arm) was to be recruited and randomly assigned, at any moment from the decision to start OAA therapy to the completion of their first oral medication cycle.

Sample Size

Sample size calculation was undertaken using procedures provided by the software program G*Power 3 [37]. As per our statistical consultant, the calculation was undertaken to determine adequate power in the determination of the potential effects of the intervention (aim 3), in which a repeated-measures ANOVA with a within-between interaction would be the statistical test used. The parameters for the power calculation included an effect size of 0.25 (standard medium effect size for ANOVA) [38], α of .01, and a power of 0.95. The sample size was further increased to account for a 30% attrition rate over the study duration, determined to be appropriate given a review of attrition rates in supportive oncology trials found a mean of 26% (95% CI 23%-28%) across 18 trials (ie, the original sample size was 36, total with added 30%, attrition is 52) [39].

Inclusion Criteria

The inclusion criteria were as follows: being 18 years or older; being seen at the study cancer center; having a diagnosis of cancer at any stage; and being about to start or within the first cycle of oral anticancer treatment (traditional cytotoxic, targeted therapy, or hormonal therapy as adjuvant treatment). Potential participants had to have access to a computer tablet or smartphone device with internet, as well as the ability to communicate, read, and write in English or French.

Exclusion Criteria

The exclusion criteria were as follows: receiving intravenous chemotherapy, immunotherapy, or oral hormonal therapy as long-term maintenance treatment for the prevention of cancer's return or growth of cancer cells after initial treatment, assisting in prolonged remission; any significant physical or cognitive limitations that would prevent the ability to fully participate in the study (as reported by the patient, primary health care provider, or research staff); and being at imminent "end-of-life," defined as a condition in rapid decline whereby active treatment is stopped and considered in the actual process of dying [40]. We also excluded patients who were already participating in an ongoing clinical trial.

OAA Experimental Intervention

All study intervention components were available remotely using a study-specific access code on Belong – Beating Cancer Together [41], a supportive digital platform with a closed community for patients, caregivers, and health care providers at the institution to create networks and connect with other patients [42]. Participants could access the platform on their smartphone or tablet and enter an access code for the study as a closed community in the platform. As opposed to a "one-size-fits-all" approach, the study intervention accords the choice to select the support received. Participants in the experimental group were provided access to all intervention components and chose which specific components to use at any time during study participation. The intervention was developed through rigorous multistakeholder consultation processes, beginning with a comprehensive review of existing OAA-related interventions and evidence by the senior author. Noting no published OAA-specific supportive interventions at the time, the senior author (CGL) secured funding from the Rossy Cancer Network to design and test an OAA intervention, including videos and e-handouts addressing potential side effects and complications related to OAA intake. After meeting with Precare, a company providing educational video resources to patients [43], the first and senior authors gathered initial intervention feedback from oncology nurses, oncologists, researchers, cancer community organizations, patient partners, and informal caregivers or family member representatives. More specifically, these stakeholders provided insights into the content, duration, and overall aspects of the videos and e-handouts, contributing to the refinement of the intervention format and delivery. The final version was thoroughly reviewed by the first and senior author and subsequently integrated into an app [41]. The multimodal OOA intervention components are mentioned in Textbox 1 and Figures 2-4 below.

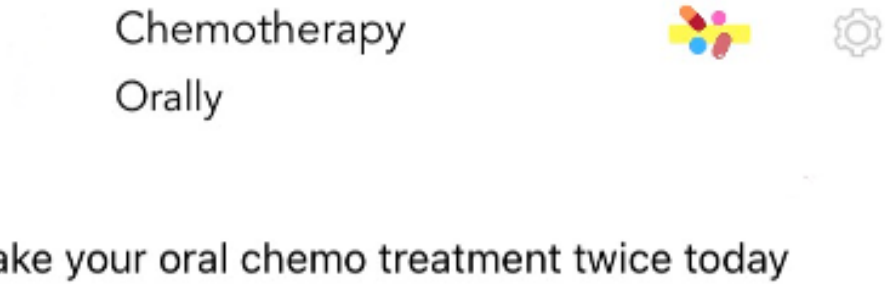
Textbox 1. Multimodal oral anticancer agent intervention components.

1. Oral anticancer agent informational videos
   - Topics: General information, side effects, support, fertility and work, and symptoms
2. Symptom management tip sheets and additional web-based resources
   - Topics: Pain, fatigue, drowsiness, nausea and vomiting, lack of appetite, shortness of breath, depression, anxiety, well-being, insomnia, fear of cancer recurrence, and work
3. Call with a nurse navigator.
   - Support and dispatch
4. Medication reminders
   - Reminder notification pop-ups
5. Any combination of services above

Figure 2. The multimodal OAA intervention contained OAA informational videos on general information (seen here), side effects, support, fertility and work, and symptoms. OAA: oral anticancer agent.

Figure 3. The multimodal OAA intervention contained symptom management tip sheets and additional web-based resources on pain, fatigue (seen here), drowsiness, nausea and vomiting, lack of appetite, shortness of breath, depression, anxiety, well-being, insomnia, fear of cancer recurrence, and work. OAA: oral anticancer agent.

Figure 4. The multimodal OAA intervention contained medication reminders as reminder notification pop-ups. OAA: oral anticancer agent.



OAA Informational Video

In the context of this study, an evidence-based animated video was developed (Figure 2). The content of the video has been reviewed by multiple stakeholders, including health care providers, patients, and caregivers. The video is available to be watched in English or French, with subtitles available in 16 languages. The video contains 4 parts: general information on oral chemotherapy, side effects, support, fertility and work, and symptoms.

Symptom Management Tip Sheets and Additional Web-Based Resources Common Physical and Psychosocial Concerns of Oral Anticancer Therapy

These e-handouts provide knowledge, facts, tips, and additional or telephone resources (Figure 3). The content has been reviewed by multiple stakeholders, including health care providers, patients, and caregivers. The e-handouts are available in French and English on the following 12 topics: pain, fatigue, drowsiness, nausea, lack of appetite, shortness of breath, depression, anxiety, sleep, fear of cancer recurrence, and work. The e-handouts are available for download in PDF format.

Follow-up Calls From Oncology Nurse

Participants in the experimental group can receive a call from the oncology nurse specific to their tumor site. A participant may request a phone call at each follow-up e-questionnaire by selecting “I would like to receive a phone call from a nurse” and identifying the topic they would like to discuss. The study coordinator forwards the participant’s name and contact number to the nurse. The participant’s symptom scores from the e-questionnaire are shared with their nurse at this time. The nurse calls the participants and speaks to them on the topic of their choice, and the interaction is documented in the patient chart as a virtual encounter.

Medication Reminders

Participants can receive daily e-reminder notifications on their smartphones to take their OAA medication (Figure 4). The e-reminders use preconfigured templates tailored to a 21-day cycle (14 days on per 7 days off) or a 28-day cycle (21 days on and 7 days off) that users must select, with options for once or twice daily reminders. Upon the conclusion of each cycle, users receive a notification prompting them to refill their prescription and reload the 21-day or 28-day cycle template.

In sum, the study intervention was designed to increase SE for OAA adherence through direct mastery experiences (self-management and reminders), vicarious experiences (video), verbal persuasion (phone calls), and feedback (self-management and reminders).

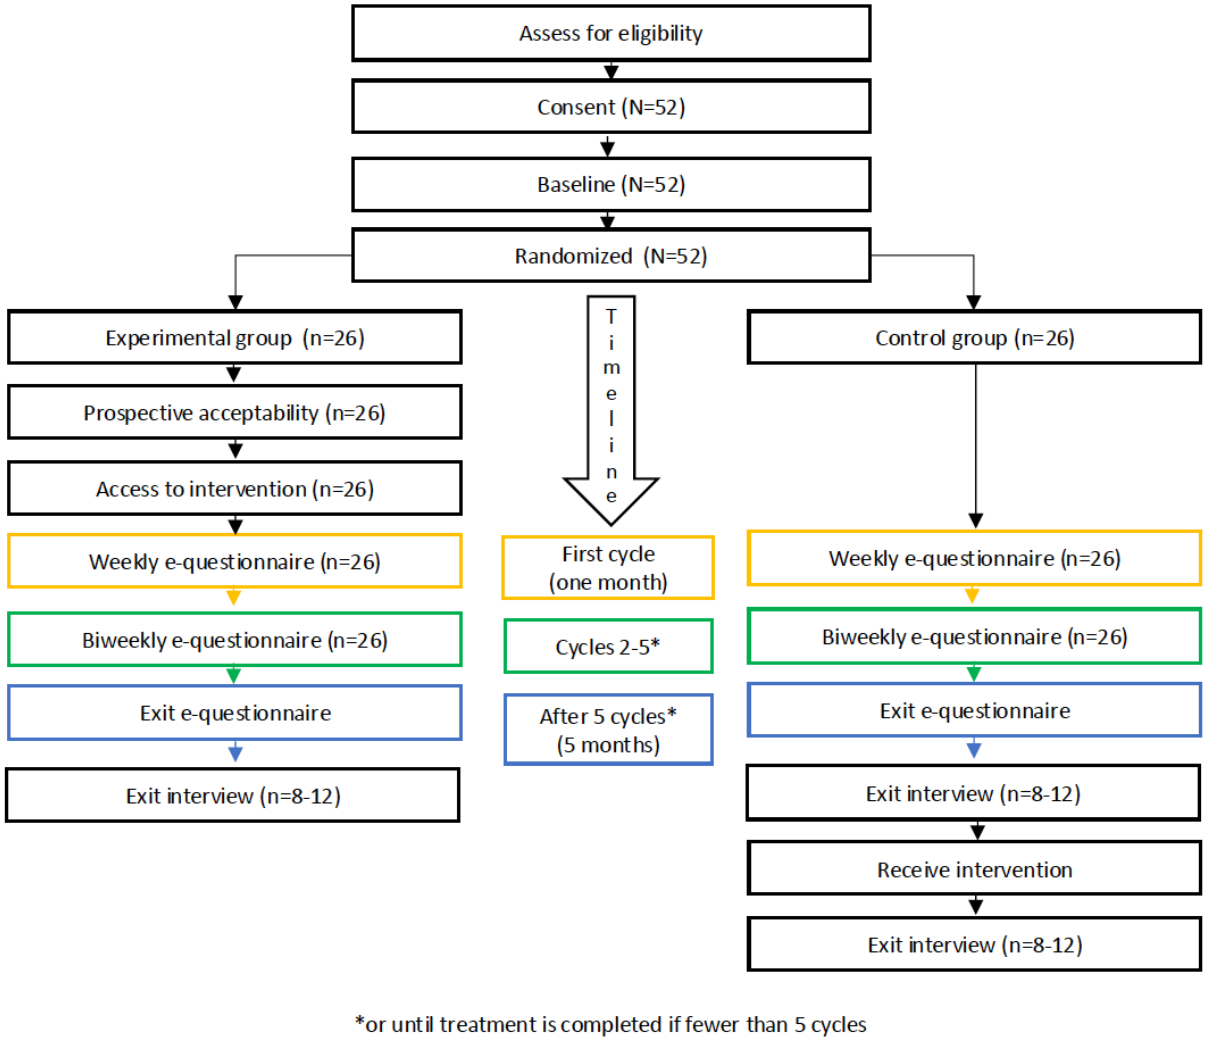
Participants in the control group continued to receive care as usual. This includes follow-up care with their oncologist, contact with their pharmacist and nurse as needed, as well as access to any internal and external supportive services from other health care professionals (eg, psychosocial oncology, social services, physiotherapist, occupational therapist, etc).

Recruitment, Consent, and Randomization

Participant recruitment occurred at the cancer center in two ways. First, a member of the oncology clinical care team (oncologist, radiation oncologist, nurse, or administrative staff) briefly explained the study and asked patients if they were interested in hearing more about the study. If yes, a member of the study team was informed (in-person, email, or telephone) and contacted the patient. Second, a study poster placed at relevant locations within the cancer center contained the contact information (QR code, email, and telephone number) of the study team. The patients then contacted the team directly.

Interested individuals met with a member of the research team in person or communicated over email or telephone. Study details were provided, and eligibility was verified. If still interested and eligible, a secure link to an electronic consent form was emailed, followed immediately by the baseline questionnaire. Participants were randomly assigned to intervention plus usual care (experimental group, n=26) or usual care only (control group, n=26). Once initial consent was given, those in the experimental group reconsented. Participants in the control group were blinded to group assignment (Article 3.7A of Tri-Council Policy Statement 2) [44]. The randomization sequence was determined on R (R Core Team), a software program, using the randomized R package for clinical trials [45]. Diagram of study design, measurement points, and timeline is shown in Figure 5.

Figure 5. Diagram of study design, measurement points, and timeline.



Data Collection

In both groups, follow-up e-questionnaires were completed every week for the first month and 2 weeks for the following 4 months, or until treatment was completed (if less than 5 months). Given the considerable variability in the duration of time patients may remain on OAAs, the study duration of 5 months was established as a long enough period in consultation with medical oncologists and pharmacists and was deemed appropriate for assessing the primary outcomes of feasibility and acceptability. Participants were monitored more closely during the first treatment cycle, as this period is critical for identifying potential toxicities and making necessary dosage adjustments. Furthermore, it is crucial to establish positive medication adherence behaviors early in the treatment process [46]. After 5 months or until OAA treatment was completed (if less than 5 months), participants completed the exit questionnaire, and a subset of participants in the experimental group (n=10) and control group (n=10) who had completed the study were invited to participate in a semistructured interview.

All e-questionnaires were completed on Qualtrics, a secure web-based electronic data capture system licensed through McGill University [47]. A data management plan between the university and the affiliated hospital was established for the study (Multimedia Appendix 1). Details of each measure and timepoint are provided in Table 1.

Baseline questionnaires completed by all participants included sociodemographic and medical characteristics, cancer information-seeking preferences, and OAA knowledge.

Table 1. Study data collection.

Objective and measure	Instrument	Items, n	Time of collection

Measures

Sociodemographics and Medical Characteristics

At baseline, participants completed a sociodemographic questionnaire identifying their sex, gender, age, marital status, work status, country of birth, languages spoken, education, and income. They were also asked to complete a medical questionnaire identifying their current diagnosis, cancer stage, coverage of their OAA medication, other medications they are taking on a regular basis, and treatment or treatments received.

Cancer Information-Seeking Preferences Scale

This brief, self-report questionnaire based on Self-Evaluation Theory [48] contains 5 statements related to distinct preferences for cancer information. Respondents select the one that best describes how they go about getting information about their cancer: (1) intense—"I seek as much information as possible about my cancer," (2) complementary—"I seek information about my cancer that adds to what I was told," (3) peer-focused—"I seek cancer information from others diagnosed with same cancer," (4) minimal—"I do not seek information about my cancer," and (5) guarded—"Cancer is stressful enough; I only seek information about my cancer that is hopeful."

In a large sample (N=2142), participants treated for cancer within the past 6 months responded to the Cancer Information-Seeking Preferences (CISP) scale and patient satisfaction survey (Ambulatory Oncology Patient Satisfaction Survey). A total of 50.2% (1076/2142) selected complementary, 25.2% (539/2142) selected minimal, 14.4% (309/2142) selected guarded, 6.4% (137/2142) selected peer-focused, and 3.8%

(81/2142) selected intense, with intense seekers reporting lower satisfaction with cancer care [48,49]. The CISP provides context to the participants' preferences and uptake of the intervention.

Knowledge

The 7-item oral chemotherapy knowledge questionnaire was developed by SA and CGL for the purpose of this study. The scale contains 7 true or false items pertaining to OAA knowledge and self-management (eg, "If I forget to take my oral chemo, I should not double the next dose").

The study feasibility (aim 1) will be determined by the recruitment rate, retention rate, response rate to e-questionnaires, and uptake of the intervention (Textbox 2).

To assess the acceptability of the intervention (aim 2), intervention burden, intervention coherence, and perceived effectiveness were assessed prospectively at baseline and retrospectively at exit [35] by participants in the experimental group. They were asked to complete the Acceptability E-scale for web-based, patient-reported outcomes in cancer care by Tariman et al [56], requiring a mean score of 80% or higher as the objective. It evaluates the acceptability and usability of computerized health-related programs in oncology. The scale has a reliability of 0.757. It contains 6 items that are rated from 1 (very difficult) to 5 (easy to understand), with total scores ranging from 6 to 30. Table 2 presents constructs and definitions of acceptability as well as baseline and exit questions. In addition, postintervention acceptability was assessed in exit interviews with a subsample of participants (n=20, 10 per group) using an author-generated semistructured interview guide developed based on relevant questions using questions based on the RE-AIM (Reach, Efficacy, Adoption, Implementation, and Maintenance) framework by Glasgow et al [57] to evaluate health behavior interventions (Multimedia Appendix 2). Questions explored participants' perceptions of OAA information and support, such as "What are your general impressions of the information and support you received during your OAA treatment?" Participant selection for interviews was convenient. Participants were approached in person or over the telephone, and interviews took place in person or over the telephone by the first author, lasting between 30-60 minutes. Only the researchers and participants were present for the interview. After the total number of subsample participants (n=20) had been interviewed, the first author analyzed the interviews to ensure data saturation had been reached. No additional interviews were required.

The potential effects of the intervention (aim 3) will be assessed by comparing experimental and control groups over time, from baseline, every 2 weeks (depending on the outcome), and after the intervention in terms of the following outcomes: medication adherence SE, medication adherence (self-report and pharmacy records), and symptom distress.

Textbox 2. Study feasibility objectives.

Recruitment rate

- Calculated by dividing the total number of participants recruited throughout the study by the number of months recruitment occurred.
- Objective: Based on clinical estimates of eligible individuals, approximately 3 to 4 participants were recruited each month.

Retention rate

- Calculated by comparing the number of participants who complete baseline e-questionnaires to the number of participants who complete study exit e-questionnaires.
- Objective: Of participants who begin the study, ≥45% complete the study, and reasons for dropout are documented if participants wish to share [39,50].

Response rate to study e-questionnaires

- Determined by the number of completed follow-up e-questionnaire assessments for participants who complete the study.
- Objective: Of participants who complete the study, ≥70% complete outcome measures across all time points. This is slightly higher than the 60% minimum required by biomedical journals [51], typical for web-based questionnaires and patient acceptability and satisfaction research [52,53].

Uptake of intervention

- Nature of intervention access (modality, topics, and time points). Uptake of the intervention will be assessed by the number of participants who access the platform, and the number of times each modality was accessed throughout the study duration.
- Objective: Of participants in the experimental group, ≥85% will access at least one intervention modality [54,55].

Table 2. Constructs and definitions of acceptability [35] as well as questions asked at baseline and exit [56].

Construct of acceptability	Definition	Question at baseline	Question at exit
Intervention burden	Perceived amount of effort required to participate in the intervention	• Do you anticipate the amount of time you will spend reading and watching video or videos in this study will be acceptable?	• Was the amount of time you spent reading the information on the e-handouts acceptable? • Was the amount of time you spent watching the video or videos acceptable? • How easy was it for you to access and use the information and support offered in the study? (overall)
Intervention coherence	Extent to which participant understands the intervention and how it works	—[a]	• How understandable was the information in the e-handouts? • How understandable was the information in the videos?
Perceived effectiveness	Extent to which the participants perceive the intervention as likely to achieve its purpose	• How helpful do you anticipate the information and support offered in this study will be in helping you manage your treatment? (treatment management) • How helpful do you anticipate the information and support offered in this study will be in reminding you to take your medication? (reminders)	• How helpful was the information and support offered in this study in helping you manage your treatment? (treatment management) • How helpful was the information and support offered in this study in reminding you to take your medication? (reminders)

[a]Not applicable.

Medication Adherence Self-Efficacy

The Medication Adherence Self-Efficacy Scale (MASES) [58] asks about participants' level of confidence in taking their medication. The original scale contains 25 items, each rated from 1 (not at all sure) to 3 (extremely sure), with a total score calculated by summing the responses. Initially developed within the context of antihypertensive medication, the scale has been modified and adapted into 24-items for oncology oral agents [33]. For this study, 4 items were removed, and 20 items were used. The 4 items removed were not deemed suitable for the study as they pertain to taking the medication for the rest of their life, coming home late from work, being in a public area, and being afraid of becoming dependent on the medication.

Medication Adherence via Proportion of Days Covered

Participants were asked to provide the name and telephone number of their pharmacy, as well as consent for the research team to contact the pharmacy for records to calculate the proportion of days covered (PDC), in order to obtain the average adherence of each participant over 5 cycles of OAAs. PDC is defined as the "sum of the days" supply for all fills of a given drug in a particular time period, divided by the number of days in the time period" [59]. PDC is preferred over the medication possession ratio as the medication possession ratio can overestimate adherence for patients who refill their prescriptions early [59]. PDC will be assessed as the mean PDC for each group.

Medication Adherence via the Medication Adherence Report Scale

The Medication Adherence Report Scale (MARS-5; Professor Rob Horne) [60] is a validated measure of medication adherence, with a Cronbach α of 0.67 [60,61]. It is the shorter version of the MARS-10. MARS-5 contains 5 items, each rated from 1 (always) to 5 (never). Total scores range from 5 to 25. In addition, participants are asked specifics about their OAA regimen such as timing, dose delays, interruptions, and stoppages [62].

Symptom Distress

Physical and psychosocial distress is measured using the Edmonton Symptom Assessment Scale Revised (ESAS-r). The current version, ESAS-r, has been revised to include psychosocial needs; depression, anxiety, and well-being [63,64]. Each item is rated from 0 (none) to 10 (worst possible). The scale has been tested in cancer populations (Cronbach $\alpha = 0.71$).

Data Analysis

Statistical analyses to be performed rely on Microsoft Excel, SPSS (version 25; IBM Corp) [65], and R (R Project for Statistical Computing) software [66]. For PDC, independent sample 1-tailed *t* tests will be performed to calculate the difference between 2 independent means of the experimental and control groups at one time point—study completion. Changes over time in MARS-5, MASES, and ESAS-r will be assessed using repeated-measures ANOVA. Between-group analyses will be conducted to examine how each group changed over time, and within-group analyses will be conducted to examine how participants changed over time.

The relationship between objective (PDC) and subjective (MARS-5) measures of medication adherence will be assessed using Spearman correlation coefficients. Oral chemotherapy knowledge at baseline and study exit will be compared using paired sample 1-tailed *t* tests.

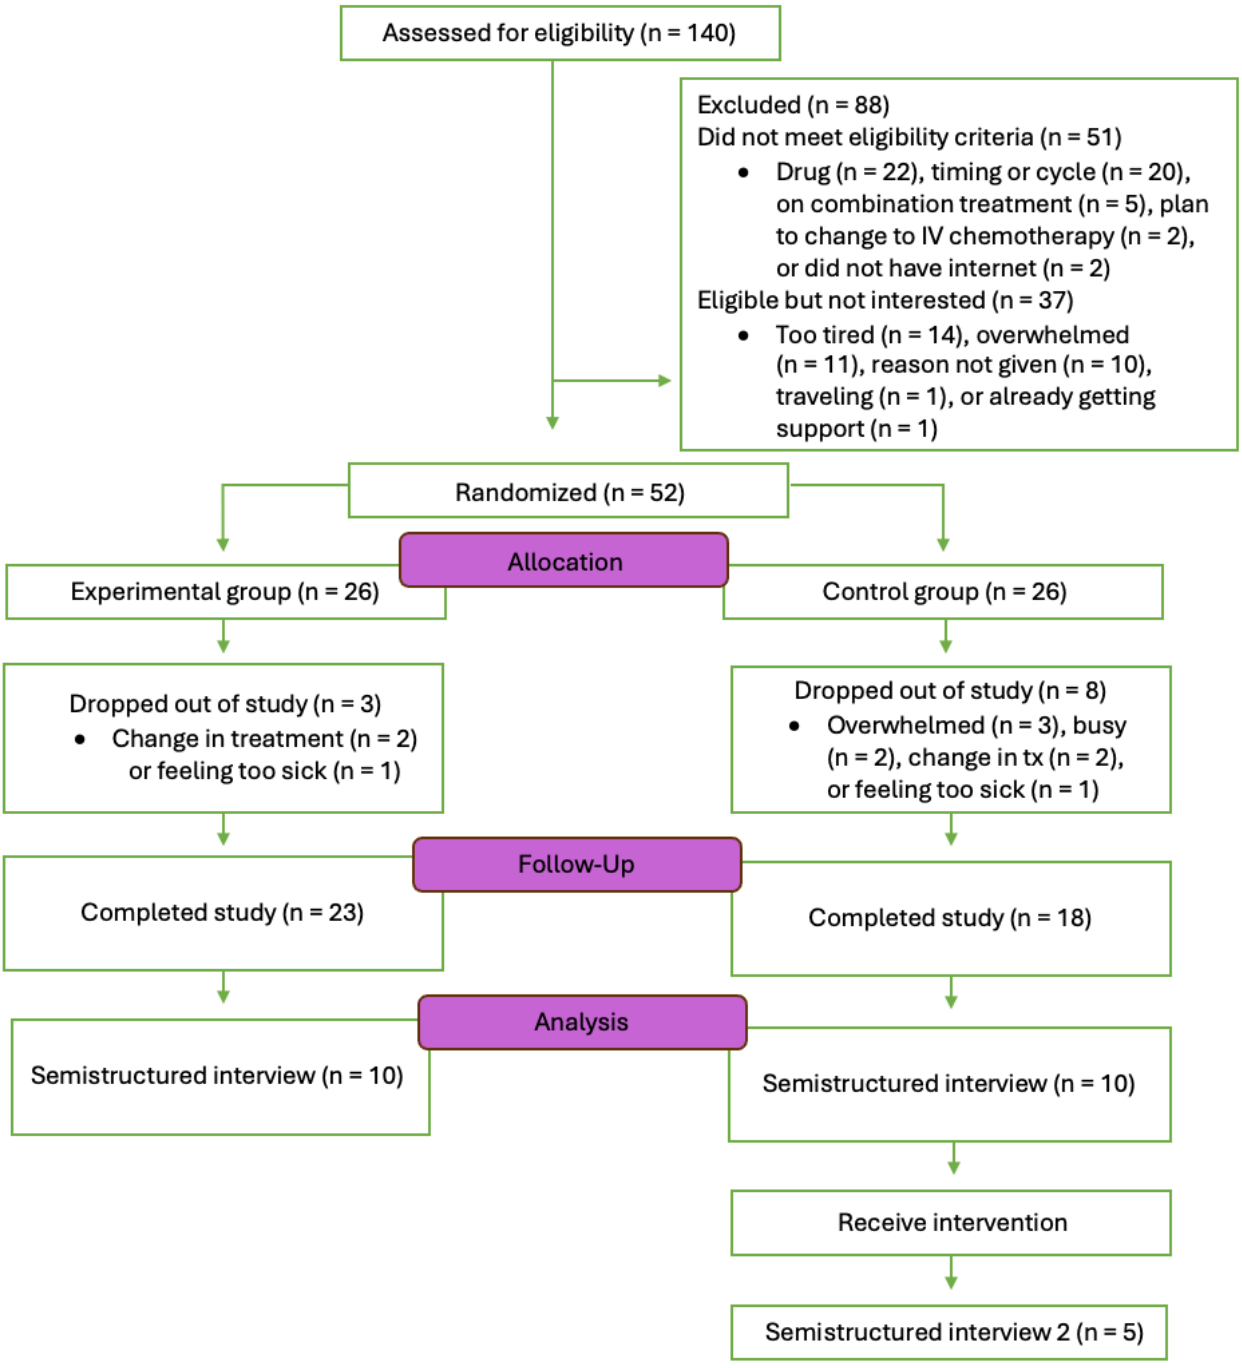
Interviews were conducted individually, audio recorded, and transcribed verbatim by the first author, a doctoral candidate at

the time with experience in qualitative research in oncology working on her dissertation. A reflexive journal was kept to document thoughts and feelings to recognize, acknowledge, and mitigate the influence of her role as a researcher and as someone with lived experience as an informal caretaker for a parent. Interview data were analyzed by the same author using thematic analysis as described by Braun and Clarke [67,68], beginning with several thorough readings of participant verbatim content to familiarize the researcher with the data and the identification of significant statements relating to the phenomenon under investigation [69]. Next, significant statements were placed into initial categories and organized into broader themes and subthemes. Themes and subthemes were reviewed, redefined, renamed, and explored as needed until no new themes emerged from the data.

Results

Data collection was completed as of December 2023 with a final sample of 41 (experimental group, n=23; control group, n=18), considering 11 dropouts after consent. Results are expected to be published in 2025 in a separate manuscript. Figure 6 presents the CONSORT flow chart for the study.

Figure 6. CONSORT (Consolidated Standards of Reporting Trials) flow diagram for the study. IV: intravenous.



Discussion

Principal Findings

Individuals taking OAAs face many challenges, ultimately impacting medication adherence. While studies have begun to test supportive interventions, there remains a lack of theory-based interventions supported by controlled studies that follow explicit reporting guidelines [70]. This pilot RCT sought to inform the study and intervention feasibility and acceptability from the perspective of patients. Given preliminary insights, it is anticipated that feasibility and acceptability objectives will be achieved. As such, the processes of the study and intervention testing will be successful, and the OAA intervention will be well received by participants. Exit interviews further explore OAA-related experiences and distinct narratives of the intervention, which quantitative measures do not capture. Study results will provide preliminary evidence to assess trends using the potential effects of the comprehensive, theory-based intervention when compared to usual care. The use of qualitative interviews will add further insight to study findings, providing context for the significance or nonsignificance of primary and secondary outcomes. As OAA use continues to grow in upcoming years, the study design and reporting of theory-based intervention will contribute much-needed insights toward how patients on these drugs can best be supported.

Of note, the testing of a remote multimodal intervention was particularly timely amid the COVID-19 pandemic, as oncology teams increasingly performed remote consultations, and patients who are immunocompromised were at higher risk for virus-related complications. Social distancing, isolation, and quarantine all further limited the support and resources available to them.

Conclusion

As remote consultations are still used for patients who are immunocompromised in the current period, the proposed intervention is still very relevant. Whether the COVID-19 pandemic may have acted as a confounding factor in this study remains unclear. In addition, since the study took place in a single setting, the next steps should include a multisite investigation to determine whether it is scalable and relevant across settings and geographical regions. The study sample is small, with 41 participants completing the study included in the final analysis for preliminary effects. Whereas the final sample is smaller than anticipated (41 vs 52), reliance on mixed methods provides complementary evidence. Dissemination activities related to the study results and its tested intervention include presentations at tumor boards, scientific publications, conference presentations, and diffusion through professional networks and webinars, as well as patient representative groups.

Acknowledgments

We are most grateful to all patients who participated in this study. We thank the oncologists, nurses, and clinical administrators who assisted in participant recruitment. We are indebted to patient partners, caregivers, and oncology team members who provided valuable feedback on the intervention. We thank Precare for making the educational videos and Belong for its assistance in making the oral anticancer agent intervention available on their app.

We would like to thank the Rossy Cancer Network for providing partial funding for this study (Cancer Care Quality and Innovation Program Research Fund—grant title: “Implementation and testing of a sustainable support program as a complement to an ongoing RCN patient-reported outcome initiative”). CGL’s work is supported by the Christine and Herschel Victor/Hope and Cope Research Chair in Psychosocial Oncology at McGill University. SA’s doctoral work was partially supported by the Maysie MacSporran Graduate Studentship and a studentship from Belong.

Data Availability

The datasets generated during this study will be available from the corresponding author on reasonable request.

Authors' Contributions

SA and CGL are responsible for study and intervention design, operationalization, randomized controlled trial implementation, data analysis, and write-up of the manuscript. CGL wrote the initial study protocol, obtained funding, and supervised the first author during her doctoral studies. CM, WG, and GB provided ongoing feedback on the study protocol and study implementation.

Conflicts of Interest

WG sits on the board of the company that provided the digital patient education but does not receive any monetary benefits.

Abstract

Background: COVID-19 worsened an already existing problem in substance use disorder (SUD) treatment. However, it helped transform the use of telehealth, which particularly benefits rural America. The lack of specialty addiction treatment in rural areas places the onus on primary care providers. Screening, brief intervention, and referral to treatment (SBIRT) is an evidenced-based strategy commonly used in primary care settings to target SUD outcomes and related behaviors. The integration of telehealth tools within the SBIRT pathway may better sustain the program in primary care. Building on Mayo Clinic's experience with collaborative care management (CoCM) for mental health treatment, we built a digitally native, integrated, behavioral health CoCM platform using a novel mobile app and web-based provider platform called Senyo Health.

Objective: This protocol describes a novel use of the SBIRT pathway using Senyo Health to complement existing CoCM integration within primary care to deliver SUD treatment to rural patients lacking other access. We hypothesize that this approach will improve SUD-related outcomes within rural primary care clinics.

Methods: Senyo Health is a digital tool to facilitate the use of SBIRT in primary care. It contains a web-based platform for clinician and staff use and a patient-facing mobile phone app. The app includes 16 learning modules along with data collection tools and a chat function for communicating directly with a licensed drug counselor. Beta-testing is currently underway to examine opportunities to improve Senyo Health prior to the start of the trial. We describe the development of Senyo Health and its therapeutic content and data collection instruments. We also describe our evaluation strategy including our measurement plan to assess implementation through a process guided by Consolidated Framework for Implementation Research methods and effectiveness through a waitlist control trial. A randomized controlled trial will occur where 30 participants are randomly assigned to immediately start the Senyo intervention compared to a waitlist control group of 30 participants who will start the active intervention after a 12-week delay.

Results: The Senyo Health app was launched in May 2023, and the most recent update was in August 2024. Our funding period began in September 2023 and will conclude in July 2027. This protocol defines a novel implementation strategy for leveraging a digitally native, clinical platform that enables the delivery of CoCM to target an SUD-specific patient population. Our trial will begin in June 2025.

Conclusions: We present a theory of change and study design to assess the impact of a novel and patient-centered mobile app to support the SBIRT approach to SUD in primary care settings.

Introduction

Limited access to substance use disorder (SUD) treatment was a problem long before COVID-19. Approximately 22 million American people needed SUD treatment in 2019, but only 13% received any intervention [1]. The COVID-19 pandemic coincided with an increase in SUD prevalence, as treatment programs were restricted or closed [2]. The National Institutes of Health described the compounding effects of the concurrent opioid epidemic and COVID-19 pandemic as a national emergency [3]. In response, the White House Office of National Drug Control Policy recommended increased funding for telehealth services and mobile phone apps.

Telehealth use has increased dramatically since the COVID-19 pandemic onset [4]. While numerous patients may benefit from its flexibility, rural patients and stigmatized populations, such as individuals with addiction, may be particularly aided [5]. Before COVID-19, rural patients already had fewer health care providers and mental health service offerings [6]. The pandemic was associated with an increased incidence of SUD in rural areas, where isolation, stress, and boredom exacerbate risks to psychological health [7]. The shortage of SUD providers impairs individuals from receiving specialty treatment and places increased pressure on primary care providers [8]. The incorporation of telehealth helps bridge this gap. We recently published a review showing that the synchronous delivery of care through video visits for SUD treatment has robust safety and efficacy evidence [2].

Screening, brief intervention, and referral to treatment (SBIRT) is the most common strategy to address problematic substance use in primary care. However, there have been significant barriers to translating it into treatment. Data combined from the 2015 to 2019 National Survey on Drug Use and Health found that only 69.9% of adults with alcohol use disorder were screened for alcohol use, with this leading to approximately 5% to 6% of adults who might benefit from treatment being referred to and eventually receiving treatment [9]. Known barriers to SBIRT use are limited clinician time, competing clinical priorities, providers' belief that the intervention will be ineffective, lack of training and experience with delivering the intervention, and the need for integration with the addiction care delivery model [10]. These factors can be addressed with adequate preimplementation support and training [11].

Collaborative care management (CoCM) is a system-based approach that integrates behavioral health care managers into primary care clinics with the support of psychiatrists to assist primary care providers in managing mental health disorders. This improves treatment access and outcomes while decreasing the need for independent psychiatric services [12]. Current evidence supports case management services delivered by various backgrounds (nursing, welfare or social workers, and mental health therapists) to strengthen service connections [13,14]. CoCM has demonstrated effectiveness in improving SUD treatment access, increasing resource efficiency, and reducing substance use [15-17]. However, addressing SUDs within CoCM poses several challenges, including organizational process and infrastructure capacity development for CoCM implementation, training behavioral health care managers, accessing specialty addiction consultation, a national shortage of SUD providers, and overcoming staff stigma [18]. CoCM also relies on symptom monitoring tools [12], and when used within addiction treatment, these must comply with federal and state confidentiality and consent regulations.

Digital CoCM adapts the traditional CoCM framework to a digital format, leveraging telemedicine platforms to overcome geographical and logistical barriers to care. Unlike traditional CoCM, which relies on in-person care teams embedded in clinics, digital CoCM uses digital tools to facilitate integration and communication between primary care providers, care managers, and consulting psychiatrists. Digital platforms allow for the integration of structured workflows, enabling asynchronous communication between providers and giving real-time updates on patient progress. This approach enhances flexibility while maintaining the core components of CoCM: care coordination, systematic case review, measurement-based care, and patient-centered outcomes [19].

Compared to stand-alone telehealth services or other SUD-focused apps, digital CoCM emphasizes integration across the care team rather than focusing solely on the patient-provider dyad. While telehealth visits allow for synchronous patient-provider interactions, they may lack systematic tracking of patient progress, team-based coordination, or integration of psychiatric consultation. SUD-focused apps typically provide self-management tools, such as cognitive behavioral therapy (CBT) modules or contingency management (CM), but they often operate outside the clinical care team and do not facilitate collaborative decision-making between primary care providers and care managers [20]. Digital CoCM bridges this gap by embedding app-based tools within a team-based care model, ensuring that technology supports both patient engagement and provider collaboration. Digitally delivered interventions can positively augment the patient-provider experience by incorporating new ways to interact [21,22], enabling the easy monitoring of clinically relevant measures of substance use and mental health symptoms, and supporting evidence-based practices. However, to our knowledge, no digital telemedicine platform has been tested to facilitate integrated SUD CoCM

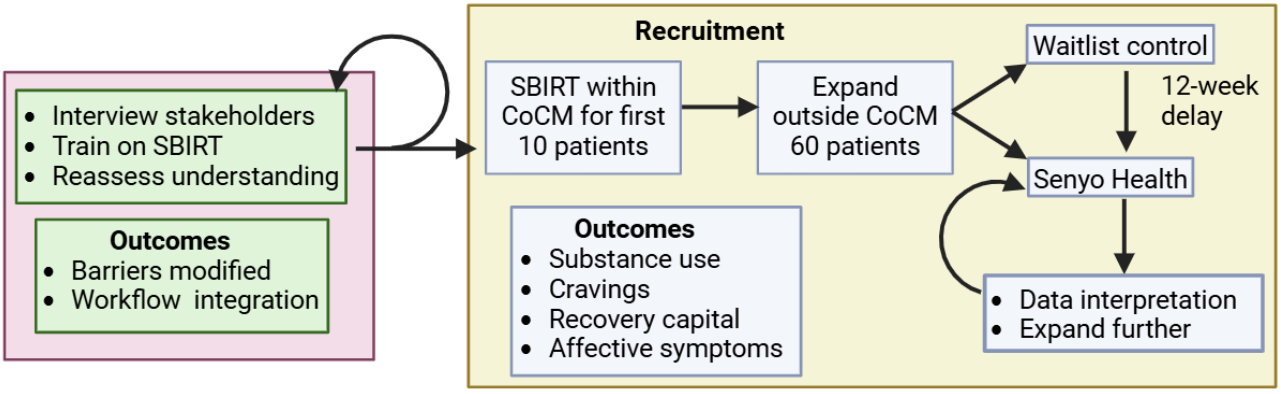
within primary care. This study aims to evaluate the implementation and clinical effectiveness of Senyo Health, a digitally native, addiction treatment and CoCM platform designed to address barriers to SUD treatment in rural primary care settings. Specifically, we aim to identify facilitators and barriers to implementation; improve the integration of SUD treatment into primary care workflows; and assess the platform's impact on substance use outcomes, treatment retention, and recovery trajectory. We hypothesize that this intervention will reduce the frequency and intensity of substance use, promote addiction recovery, and be well received by primary care staff. This protocol details the iterative design, development, pilot-testing, and randomized controlled trial study stages.

Methods

Study Design

This is a mixed methods study. The first stage is focused on implementing SBIRT into primary care and identifying barriers. During this stage, we will use Consolidated Framework for Implementation Research (CFIR) [23]. The CFIR's core domains include intervention characteristics, which focus on the attributes of the intervention itself, such as its complexity and adaptability. The outer and inner settings examine the external and internal contexts, including factors like patient needs, organizational culture, and readiness for implementation. Finally, the characteristics of individuals and the process domains address the roles of individuals involved and the steps taken to implement the intervention, such as planning and engaging stakeholders. The second stage is a waitlist randomized controlled trial studying the effectiveness of the Senyo Health platform in decreasing substance use over a 12-week period (Figure 1). The intervention will have 4 core components that will be iteratively improved based on stakeholder feedback. First, each patient will receive digitally native CoCM for SUD with weekly web-based check-ins with licensed alcohol and drug counselors (LADCs), who will be the main point of contact for patients enrolled in the study. Consistent with CoCM, standardized symptom monitoring and monthly reviews of all clinical cases will occur with the LADC and the overseeing psychiatrist. Second, the patient will be offered, initiated, or continued on medications to manage psychiatric and addiction diagnoses and symptoms. Third, the patients will use a digital clinical platform to complete a set of CBT and behavioral activation–based psychotherapeutic modules. Fourth, patients will use a digital CM platform through an app on their phones.

Figure 1. Study flow diagram. The study is an exploratory, sequential, mixed methods design. The initial study phase is qualitative (left, pink square) with a focus on interviewing clinical stakeholders (physicians, nursing, and medical support staff), training on SBIRT, and reassessing their understanding and experience to iteratively improve the process. The second study phase is quantitative (right, yellow rectangle) with outcomes noted. The first 10 patients will be recruited from ongoing CoCM for mental health services after screening positive on validated alcohol and drug use measures. We then will recruit an additional 60 patients, who will participate in a randomized controlled trial of a 12-week intervention with Senyo Health (active phase) or to a 12-week waitlist control group who will subsequently receive the active intervention. These results and feedback will be used to iteratively improve the intervention after study completion. CoCM: collaborative care management; SBIRT: screening, brief intervention, and referral to treatment.



Ethical Considerations

This study was reviewed and approved by the Mayo Clinic Institutional Review Board (IRB) for human research (#24-007758) in accordance with institutional policies and federal regulations governing human participant research. The IRB determined that this study requires full board review, and no exemption or waiver was granted. Informed consent will be obtained directly from all participants prior to study enrollment, and participants will have the ability to opt out at any time without consequence. This study does not involve secondary data analysis requiring additional consent considerations. No identifiable patient information will be reported, ensuring participant confidentiality and data security. Data collected by the app system are securely transferred using industry-standard encryption to the "Backend Services" (ie, Mayo Clinic servers behind Health Insurance Portability and Accountability Act [HIPAA]–compliant firewall). This cloud-based infrastructure serves and communicates with the patient-facing app. The Backend Services contain all data and analytics specific to the app clients (participants, researchers, and providers). No protected health information is contained in the app itself. All data used by the app follow internationally recognized security standards, including the National Institute of Standards and Technology SP800-53 and HIPAA. All patient information is automatically encrypted when entered in the system, allowing for secure data transfer from the participant device to the provider interface and storage. The treatment phase of this project uses the CM method. Participants earn points for completing treatment tools within the Senyo app. They turn in those points for rewards of specified dollar amounts. These dollar amounts are loaded on a reloadable cash card (ClinCard).

The app will notify study staff of the dollar amount, which will be loaded onto the card and documented in the research participant remuneration application system. The amount of points a participant can earn is approximately 1400 (converts to US $350), but this amount will vary depending on participation and points received. In the follow-up and waitlist phase, participants will receive US $25 for each visit where they complete interviews and questionnaires. Those assigned to the waitlist phase will have an additional 12 weeks of participation than those assigned to the intervention phase. Remuneration will not be provided during time on the waitlist.

Senyo Health Intervention

Overview

Senyo Health has several core features that enable it to deliver digital CoCM for SUD treatment. Senyo offers several well-studied, app-based components to users, including asynchronous CBT modules, CM, behavioral activation, and an interface to interact with the program LADC. We chose these features as our initial intervention based on our research that showed CBT and CM had significant effect sizes for improving substance use-related outcomes, with CM having a large effect [20]. A group of licensed drug counselors meeting an hour a week over the course of several months with a senior patient education specialist employed by Mayo Clinic took individual paper copies of patient education content that presented CBT-based concepts and combined them with CBT content found in National Institutes of Health CBT Content built for "Project MATCH" [24]. This process resulted in the production of 16 modules.

Traditional care coordinator and patient coordination visits involve a comprehensive assessment of the patient's physical, mental, and social health needs. It includes collaborative care planning with input from various health care providers, patient education, and regular follow-up. These visits are typically done in person or over the phone. To add digital care coordination, we incorporated the ability to communicate directly with a LADC care coordinator through the app. Furthermore, the Senyo platform enhances care coordination by providing the care coordinator with a desktop portal directly linked to the patient's mobile phone app. The care coordinators have immediate access to the patient's progress through an interface that showed the patient's use of the mobile phone app features, survey results, and activities. The platform also allows the care coordinator to do video-based conversations that more closely mimic in-person care coordination visits.

The app was designed to be simple and user-friendly. When first using the app, initial prompts are designed for the user to create personalization and review security or privacy settings. Figure 2 displays the patient's to-do list, a behavioral activation goal (walking), and the points received for completing that goal. Figure 3 displays the chat feature, which is a communication portal with the LADC. Modules and surveys can be assigned in response to current symptoms in real time.

Figure 2. Screenshots from Senyo Health app that the individual using the app sees. Panel (A) shows the initial personalization. Panel (B) shows the current "To-do List" and also displays the chat icon at the bottom of the panel. Panel (C) shows a behavioral activation task, and panel (D) showcases the points awarded for completing this task.

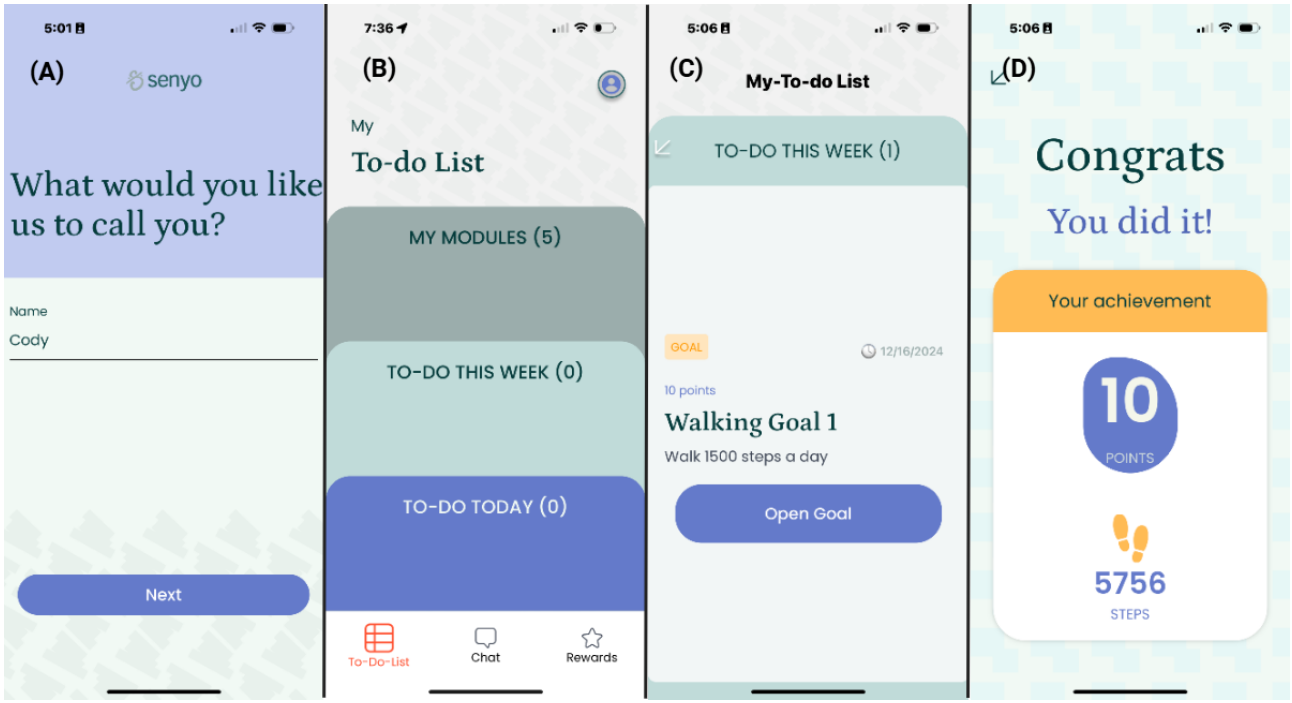


Figure 3. Senyo Health chat feature being displayed from the perspective of the recovery coach. The left is conversations with multiple patients. Once selected, the full conversation appears in the center of the screen, with the recovery coach able to text back and forth. Surveys, modules, and activation tasks can also be assigned to the participant through the chat.

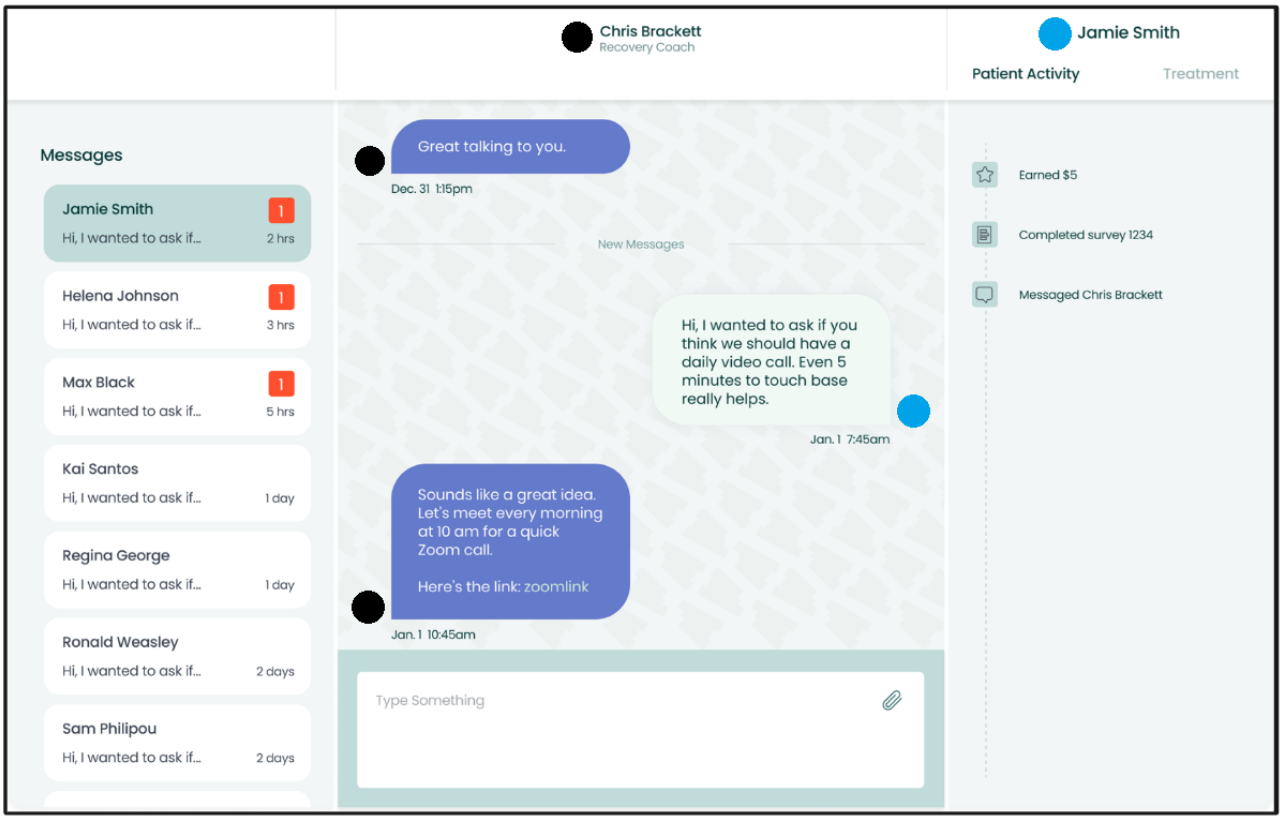

CBT Modules

Apps allow for the asynchronous delivery of therapeutic content that participants can use at any time. Current research supports delivering asynchronous content through "modules" or "activities." Psychotherapeutic modules within apps contain brief text-based content, videos, and related questions that patients can experience independently whenever convenient. CBT is the most researched content type for asynchronous modules [15,25,26]. "Activities" within apps are usually actions that the patient performs, such as filling out a survey, doing a mindfulness exercise, or being physically active [27]. Senyo Health currently contains 16 modules with content based on Mayo Clinic patient education pamphlets. Topics include "addictive thought patterns," "living with emotions in recovery," "self-esteem and relationships," "my recovery building blocks," "self-care in recovery," "cravings," and "relapse prevention."

CM Component

CM is a behavioral therapeutic intervention where monetary or prize-based rewards are "contingent" on objective evidence of drug abstinence and abstinence-promoting behaviors, such as attending mutual support meetings and counseling sessions [28]. Therefore, CM does not deliver education or concepts for individuals to learn; instead, it is a strategy to encourage positive behaviors. CM has decades of research representing hundreds of controlled trials demonstrating its safety and efficacy in assisting in-person SUD treatment [28,29]. It is arguably one of the most effective therapeutic strategies available to date but can be challenging to implement within conventional in-person treatment programs [30]. "ReSET" and "ReSET-O" are Food and Drug Administration–approved products that are available for prospective patients through a prescription that use CM to encourage the completion of in-app modules [25,26]. Digitally delivered CM through an app appears to improve engagement at a similar level to CM delivered in person [31].

The incorporation of CM-based token economy architecture into a CoCM platform makes Senyo Health unique [32]. The app awards points for completing surveys, modules, and activities. The points per action are customizable through the research interface, allowing for the adjustment of relative incentives associated with each task. Participants can use points to purchase rewards through a reloadable card (ClinCard). The purchased rewards will be tracked and documented in the research participant remuneration application. For this study, the point value is US $0.25 per point. One point is earned for each page of a module, minute of a video, and question in a survey.

Activity or Goals

Senyo Health was built to work with Apple and Google health kit wearable platforms to gather data from wearable device sensors. If a device is detected and the patient authorizes this, the wearable device sensor will track activity, heart rate, and oxygen saturation. These data will be used to encourage physical activity by connecting sensor data to CM rewards. These data will only be collected from participants who already have and wear a personal device; the study will not provide such device to participants.

LADC to Patient User Interface

The LADC will use the provider portal to communicate through the app with their patients. Social rewards through apps, such as support from a clinician or peer via messaging or telephone, produce significantly greater user engagement than fully automated apps [32]. Typically, this support aims to maintain patient adherence with the app, monitor user progress through periodic symptom assessments, assist the patient in understanding therapeutic concepts or skills training, and triage patients who do not respond to app-based interventions [33].

Study Sample and Recruitment

Overview

The implementation phase will start with a pilot within a rural primary care site in the upper Midwest region of the United States that is familiar with the CoCM model for mental health treatment. After following the implementation strategy below at the initial location, we will expand to 2 additional primary care sites—1 for a rural service population and 1 for a nonrural service population. This staged rollout will allow for iterative improvements for the subsequent sites based on knowledge gained from the first site.

Provider Engagement and Implementation

Preimplementation

Clinic engagement efforts will start by recruiting a primary care champion at the primary care site. Other primary care clinic key stakeholders (physicians, nursing, CoCM staff, and medical support and administrative staff) will be included as appropriate. Focus groups and interviews with providers and staff engaged in the SBIRT workflow will assess attitudes and perceived barriers toward SBIRT, the use of medications for addiction treatment (buprenorphine, acamprosate, etc), and the use of digital delivery of SUD treatment within CoCM. Focus groups will be interviewed using a semistructured interview based on the CFIR interview guide. Please see Multimedia Appendix 1 for details.

Implementation: Training, Supervision, and Refinement

Research team members with experience treating SUD in primary care clinics will provide education to providers at the participating site. We will be scheduled as part of a regularly recurring staff education curriculum to provide didactic base education on the project (specifically the screening metrics, conducting a brief intervention, and how to refer to this study). The LADC will support voluntary follow-up training on brief interventions, motivational interviewing, and the referral process. Primary care champions at each participating site will encourage other site providers to attend training and initiate medications for addiction treatment for patients with confirmed moderate and severe SUD diagnoses. These champions will also liaise with the LADC.

Throughout the implementation approach described, we will gather feedback from the primary care team on SBIRT, the Senyo Health platform, the CoCM team, and LADC to evaluate the processes. Primary care providers, nurses, key administrators, and clinic staff from each of the sites will be identified for interviews. Feedback on these components will be used to iterate and refine our strategy.

SBIRT Protocol

Screening

Universal patient screening with the Drug Abuse Screening Test (DAST) [34] and the Alcohol Use Disorders Identification Test-Consumption (AUDIT-C) [35] is an eventual goal. These instruments help determine the need for treatment referral using the SBIRT care pathway. The AUDIT-C is already frequently implemented across primary care; however, the DAST is not. Screening frequency will be explored in the feasibility stages based on feedback from clinic staff and leadership. While the US Preventive Services Task Force recommends all adults are screened for substance use, this may not be feasible in all clinic workflows. Stakeholder feedback will monitor excessive screening burden, and process iteration will attempt to minimize unnecessary rescreening to optimize overall results.

Brief Intervention

The brief intervention stage is where the SBIRT pathway often stalls out. Implementation of a brief intervention will be collaborative and iterative with the initial pilot site. FRAMES [36], which consists of feedback, responsibility, advice, menu for change, empathy, and enhancing self-efficacy, will be the primary component of this intervention. If granted permission by the patient in the screening stage, a LADC will provide a brief intervention to the patient (ie, personalized feedback, education, and motivational interviewing). The primary care provider is at liberty to provide some initial counseling to the patient, but the full FRAMES-based structure of the brief intervention is deferred to the LADC. In this modification of the traditional SBIRT framework, the goal is to minimize the additional clinical burden on the primary care providers and emphasize the value of the CoCM program in augmenting the capabilities and capacities of the primary care team. The primary goal of the brief intervention as conducted by the LADC is to facilitate patient enrollment in CoCM or referral to a higher level of care if needed.

Referral

Patients will be informed about local treatment options for treatment as usual and about the option to participate in this study by enrolling in the Senyo CoCM program. They will be allowed to choose which option they feel is best for them. Once the process runs smoothly at the pilot site, we will expand to the next selected site.

Treatment

All patients who consent to study participation will receive care through the Senyo Health platform. However, randomization will determine if this is provided immediately or if access is delayed by 12 weeks (ie, waitlist design). These patients will have outcomes closely monitored as described in the Study Procedures section. To ensure all eligible patients receive treatment regardless of trial participation, study coordinators will attempt to follow up with those who chose treatment as usual to monitor if they do ultimately receive treatment.

Study Criteria

The intervention will be piloted to 10 patients who screen positive on the DAST or AUDIT-C and are already participating in CoCM for depression within primary care (no randomization). In addition to screening results, the clinical team will use their clinical judgment to determine eligibility, prioritizing patients for whom a SUD appears to be the primary psychiatric diagnosis rather than a mood or anxiety disorder. Once these patients have been recruited effectively and we have solidified our implementation strategy, we will broaden screening to primary care patients not currently in CoCM at the participating site. An additional 60 patients will be randomly assigned to immediate access to Senyo Health versus the waitlist. The 30 participants randomly assigned to the waitlist arm will be later added to the active arm (Senyo Health platform), for a total of 70 patients receiving active intervention by study conclusion. A computerized random assignment list will be generated by the study statistician for the study coordinator to assign enrollees sequentially, stratified by sex and restricted to every 10 cases, ensuring equal numbers per group. Due to the nature of the intervention and trial design, no one will be blinded. The study will recruit patients from Mayo Clinic primary care clinics at 3 sites after they have agreed to participate, with 2 serving primarily rural patients and 1 serving primarily nonrural patients.

Inclusion criteria are as follows: age 18 years and older; ability to read, write, and understand English; minimum DAST (1+) or AUDIT-C (3+) scores; and access and willingness to use a mobile device for asynchronous (text) and synchronous (video visits) engagement with care. Exclusion criteria are as follows: already participating in or about to initiate treatment in another structured addiction treatment program; diagnosed personality pathology as the primary presenting concern based on clinical judgment, severe cognitive impairment (eg, intellectual disability or dementia), or psychosis; inability to actively participate in and learn from psychotherapeutic interaction based on clinical evaluation and clinical judgment; needing a higher level of mental health care as demonstrated by American Society of Addiction Medicine assessment; and decline to answer suicidality questions.

Study Procedures

Overview

Once primary care patients have selected the study treatment path, the steps outlined below will occur. These include obtaining and signing informed consent, collecting medical and psychiatric history for comorbidities through patient interview, and answering validated questionnaires on mood, anxiety, and their overall strengths and resources to achieve substance use cessation (ie, recovery capital). Recovery capital is a biopsychosocial model of recovery from addiction, which encapsulates the interpersonal strengths and resources an individual can leverage in pursuit of substance use cessation [37]. Next, participants will be randomly assigned to the waitlist or active intervention. Once randomly assigned, participants will complete visits through a clinical treatment phase and a follow-up phase. The waitlist group will serve as a “waitlist” control and be asked to “cross over” and receive the active intervention after 12 weeks on the waitlist.

Study activities are listed in Textbox 1 and detailed in Table 1.

Textbox 1. Study activities.

- Baseline visit
  - Obtain informed consent from the participant.
  - American Society of Addiction Medicine diagnostic interview [38] conducted by a licensed alcohol and drug counselor (LADC).
    - Participants must meet the criteria for outpatient treatment or indicate that outpatient is their preference.
  - Questionnaires: Brief Substance Craving Scale [39]; Brief Assessment of Recovery Capital [40]; self-reported substance use based on the Timeline Followback [41]; and psychiatric comorbidities measured via Generalized Anxiety Disorder-7 [42], Patient Health Questionnaire-9 [43], and Epworth Sleepiness Scale [44].
  - Treatment attendance monitoring questionnaire.
  - Urine drug test—check for certain drugs, including alcohol and illicit substances (ie, cocaine and methamphetamine).
  - Randomization to active intervention versus waitlist arms.
  - Set up active participants in the Senyo Health app.
- 12 weekly visits with LADC and pertinent study staff during the clinical treatment phase.
  - LADC will provide clinical counseling. The total number of counseling visits will be up to the discretion of the LADC, with a target goal of at least 1 hour weekly.
  - Questionnaires: Brief Substance Craving Scale [39], Timeline Followback [41], Generalized Anxiety Disorder-7 [42], Patient Health Questionnaire-9 [43], and Epworth Sleepiness Scale [44].
- Additional items monthly on weeks 4, 8, and 12.
  - Urine drug screen.
  - Brief Assessment of Recovery Capital [40].
- Final visit of active treatment (week 12).
  - Acceptability of Intervention Measure.
  - Intervention Appropriateness Measure.
  - Feasibility of Intervention Measure.
  - System Usability Scale [45].
- The follow-up phase begins immediately after completion of 12 weeks of active treatment. Visits will occur at weeks 4, 8, and 12, and at 1 year.
  - Questionnaires: Brief Substance Craving Scale [39], Timeline Followback [41], Generalized Anxiety Disorder-7 [42], Patient Health Questionnaire-9 [43], Epworth Sleepiness Scale [44], and Brief Assessment of Recovery Capital [40].
  - Urine drug screen.
- Individuals randomly assigned to the waitlist phase will follow the “follow-up phase” schedule during their 12 weeks prior to active intervention.

[j]AIM: Acceptability of Intervention Measure.

[k]IAM: Intervention Appropriateness Measure.

[l]FIM: Feasibility of Intervention Measure.

Outcomes

This protocol has 2 phases. For the initial implementation phase, the primary outcome will be a thematic analysis of coded structured interviews of clinic stakeholders, with a focus on whether noted SBIRT barriers were effectively modified during implementation. For the clinical trial phase, the study end point is the week 12 assessment of the primary outcome measure, overall substance use as measured by Timeline Followback. We anticipate that patient involvement in the active phase will lead to a significant reduction in substance use relative to the end of the waitlist period. Secondary outcomes will explore abstinence rates, treatment retention, along with treatment effects on craving, recovery capital, psychiatric well-being (Patient Health Questionnaire-9, Generalized Anxiety Disorder-7, and Epworth Sleepiness Scale), and use of clinical services throughout the intervention and follow-up periods.

Data Analysis

Qualitative interviews will be recorded, transcribed, and coded on a rolling basis using a rapid, template-based approach derived from the interview protocols [46]. Quantitative clinical treatment outcomes will be analyzed by comparing participant data at baseline, weekly during the intervention, and 12 weeks after the treatment (after completion of LADC visits). Our recent meta-analysis indicated that CM delivered through an app had a large effect size for improving substance use–related outcomes relative to control conditions [20]. Using this to inform our power calculation, there is greater than 0.80 power to see a large effect size between active and waitlist groups at the primary study end point. We will use information from this pilot to inform sample size calculations for a larger controlled efficacy trial. Several exploratory end points (eg, anxiety and depression) will be evaluated to contextualize the primary end-point effect. We will use likelihood methods (eg mixed models) that allow

for data that are missing at random, so we will not impute any missing data. Intention-to-treat will be used.

Safety Monitoring

During the study, the LADC will be the first point of contact with the patient. Their app-based communications with the patient will focus on assessing symptoms, addressing clinical concerns, and providing brief encouragement to continue predetermined goals. The LADC will meet with the study psychiatrist and review the history obtained from the patient during their initial evaluation. The LADC will write a formal weekly update note on each patient, and monthly clinical tracking scores will be reviewed and reported to the consulting psychiatrist. Psychiatric recommendations for the management of addiction concerns and related mental health issues (ie, worsening mood or suicidality) will be reported back to the primary care providers, who will ultimately remain responsible for clinical decision-making and the treatment plan that may involve starting medications as a part of their clinical care. This patient review and consultation system will be managed through the provider portal, which will also serve as the patient population registry for quantitative tracking of clinical concerns with specific and quantitative end-point treatment goals.

Once a patient is enrolled in the study, the LADC and study staff will use the American Society of Addiction Medicine criteria to determine ongoing appropriateness for the current level of care [38]. To stay in the study, participants must remain eligible for outpatient SUD care. If the participant's American Society of Addiction Medicine criteria worsens enough that psychiatric recommendation is a higher level of care, they will be referred clinically to residential SUD treatment. The participant's active treatment phase will be stopped and moved into the follow-up phase for the schedule of visit. Adverse events will be reported to the psychiatrist for evaluation and reviewed for reporting requirements to the IRB.

Results

The Senyo Health app was launched in May 2023, and the most recent update was in August 2024. Our funding period began in September 2023 and will conclude in July 2027. This protocol defines a novel implementation strategy for leveraging a digitally native, clinical platform that enables the delivery of CoCM to target an SUD-specific patient population. Our trial will begin in June 2025.

We have not yet started enrollment in the primary study. In December 2024, focus group testing of the mobile app with people who have SUDs and are in treatment was completed. LADCs who reviewed the mobile and desktop apps were also interviewed. Their feedback has been used to improve the interface, design, and fix bugs, preparing for the primary study enrollment.

Discussion

Overview

This protocol builds from the large literature base that has described the positive effects of telehealth both before and after the COVID-19 pandemic [2,47]. Most treatment-seeking individuals report high patient satisfaction with telehealth [47]. Specific to alcohol use, digitally delivered interventions have been shown to significantly decrease heavy and binge drinking for both male and female patients and increase treatment retention at 1 year [48,49]. The use of telehealth among Medicare beneficiaries with an opioid use disorder was significantly associated with greater treatment retention and reduced odds of medically treated overdose [50]. App engagement, however, is typically low for traditional health-related apps. Individuals often use these apps for less than 1 week [31]. User time, effort, and attention can measure user engagement [51,52]. Greater engagement has been correlated with improved abstinence rates among apps incorporating CM and CBT modules [53]. Social rewards through apps, such as support from a health care provider via messaging, also produce significantly greater user engagement than fully automated apps [32]. These are core features of Senyo Health and help differentiate it from other interventions.

Additionally, the use of digital interventions to drive changes in recovery capital is largely unknown. A study of individuals engaging through a recovery-based web page noted that positive digital interactions help bind individuals within groups, supporting the overall recovery process [54]. This is reflecting community involvement and social connectedness, which are important aspects of recovery capital. Little else is known about the use of digital interventions in this space.

It is important to note that app creation is expensive. Additionally, apps are slow to create and typically costly to update. Senyo Health was created with sustainability in mind. It is owned solely by the Mayo Clinic, is fully operational, and is actively in use. New modules can be created within a desktop-based application directly linked to the app that we call the "researcher portal." The researcher portal allows for easy and rapid creation of new content without the need for changes to the app's code or new versions of the app to be pushed to the App Store. This allows for easy iterative improvements to existing content with no development costs. This feature dramatically reduces long-term costs and allows for real-time improvements based on user feedback.

Principal Findings

We will use mixed methods (interviews and questionnaires or scales) to evaluate implementation outcomes. We anticipate the identification of facilitators and barriers for the successful implementation of SBIRT and Senyo Health within a rural primary care workflow. Based on these findings, our hope is that through iterative enhancements, the rollout from site 1 to sites 2 and 3 will be increasingly streamlined.

While engaged in treatment services, substance use–related outcomes typically improve overall. Our proposed program is a combination of multiple evidence-based interventions, and as such, we expect a significant improvement in the active arm versus the waitlist control group. Additionally, we anticipate seeing recovery capital growth as individuals are engaged in treatment. As this growth has been significantly associated with decreased cravings [55] and past 30-day abstinence of alcohol and methamphetamine use [56,57], we hypothesize a significant

correlation between substance use and recovery capital changes. As recovery capital growth for female patients has been reported as suppressed compared to male patients while in treatment [58], we will also explore possible sex differences.

Limitations

As with all pilot trials, there are potential barriers. This intervention relies on wireless internet or cellular data capabilities. Access to these is improving across the United States; however, residents in rural areas, which is our main target population, have disparities in internet access [6,59]. We do not anticipate that this will affect the app, as the media is cached or can be buffered; however, it may negatively impact live counseling sessions. This will need to be monitored and will be individual-specific. The study also relies on the willingness of primary care patients to participate in a novel addiction treatment paradigm. We suspect that the flexibility, convenience, and potential receipt of positive reinforcers through CM will aid in recruitment. Additionally, because patients in primary care often have an unmet need for specialty addiction treatment, we anticipate strong interest and engagement with this intervention. Finally, a lasting intervention will require clinical champions at primary care sites to help foster interest among treatment staff. If clinical providers are not interested, this will hamper dissemination to patients. The initial qualitative aspect of this trial, which focuses on facilitators and barriers, will be pivotal in maximizing the potential long-term success of this intervention.

Conclusions

Addiction is widely prevalent and negatively impacts health from both acute and chronic use. Treatments are available; however, uptake is low, and access is limited. Senyo Health is a digitally native platform that combines multiple evidence-based interventions to address and treat SUDs. Its flexibility is particularly useful for rural populations, who often experience severely limited access to treatment. Senyo Health is freely available for download to be used without CM, LADC, or CoCM components. However, we feel that these aspects are essential for the highest treatment efficacy.

Abstract

Background: Practicum is indispensable for the development of professional practitioners; yet, trainees may encounter psychological distress, especially anxiety, brought on by new challenges. Research stated that a positive mindset promotes better learning and mental status. Well-designed interventions have been shown to relieve anxiety and help trainees thrive in their practicums and professions. The proposed study adapted an integrated intervention, We-SMILE (Web-Based Single-Session Intervention of Mindset on Intelligence, Failure, and Emotion), for improving prepracticum anxiety and coping. We-SMILE has the potential to be a low-intensity self-help prepracticum intervention to support students in adjusting their mindsets and overcoming the challenges in practicum.

Objective: Using a 2-arm randomized controlled trial, this study aims to examine the efficacy of We-SMILE on reducing anxiety (primary outcome) and enhancing psychological status, psychological well-being, learning orientation, academic self-efficacy, and confidence (secondary outcomes).

Methods: A total of 117 students will be recruited from the social work and counseling programs and randomly assigned to existing prepracticum training (training as usual [TAU]) or that plus the We-SMILE. Participants will be assessed repeatedly at 3 time points: baseline, 2 weeks post intervention, and 8 weeks post intervention. The outcomes will be measured by validated items and scales on anxiety, mindsets, psychological well-being, and the Failure Mindset Scale. Recruitment for the pilot study was initiated in May 2024 during social work and counseling prepracticum briefing sessions. Participants were randomly assigned to the intervention or TAU group. The intention-to-treat (ITT) analysis principle and linear regression–based maximum likelihood multilevel models will be used for data analysis.

Results: This study has received research ethics approval in May 2024. Participant recruitment started at the end of May 2024, and enrollment was ongoing as of when this protocol was submitted. Data collection and analyses are expected to be complete in 2025.

Conclusions: The randomized controlled trial will compare the efficacy of the We-SMILE intervention group and the TAU group. The results of this study will benefit practicum students, fieldwork supervisors, and social work and counseling programs.

implicit theory; growth mindset; social work students; counselling students; practicum; anxiety

Introduction

Prepracticum Anxiety

Practicum is an essential educational component of professional training [1,2], bridging the gap between theory and practice and enhancing the professional capacity and core competence of future practitioners [3,4]. The quality of fieldwork profoundly influences social work trainees' personal, intellectual, and professional development [4], per communication skills, critical reflection, professional growth, creativity, innovation, and self-efficacy [1,5]. Students and alumni frequently highlight their field experiences as pivotal in preparing them for their future roles [1]. Research indicated that continuous improvements in fieldwork training benefit the training of future practitioners, such as integration of resources, collaboration across sectors, and improvements in curriculum design [1,4,5]. Through practice and feedback, trainees gradually evolve from knowledge receivers to social workers and competent practitioners [6]. However, the process can be challenging and sometimes frustrating, with obstacles such as the rigorous training process and mental distress [4].

Research showed that students indeed face various challenges during practicums, which can be categorized into professional and individual levels [7]. At the professional level, anxiety and stress may rise when students experience issues with engagement, poor relationships, etc, related to trainers and supervisors [1,2,8,9] and are often exacerbated by the distinct cultural context and intense competition [6,7]. Moreover, although the programs usually prepare students for their placements, they may overlook the specific complexities of the work environment and the higher expectations of professional skills [4,10]. On the flip side, students probably encounter mental difficulties (eg, anxiety, stress, and compassion fatigue), financial pressures, maladaptive coping, physical problems, etc [7,11-15]. It has been noted that excessive anxiety and negative emotions can interfere with the practicum process [16]. Being adequately prepared to confront the challenges and difficulties in practicum is crucial for the learning outcomes and well-being of social work and counseling trainees.

Different coping mechanisms among students can lead to varied training outcomes. Clinical practicum students with the abilities to both manage their emotions and understand the emotions of the people around them have been shown to achieve better patient outcomes and patient satisfaction [2]. For example, dietitian students who effectively manage stress report the most supported feeling [10]. Conversely, students may doubt their abilities and talents if they find it tough to handle critical feedback and expectations from their supervisors and placement agency staff, besides the discrepancy between their preconceived notions before the practicum and the real situation [4,9]. Thus, fostering a positive attitude toward negative emotions, challenges, and feedback is essential to facilitate better learning outcomes and maintain trainees' mental health.

Existing Interventions and Gaps

The existing intervention approaches have broadly been delivered from 2 perspectives: the external perspective, such as transition support programs and peer group supervision [17-19], and the internal perspective, such as mindfulness training [20]. Transition support programs usually focus on supervisory support, transition-supportive learning activities, professional behavior and practice, and student internship responsibilities [4,18]. These programs are beneficial to students' mental health, specifically lowering anxiety, increasing confidence, improving preparation levels, and enhancing professional knowledge and skills [4,17]. Moreover, researchers examined the efficacy of peer group supervision in a practicum setting for counseling students [19] and found it was helpful to stimulate and bolster participants' professional self-efficacy, self-confidence, and feelings of pleasure and happiness [21]. However, several pertinent studies particularly highlighted mindfulness interventions for social work and counseling practicum trainees [22-24]. Mindfulness as a self-care practice was valuable for managing trainees' anxiety and strengthening self-care [20,25].

There is a notable lack of research evaluating the implementation of stress and anxiety management interventions in practicum settings for social work and counseling trainees. First, many studies usually develop and apply multiple-session interventions and must be led by professionals, expanding the trainers' workload [26]. More importantly, full-time employees and interns generally face different work tasks, challenges, and pressures [27]. However, existing interventions lack clear definitions and distinctions, so more evidence from interns' perspectives is needed. Lastly, the current interventions require more objective and reliable outcome indicators and well-designed randomized controlled trials. Thus, a low-intensity self-help prepracticum intervention to increase the preparation levels of social work and counseling trainees is desired.

Mindset Intervention

Mindset, which refers to implicit theory, means an individual's belief in the changeability of his or her attributes [28]. Individuals with growth mindsets believe that their attributes are changeable. Believing intelligence and emotion are temporary and evolving will prompt one to make efforts at learning and emotion regulation. In contrast, a fixed mindset indicates the belief that one's attributes are immutable [29-31]. The extant literature shows that the fixed mindset is related to more anxiety and stress, while the growth mindset contributes to proactive coping with anxiety and stress and resilience in the face of drawbacks [28,32]. Mindset is found to be a modifiable factor in intervention, which is essential in clinical psychology, therapy, prevention, and early intervention. These days, the growth mindset has been gradually introduced into practice and has yielded positive results [31,33,34].

Nevertheless, little research has been conducted on integrated mindset interventions, and there is very limited evidence for

this initiative. As mindsets can be domain-specific, one may have different mindsets regarding various domains [35]. When one faces a challenge, multiple mindsets may interact and intervene in one's coping behaviors. As for prepracticum trainees, their anxiety is multifaceted. Instilling growth mindsets regarding intelligence, emotion, and failure-is-enhancing mindsets, respectively, is worthwhile in easing anxiety and stress coping [36]. An integrated mindset intervention may be more efficient in reducing anxiety related to practicum, thereby preparing for the challenges that may be encountered.

Integrated Mindset Intervention: We-SMILE

This research has adapted an existing integrated mindset intervention by the principal investigator (PI: SZ), that is, PC-SMILE (Parent-Child Single-Session Mindset Intervention on Intelligence, Failure, and Emotion) for secondary school students [37]. The design is grounded in implicit theory research and supported by emerging evidence of the effect of brief interventions [38-42]. PC-SMILE is a 45-minute intervention that aims to instill growth mindsets of intelligence, failure-is-enhancing, and belief-in-change of emotion using neuroplasticity and real-life examples among students. The efficacy of PC-SMILE is being examined with a 3-arm randomized controlled trial [37].

The current protocol endeavors to modify the child-version of PC-SMILE for practicum trainees in social work and counseling programs, namely, We-SMILE (Web-Based Single-Session Intervention of Mindset on Intelligence, Failure, and Emotion). We-SMILE adheres to the core concepts of PC-SMILE with specific adjustments to practicum trainees' circumstances, that is, intending to introduce growth mindsets about intelligence, failure, and negative emotion to prepracticum students. We-SMILE starts with stories mirroring scenarios from social work and counseling practicum, followed by key principles from implicit theory, learning mechanisms, and emotion regulation, and finally supports these conceptions with solid evidence from research. One highlight of We-SMILE is that it includes a session dedicated to time management, an issue that new practicum students often struggle with. In this section, students are introduced to effective time management tools and ways of enhancing awareness of allocating time without burning out. Then, transferred to self-care methods to manage emotions caused by practicum experiences.

Aims

The protocol aims to assess the efficacy of We-SMILE through a 2-arm randomized controlled trial.

The primary objective is to evaluate the efficacy of We-SMILE in reducing anxiety related to practicum among social work and counseling trainees compared to the training as usual (TAU) group.

The secondary objective is to evaluate the efficacy of We-SMILE on secondary outcomes, including (1) relieving depression, anxiety, and stress; (2) improving psychological well-being; (3) enhancing learning orientation; and (4) increasing academic self-efficacy and confidence related to practicum compared with the TAU group.

Methods

Design of We-SMILE and Implementation Strategies

Patient and public involvement is a key principle we adopted in the intervention design and implementation strategies. The intervention design was coproduced by the research team and student advisory group who have completed at least one practicum training.

The first step is preintervention development. The needs for prepracticum mindset training were identified through interviews with the students who completed their summer practicum in 2023. Second, during intervention development, a student advisory group of 3 social work students was invited to participate in pilot studies and provide suggestions on the initial questionnaires, videos, and the final intervention regarding content consistency, process clarity, ease of understanding, and intervention duration. Third, after the pilot study in May 2024, participants' open-ended feedback will be collected for intervention improvement. We also invited 3 participants to interview for detailed comments. Based on the feedback and comments, further improvements were made. Thematic analysis will be conducted to integrate participants' feedback to identify what they perceive as the most beneficial aspects of the intervention and those most in need of improvement. Coproduction is helpful to ensure the intervention's acceptability, feasibility, relevance, and effectiveness. Fourth, about implementation strategies. The implementation process was co-designed with the fieldwork coordinators. We collected feedback from supervisors and teachers in the social work program. They will help send invitations to upcoming prepracticum social work and counseling students during briefing sessions and share the research link with the students via WhatsApp group once this study begins. Our study adheres to the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist (version 1.6) and follows the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) guidelines (see Multimedia Appendices 1 [43] and 2 for details).

The intervention is a 45-minute web-based course, finally consisting of five elements: (1) an introduction to a proactive mindset, including neuroplasticity, the malleability of intelligence and emotion, and the importance of failure and feedback in the learning process; (2) stories and testimonials during practicum, which emphasize the belief in change; (3) short videos about allegories of developing intelligence, emotion, and failure mindsets; (4) common questions and misconceptions about growth mindsets; and (5) self-persuasive writing exercises in which participants write down their thoughts and suggestions for others about growth mindsets. Figure 1 displays the intervention home page, Figure 2 provides an example of a story emphasizing the positive aspects of failure, and Figure 3 presents the neuroplasticity foundation linked to a growth mindset. Participants in the TAU group will be provided with the We-SMILE after completing the 8-week follow-up.

Figure 1. Home page of We-SMILE. We-SMILE: Web-Based Single-Session Intervention of Mindset on Intelligence, Failure, and Emotion.

Figure 2. A screenshot from one of three short stories about failure. In the screenshot, Red Bean says, “If only I’d eaten the fourth vegetable and meat bao straight away, just one would have filled me up!”.

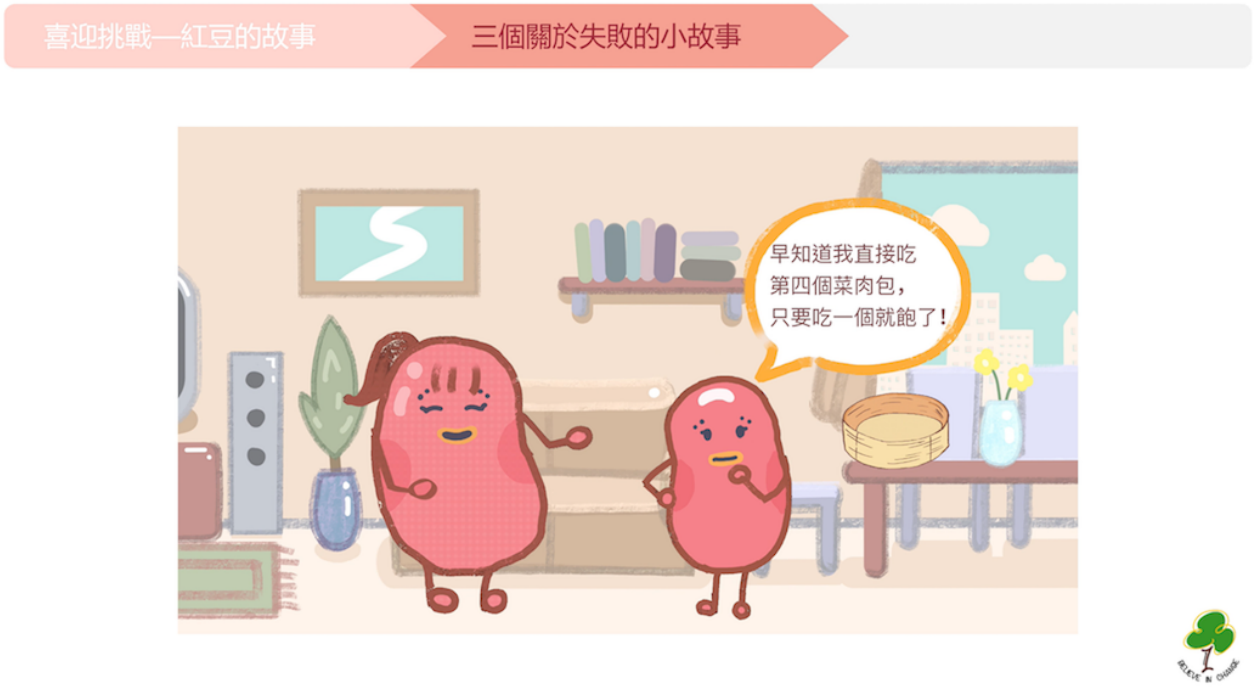

Figure 3. A screenshot demonstrating the neural changes in a learner. The image and text indicate that “Through practice, the connections between neurons can be strengthened, establishing broader connections. We can see that as practice time increases, the neural network becomes progressively more enriched. This is the change that our brains undergo during the process of behavioral change. In fact, the changes in brain neurons go far beyond this. Let's continue to explore.”.

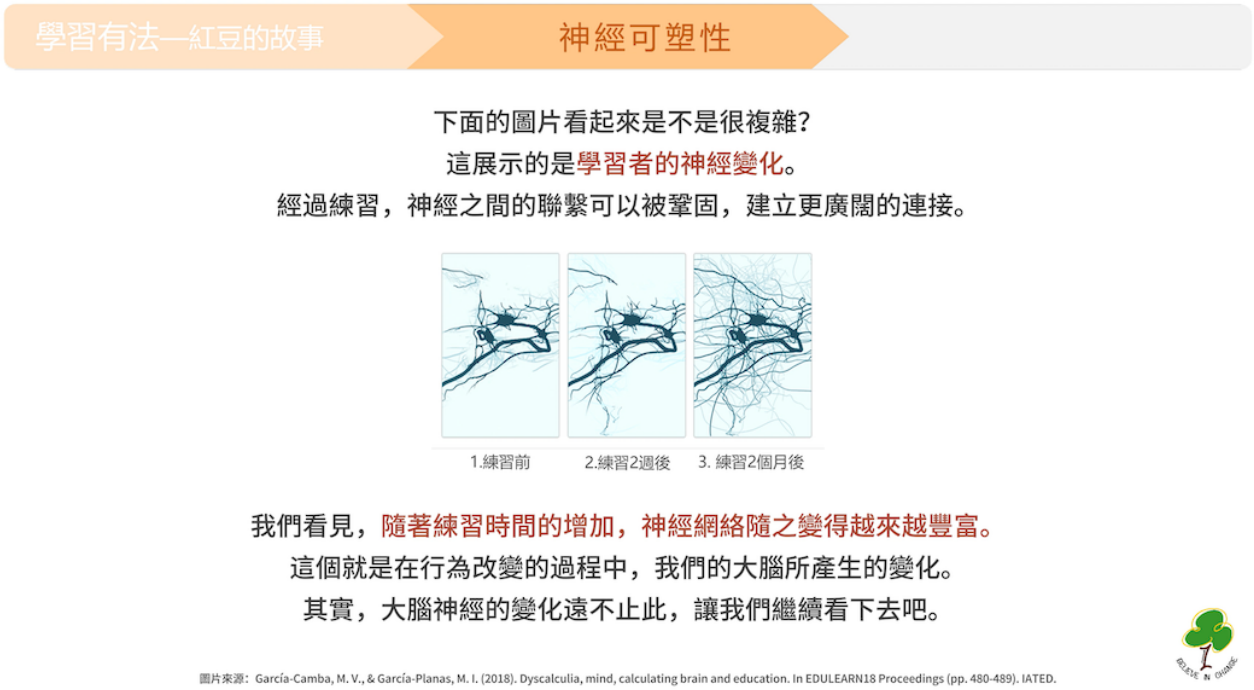

Randomization Process

Randomization will be performed via the randomization module of Qualtrics with a 1:1 allocation, whereby students will be allocated to either the We-SMILE group or the TAU group. Students assigned to the We-SMILE group will receive the intervention link immediately, while participants in the TAU group will be provided with the course 8 weeks later. Both groups will be taught by instructors with equivalent qualifications and expertise in the subject matter to ensure consistency in the teaching quality. Concealment can be ensured as participants complete the survey individually and randomization is set after the baseline assessment. The data will be collected at 3 intervals: baseline, 2 weeks after the intervention, and 8 weeks after the intervention; that is, the research team will send the link of follow-up questionnaires to participants at the corresponding time.

Sample Size and Power Analysis

This study targeted prepracticum social work and counseling students during the period 2024-2025. The sample size is 117, based on the number of trainees. The G*Power is used to determine the target sample size, achieving adequate efficacy to detect mean group differences of small (d=0.2), medium (d=0.5), and large (d=0.8) effect sizes using 2-tailed tests with α=.05. Although previous studies have indicated that the ideal is to detect small effects, the target sample of 117 in this study may reflect the ability to detect moderate to large effects (slightly greater than 0.5) due to limitations on the number of students in the programs [44].

Participant Eligibility

Undergraduate and postgraduate prepracticum students in social work and counseling programs from universities in Hong Kong and Mainland China are eligible. Inclusion criteria are students who (1) are about to start the practicum soon, (2) can read and write Chinese, and (3) consent to participate. Exclusion criteria are students who (1) do not consent to participate, (2) cannot concentrate for at least 45 minutes to complete the intervention and questionnaires, (3) have a disability or serious physical or mental illness resulting in poor condition, and (4) do not participate in the practicum.

Measurements

Figure 4 illustrates the specific research arrangements and measurement schedules.

Demographics

Name, gender, ethnicity, year of birth, year of study, program type, program name, student number, practicum mode, previous social work experience, and other work experience will be collected at baseline. Students' university numbers will be collected again at 2 follow-ups for matching. Collected students' names and university numbers are solely for administrative purposes, such as matching pre- and postintervention data and ensuring accurate contact with participants for compensation after this study.

Fidelity Checking

Mindset about intelligence will be assessed by a 3-item Growth Mindset Scale developed by Dweck et al [45] with high internal reliability across studies, including "you have a certain amount of intelligence, and you can't really do much to change it," "your intelligence is something about you that you can't change very much," and "you can learn new things, but you can't really change your basic intelligence." Each item will be rated from 1=strongly disagree to 6=strongly agree. A higher average score means participants believe less that they can become smarter if they work at it. The reliability was reported in adolescents with Cronbach α of 0.71 [46].

Mindset about failure will be measured by the 6-item Failure Mindset Scale [47,48]. The first 3 items indicate that failure can be a positive motivation (eg, "The effects of failure are positive and should be utilised"), while the last 3 items indicate that failure is a setback (eg, "The effects of failure are negative and should be avoided."). Each item will be rated from 1 (strongly disagree) to 6 (strongly agree). The Cronbach α was 0.76 [48].

Primary Outcome Variable

Anxiety related to practicum will be measured by 4 items proposed by Gelman which parallels with the evaluation often used in social work practice [16], including 1 direct measuring item: "level of anxiety about starting the practicum," and 3 indirect measuring items: "how much your anxiety will interfere with their learning," "how prepared you are for the practicum" and "how excited you are to participate in the practicum" [16,49]. Each statement will be rated on a 10-point Likert scale, ranging from 1=completely not anxious, very small, completely unprepared, and completely unexcited to 10=extremely anxious, very great, perfectly prepared, and extremely excited [16]. The Cronbach α was 0.70 [50].

Secondary Outcome Variables

Depression, anxiety, and stress will be assessed by the simplified 12-item Depression Anxiety Stress Scales (DASS-12) [51,52]. The items of DASS-12 were shortlisted from the DASS-21, such as "I found it hard to wind down" [51,52]. Each item will be rated from 0=never to 4=almost always according to the participant's status over the past week. A higher score indicates a higher level of recognition of one's recent mental distress symptoms. The Cronbach α was 0.90 [52].

Psychological well-being will be measured using the 7-item Short Warwick-Edinburgh Mental Well-Being Scale [53,54]. One example item is "I've been feeling optimistic about the future." Each item is rated from 1 (none of the time) to 5 (all of the time). Higher scores suggest better mental well-being. The Short Warwick-Edinburgh Mental Well-Being Scale was validated in Hong Kong, and the Cronbach α was 0.89 [55].

Learning and performance orientation will be assessed by 11 adapted items from learning orientation and performance orientation scale [56], with 5 items measuring the learning orientation (eg, "I like to learn new knowledge in practicums") and 6 items measuring performance orientation (eg, "I like to seek rewards in short term for my efforts"). Each item will be rated on a 5-point Likert scale from 1=strongly disagree to 5=strongly agree. Reliabilities were reported of Cronbach α with 0.65 and 0.56 [56].

Academic self-efficacy will be measured by 5 adapted items from the Bandura Self-Efficacy Scale [57]. Example items are "I believe that as long as I study diligently, I will be able to master practical skills" and "as long as I am diligent, I can master all of the skills learned during the internship." The items will be scored from 1=strongly disagree to 5=strongly agree and reported a Cronbach α of 0.84 [57].

Confidence related to practicum will be assessed by a 6-item self-developed scale. Items generated from interviews with social work students, such as "I am confident that I can listen to comments from supervisors/colleagues/service users with an open mind" and "I am confident that I can manage my time well and cope with my practicum work and schoolwork at the same time." Each item needs to be rated from 1=strongly disagree to 5=strongly agree. A higher total score represents a higher level of confidence.

Intervention Feedback

Intervention feedback contains both close-ended and open-ended questions. The close-ended intervention feedback will be measured using an adapted 12-item 5-point Likert scale based on the Theoretical Framework of Acceptability scale [36]. The items include affective attitude, burden, perceived effectiveness, opportunity costs, and specific acceptability. A sample item is "does this course affect your daily schedule?" The open-ended question invites participants to share their thoughts about the intervention: "Do you have any other suggestions or feedback about this programme?"

Motivation will be measured using 2 self-designed items: "How much do you want to improve your ability to cope with challenges?" and "how much do you want to use what you have learned in the course to cope with challenges in your current or future practicum?" The items will be measured on a 6-point scale from 1=extremely not willing to 6=extremely willing. Higher scores indicate that participants are more motivated to learn from the intervention, apply it to their practice, and are intrinsically more willing to improve their status.

Pilot Study

The pilot study is initiated at the end of May 2024, before the commencement of the first batch of social work and counseling students' practicum. An overview of the intervention study is incorporated into the prepracticum briefing to attract participants. Upon obtaining consent, program supervisors will distribute the intervention course link to the students. Alongside standardized questionnaires, participants are invited to offer open-ended feedback on the intervention to facilitate future revisions and enhancements after finishing. Examples of feedback we currently received include "The content and duration can be condensed. The principle about red beans' story is something I believe everyone understands. It's better to directly point it out" and "If the voiceover is done by a real person, it would feel more authentic. The sound effects in the stories are very interesting" In the next revised version, the intervention will be shortened and improved with human voice dubbing from a professional actress.

Follow-Up Plan for Distressed Participants

Follow-up plans have been established to support participants who experienced severe distress during the trial. Research staff have been trained to respond to reports of distress from participants. If severe distress is identified, participants will be referred to appropriate resources, including counseling services and crisis hotlines provided by schools, government agencies, and nongovernmental organizations. Additionally, guidance on seeking professional help is included in the information sheet given to participants. Ensuring the mental health and well-being of participants is always our top priority.

Analytic Plan

Data analysis will be conducted according to the intention-to-treat (ITT) analysis principle, and missing data will be processed using multiple imputations. Descriptive analyses will be used for the distribution of demographics and all outcome variables. Analysis of covariance will be deployed to compare postintervention outcomes between the intervention and TAU groups, controlling for baseline differences. This approach ensures that the observed effects can be attributed to the intervention rather than preexisting differences, thereby enhancing the validity of the results. Generalized estimating equations will be applied to process data from repeated measures to initiate subgroup analyses and to assess differences in the efficacy of the intervention among participants with different work experiences, emotional states, and mindsets. Because of the cluster randomization, a 2-level analysis will be conducted [58]. Additionally, multilevel regressions will be used to test group effects, time effects, and their interactions on outcome variables. A *P* value of <.05 will be considered statistically significant, and all statistical analyses will be performed using SPSS (version 26; IBM Corp).

Data Quality Assurance

Respondents can review and change their answers through a "back" button. The investigators will be responsible for the quality control of the data. Data with response times that are too long or too short, as well as expired responses, will be excluded. Completion times from the pilot study will be used to determine thresholds for early or late submissions. The first entry will be kept to avoid duplicate entries. Two attention-checking items are embedded to identify careless responses.

Protocol Amendments

In general, the research will be conducted following the protocol. The protocol should be seriously and carefully revised and reapproved by the ethics committee of the PI's university if major modifications are necessary for any reason or if the change will impact the conduct of this study and the interests of the participants. Minor adjustments that do not have significant impacts on this study and participants will be recorded for subsequent supplementation of ethical and trial materials.

Ethical Considerations

This study has received research ethics approval from the institutional review board of the PI's university (HSEARS20240512001-01). Students who click the link sent by supervisors and teachers will first read the information sheet and sign the consent form. The participants can decide when to start and withdraw from the intervention. The primary investigators will be responsible for the management of research data. All identifying information of participants will be anonymized during the research process, including data analysis, results reporting, and publication. The data will be generated directly from the web-based survey platform and will be stored at the PI's university. All database files will be password-protected and can only be accessed by direct researchers. Researchers who have permission to access the data will be appropriately trained to maintain data confidentiality, integrity, and basic data security measures. All data and backups will be maintained till 5 years after the completion of the research. Each eligible participant will be contacted by the research team and receive HK $100 (US $12.87) supermarket vouchers after completing all the questionnaires.

Results

The project was funded by the Departmental Teaching and Learning Grant of the Department of Applied Social Sciences at PI's university (grant 8AL1). Recruitment began in May 2024, and data collection is expected to end in April 2025. Data collection is currently underway. The results are scheduled to be released in August 2025. We plan to issue a publication and may also disseminate the results at conferences. The flow of this study is shown in Figure 5.

Discussion

Principal Findings

The purpose of this study is to initiate a randomized controlled trial among prepracticum social work and counseling students, assessing the efficacy and acceptability of a digital integrated growth mindset intervention (We-SMILE). It is expected that the We-SMILE group will present lower anxiety related to practicum and more positive secondary outcomes compared to the TAU group. Although this is a single-session, web-based self-help intervention, its efficacy, effectiveness, and sustainability should not be overlooked, as it may continue to serve a useful purpose beyond the project period [44].

We-SMILE is an innovative, convenient, and promising intervention for prepracticum training with a focus on the growth mindset. The We-SMILE will be the key deliverable of the proposed project and has several remarkable advantages. First, We-SMILE is theory-based. Extant interventions with similar core concepts from Western or local practice have been found effective in improving mental health [28,36,40]. Second, patient and public involvement and the coproduction process involving students and fieldwork supervisors ensure We-SMILE to be a tailor-made intervention for practicum trainees. Third, the web-based and nonstigmatizing natures increase accessibility and flexibility for young individuals. Once the efficacy of We-SMILE is established, the integrated mindset prepracticum intervention can help hundreds of students be psychologically prepared for fieldwork training. While providing mental support, it can also supplement practicum education as a readily accessible module to enhance the training outcomes of social work and counseling students. Additionally, this study will provide clear implementation protocols and strategies to increase transparency. The intervention study can be replicated, developed, and referenced as a basis for future research and the design of single-session growth mindset interventions.

Strengths

Based on previous research indicating the lack of interventions targeting prepracticum training, the proposed study fills this gap by focusing on improving the growth mindset in this particular population. The project will benefit multiple parties. The immediate beneficiaries will be social work and counseling students. The intervention is designed to tune trainees' mindsets regarding how they perceive the learning process, feedback, failure, and emotion. It could help prevent a high level of anxiety and fear about receiving negative feedback and facilitate students building resilience in fieldwork training. Second, it could benefit fieldwork supervisors. We-SMILE offers a flexible intervention option as a concise psychoeducational tool that seamlessly fits into prepracticum preparation. It does not require an extra workload for supervisors and can easily be distributed for students' needs and reference. Alternatively, the intervention can be used as a specialized component of the existing

prepracticum training or incorporated into classroom teaching. Third, it may benefit the social work and counseling programs as a whole. We-SMILE provides an accessible intervention to assist social work and counseling students in transitioning into future workplaces with lower levels of distress, better self-efficacy, and becoming mentally prepared, which will in return improve the outcome and quality of education programs.

Limitations

Some limitations in this intervention require further consideration and refinement. First, this study only targets students in social work and counseling programs. The number of participants in each cohort will be limited. We may not be able to recruit a sufficient sample size if practicum trainees are occupied by coursework and internships and become too busy to complete the intervention course. There is a need to expand the scope of implementation by including a larger sample in the future to demonstrate that the intervention could be adapted into training for other education and health care domains. Second, as this study does not differentiate individuals with various levels of anxiety states, the effectiveness in reducing anxiety may not be significant for those students with no or low levels of anxiety, thus, it may affect the overall statistical significance. Therefore, we may conduct subgroup analyses to address this issue.

Conclusion

This study aims to develop a digital single-session integrated growth mindset intervention (We-SMILE) and to evaluate its efficacy and acceptability using a 2-arm randomized controlled trial among practicum trainees of social work and counseling programs. If proven effective, our study will provide a potential model for the implementation of a brief, low-dose, single-session intervention. In return, We-SMILE may also contribute to the development of accessible, highly adaptable, low-cost, and sustainable interventions in mental health education on a larger scale.

Acknowledgments

This work was supported by the Departmental Teaching and Learning Grant of the Department of Applied Social Sciences at The Hong Kong Polytechnic University (grant 8AL1). We thank social work students who served as student helpers in the coproduction of the intervention, including Oscar Cheung, Alfie Li, and Tim Lam. We also thank the students in the pilot study who provided helpful comments for intervention improvement. The social work or counseling program leader, supervisors, and student assistants contributed greatly to the development and conduct of the intervention and are gratefully acknowledged.

Data Availability

Data generated and analyzed during this study is not publicly available due to privacy and confidentiality issues but can be obtained by contacting the corresponding author upon reasonable request.

Authors' Contributions

SZ proposed this study concept, was responsible for the intervention design, funding acquisition, study supervision, paper writing, review, and revision. YW participated in the intervention design, data collection, paper writing, and revision. AX worked on the intervention design and paper revision. and SSKW, KY, and JTYL facilitated the data collection. All authors read and approved this paper.

Abstract

Background: In India, heavy menstrual bleeding or menorrhagia (*Raktapradara*) constitutes about 15% to 20% of all gynecological admissions in an institution. Of these, 43% of patients are aged 20-40 years. This condition is worsening because of the high prevalence of anemia among Indian women. Menorrhagia can have a significant impact on women's lives. Medical treatment is usually the first choice in excessive bleeding, but it reduces menstrual blood loss by only 50%, and up to 50% of women undergo surgical treatment within 5 years. However, none of these treatments proved their definite efficacy in spite of the high price and side effects. This condition presents a major financial burden on health care services. In Ayurveda, encouraging work has been done on the compound drug *Ashokarishta*, and the drug *Trinakantamani pishti* is indicated in Ayurvedic classics and the *Ayurvedic Formulary of India*. Also, these medicines have been used in Ayurvedic practice for a long time. However, no clinical trial has been carried out on these formulations.

Objective: The primary objective is to evaluate the efficacy of Ayurvedic intervention in the management of menorrhagia, and the secondary objective is to assess the efficacy of Ayurvedic intervention on the quality of life of the women with menorrhagia.

Methods: This ongoing study is an open-label, interventional, randomized controlled trial, with a sample size of 140 in the treatment and control groups combined (including 20% dropouts), and will be carried out within the duration of 36 months. Participants in the treatment group will receive Ayurvedic treatment, that is, 20 mL of *Ashokarishta*, 250 mg of *Trinakantamani pishti*, and 1 iron and folic acid tablet (100 mg of elemental iron and 1.5 mg of folic acid) twice a day orally for 3 months. Participants in the control group will receive a 500-mg tranexamic acid tablet thrice a day for 7 days from the first day of menses for 3 cycles and 1 iron and folic acid tablet twice a day orally for 3 months. The primary outcomes are changes in the amount of uterine bleeding evaluated by the Pictorial Blood Loss Assessment Chart, changes in the duration of bleeding, and attainment of a normal quantity of blood loss during the interval of cycles. The secondary outcome is changes in the Menorrhagia Impact Questionnaire.

Results: As of December 2024, a total of 79 patients have been enrolled. Data analysis should be completed by February 2026. The study will be reported following standard guidelines for reporting randomized controlled trials. Clinical results will be disseminated through conferences and peer-reviewed publications in a relevant journal.

Conclusions: The Ayurvedic approach may provide an evidence-based therapeutic tactic for the management of menorrhagia.

KEYWORDS

Ashokarishta; Trinakantamani pishti; tranexamic acid; menorrhagia; Raktapradara

Introduction

Normal menstrual bleeding is cyclical, with 3-5 days in durations and 50-60 mL of bleeding in normal color, as described in Ayurvedic classics. However, when the normal menstrual bleeding pattern is altered in reference to duration, amount, color, and cycle, the conditions are called *Artavadushti*; *Raktapradara* is one of them, and it is comparable to menorrhagia. In India, menorrhagia constitutes about 15% to 20% of all gynecological admissions in an institution. Of these, 43% of patients are aged 20-50 years. This condition is worsening because of the high prevalence of anemia among Indian women [1]. Heavy menstrual bleeding (HMB) can have a significant impact on women's lives. HMB or menorrhagia is clinically defined as greater than or equal to 80 mL blood loss per menstrual cycle [2,3]. It is, however, the woman's perception of her own menstrual loss that is the key determinant in a referral and, indeed, subsequent treatment. In allopathic medicine, various medical treatment options are available, but many women proceed to surgery due to treatment failure or hormonal side effects. Surgery introduces the risk of bowel, bladder, and ureteric damage, as well as hemorrhage, infection, and even death [4]. So, there is a clear unmet clinical need for better medical treatments for this benign but incapacitating condition. *Ashokarishta* is a compound drug, consisting of 14 drugs described in the *Stree rogadhikara* (female disorders) section of the *Bhaishajya Ratnavali* book of Ayurveda [5]. The *phalashruti* (benefits at the end of the composition) of this medicine says that, by using the medicine for more than one month, it cures pain due to menorrhagia, fever, several types of hemorrhages, hemorrhoids, etc. *Trinakantamani pishti* [6,7] is a drug also mentioned for *Raktapradara* (HMB or menorrhagia) in Ayurvedic classics. As the effect of this medicine is mainly in bleeding disorders, it was decided to evaluate its efficacy in *Raktapradara* (Table 1). Some encouraging work has been done on the effect of *Ashokarishta* [8-10] on *Raktapradara*, but no work has been carried out on *Trinakantamani pishti* along with *Ashokarishta*. Tranexamic acid is a safe and effective form of medical therapy in women with menorrhagia; it also increases the quality of life in these women [11]. So, this study is planned to evaluate the efficacy of Ayurvedic treatment modalities in the management of menorrhagia and to assess the efficacy of Ayurvedic intervention on the quality of life of the women with menorrhagia, compared to the control intervention (tranexamic acid).

Methods

Study Setting

This study will be conducted at Vardhman Mahavir Medical College and Safdarjung Hospital, New Delhi, India.

Eligibility Criteria

Inclusion Criteria

Participants will include those aged 20-50 years with menorrhagia—that is, regular (21-35 days) cycle with HMB loss, subjectively or objectively defined (Pictorial Blood Assessment Chart [PBAC] score of more than 100 points) [12], or prolonged bleeding (bleeding more than >7 days) for 3 consecutive cycles—who are willing and able to participate in the study.

Exclusion Criteria

Participants with any of the following will be excluded: anemia (hemoglobin level <7%); hypertension; diabetes mellitus; hepatic or renal disease; cardiac disease; organic lesions of the reproductive tract due to conditions such as tuberculosis, carcinoma, and congenital deformities; pelvic inflammatory disease or cervicitis; evidence of malignancy, cervical intraepithelial neoplasia, or cervical carcinoma; history of untreated sexually transmitted disease or being HIV positive; past history of atrial fibrillation, acute coronary syndrome, myocardial infarction, stroke, or severe arrhythmia in the last 6 months; lactating women; current or previous use of oral contraceptive pills, glucocorticoids, antiandrogens, ovulation induction agents, antidiabetic drugs, antiobesity drugs, or other hormonal drugs recently (unless there is a washout period of 1 month); hypersensitivity to the trial drugs or any of their ingredients; currently participating in any other clinical trial or participated in past 6 months; or any other condition that the principal investigator thinks may jeopardize the study.

Study Interventions (Investigational Products)

Participants in the treatment group will receive 250 mg of *Trinakantamanipishti* twice a day orally before meals, 20 mL of *Ashokarishta* twice a day orally before meals, and 1 iron and folic acid tablet (100 mg of elemental iron and 1.5 mg of folic acid) twice a day orally after meals for 3 months. The treatment group's medicines (investigational products) will be procured from Good Manufacturing Practices–certified pharmacies, namely, Indian Medicines Pharmaceutical Corporation Ltd. and Central Ayurveda Research Institute, along with the Certificate of Analysis to ensure the quality and safety of the medicines. The study drugs will be kept in a secure place and will only be supplied to the participants under the guidance of the investigator. A record will be maintained for the drug dispensed.

Any discrepancies between amounts dispensed and returned will be explained.

Participants in the control group will receive a 500-mg tranexamic acid tablet thrice a day for 7 days from the first day of menses for 3 cycles and 1 iron and folic acid tablet twice a day orally for 3 months.

Strategies to Improve Adherence to Study Protocol

The compliance of taking trial drugs will be assessed at each visit during the follow-ups (30-day intervals) by assessing the approximate quantity consumed. The participants will be asked to return the empty container of medicine at the time of each follow-up visit. Repeated reminders will be given over the phone or through family members and project staff for regular taking of medicine.

Outcome Measures

Primary Outcome Measures

Primary outcome measures are changes in the amount of uterine bleeding evaluated by the PBAC, changes in the duration of bleeding, and the attainment of a normal amount of blood loss during the interval of cycles, evaluated at baseline, the end of every cycle up to 3 cycles, and follow-up visits.

Secondary Outcome Measure

The secondary outcome measure is changes in the Menorrhagia Impact Questionnaire (MIQ) [13], evaluated at baseline, the end of intervention period, and follow-up visits.

Safety Outcomes

The safety of the trial intervention will be evaluated by recording the incidence of adverse events on every scheduled follow-up visit. All adverse events during the study timeline will be recorded and monitored per the Good Clinical Practice Guidelines. The investigator will report the same to the institutional ethics committee and the sponsors at the earliest opportunity. To assess the safety, hematological and biochemical investigations such as complete blood count and liver and kidney function tests will be done at baseline and the end of the intervention period.

Sample Size

To calculate the sample size, we anticipated a difference of 70 units in average PBAC score after treatment between the two groups (*Trinakantamanipishti* along with *Ashokarishta* vs tranexamic acid tablet), with an SD of 137 units based on the results of the previous study [14]. With 95% confidence level (α=.05) and 80% power, the number of patients to be enrolled in the study was calculated using the following formula:

where $Z_{1-\alpha/2}$=1.96, $Z_{1-\beta}$=0.84, σ=137, and δ=70.

Expecting a dropout rate of 15%, the number of patients is estimated to be 60 + 9 = 69. Thus, approximately 70 patients should be enrolled in each group.

Randomization and Allocation

A randomization chart will be generated with the help of computer-generated random numbers. Participants will be randomized in a ratio of 1:1 to either of the two groups. The randomization schedule will be strictly controlled and remain with the biostatistician/data analyst. Sequentially numbered, sealed, opaque envelopes will be used to conceal the allocation.

Study Procedure

The participants will be screened for menorrhagia as per the inclusion criteria. Prior to any trial-related activity, the investigator will give the verbal information and written information in a printed form about the trial to the participant, parents, or guardians to read and understand. The investigator would ensure that the participants are fully informed about the aims, procedures, discomforts, and expected benefits of the trial. It must be emphasized that participation is voluntary, and participants have the right to discontinue the trial at any time without any prejudice. A voluntary, signed informed consent will be obtained from the participants prior to any clinical trial–related procedure.

After the screening, if the participants are found to be suitable, then they shall be enrolled in the study after signing the consent form. The required investigations will be carried out, and subsequently, within one week or as soon as laboratory values are received and found to be within permissible limits, the participants will be enrolled in the study, and that day will be considered visit 1 or the baseline visit. The treatment will be given to the participants after fulfilling all the formalities as per the protocol. The subsequent follow-ups will be on the 30th day (visit 2), the 60th day (visit 3), the 90th day (visit 4), the 120th day (visit 5), and the 150th day (visit 6; ie, completion of active treatment). Participants will visit the study site 6 times during the trial. The details of the activity during each visit are presented in Table 2 and Figure 1.

Table 2. Study schedule.

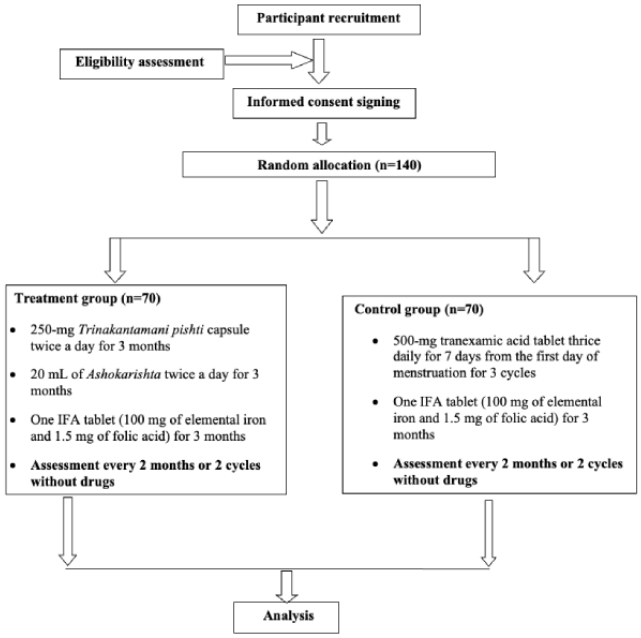
Figure 1. Flowchart of the study procedure.



Timelines With Deliverables

The total study period spans 36 months and is divided into four distinct phases. During the initial phase, which lasts from months 1 to 6, efforts will focus on procuring standard trial drugs and finalizing laboratory arrangements. Additionally, tasks such as staff recruitment, equipment procurement, and finalization of case report forms (CRFs) will be undertaken. The second phase, covering months 7 to 23, will be dedicated to the recruitment of participants for the study. Subsequently, months 24 to 34 will constitute the treatment period, during which participants will undergo interventions as per the study protocol, with follow-up assessments conducted accordingly. Finally, in the last phase spanning months 35 to 36, data compilation, analysis, report preparation, and publication will be the primary activities, culminating in the dissemination of study findings.

Laboratory Tests

The laboratory tests (hematological tests, biochemical tests, and ultrasonography) will be conducted in a National Accreditation Board for Testing and Calibration Laboratories–accredited laboratory. Hematology (hemogram, lipid profile, fasting blood sugar and postprandial blood sugar levels, and hemoglobin A_{1c} level); liver function test; kidney function test; venereal disease research laboratory test; HIV test; hepatitis B surface antigen test; ultrasonography (transabdominal sonography or transvaginal sonography); coagulation profile; hormonal test like thyroid profile, serum prolactin test, serum follicle-stimulating hormone test, and serum luteinizing hormone

test; routine urine culture; and microscopic urinalysis will be carried out at baseline and the end of the treatment (90th day). Coagulation profile will also be done at the middle of treatment (30th day).

Data Collection, Management, and Analysis

The data collection will include all information in the CRFs. All participants will be assigned an enrollment number, which will be used on CRFs and electronic databases. Consent forms and CRFs will be stored in locked cupboards, and electronic databases will be password protected. The data will be entered using the double-entry method for accuracy. All data will be accessible to the principal investigator and coinvestigators during and after the study has been completed and will be available to sponsors and monitors as required. Data will be stored for 5 years before being destroyed. In case of dropout, 10% data will be inserted through the imputation technique. Proper documentation will be done to ensure its accurate interpretation and verification. The analysis will be done by the Central Council for Research in Ayurvedic Sciences statistical unit.

Statistical Methods

Continuous variables will be presented as mean, SDs, medians, and ranges. Categorical variables will be summarized with frequencies and percentages. When inferential analyses will be conducted for continuous variables, they will be tested for normality. Nonparametric methods will be used to compare nonnormal data. Within-group comparison will be done using a paired *t* test (1- or 2-tailed, as suitable), while between-group comparisons will be done using an independent sample *t* test (1- or 2-tailed, as suitable) for the data following normal distribution. Nonnormal data within the group will be compared using the Wilcoxon sign rank test, while between groups comparison will be done by using the Mann-Whitney *U* test. Categorical data between groups will be compared using the chi-square or Fisher exact test. A 2-sided *P* value of <.05 will be considered statistically significant. Per-protocol and intention-to-treat analyses will be carried out at the end of the study. All data will be analyzed using Stata (version 16.1; Stata Corp).

Ethical Considerations

This research protocol had been reviewed and approved by the institutional ethics committee of Vardhman Mahavir Medical College and Safdarjung Hospital (S. No. IEC/VMCC/SJH/NOTE/2023-Feb/06). Participants will receive an information sheet with the research details given in two languages (Hindi and English). Voluntary signed informed consent will be obtained from the participants before any clinical trial–related procedure. The participants will be informed by the investigator that all trial data recorded will be treated with strict confidence. During documentation and analysis of the trial, the individual participant will only be identified by their enrollment number.

Participant confidentiality will be guaranteed, and only researchers will have access to the data. Participants are nominally compensated for their loss of wages and transportation costs by paying an amount of IND 100 (US $1.19) for every visit to the hospital during the study period.

Data Safety and Monitoring

The safety of the trial intervention will be evaluated by recording the incidence of adverse events on every scheduled follow-up visit. All adverse events during the study timeline will be recorded and monitored per the International Council for Harmonization of Technical Requirements for Pharmaceuticals for Human Use's Guideline for Good Clinical Practice. The investigator will report the same to the institutional ethics committee and the sponsors as soon as possible.

For facilitating appropriate reference standards for scientific, ethical, and safety issues before the trial begins, this protocol has been developed according to the 2013 SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) and CONSORT (Consolidated Standards of Reporting Trials) statements [15].

After completion of the study on 25% of the total participants, the data will be analyzed for the safety of the trial drugs. The project monitoring committee will monitor the trial's progress through review meetings and site visits as per the requirement to ensure strict adherence to the trial protocol and correct completion of the CRF.

Drug Compliance

The compliance of taking trial drugs will be assessed at each visit during the follow-ups (30-day intervals) by assessing the approximate quantity consumed. The participants with equal to or more than 80% compliance will continue in the study. The participants will be asked to return the empty container of medicine at the time of each follow-up visit. Repeated reminders will be given over the phone or through family members and project staff for the regular taking of medicine.

Prior and Concomitant Medication

Participants will receive clear instructions not to take any medication other than the trial drugs for any condition without prior consultation with the investigators. The investigator will advise participants to promptly report any additional signs, symptoms, or unusual occurrences and to seek guidance accordingly. Additionally, the investigator will diligently document any other medications taken by the participants for comprehensive recordkeeping.

Rescue Medication

Permission will be given for the use of rescue medication for alleviating any emergency condition as per the discretion of the investigator. It will be documented in detail in the CRF.

Results

As of December 2024, a total of 79 patients have been enrolled. Data analysis should be completed by February 2026. The study will be reported following standard guidelines for reporting randomized controlled trials. Clinical results will be disseminated to the public through conference presentations and peer-reviewed publications in a relevant, open-access journal.

Discussion

Conclusion

Ayurveda scholars correlate *Raktapradara* with menorrhagia (National Ayurveda Morbidity Code: EL-4) based on the similarities in causes, clinical features, and treatment. This paper describes the protocol for the Ayurvedic management of menorrhagia. We undertook a randomized controlled trial to objectively assess the efficacy of Ayurvedic treatments for the management of menorrhagia and compared it with standard conventional treatment. The changes are assessed objectively by using the PBAC score and MIQ as the outcomes for participants with menorrhagia.

Studies have demonstrated promising results of some Ayurvedic interventions for managing *Raktapradara*. With this study, we aim to observe the effectiveness and safety of Ayurvedic management using the formulations of *Ashokarishta* and *Trinakantamani pishti* in reducing symptoms associated with menorrhagia, such as HMB. If beneficial, this study could contribute significantly to integrative approaches for managing menorrhagia.

Strengths and Limitations

The strengths of this study include its randomized design and the inclusion of enough participants to allow for adequate statistical power for subgroup analyses. This study uses the PBAC score and MIQ, which are well-validated instruments to assess menorrhagia.

One potential limitation of this study is that the investigators were aware of the participants' group assignment, and therefore, bias in favor of any particular group cannot be excluded. However, every effort was made to ensure blinding of the participants during the group allocation. An independent evaluator blind to study conditions was responsible for administering all study measures. The protocol may also serve as a reference for the planning of similar clinical trials.

Acknowledgments

The authors are thankful to the institutional ethics committee, for approving the protocol, and to the Vardhman Mahavir Medical College and Safdarjung Hospital, for allowing the study to be conducted at their facilities. The study was funded by the Central Council for Research in Ayurvedic Sciences, New Delhi, India. Patients and/or the public were not involved in the design, conduct, reporting, or dissemination plans of this research.

Data Availability

The findings will be disseminated to the public through conference presentations and published in open-access, peer-reviewed journals. Analyzed data will be made available for interested researchers with a reasonable request after the publication of the results.

Authors' Contributions

SR, SM, US, SO, and BG developed the protocol. SR and SM registered the protocol and generated the first draft of the manuscript. SM revised the manuscript according to suggestions. The manuscript was reviewed and approved by all authors.

Conflicts of Interest

None declared.

Abstract

Background: The hospital experience is often marked by fear and pain, particularly for children undergoing medical procedures. Sedation is commonly used to alleviate patient anxiety, but it poses additional health risks. Caregivers, usually the parents, also experience emotional distress during the child's hospital stay, which can further exacerbate the child's anxiety and pain. While various interventions exist to ease patient distress, few consider the emotional well-being of caregivers.

Objective: This study aims to explore the effectiveness of a cooperative virtual reality (VR) game as a novel nonpharmacological solution to reduce anxiety and pain for both pediatric patients and their caregivers during medical procedures. Specifically, we aim to investigate whether the VR game "Sweet Dive VR" (SDVR), designed for children aged between 6 and 12 years to play with 1 caregiver, can alleviate anxiety and pain during different types of needle punctures and Kirschner-wire removal.

Methods: A prospective multicenter randomized clinical trial will be conducted. Eligible participants will be identified by scanning the hospital information system, and group allocation will follow stratified randomization. During the medical procedure, patients in the VR condition will play SDVR with a caregiver present, while patients in the control group will listen to a recording of gently crashing waves. Data collection will be carried out through self-reports of patients and caregivers using visual analog scales and questionnaires at 2 measurement time points: before and after the intervention. In addition, observation by the interviewers will occur during the intervention to capture emotional and pain reactions as well as interaction quality between patients and caregivers and smoothness of the procedure flow using a structured observation protocol. The measured variables will encompass patient affect and pain, caregiver affect, player experience, patient experience, and the flow of the procedure.

Results: As of November 2024, we enrolled 39 patients and caregivers, 28 of whom completed the study. Data collection is still ongoing.

Conclusions: Cooperative VR gaming, as exemplified by SDVR, emerges as a promising intervention to address anxiety and pain in pediatric patients while involving caregivers to support the emotional well-being of both parties. Our approach strives to foster positive shared experiences and to maintain trust between children and caregivers during emotionally challenging medical situations.

Introduction

Background

Fear and pain characterize the hospital experience. Children, due to a lack of understanding of the situation, often show extreme anxiety reactions even in objectively harmless situations such as magnetic resonance imaging [1]. Hence, the patient's anxiety and stress can complicate treatment procedures and interfere with the healing process [2-4]. As a result, it is a common practice to sedate patients by administering medication. However, the use of such medication is associated with additional health risks [5], particularly in the context of child development [6]. An additional factor that can influence the emotional experience of child patients is their caregivers, in most cases a parent. Caregivers are also under extraordinary emotional pressure during the child's stay in hospital. If a medical procedure causes intense fear or pain, it can strain the caregiver-child relationship, especially if the child perceives the caregivers as siding with medical staff instead of supporting them—for example, by helping to physically restrain the child [7]. As a result, anxiety, stress, and pain of patient and caregiver can mutually depend on and reinforce each other [8]. While there are numerous pharmacological and nonpharmacological options to ease the patient, the experience of the caregivers is rarely the focus of such interventions.

Therefore, it is advisable to explore nonpharmacological solutions to reduce anxiety and pain. Distracting patients from the medical situation in a controlled manner is an approach that has proven successful for a large variety of media such as movies, music, or toys [9]. The use of immersive technologies such as digital games and virtual reality (VR), in particular, has been shown to be effective in reducing anxiety and pain in a variety of medical situations in numerous studies, especially for needle-related procedures, burn care, and in dental medicine [9-13]. However, these solutions typically address only the patient, which may lead to patients and caregivers feeling disconnected from each other. VR has the potential to result in patients feeling separated from their caregivers due to the sensory shielding provided by wearing a head-mounted display (HMD), which is necessary to create the desired level of immersion. This, in turn, could have an unintended anxiety-increasing effect.

Approach

We are pursuing a new approach in our work: we have developed the cooperative, asymmetrical VR game "Sweet Dive VR" (SDVR) that involves the patient and a caregiver equally in the gameplay and promotes joint communication [14]. In this way, both parties are distracted from the intimidating medical situation without being artificially separated from each other. Involving caregivers in the game, thereby creating positive shared player experiences, can be a way of maintaining children's trust and reducing feelings of helplessness for both children and caregivers [15]. In addition to the game-related interaction with the child, the caregivers are given the task of reacting to certain steps of the medical procedure (eg, the application of a disinfectant or an oxygen cannula) by triggering in-game events. In this way, we achieve synchronization of the virtual world with the patient's real-world sensory impressions, which is intended to preserve and strengthen immersion for the patient on the one hand, while supporting the caregivers' sense of agency. SDVR was designed for children aged between 6 and 12 years and for application during needle-related procedures, in particular port punctures, bone marrow punctures, central and peripheral venous catheterization, and venipunctures. However, we are also planning to test our approach with more painful procedures, such as Kirschner-wire removal.

Objectives

While several different works have successfully used VR games as a distraction during painful procedures [14-16], SDVR is, to the best of our knowledge, the first game that involves both the patient and the caregiver and aims to enhance the emotional experience of both. This study aims to evaluate the effectiveness of using cooperative VR games during medical procedures to improve patient and caregiver experiences. Specifically, we examine whether SDVR can reduce patients' anxiety, pain, and agitation; improve cooperation; and positively influence caregivers' emotional states compared to a control condition in which a calming atmosphere is created by playing natural ocean wave sounds to promote relaxation.

Methods

Hypotheses

In this study, we investigate whether targeted distraction from anxiety- and pain-inducing medical procedures through cooperative VR gaming can reduce experienced pain and anxiety while fostering well-being for both the patients and their caregivers. A list of our hypotheses is presented in Textbox 1. Hence, the primary outcome of the study is a reduction in pain and anxiety ratings of the patient (hypothesis 1) as well as an improvement in the caregiver's emotional experience (hypothesis 2). Our intervention relies on targeted distraction through sensory immersion for the patient as well as cognitive immersion and game fun for the patient and caregiver. Thus, distraction from the medical procedure represents a further end point of the study (hypothesis 3 and hypothesis 5).

The smooth execution of the medical procedure, characterized by the cooperativeness of the patient and caregiver, the needlessness of sedation or fixation, and an uninterrupted flow, will be assessed as a secondary end point (hypothesis 4). Moreover, this study aims to evaluate the quality of SDVR with respect to the player experience of both patient and caregiver (hypothesis 5).

Textbox 1. A list of hypotheses.

Hypothesis 1: patient affect and pain

a. Patients playing Sweet Dive VR (SDVR) during the procedure will report reduced levels of *anxiety* compared with those in the control group.

b. Patients playing SDVR during the procedure will report reduced levels of *pain* compared with those in the control group.

c. Patients playing SDVR during the procedure will exhibit decreased *motoric activity* compared with those in the control group.

d. *Observer's* ratings of *patient cooperation* during the procedure will be improved in the SDVR group compared with those in the control group.

e. *Caregivers'* ratings of patient *pain* will be lower in the SDVR condition than in the control condition.

f. *Caregivers'* ratings of patient *anxiety* will be lower in the SDVR condition than in the control condition.

g. *Observers'* ratings of patient *pain* will be lower in the SDVR condition than in the control condition.

h. *Observers'* ratings of patient *anxiety* will be lower in the SDVR condition than in the control condition.

Hypothesis 2: caregiver affect

a. Caregivers in the SDVR group will experience more *positive emotions* during the procedure compared with those in the control group.

b. Caregivers in the SDVR group will experience fewer *negative emotions* during the procedure compared with those in the control group.

c. *Observer's* ratings of *caregiver cooperation* during the procedure will be improved in the SDVR group compared with those in the control group.

Hypothesis 3: player experience

a. The more positive the player experience of the patients in the SDVR group is, the lower will be the *patients'* intensity of *anxiety* during the procedure.

b. The more positive the player experience of the patients in the SDVR group is, the lower will be the *patients'* intensity of *pain* during the procedure.

c. The more positive the playing experience of the *caregivers* in the SDVR group, the less negative will their *emotional experience* be.

Hypothesis 4: patient experience

a. In the SDVR condition, more patients will have a feeling of *being in control over the situation* than those in the control condition.

b. In the SDVR condition, more patients will report being *distracted* from the procedure than those in the control condition.

c. The number of *patients* reporting that SDVR reduced their *agitation* will be greater than those reporting that listening to ocean waves reduced their agitation.

d. *Patients* in the SDVR condition will be more *surprised by the pain* than those in the control condition.

Hypothesis 5: flow of the procedure

a. The *observers'* rating of the *overall quality of the procedure* will be higher in the SDVR condition than in the control condition.

As interviewing children about their emotional and physical experience is a methodological challenge due to various biases, and because we strive for an objective assessment of the patient's and caregiver's experience, we follow a comprehensive, holistic approach in our methodology and the instruments used. In addition to the patients' and caregivers' self-reported emotional experiences, we also ask the caregivers to assess the patient's anxiety and pain. In addition, the interviewers use a structured observation protocol to assess the patient's experience, the gaming situation, and the course of the medical procedure.

Potential Confounding and Influencing Factors

The meta-analysis carried out by Eijlers et al [11] indicates that VR-based distraction from anxiety and pain is more efficacious in younger children than in older children. Age and gender influence the perception of pain and anxiety during medical procedures. Younger children tend to report more pain during procedures such as venipuncture [16]. In self-reporting, girls tend to report more pain than boys [17]. However, older children and boys tend to rate pain and anxiety differently compared to younger children and girls [17]. Age and parental predictions of distress are substantial predictors of pain and anxiety on blood tests [18]. Therefore, age and gender will be considered as possible influencing factors in the analysis.

Our intervention addresses a range of medical procedures that have shown to be highly anxiety- and stress-inducing in pediatric patients but can generally be performed without anesthesia. It is possible that patient anxiety and pain ratings differ for different procedures and that these perceptions influence the effect of our intervention.

Fundamental anxiety as a patient characteristic (ie, trait anxiety) is also a likely influencing factor for anxiety and pain ratings [19]. Furthermore, there is evidence in the literature of a link between perceived anxiety and postoperative recall of pain [20], which could influence patients' retrospective assessment of their pain. Therefore, we will consider the assessment of the caregivers and the observation of the interviewers in our study.

A well-documented phenomenon that negatively impacts the VR gaming experience is simulator sickness, which includes symptoms such as nausea, dizziness, headaches, and eye strain. There is evidence that children are less likely to react to VR exposure with these negative symptoms [21], but there have been few studies on the possible relationship between age and different forms of visually induced motion sickness. Nevertheless, we will record any indications of simulator sickness before and after the intervention as the described symptoms may relate to patients' general health state. We have elaborated more on that topic in the Methods section, under the Simulator Sickness subsection.

Previous hospital experience, particularly about the previous interventions of the same or similar nature, as well as needle-related phobias and trauma, can influence the patient's emotional response to the medical situation and will therefore be documented during screening. The actual diagnosis will also be recorded to assess the overall psychological situation of the patient and caregiver.

Ethical Considerations

This study was approved by the ethics committee of the medical faculty of the University of Duisburg-Essen (22-10873-BO). The ethics committees of the other study centers, Universitätsklinikum Hamburg-Eppendorf, Germany, Ethik-Kommission der Ärztekammer Hamburg (approval 2023-200739-BO-bet) and Ethikkommission des Universitätsklinikum Schleswig-Holstein, Lübeck, Germany (approval 2023-708), also saw no ethical or legal objections to this study.

All patients and caregivers will be fully informed about the background and procedure of the study during the recruitment process before they consent to participate in the study. Both the legal guardians and the children must give their written consent to participate in the study. They will be informed about the protection of their personal data and their digital rights in accordance with the European General Data Protection Regulation.

During the onboarding process, the collected data will be pseudonymized. An individual, random participant ID will be created during enrollment and stored with the patient ID separate from the survey answers. Once data collection is complete, the pseudonymization table will be deleted so that the data are anonymous from this point on. The children will be informed of the possibility that they might undergo the procedure in the control group without HMD and sedation or anesthesia. Participants in the control group will be allowed to try the game after completing the medical procedure.

Study Design

The study presented here is a prospective multicenter randomized nonblinded clinical trial. This study refers to protocol version 19 (March 1, 2023), which is registered in the German Clinical Trials Register (DRKS00033544). Any changes to the protocol will be submitted as an amendment to the responsible ethics committee of the University Hospital Essen for approval and filed in the DRKS. Data collection will take place at the University Hospital Essen, the University Hospital Schleswig-Holstein in Lübeck, and the University Hospital Hamburg-Eppendorf, all 3 located in Germany. Patients in the VR condition will play the game SDVR with 1 caregiver during the medical procedure. The beneficial effects of VR and digital games in distracting from anxiety and pain compared to the standard of care (ie, no intervention for distraction or sedation) have been demonstrated in numerous studies [9,11-13]. Therefore, our study particularly focuses on the effect of the shared gaming experience and addresses both the patient and the caregiver as recipients of the distraction and mood-enhancing intervention. Furthermore, to avoid the results being biased simply by the patient's experience of getting an "extra treatment" and additional attention from the medical staff during participation in the study, we will compare the experimental condition with a control condition in which the patients and caregivers will also receive special treatment. Acoustic relaxation techniques are straightforward and unobtrusive to implement in medical procedures, making it possible to address both patients and caregivers simultaneously. In contrast to guided imagery, which requires active mental engagement—often challenging in stressful or painful situations—nature sounds offer a passive form of relaxation. This passivity makes them more accessible and appealing across a range of ages and cognitive abilities. Another option could be passive music therapy; however, natural sounds present a more universally neutral and calming experience, as they bypass personal musical preferences and the emotional resonance often associated with music. Therefore, we chose to play a recording of ocean waves to foster a calming atmosphere during the procedure.

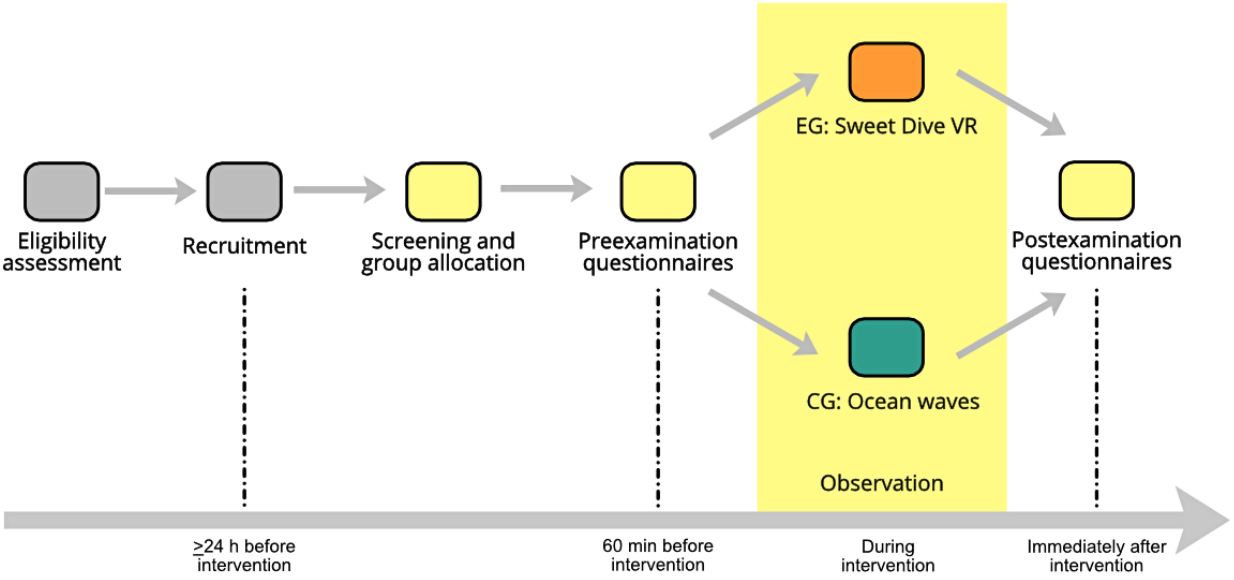
Procedure

A diagram of the study procedure is shown in Figure 1. Patients meeting the eligibility criteria (Textbox 2) will be identified in the hospital information system. Patients and their caregivers will then be contacted by telephone or during their next stay in the hospital. They will be fully informed about the background and aim of the study, the procedure, and the 2 experimental conditions. Patients and caregivers will then have at least 24 hours to consider whether they want to participate. Refusals and their reasons will be recorded anonymously.

If they agree to participate, patients and caregivers will be asked to give their written consent. During registration, the patients will then complete the screening questionnaire together with an interviewer, based on which the randomized, stratified group allocation will be automatically performed. All questionnaires aimed at patients will be completed together with the interviewers. The task of the interviewers is to read out the questions and items if necessary and to help with comprehension problems. The interviewers are trained accordingly so that they do not interfere with the patient's response behavior and do not suggest answers.

The participants will be requested to arrive 60 minutes before the actual appointment. During this time, the patients and caregivers will fill out the preexamination questionnaires in parallel. The participants will be reminded once again that participation is voluntary and that they can withdraw their participation at any time.

Figure 1. Study procedure timeline. Participants are assigned to either the experimental group (ie, Sweet Dive VR; SDVR) or the control group (ie, ocean waves). Pre- and postexamination questionnaires are administered to patients and caregivers. The interviewers assess the situation during the intervention using an observation protocol. CG: control group; EG: experimental group.



Textbox 2. Participant inclusion and exclusion criteria.

Inclusion criteria

- Age 6 to 12 years (applies for patients only)
- Procedure possible without sedation or anesthesia (applies for patients only)
- Sufficient knowledge of German (applies for patients and caregivers)
- Ability to hold and operate a game controller (applies for patients and caregivers)

Exclusion criteria

- Visual impairments (eg, lack of stereo vision and color blindness; applies for patients only)
- Severe cognitive impairments (as assessed by the caregivers and physicians; applies for patients and caregivers)
- Diagnosed with epilepsy (applies for patients only)

Termination criteria

- Desire to end participation (applies for patients and caregivers)
- Clear signs of severe simulator sickness (applies for patients only)
- Extreme pain (applies for patients only)
- Extreme anxiety (applies for patients only)
- Other adverse events (applies for patients and caregivers)

In the SDVR condition, patients and caregivers will receive a verbal, written, and illustrated explanation from the interviewer about the process, goal, and controls of the game as well as a brief introduction to the background story either as a short video or in the form of a short picture story. The caregivers will be instructed that they can start the game using the buttons on the controller and trigger events in the game that correspond to the treatment steps.

After the patients and caregivers have entered the examination room, in the SDVR group, the interviewer will help the patient put on the HMD and hand them the controller. The caregivers will receive the game controller and can then start the game session. In the control condition, the audio file will be played from a tablet or notebook.

We made special efforts to make the setup process as straightforward and quick as possible to enable noninvasive and seamless integration into the medical procedure. The VR app starts automatically as soon as the HMD is switched on (ie, the so-called “kiosk mode”). The necessary realignment of the perspective in the virtual world to the patient’s position can be triggered simply by pressing a button on the game controller. The technical setup process, including a functional test of all components (eg, Bluetooth connection to the game controller), takes just 5 minutes on average and can be prepared before the

actual treatment. Setting up and adjusting the HMD for the patient and handing over the game controller to the caregiver takes a further 1 to 2 minutes on average.

During the procedure, the interviewer will observe the medical situation, the patient's reactions, and the interaction between the patients and the caregivers. The observations will be documented in an observation protocol.

At the end of the intervention, the postexamination questionnaires will be completed by the patients and caregivers. Interruptions and premature terminations of the intervention will be recorded, and the reasons will be noted. Children in the control condition will be allowed to try out the game after the end of the experiment.

If a participant wishes to terminate the intervention or if one of the termination criteria described in Textbox 2 is met, the intervention will be discontinued immediately, and the participant will return to the standard of care, and a note will be made in the observation protocol.

Participants

Sample

Patients requiring port puncture, lumbar puncture, peripheral or central venous catheter insertion, or Kirschner-wire removal will be enrolled, each with 1 caregiver. Given the complexity of the planned study setting and its integration into the clinical processes, we performed a sensitivity analysis to ensure an appropriate test strength and sample size. We anticipate that the recruitment of 78 patients and caregivers each is feasible. On the basis of a power analysis with the G*Power software [22] and starting from a 2-sided *t* test with a significance level of α=.05 and a test power of 80%, we determined that a medium-size effect of approximately Cohen *d*=0.64 can be achieved with a corresponding sample size of 39 participants per group. In view of these statistical parameters and considering the objectives of the study, we decided that recruiting 26 participants in each of the 3 participating study centers would provide an appropriate balance between practical feasibility and statistical power.

Randomization and Stratification

Assignment to the experimental conditions will be automated by a study management software. The recruiters will have no opportunity to influence the assignment at any time. Allocation will use the method of stratified randomization using a minimization algorithm. Consequently, the patient-related variables (ie, strata) used for sample stratification, are as follows: (1) trait anxiety (State-Trait Anxiety Inventory for Children–trait anxiety), (2) age, (3) type of intervention, (4) previous experience with the procedure, and (5) sex. The minimization algorithm attempts to allocate a new patient to a group in such a way that the difference between the 2 groups is minimal for each stratum. If no clear allocation can be achieved with this procedure, a random allocation will be made.

Material

Experimental Condition: SDVR

The players' mission will be to catch as many fish as possible for a medical examination after a cargo ship lost a container filled with candy. The patient and 1 caregiver will play the game cooperatively. The core mechanic of SDVR is attracting and catching fish. To attract a fish, the patient can drop a piece of candy into the water by pressing a button. A transport box moves horizontally on the upper edge of the screen from left to right and back. When the box is precisely above the fish, the patient must press another button at the right moment to bring it down and cover the fish. In the next step, the patient must inform the caregiver verbally so that the caregiver can press a button on the gamepad to move the box upward. The fish is then considered to be collected, and the process can start all over again. The number of fish collected will be shown to the VR player in a head-up display (Figure 2). The gameplay is infinite; that is, there is no fixed game end or goal. This way, we can respect the variable length of the treatment.

Figure 2. In "Sweet Dive VR," the patient must attract a fish with candy and move the box down in the right moment to collect it. Next, the caregiver must move the box up again. The head-up display in the upper-left corner indicates the number of collected fish (top row) and events associated with the medical procedure triggered by the caregiver (bottom row).

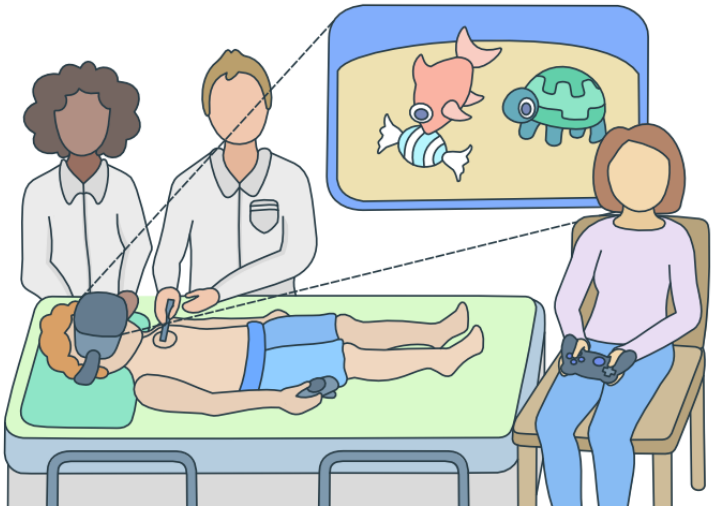
The game was designed to be played in a supine position (Figure 3). Consequently, the player's perspective has been adjusted so that, while lying on their back, they not only look up at the virtual sky (ie, the virtual water surface as in the case of SDVR) but can also see the horizon and the ground. By slightly shifting the virtual camera, a natural visual impression is possible, suggesting that the player is standing. In numerous previous

tests, we have not registered any negative effects such as simulator sickness.

The key feature of our game design is the inclusion of a caregiver in the gameplay as a second player. Through the asymmetrical game design [23], we can distract both the patient and caregiver from the treatment and create a shared positive experience. While both players must cooperate to pursue their shared objective (ie, catching the fish), they have different mechanics at their disposal to achieve that objective. However, not only are the actions available to the 2 players different but also the information about the game world is different. While the patient can see the game world via the HMD, the caregiver lacks all visual and auditory cues about the current game state (Figure 3). Thus, the caregiver is completely dependent on the communication of their child. Consequently, a high degree of concentration on the game events and the verbal communication of both players is required, which thus becomes an essential mechanic of the game and enhances the immersion of both players [14]. With the children giving verbal instructions to their caregivers, the game is designed to support their feeling of being in control over the situation. Moreover, the strong focus on communication between caregivers and children should enhance the sense of familiarity, security, and connectedness within the emotionally challenging situation. In addition to interacting with the child through the game, caregivers are assigned the task of responding to specific steps of the medical procedure (eg, the application of a disinfectant or an oxygen cannula) by triggering corresponding in-game events. This approach synchronizes the virtual world with the patient's real-world sensory experiences, thereby preserving and enhancing the patient's immersion. Concurrently, it grants caregivers a sense of agency and participation in the medical situation, reinforcing their involvement in the process.

As this study focuses on the description of the research protocol for the clinical evaluation of our approach, we refrain from delving deeper into the design rationale here and refer to the planned publication elsewhere.

Figure 3. Schematic representation of the medical procedure and the patient-caregiver interaction in the asymmetric game design.



Control Condition: Audio Recordings of Ocean Waves

The research field of environmental psychology explores the positive effects of natural environments on human experience [24], including in medical contexts [25,26]. It has been shown that exposure to natural environments can reduce acute and anticipatory stress. Annerstedt et al [27] showed a stress-recovery–promoting effect of birdsong in a virtual forest scenario. Liszio et al [28] have shown that the audiovisual presentation of virtual underwater environments significantly reduces acute and anticipatory stress. However, research on the effect of solely auditive presentation of nature sounds on the emotional experience of patients in medical situations is scarce; however, there is some evidence in the literature. Moreover, several studies indicate a significant reduction of patient anxiety and agitation during percutaneous coronary intervention [29] and coronary artery bypass graft surgery [30,31] when listening to nature sounds.

In the control condition, a 30-minute recording of ocean waves will be played instead of the VR game. Recording will start with a 1-minute introduction by the same soothing voice that narrates the companion character "Turtle" in SDVR. From then on, only the sound of the waves will continue.

Hardware

Patients in the VR condition will play the game with a Pico G2 4K HMD (Figure 4, left). The device is a stand-alone HMD in which all calculations are performed on the device itself, so that no additional computer is required. The HMD has 3 df and can therefore only be used when sitting or lying down. User inputs are made via the associated controller, which resembles a simple remote control. A larger touchpad is located on the controller, which works like the directional pad on a typical game controller. In addition, the controller has a trigger button that is operated with the index finger. It can be controlled with 1 hand using either the left or right hand. We chose this hardware for the following reasons: the housing is comparatively easy to disinfect, as all external components are either hard plastic or rubber. Comparable devices from other manufacturers typically use foam covered with fabric for the face pad and elastic fabric for the headbands, which do not meet health care hygiene standards. Furthermore, no user account from third-party

providers is required for operation. Apps can also be started in a so-called kiosk mode, that is, the corresponding app starts automatically when the device is switched on, which makes it much easier to use in the fast pace of everyday clinical practice. Finally, the standard controller's small design and reduced number of buttons simplify operation with small hands. Children have no problems holding the controller and reaching all the buttons with their fingers. The symmetrical design allows operating the controller with either the left or right hand.

For the caregiver, we will use a conventional gamepad as an input device for the game. The gamepad and HMD are connected via Bluetooth. The advantage of using a common gamepad is that many people are familiar with the layout of the buttons and the handling while the acquisition costs are low.

For data collection, we will use tablet PCs. These will also be used to play the recording of ocean waves in the control condition.

Figure 4. The Pico G2 4K head-mounted display with controller (left) and conventional gamepad (right) used in the experimental condition during the medical procedure.

Psychometric Assessment

Emotional Experience

State and Trait Anxiety

The State-Trait Anxiety Inventory is an established questionnaire for measuring anxiety [32] (Table 1). It was developed to measure both state anxiety and the personality characteristics of anxiety (ie, trait anxiety). The questionnaire consists of 2 scales, one for assessing state anxiety and one for assessing trait anxiety. In this study, we will use the German translation provided by Laux et al [33].

For the child survey, we will use the German translation of the adapted State-Trait Anxiety Inventory for Children [19]. This adaptation is characterized by a reduced number of 20 per scale items and a simplified response scale as compared to the original State-Trait Anxiety Inventory. In addition, the rating options are reduced to 3, ranging from 1 (low anxiety) to 3 (high anxiety).

In addition, we will implement a visual analog scale (VAS), which provides an effective method of assessing children's affective state as it offers a simple and easy to understand way of quantifying emotions. We will use the scale "Anxiety" by Gräßer et al [34]. This is based on a scale from 0 (not at all) to 10 (very strong). By simultaneously presenting an illustration the children can identify with and scaling the values from 0 to 10 on a line, children can express their emotional experience in a precise and differentiated way. For comparability between the children's self-report and the impressions of the caregivers and the interviewers, we will also ask the caregivers and the interviewers to rate the patients' pain perception on the same VAS.

Table 1. Breakdown of the psychometric instruments administered (ie, questionnaires, visual analog scales, and self-designed questions) for each respondent group and measurement time.

Respondents and measurement time	Psychometric instrument
Children	
Screening	• STAIC-T[a]
Preintervention measurement	• STAIC-S[b] • VAS[c] anxiety • PANAS-K[d] • SSQ-C[e]

[a]STAIC-T: State-Trait Anxiety Inventory for children–trait anxiety.

[b]STAIC-S: State-Trait Anxiety Inventory for children–state anxiety.

[c]VAS: visual analog scale.

[d]PANAS-K: German translation of the Positive and Negative Affect Schedule for Children.

[e]SSQ-C: Child Simulator Sickness Questionnaire.

[f]PXI: Player Experience Inventory.

[g]PANAS-C-P: parent version of the Positive and Negative Affect Scale for Children.

[h]Sweet Dive VR only.

[i]CHEOPS: Children's Hospital of Eastern Ontario Pain Scale.

Positive and Negative Emotions

To assess the participants' affective state, we will use the positive affect negative affect schedule (PANAS) [35]. The questionnaire consists of 2 separate scales, one for positive affect (PA) and one for negative affect (NA). Each scale comprises a list of words that describe different emotions or moods. Respondents will be asked to indicate the extent to which they felt each of these words either "when thinking about the medical procedure" (before measurement) or "during the medical procedure" (after measurement).

For the caregivers, we will use the original questionnaire translated to German by Janke and Janke and Glöckner-Rist [36]. This version comprises 20 adjectives that describe emotional states. The rating scale describes the intensity with which these emotional states were experienced on a 5-point scale from 1 (not at all) to 5 (extremely). For the 2 dimensions PA and NA, the sum scores are formed from the intensity ratings of the corresponding items.

In addition to describing their own emotional experience, the caregivers assess the children's emotional states using the parent version of the Positive and Negative Affect Scale for Children, which we will use in the German translation provided by

Großheinrich [37]. The scale consists of 2 subscales to determine the children's PA (12 items) and NA (15 items) according to the caregiver's impression on a 5-point scale from 1 (very little or not at all) to 5 (extremely).

The participating children will be administered an adapted version of the original PANAS (PANAS-C) developed by Laurent et al [38]. To our knowledge, because no official German translation of the children's version of the PANAS-C exists, we used this version as a starting point and compared the items with the German translations of the adjectives according to Janke and Glöckner-Rist [36]. As the PANAS-C comprises 30 items, rather than 20 items as in the version by Janke and Glöckner-Rist [36], additional adjectives for which no translation could be found were translated by the authors.

Pain

To measure the children's perceived pain, we will use the VAS "Pain" by Gräßer et al [34], equal to the measurement of anxiety (as mentioned earlier). Again, we will ask the patients, the caregivers, and the interviewers for a rating.

The interviewers will rate the observed pain-associated behavior of the child using the Children's Hospital of Eastern Ontario Pain Scale [39]. It can be used to monitor the effectiveness of interventions to reduce pain and discomfort in young children. The result is a pain score between 4 (no pain) and 13 (severe pain).

Player Experience

Overview

We will use the German translation of the Player Experience Inventory (PXI), which was developed by Graf et al [40], to assess the caregivers' experiences while they play SDVR. The PXI consists of 10 dimensions that describe aspects of the player experience, allowing for a systematic analysis of the game design. Each dimension comprises 3 items, which are rated on a 7-point scale ranging from –3 (strongly disagree) to 3 (strongly agree).

For evaluating the caregivers' experience, we will consider only the following constructs: "ease of control," "goals and rules," "challenge," "meaning," "curiosity," and "mastery and immersion." We will exclude the constructs "progress feedback," "audiovisual appeal," and "autonomy" from the evaluation of SDVR because the game does not have any audiovisual component for caregivers.

To date, there is no suitable and validated version of the PXI for children. As the PXI in its complete form is quite extensive and, in our experience, some item formulations are difficult for younger children to understand, we created a variant by selecting 1 item from each of the 10 dimensions that is clear and easy to understand. In the first round, 3 of the authors—an educator and health play specialist, a pediatric nurse with significant expertise in child-friendly medical language, and an entertainment computing specialist—independently selected 1 item per dimension that, in their opinion, met the criteria of representativeness for the dimension, child-appropriate concept complexity, and child-appropriate language. In the second step, the items for which there was no agreement between the 3 reviewers were discussed until consensus was reached. Moreover, we reduced the response options to a more child-friendly 5-point scale from −2 (strongly disagree) to +2 (strongly agree). It should be noted that this is a tentative, empirically unvalidated version. The data collected in the study may provide the basis for future efforts to develop a suitable player experience metric for children. For the sake of reproducibility and transparency, we included the final list of items in Multimedia Appendix 1.

The interviewers will be asked to assess the child's player experience by rating the statements "The child had fun playing."; "...was completely immersed in the play world."; "...gave the caregiver clear, game-related instructions."; "...understood what his role in the game was."; "...had no problems with the controls of the game"; and "...was optimally challenged by the game" on a 7-point Likert scale.

Presence

According to our assumptions, playing a VR game creates presence, which can be explained as a redirection of the user's attentional focus from the real to the virtual world. Hence, the experience of presence is an indicator of distraction from the medical situation. As there is no questionnaire designed for children to measure their sense of presence, we will use 5 items from the German Igroup Presence Questionnaire [41]. These 5 items describe how conscious the players were of the actual world and how real the virtual world seemed to them. The vocabulary used in these items is less abstract, which makes it easier for children to comprehend. The items are rated on a 7-point scale from 0 (strongly disagree) to 6 (strongly agree).

Simulator Sickness

Simulator sickness is a possible adverse side effect of VR exposure. To diagnose simulator sickness, we will use the Child Simulator Sickness Questionnaire adapted by Hoeft et al [42] and translated to German by us. The questionnaire comprises 7 items describing different symptoms summarized in dimensions "nausea," "oculomotor," and "disorientation." Each symptom is rated on a 3-point scale ranging between 0 ("not at all") and 3 ("very much").

However, it should be noted that our target group will consist of children who are sick. Thus, it is likely that some participants, due to their illness, will experience symptoms that are also associated with simulator sickness. Therefore, we will ask the participants to rate their symptoms before (ie, before measurement) and after (ie, after measurement) the VR exposure.

Patient Experience

We will use several simple self-designed questions to assess specific aspects of the patient experience from the perspective of the children, the caregivers, and the interviewers, including a sense of control, perceived distraction from the medical situation, excitement, and surprise at the onset of pain.

Procedure Flow

The interviewers will be asked to evaluate the course of the medical procedure using the statement "Please evaluate the willingness of the patient and the accompanying person to

cooperate regarding the examination procedure" (1="very uncooperative"; 5="very cooperative"). In addition, they will be asked to rate the overall procedure on a 5-point star scale. We will also track all premature terminations of the intervention and the reasons given by participants, if any.

Data Collection and Analysis

All questionnaires will be completed electronically using the LimeSurvey (LimeSurvey GmbH) software to prevent data loss, incorrect data, or duplicate entries. Data will be stored anonymously on secured servers at the University Hospital Essen. The signed declarations of consent will be stored separately from the data collected. No identifying data will be stored in the dataset. The dataset will be stored separately from security-relevant patient data. Only the persons involved in the data analysis (SL and OB) will have access to the final dataset. Methods of descriptive and inferential statistics will be used to analyze quantitative data.

Results

Data collection is ongoing at the time of publication of this study. As of November 2024, we enrolled 39 patients and caregivers, 28 of whom completed the study (Multimedia Appendix 2 presents the participant flow diagram).

Discussion

Overview

Although anxiety and pain at the hospital cannot always be avoided, there are situations in which the emotional experiences of patients and their caregivers can be improved in a controlled and safe manner using comparatively simple means. VR gaming has proven to be a suitable, effective measure for distracting pediatric patients in pain and anxiety-ridden situations and thus as a nonpharmacological analgesic. We take this approach one step further and involve the caregivers in the game. Therefore, our aim is to make the medical procedure as pain-, anxiety-, and stress-free as possible for patients and their companions to enable the most positive patient experience possible. With our intervention, we aim to increase the cooperativeness of patients and caregivers and thus optimize the course of the medical procedure in terms of minimizing health risks for the patients as well as the necessary time and personnel resources. In the study presented here, we use the VR game SDVR, a cooperative multiplayer game based on cooperation between patient and companion specially designed for this use case.

Challenges

In our effort to enhance the experience for pediatric patients and their caregivers, we acknowledge the challenges associated with maintaining immersion and comfort during medical procedures, particularly when patients are visually and auditorily shielded from the real world; that is, some patients might feel uncomfortable when touched while visually and auditorily shielded from the real world [43]. In this context, it should be noted that there is currently no HMD that has been optimized for children's heads. All existing devices on the market are designed for adults in terms of weight, dimensions, lens distance, and so forth. Consequently, patients may perceive the HMD as a strain and wish to discontinue wearing it during the procedure. In the study, we record such cases and the patients' reasons.

Furthermore, unexpected real-world sensations (eg, phone calls, medical staff coming and going, and noises from medical equipment) that interfere with the virtual environment may "break" immersion and distraction [44]. Our approach addresses these concerns by integrating real-world stimuli into the VR gaming environment, thereby enhancing immersion and minimizing potential disruptions. By allowing the caregivers to trigger events in the game from the outside, real-world stimuli and game-related sensations can be aligned.

We might also encounter patients who are not eager to wear the HMD and engage in the game as they may perceive a sense of losing control over the situation. Previous adverse experiences with the same or similar medical procedures may have resulted in trauma and left patients so emotionally compromised that they perceive any additional treatment (ie, wearing the HMD) as an excessive burden. Reaching such patients with alternative interventions is generally very difficult.

As mentioned earlier, studies show that there is a relation between pain perception and age [16,17]. Against this background, the wide age range of our study is beneficial as it allows us to examine this relationship. In the results report, we will compare our findings with those of other studies to derive potential recommendations on the use of VR game–based pain distraction for pediatric patients of different age groups.

When designing our specific VR application SDVR, we already focused on seamless integration into medical treatment processes. Nevertheless, integrating VR into medical situations brings several challenges, and solutions and workflows must be found. These include the maintenance of the hardware (eg, system updates, battery charging, storage, and disinfection) but also the training of staff in the use of the technology. A VR solution can only provide real added value if it can be easily and safely integrated into the highly standardized processes of the hospital. It must be borne in mind that medical staff are primarily responsible for medical tasks, and experience has shown that, in many cases, they are already working to their capacity. In addition, previous experience and technological expertise cannot always be assumed. If a VR solution does not take these circumstances into account, there is a high risk that the technology will not be accepted and therefore not used. We tried to take these circumstances into account when developing SDVR and our intervention concept and want to use the planned study to check whether we have succeeded.

Limitations

There are some restrictions regarding the study design and methodology. Answering self-report questionnaires about their emotional and perceptual experience can be difficult for younger children. Although we use instruments specially adapted and, where available, validated for children. The interviewers are trained to assist the children in answering the questionnaires without influencing their answering behavior. However, bias cannot be completely ruled out due to children's psychoemotional and cognitive development including language

skills, focus, and motivation. Sometimes the caregivers need to be kept from trying to influence the child when answering the questions. Given the nature of the matter, the study cannot be blinded. Therefore, it is not possible to fully objectify the interviewer's assessment during the intraoperative observation.

The duration of exposure to the alleged anxiety- and pain-reducing stimuli (ie, SDVR and recording of ocean waves) cannot be standardized due to the variable length of the medical procedure. Therefore, it is not possible to determine whether the duration of the intervention influences the experience of patients and caregivers. In addition, the reality of daily practice in the hospital does not allow for a fully standardized, perioperative measurement of the relevant experience-related variables. Therefore, our study protocol defines realistic time frames before and after the procedure, representing a reasonable compromise between temporal proximity to the events and feelings under investigation, integration into hospital operational processes, and standardization with sufficient time for the participants to complete the questionnaires.

Conclusions

This study represents a significant step forward in addressing the challenges of managing anxiety and pain in pediatric medical settings. By harnessing the immersive potential of VR gaming and actively involving caregivers in the process, we strive to create a supportive and stress-free environment for patients and their caregivers. Despite the complexity inherent in our presented study design, we are confident that our work contributes to advancing nonpharmacological interventions in pediatric health care.

Acknowledgments

The authors would like to thank in advance all participating patients and their caregivers who supported us in our research. They would also like to thank in advance the teams at the participating study centers for their cooperation during recruitment. Special thanks to Dr Brigitte Bäuerlein, who lent the authors her voice for Sweet Dive VR. The authors further thank Sarah Haefs for creating the logo and illustrations and Anastasia Chernetskaya for her support in modeling the 3D assets.

Data Availability

The datasets generated and analyzed during this study are available from the corresponding author on reasonable request.

Abstract

Background: Specific learning disorder (SLD) of reading skills impacts approximately 7% of children. Speech and reading therapy is currently the gold-standard intervention for improving children's reading abilities. However, intensive interventions are difficult to implement. Recently, numerous studies have investigated the interest of game- and home-based training approaches to enhance children's motivation and facilitate intensive learning activities in home settings. The serious game Poppins Clinical integrates rhythm and specific written language exercises to improve reading skills in children with SLD.

Objective: This study aimed to assess the noninferiority of Poppins Clinical combined with a reading specialist session once every 2 weeks versus a reading specialist session every week, on the reading skills of children with SLD.

Methods: A total of 306 children with dyslexia will be recruited for this study and randomly assigned to either the experimental or control group. Children in the experimental group will use the serious game Poppins Clinical at home for 20 minutes, 5 days a week, and attend 1 reading therapy session every 2 weeks. The control group will participate in one reading therapy session per week. Poppins Clinical combines rhythm and language exercises integrated into an engaging game designed to maintain user motivation. We will use a noninferiority paradigm to assess the clinical impact of both interventions in terms of reading accuracy, reading speed, and reading comprehension. We will also investigate the evolution of phonological and visual-attentional skills. However, we will explore the impact of the protocol on parental stress and children's perception of their difficulties. Finally, we will also assess the cost of medical care and the impact of introducing the serious game Poppins Clinical on reading therapy. To facilitate recruitment and ensure the representativeness of our sample, the evaluation of the children will be conducted via videoconference using standardized tests that have been adapted for videoconference administration.

Results: Patient recruitment is expected to start in December 2024, with study completion by the end of August 2025.

Conclusions: This study should allow us to assess the interest in using the serious game Poppins Clinical in addition to reading therapy to improve reading abilities in children with SLD.

Introduction

Specific learning disorder (SLD) with impairment in reading is a type of SLD classified as a neurodevelopmental disorder according to the *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders* [Fifth Edition]). The disorder affects reading and spelling abilities as well as related language processing skills such as phonological skills or auditory attention, despite adequate instruction, and in the absence of general cognitive or sensory deficits [1]. Yang et al [2] estimated the prevalence of SLD at around 7% in primary school children, suggesting that this disorder represents a considerable public health challenge.

It is now well established that SLD is caused by problems at the level of phonological representation, characterized by difficulty in accessing or manipulating speech sounds [1]. Recently, several studies revealed a deficit in the temporal processing of speech, which could explain the phonological deficit observed in people with SLD [3-5]. This deficit does not seem to be specific to the processing of speech but applies to the temporal treatment of the auditory signal in general. Effectively, the ability to process rhythm in music is linked with the processing of linguistic prosody in children and adults. However, musical rhythm perception skills predict metaphonological and reading skills [6,7]. People with SLD have difficulty estimating changes in the amplitude of the sound envelope over time [8], processing short durations [5], preattentive processing of vowel duration and voicing establishment [9], and also processing rhythmic information. This is particularly the case in the synchronization of simple rhythmic sequences, such as a metronome, or complex ones, such as music, where people with SLD are more variable [4,10,11]. They also have difficulty identifying whether a sequence is regular or not [11,12]. Rhythm perception and production skills even predict reading skills in children with SLD with reading deficits [12]. Regarding the strong link between rhythm perception and reading skills, several studies tried to improve reading skills in children with SLD through musical training [13]. Among them, some studies specifically focused on the training of rhythm skills. As an example, Flaugnacco et al [12] compared the impact of rhythm training to art training on phonological and reading skills in children with SLD. In this randomized controlled trial including 46 children with SLD, children receiving the rhythm training significantly improved their phonological and reading skills, more than the group of children receiving art training.

The “Recommendations for good practice in the assessment, prevention, and treatment of written language disorders in children and adults” by the Collège Français d’Orthophonie [14] describe three different modes of intervention for patients affected by SLD: (1) corrective treatment targets underlying cognitive deficits (eg, phonological or visual-attentional deficits) and various processes involved in identifying written words (eg, graphophonological conversion, phonological decoding, orthographic memory, and orthographic recoding), (2) adaptive treatment aims to reinforce the reader’s natural compensatory strategies (eg, lexical orthographic memory formation), and (3) compensatory treatment seeks to reduce written language disorders by replacing deficient cognitive functions (eg, using digital aids). These modes of intervention are not mutually exclusive and should be combined or alternated according to a treatment plan defined for each patient. However, when possible, corrective treatment should be the first option applied to a patient. For the intervention to be effective, it must be intensive (5 times a week). Achieving this intensity is not feasible in conventional in-person speech and reading therapy, where therapists are generally limited to scheduling 1-2 sessions per week [15]. Therefore, learning activities must also be carried out at home to ensure sufficient training frequency.

In recent years, there has been growing interest in digital technologies and game-based assessment, training, and rehabilitation methods for neurodevelopmental disorders [16,17]. As defined by Mayer [18], serious games have the motivational and playful characteristics of games, but their main objective is to achieve a measurable change in the player’s skills. The playful nature of these games leads to increased interest and attention from the player, which in turn encourages greater effort [18,19]. However, the digital tool appears to be a preferred learning tool for school-age children [20]. Digital tools also enable the multimodal, sequential, and simultaneous presentation of information, allowing the player to interact with the device in various ways [21]. A recent review of serious games for people with SLD supports their effectiveness in developing reading abilities, particularly those targeting sound and letter association and action video games [22]. In addition, serious gaming could be an ideal medium for training rhythmic skills, as rhythmic synchronization is one of the easiest musical skills to isolate [23]. Furthermore, serious games enable the use of an active musical framework in which body movements, emotions, and intentionality influence each other, maximizing the demands on the audio-motor loop and enhancing anticipatory and predictive processing [24]. Indeed, serious games provide an interesting medium to combine musical training with grapheme-phoneme correspondence, as recommended by recent guidelines [14]. The serious game Poppins Clinical was created to combine written language exercises and rhythm training, allowing children with SLD to practice at home and improve their reading skills. The rhythm training part is the most original component and has been used with children with neurodevelopmental disorders, showing improvement in rhythm skills within the game [25]. A randomized placebo-controlled trial involving 154 children with SLD tested the rhythm training part or a placebo game for 2 months [26]. The results showed improvement in reading accuracy and speed, supporting the

efficacy of Poppins Clinical to improve reading skills in children with SLD. Written language exercises have been added to the rhythm training to match the most recent recommendations [14].

The use of new technologies, including serious games, raises several questions, notably regarding how these new technologies are used in the current health system [27]. Specifically, cost-effectiveness data is lacking. It is crucial to evaluate the impact of a technology compared with its cost [27]. In addition, the impact of a new treatment must also take into account other variables such as treatment adherence or safety. To assess these points, a number of trials use a noninferiority paradigm [28,29]. The objective of these trials is to evaluate if a new treatment can be considered not worse than the gold-standard treatment by an acceptably small amount, with a given degree of confidence [30]. In this type of trial, defining the noninferiority margin is crucial [30]. This margin represents the threshold below which any difference in efficacy is considered clinically acceptable. Elicited health costs can be considered to evaluate the gain of the treatment. These costs may be divided into three types of costs: direct costs related to resources used, indirect costs related to productivity loss, and intangible costs as costs related to pain and endurance [31]. As an example, Schmidt et al [32] identified 31 subcategories of "out-of-pocket" costs such as transportation, insurance, or technology-related costs, that could be considered when looking at health expenditures.

The objective of this paper is to present the methodology of a randomized controlled trial aimed at comparing the effectiveness of Poppins Clinical combined with one reading therapy session every 2 weeks to one reading therapy session per week, on the reading skills of children with SLD, using a noninferiority paradigm. Safety, treatment adherence, and cost will also be considered.

Methods

Study Design and Objectives

This study is an interventional, multicenter, noninferiority randomized trial with two arms. The main objective is to evaluate the noninferiority of Poppins Clinical combined with one reading therapy session every 2 weeks (experimental arm) compared with one reading therapy session every week (control arm) on the reading accuracy (the primary end point) of children with SLD and reading impairment.

Secondary objectives include comparing the experimental group to the control group in terms of safety, reading speed, reading skills, phonological awareness, parental stress, parent quality of life, and text comprehension (secondary end points). Costs related to medical care and therapy between the experimental and control groups are also investigated. This protocol follows SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) guidelines (checklist provided in Multimedia Appendix 1).

Study Population

The study will include 306 participants. The justification for the sample size is given below in the *Statistical Justification of the Sample Size* section.

Inclusion criteria require participants to have a confirmed diagnosis of SLD with a reading deficit, as defined by a speech-language assessment. This diagnosis must align with the *DSM-5-TR* (*DSM-5*, Text Revision) definitions, with reading and/or transcription test scores showing an SD of at least –1.4 or below the 20th percentile, or –2 SD and below the 10th percentile on two such tests. Eligible participants will be children aged 7-11 years, enrolled from CE1 to CM2, who have been receiving reading therapy once a week for less than 2 years. Other criteria include fluency in French or bilingualism in French at home, at least 3 years of schooling in France, and access to a tablet or smartphone at home. In addition, participants must be affiliated with the French National Insurance system, and both the child and their legal guardians must provide informed consent and agree to follow the study protocol. Only one child per family will be enrolled.

Exclusion criteria will exclude individuals who have previously used Poppins Clinical or its earlier version, Mila-Learn (Poppins). Children with unstabilized chronic illnesses, autism spectrum disorders, or documented intellectual disabilities will not be eligible. Participants with vision or hearing impairments that would prevent the use of a tablet or smartphone, as well as those engaged in other interventional studies that may affect the trial's outcomes, will also be excluded.

Study Procedure

First, participants will be informed about the study either by their therapists or via web-based social media platforms. Two clinical sites in Paris and Poitiers, France, will be in charge of the screening and recruitment. Potentially eligible children and their legal representatives will receive study information during an informational visit. If interested, legal representatives will be asked to sign the informed consent form. Speech and reading therapists working with the participants will also be officially informed about the study, and their consent will be collected. The study investigator will then verify whether the participant meets the study criteria and determine their eligibility during an inclusion visit, which can be conducted either on-site or via videoconference. During this visit, verbal assent will also be obtained from the child. Following this, a baseline evaluation (T1) will be conducted by a speech therapist from the clinical site via videoconference, and questionnaires will be provided to both the patients and their legal guardians. These assessments will be performed under the same conditions as renewal evaluations, using standardized tests that have been adapted for videoconference administration.

Patients will then be randomized into one of two groups: the experimental arm or the control arm. Randomization will be carried out by the Contract Research Organization (CRO) using blocks of size six to maintain a 1:1 ratio, with stratification based on the participant's schooling level.

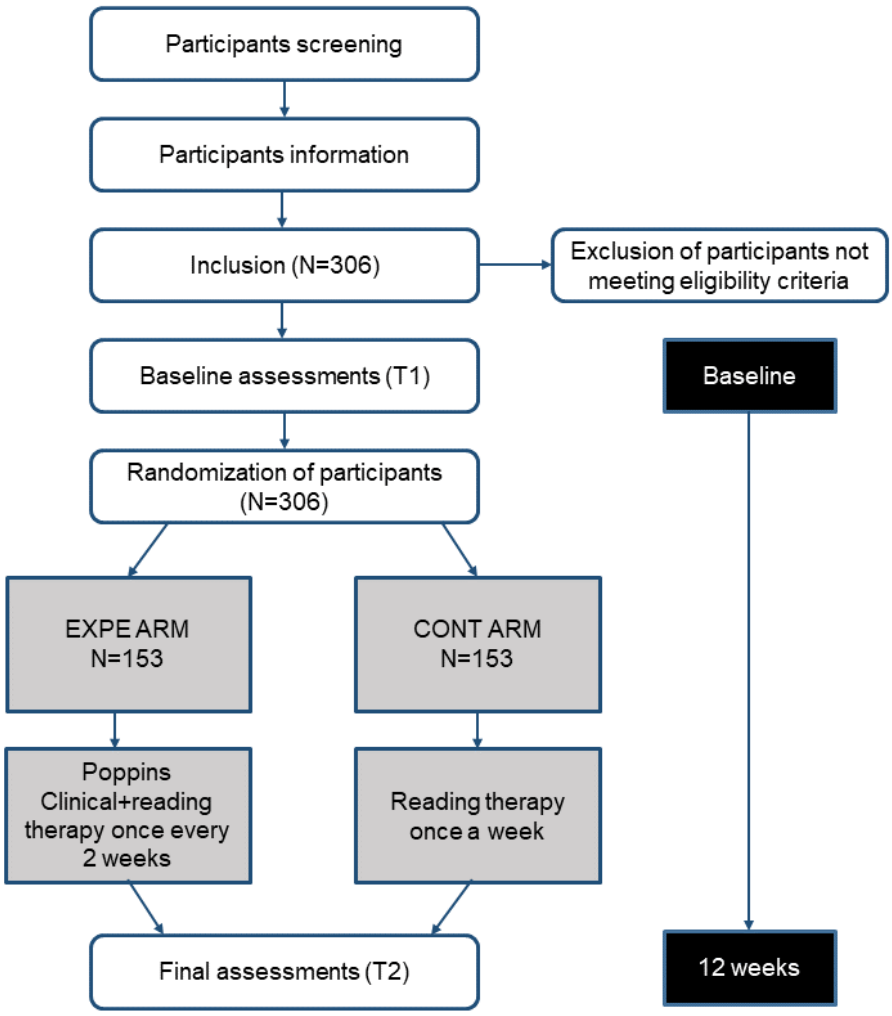
Patients assigned to the experimental arm will undergo 12 weeks of reading therapy, with one session every two weeks. In addition, they will use the medical device Poppins Clinical for 20 minutes per day, 5 days a week, over 12 weeks. The Poppins Clinical device is provided free of charge to families during the three-month training period. Each family must create an account in the game using a specially generated link designed to track

study participants. The patient's playtime is recorded by Poppins Clinical—the time spent on each exercise is tracked, enabling the app to monitor the children's daily playtime. The patient will receive a notification on their tablet every Monday encouraging them to play, and another on Saturday to motivate them to reach the playtime goal. If they have not played during the week, the child will receive an additional notification the following Wednesday to encourage them to play. The first day of training in the Poppins Clinical group must be performed within 2 weeks after the baseline evaluation (T1). Patients in the control arm will continue to receive a weekly reading therapy session, as per common practice in France [15]. To control for potential bias related to the formation of speech and reading therapists, years of graduation and the training courses followed in the last 5 years will be recorded.

A second evaluation (T2) will take place via videoconference 12 weeks (+ or - 14 days) after the first day of training with Poppins Clinical for the experimental arm, or 12 weeks after the baseline evaluation for the control arm. Questionnaires for patients, their legal guardians, and speech and reading therapists will be collected at this time. Please refer to Figure 1 for a flowchart of the study procedures.

Throughout the trial, investigators and evaluators will remain blinded to the patients' group assignments. However, patients and their speech and reading therapists will not be blinded to the allocation. To maintain blinding of the investigators and evaluators, the CRO's safety department will be responsible for recording all adverse events and device deficiencies.

Figure 1. Study procedure flowchart. CONT: control group; EXPE: experimental group.



Experimental Intervention: Poppins Clinical

As aforementioned, we have already examined the impact of the first version of the digital medical device Poppins Clinical on the reading abilities of children with SLD. This version consisted of musical training in the form of a serious game [26]. Based on the new recommendation from the Collège Français d'Orthophonie [14], a new version of Poppins Clinical has been developed that combines the initial musical training program with a written language training program.

Poppins Clinical is now an app available on tablets and smartphones (iOS [Apple Inc] and Android), where children are led to carry out different activities divided into two categories: language activities and musical activities. Depending on the child's performance, the difficulty of the proposed activities is adapted. Poppins Clinical contains several short activities, allowing for a variety of activities within a single session. Each activity lasts an average of 1.40 minutes, ensuring that it does not demand too much sustained attention from the child [33,34]. This structure of short activities ensures a fluid,

coherent, and continuous experience for the user. To offer an experience suitable for as many children as possible (aged 7-11 years, both gamers and nongamers, with a wide range of tastes), the visual and narrative aesthetics of Poppins Clinical align with mainstream video game standards such as Rayman (Ubisoft) and Mario games (Nintendo), which are designed for all audiences.

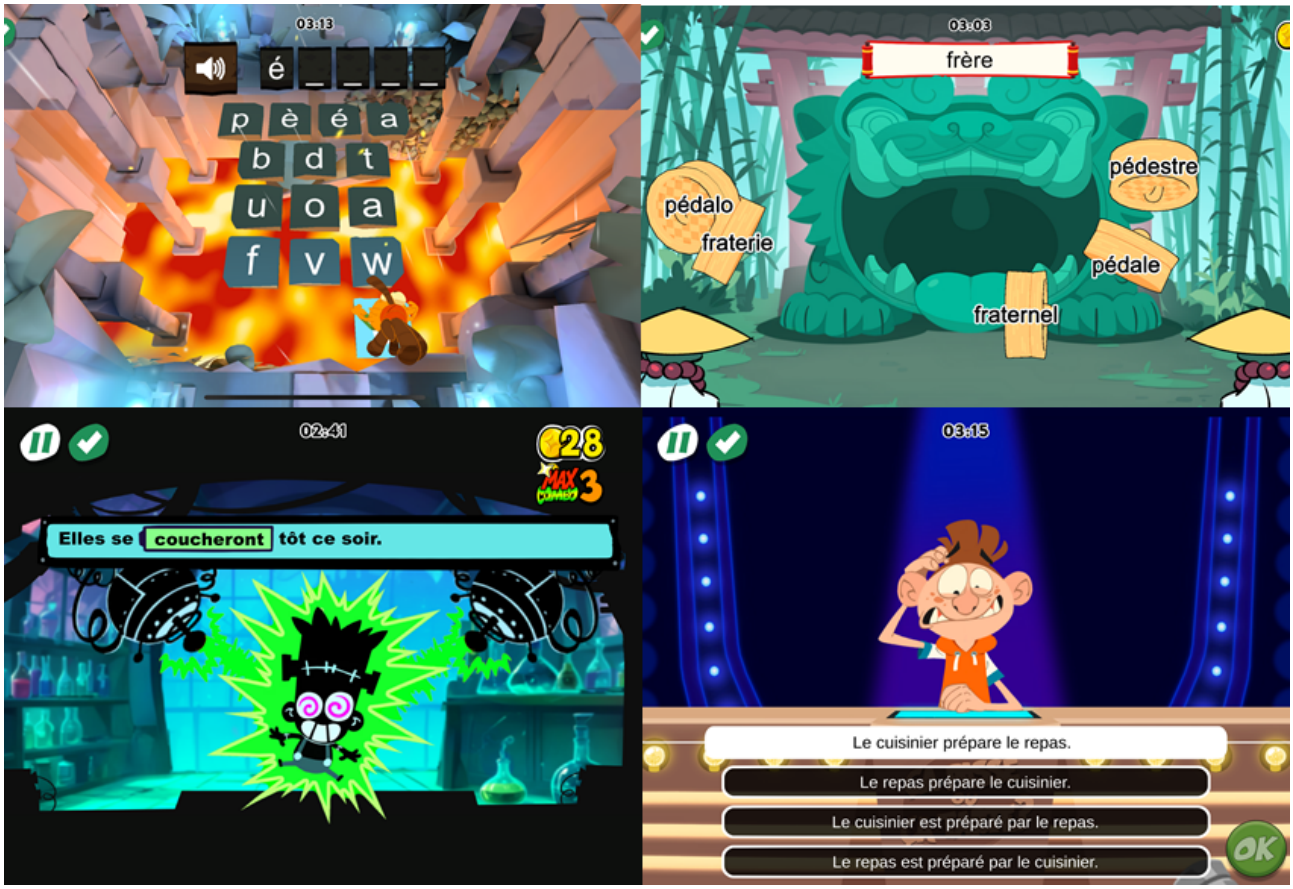
Musical Activities

The musical activities consist of rhythmic tasks described in a previous paper [25]. In summary, all these tasks were designed to work on rhythm, as rhythm appears to be directly related to reading skills, whereas melody is not [35]. However, children with SLD showed deficits in rhythm processing [8,9]. Each task also requires the mobilization of other skills such as attention, inhibition, working memory, and motor skills, which are often impaired in children with dyslexia [36].

Written Language Section

The written language section combines exercises to enhance phonological awareness, reading speed, and writing accuracy (Figure 2). All exercises are proposed to associate phoneme and grapheme as recommended by the College Français d'Orthophonie [14]. Words presented in the game were chosen from the Manulex database, considering their frequency, length, and orthographic difficulty. Syntactic difficulties and vocabulary frequencies were also considered in the selection of sentences and texts presented in the game.

Figure 2. Screenshots of written language tasks from Poppins Clinical.



Four types of exercises have been developed to work on different skills used to access written language:

1. Underlying processes: In Poppins Clinical, various activities are based on the ability to identify the sounds contained in a word (phoneme or syllable), thus calling on phonological and meta-phonological skills. These include activities to classify words according to the sounds that make them up. However, the activities (language and music) are carried out in various forms and require interaction with the digital tool in several ways, calling on visual attention skills, executive functions, and praxis.
2. Graphophonology: Various activities are based on matching graphic representations with their corresponding sounds (syllables and words). The aim is to teach the player to link a graphic form to a phonological representation, in reading activities such as categorizing written words.
3. Orthographic skills: Transcription activities are based on the ability to write words by working on lexical spelling (eg, knowledge of spelling irregularities), grammatical spelling (eg, differentiation of "et" or "est"), inflectional morphology (eg, plural marks), and derivational morphology (eg, recognizing prefix-radical-suffix structures). Activities such as word completion are proposed here.
4. Semantics: Semantics activities are based on understanding written language. This involves knowing the vocabulary, understanding syntactic structures (eg, subordinate clauses) and textual structures (eg, organization of ideas in a text), and making inferences. This involves activities such as

carrying out written instructions or putting a story in chronological order.

Outcomes

The primary outcome of this study is reading accuracy, which will be measured by the number of correctly read words using the EVALEO (Ortho Edition) [37] 2-minute word reading test (EVAL2M). Noninferiority will be evaluated 12 weeks after the start of training with Poppins Clinical for the experimental group or 12 weeks after the baseline evaluation for the control group.

Safety will be assessed by monitoring adverse events reported by patients during the 12-week study duration.

Seven secondary outcomes will also be investigated. Noninferiority in reading speed, measured by the number of words read using the EVAL2M [37], will also be evaluated. In addition, noninferiority in word reading skills (speed and accuracy) and meta-phonological skills will be assessed using respectively the Alouette-R [38] text reading test and the BALE Phoneme Suppression Test [39].

The impact of Poppins Clinical on parents' stress levels and quality of life will be measured using the Parenting Stress Index-Short Form (PSI-SF) and the EQ-5D-5L [40] quality of life questionnaire. Text comprehension will also be assessed through the computerized BMT-i test battery [41], evaluating correct answers to comprehension questions, as well as reading precision and speed. A cost evaluation will be conducted by administering a questionnaire to parents to evaluate the health and economic value of Poppins Clinical. The objective is to determine in each group the direct and indirect health care costs, including, treatment costs (eg, number of appointments and costs of each session) and work-related costs (eg, the number of days off used for health purposes).

A total of 5 exploratory end points will be investigated. The effect of Poppins Clinical on visual attention span will be assessed with the EVALEO test, using correct answer scores. The patient's quality of life and reading and writing difficulties will be evaluated using the PedsQL 4.0 CORE [42] young child report and a self-assessment grid for reading and writing difficulties [43]. The perceptions of parents and speech therapists regarding the study's impact on therapy will be captured via an adapted questionnaire. Finally, predictive factors of training effectiveness with Poppins Clinical will be explored to improve the individualization of the program and the use of the device through connection data.

All the outcomes are described in Table 1.

All outcomes will be evaluated 12 weeks after the start of training for the experimental group or 12 weeks after the baseline evaluation for the control group. Participants of the experimental group will have up to 14 calendar days to start training with Poppins Clinical once the baseline evaluation is completed. The results will be entered into an electronic case report form (eCRF) hosted on the web by the CRO, which will be responsible for data monitoring and treatment.

Table 1. Measured outcomes investigated in the protocol.

Outcome	Measure
Primary outcome	Reading accuracy is measured by the number of correctly read words (EVAL2M)
Safety secondary outcome	Number of adverse events reported during the study
Secondary outcome 1	Reading speed is measured by the number of read words (EVAL2M)
Secondary outcome 2	Word reading accuracy and speed (Alouette-R)
Secondary outcome 3	Cost evaluation
Secondary outcome 4	Phoneme suppression skills (BALE)
Secondary outcome 5	Parental stress levels measured using the Parenting Stress Index Short Form
Secondary outcome 6	Parent's quality of life measured using the EQ-5D-5L
Secondary outcome 7	Reading precision, speed, and comprehension (BMT-i)
Exploratory outcome 1	Visual attention span (EVALEO)
Exploratory outcome 2	Child's quality of life (PedsQL 4.0 CORE)
Exploratory outcome 3	Child's perception of reading and writing difficulties [43]
Exploratory outcome 4	Perception of parents and speech therapists on the impact of the protocol on the child (custom questionnaire)
Exploratory outcome 5	Evaluation of predictive factors of training effectiveness

Statistical Justification of the Sample Size

The sample size determination was based on the primary end point, which is to demonstrate the noninferiority of a follow-up with reading therapy every 2 weeks, in addition to the use of the digital medical device (Poppins Clinical), compared with a follow-up with reading therapy every week, on the evolution of reading accuracy over 12 weeks. The null (H0) and alternative (H1) hypotheses for noninferiority trials may take the following form:

1. H0: experimental (EXPE) is inferior in terms of the mean response, $\mu EXPE - \mu CONT \leq -\Delta NI$.
2. H1: experimental is noninferior in terms of the mean response, $\mu EXPE - \mu CONT > -\Delta NI$.

Where μEXPE is the mean of the outcome in the experimental arm, and μCONT is the mean of the outcome in the control arm. The noninferiority limit, –ΔNI, is defined as the threshold at which the mean difference between the experimental arm and the control arm becomes clinically unacceptable.

The noninferiority margin was determined through a formal expert committee meeting, combining independent experts and investigators. The committee was structured to ensure both independence and relevant expertise. Two independent experts were selected for their complementary expertise: a neuropediatrician who pioneered diagnostic recommendations for learning disorders in France, and a speech therapist who codeveloped the standardized assessment tool used as the primary outcome in this study (EVALEO 6-15). The two investigators of the study, both professors in child psychiatry with extensive research experience in neurodevelopmental disorders, provided their methodological expertise. A fifth expert, a neuropsychologist with experience in written language rehabilitation guidelines and as a reviewer of good practice recommendations, was included as a scientific advisor. All experts were active clinicians and researchers in learning disabilities.

The committee's decision was informed by empirical data from the previous randomized controlled trial (ML-01), showing a natural progression of 7.7 (SD 12.9) correctly read words over 8 weeks in the placebo group [26]. Based on these data and their collective clinical experience, they established that a difference of 5 words or fewer between groups would represent a clinically acceptable margin of noninferiority. This threshold was unanimously approved by the full committee after a structured discussion of potential age-related variations in reading progression.

The SD of the outcome in each group was estimated at 12.7 words from the ML-01 study [26]. The maximum acceptable inferiority for experimental versus control on the primary outcome is therefore expected to be a standardized difference (Cohen d=0.39), which corresponds to a label between small or medium, depending on the guidelines (R effect size package) [44].

Considering a one-sided significance level of 2.5% and a power of 90%, it is necessary to include 137 participants per group (G*Power 3.1). Assuming a 10% drop-out rate, the final estimate is 306 participants in total (or 153 participants per arm).

Statistical Methods

This trial uses a noninferiority and possibly superiority hypothesis testing framework between groups for primary, secondary, and exploratory outcomes. We will report the results in accordance with the noninferiority trials extension of the CONSORT (Consolidated Standards of Reporting Trials) 2010 statement. Tests for noninferiority will be one-sided and performed using a 2.5% significance level. All other tests will be two-sided, performed using a 5% significance level. The type I error rate will be controlled using a hierarchical testing procedure for secondary end points. A subsequent end point will only be tested if the previous end point's test for noninferiority is statistically significant.

Criteria Analysis

According to CONSORT 2010, interpreting a noninferiority trial's results depends on where the CI for the treatment effect lies relative to the margin of noninferiority –ΔNI and the null effect. The lower bound of the one-sided (1–α)×100% CI for the treatment effect must be above the margin –ΔNI to declare that noninferiority has been shown [45].

Once noninferiority is evident, it is acceptable to assess whether the new follow-up appears superior to the reference follow-up, using an appropriate test or CI, with a significance level defined a priori and with an intention-to-treat (ITT) and a per-protocol (PP) analysis. All randomized patients will be included in the ITT analysis, including children assessed at T1 or T2, after the time allowed by the protocol. The PP population will include only participants without major deviations. These patients must have completed at least 50% of the prescribed training time and at least 50% of the reading therapy sessions outlined in the protocol.

In this context, if the noninferiority is shown (based on both ITT and PP analyses), superiority will then be tested for the same primary end point, as described in the European Medicines Agency (EMA) guidelines [46]. Superiority will be tested using a t test at a 2-sided 5% significance level.

The type I error rate will be controlled using a hierarchical testing procedure for secondary end points. A subsequent end point will only be tested if the previous end point's noninferiority test is statistically significant.

Safety Criterion Analysis

The safety population includes all participants who will use the DM Poppins device at least once. This safety population will be used for the safety analysis. Adverse events will be reported by the participant's parents to the CRO's Safety Department or the patient coordinator and will be recorded in the eCRF form. The form will contain all necessary variables to define the date, severity, and relationship to the study device, as evaluated by the investigator (see Textbox 1).

Textbox 1. Summary of descriptive statistics of adverse events and device deficiencies.

For adverse events:

- Type of adverse event
- Severity
- Evolution
- Relationship with the device
- Number of episodes
- Time of onset of the adverse event (defined as the time from first use to the earliest date of the adverse event)
- Number of participants with at least one episode (and percentage)
- Discontinuations will also be summarized.

For device deficiency:

- Type of device deficiency
- Duration of the deficiency

Ethical Considerations

The study protocol was approved by the local ethics committee (Comité de protection des personnes for Sud-Est-1; number 2023-A02723-42) and national regulatory agencies (Agence nationale de sécurité du médicament et des produits de santé and Commission nationale de l'informatique et des libertés; N°IDRCB 2023-A02723-42).

Before consent, the patient and their parents will receive a patient information sheet via email. This document will provide the participant and legal guardian with a comprehensive explanation of the study, including its rationale, procedures, benefits, and risks. It will also emphasize that participation is voluntary and that the participant may withdraw from the study at any time without any negative consequences. In addition, a physician will discuss this information with the participant and legal guardian, allowing them sufficient time and opportunity to ask questions and make a decision about whether to participate in the study.

It will be clearly stated that the participant is free to withdraw from the study at any time and for any reason, without affecting their future care, legal rights, and the obligation to give a reason for withdrawal.

Written informed consent must be obtained from the legal guardian in accordance with local practices and regulations before any study assessments or tests are conducted. Written consent will be obtained by signing and dating the approved consent forms. No study assessments or procedures will be conducted until written informed consent has been provided. A description of the consent process must be documented in the participant's medical record.

The parents will provide their signature at the end of the consent form, and a delegated site team member will countersign it. Consent will be obtained either via an electronic signature or a wet ink signature. A copy of the fully executed informed consent form will be provided to both the participant and their parents (either in paper form or sent electronically via email), and a copy will be securely retained by the site in a restricted-access area.

Identifiable participant details (such as name and date of birth) will be held in a separate database from the research database after receiving the participant's consent. The research database will never hold personally identifiable information. Automatic reminders will be sent to participants by doing a one-time recall of identifiable information, matched with the unique study ID.

Given the patient's condition (specific learning disability with reading deficit) and their age thus potentially being unable to provide written consent, the child will provide verbal assent to participate in the trial. The investigator will read the content of the consent form during the information visit, clearly stating that the child is free to decline their participation at any moment. The consent form is adapted to an appropriate language to facilitate the children's understanding. An audio track of the consent form content will also be sent to the parents via email, in case the child would like to listen to it again. Once the child verbally agrees to participate in the trial, the investigator will sign the consent form (either electronically or wet ink) on their behalf and register it in the eCRF.

An information letter for the speech and reading therapist in charge of the participants will also be sent by email to the participant's parents. Parents will be asked to forward it to the speech and reading therapist to inform them of the study and that compensation is provided for them if the participant participates.

The compensation for the speech and reading therapist aims to cover their involvement in the study (they will receive by email the attribution group of their patient and might be asked to rearrange their session schedule to comply with the study protocol) and to compensate for missed sessions (for speech and reading therapist who follow up with patients in the experimental group). Compensation is disclosed to the speech and reading therapists only after the participant signs the informed consent and is detailed in an email that is directly sent to the speech and reading therapists. For further information, the speech and reading therapist can ask for an appointment

with the dedicated support team (assured by an independent third party), if desired. Speech and reading therapists will be asked to agree to the collection of their personal data (name and email address) to receive information about the study via email and to complete a questionnaire at the end of the trial.

Results

We expect to enroll 306 patients within 6 months from the start of the inclusion phase. Considering that children's participation lasts 3 months, we expect to have the results of this study by the end of August 2025.

Discussion

Principal Findings

The objective of this study is to assess the noninferiority of the serious game Poppins Clinical combined with one reading therapy session every 2 weeks, compared with a reading therapy session every week. To achieve this, we will use a noninferiority trial to measure the acceptance of the new intervention with Poppins Clinical. Our primary outcome will be the number of correctly read words with the EVAL2M test, which is a standard and recent test used in reading therapy. We expect that the experimental group's outcomes will remain within the established noninferiority margin relative to the control group for reading tasks (speed, accuracy, and comprehension), visual span, phonology, and measures of quality of life and parental stress. In addition, we anticipate that the children will be able to adhere to the training program over 3 months when combined with speech therapy sessions, during which the speech therapist can monitor the child's progress. Finally, we expect parents and speech therapists to easily integrate Poppins Clinical–based training into their daily routines. Therefore, Poppins Clinical would demonstrate good integration into the child's care pathway, positively impacting the medico-economic aspects of the treatment, such as improving access to care or simplifying travel for families.

The noninferiority margin represents the maximum clinically acceptable difference between the new treatment and the active control that still allows concluding noninferiority. This margin should be based on a clinical basis, but methods for defining the noninferiority margin can vary widely [47]. The methods used to define the noninferiority margin are frequently not detailed in noninferiority trials, although the choice of the noninferiority margin may strongly impact the conclusion regarding noninferiority trials [47]. Currently, there is no consensus about the best method for defining the noninferiority margin. Previous trials and historical data should be considered if available, however, such data do not always exist. To our knowledge, there is no previous trial or historical evidence regarding the margin that could be clinically relevant in SLD therapy. In that case, the choice of the margin is often based on experts' opinions [29,47]. The clinically significant margin was determined through consultation with an independent expert committee. A threshold of –5 correctly read words was established as the noninferiority margin based on clinical data and expertise. This decision was based on data from a previous double-blind randomized controlled trial showing a natural progression of 7.7 (SD 12.7) correctly read words over 8 weeks [26] and was unanimously approved by a committee of experts combining clinical experience in learning disabilities with methodological expertise.

The choice of population and how to handle missing data may also affect trial results. ITT analyses may favor noninferiority results, while protocol violations may dilute potential differences between the treatment arms, favoring noninferiority results. Therefore, it is preferable to analyze noninferiority trials using both the ITT and PP approach [48]. We will conduct statistical analysis using both the ITT and PP populations. The PP population includes only participants who have completed at least 50% of the training time prescribed by the protocol. To ensure consistency in reading therapy care within the PP population, each participant must complete at least 50% of the reading therapy sessions outlined in the protocol.

We will also conduct noninferiority analysis for reading skills with texts with and those without meaning. The use of several reading tests will allow us to explore different aspects of reading such as accuracy, speed, and comprehension. The use of two texts, with and without meaning, should help us address the possible compensation that patients might use during reading by relying on the context of the text to increase their performance [49]. To avoid an effect between the test and retest for the evaluation of reading understanding, we will use two different texts between the pretest and posttest. Both texts come from the EVALEO 6-15 [37] and are equivalent in terms of syntactic complexity, word frequencies, and length.

However, we will look at the medical costs in both groups during the study. Effectively, the benefit of a new treatment may also be considered in terms of time consumption (eg, transportation and appointments), costs for the family and the patient, as well as costs for society, as speech and reading therapy are reimbursed by the social health insurance in France [28,29]. Gentili et al [50] conducted a literature review on the impact of medical costs of the use of digital health interventions. It appears that more and more evidence suggests a generally favorable effect of digital interventions in terms of costs and health outcomes. The findings show a positive impact, especially for studies that implemented a new mobile app or a web portal intervention, as is the case for Poppins Clinical. Benefits seem to be particularly important in rural areas [50].

Finally, we will perform questionnaires to assess the quality of life and perceived reading difficulties of the patient. Effectively, it is important to evaluate if the impact of an intervention is perceived by the patient and should have an impact on their daily life [51]. However, we will take into account parents' and speech therapists' perceptions of the impact of the protocol on reading therapy in terms of motivation, satisfaction, and time dedicated to work at home and in-person therapy. We seek to evaluate if the introduction of home training with the serious game Poppins Clinical may negatively or positively affect family time and reading therapy. We will track the stress of parents, as the introduction of home training could be time-consuming and raise behavioral problems (such as rejection to use the device). However, most web- and game-based interventions used with patients with SLD are well accepted by patients and

their parents [52,53]. Home training may benefit the link between the child and the parents, supporting their interaction and giving them a structured environment to help the child make new learning [54].

Some limitations can be identified in our study. First, the participants are not blinded to their group allocation. This was not feasible, as the protocol affects the frequency of reading therapy sessions, and it would have been unethical to reduce the number of reading therapy sessions to replace them with a placebo. In addition, we will conduct multiple analyses, which could increase the risk of a Type I error. To control for this, we will use a hierarchical testing procedure for secondary end points. A subsequent end point will be tested only if the previous end point's noninferiority test is statistically significant. Finally, we cannot control what reading therapists do during therapy sessions. However, we will monitor the training of the reading therapists by recording their year of certification and any recent training they have completed.

Conclusion

We plan to conduct a single-blind randomized controlled trial to compare the effect of the serious game Poppins Clinical, combined with a reading therapy session every 2 weeks, to reading therapy alone every week on reading skills in children with SLD. To compare the clinical impact of both interventions, we will use a noninferiority design. We will also explore phonological and visual-attentional skills and the impact of the intervention on children, parents, speech and reading therapists, and patient care organizations. The trial results will be submitted to a research journal and summarized for the study participants.

Acknowledgments

We would like to thank Monique Touzin, Catherine Billard, Prof Fabrice Denis, Catherine Grosmaitre, and Michel Habib for their contributions throughout the various stages of this project. We also thank the investigative centers and physicians who facilitated this work, including Joana Matos, Alice Oppetit Clément Villiers, Cécile Pernossi, Claire Lechevalier, Manon Ranvier, and Anne Delepine. This work was supported by the Plan France 2030 (France's national investment strategy program).

Data Availability

The datasets generated or analyzed during this study are available upon reasonable request from the corresponding author.

Abstract

Background: Individuals who are socioeconomically disadvantaged have high smoking rates and face barriers to participating in smoking cessation interventions. Computer-tailored health communication, which is focused on finding the most relevant messages for an individual, has been shown to promote behavior change. We developed a machine learning approach (the Adapt2Quit recommender system), and our pilot work demonstrated the potential to increase message relevance and smoking cessation effectiveness among individuals who are socioeconomically disadvantaged.

Objective: This study protocol describes our randomized controlled trial to test whether the Adapt2Quit recommender system will increase smoking cessation among individuals from socioeconomically disadvantaged backgrounds who smoke.

Methods: Individuals from socioeconomically disadvantaged backgrounds who smoke were identified based on insurance tied to low income or from clinical settings (eg, community health centers) that provide care for low-income patients. They received text messages from the Adapt2Quit recommender system for 6 months. Participants received daily text messages for the first 30 days and every 14 days until the end of the study. Intervention participants also received biweekly texting facilitation messages, that is, text messages asking participants to respond (yes or no) if they were interested in being referred to the quitline. Interested participants were then actively referred to the quitline by study staff. Intervention participants also received biweekly text messages assessing their current smoking status. Control participants did not receive the recommender messages but received the biweekly texting facilitation and smoking status assessment messages. Our primary outcome is the 7-day point-prevalence smoking cessation at 6 months, verified by carbon monoxide testing. We will use an inverse probability weighting approach to test our primary outcome. This involves using a logistic regression model to predict nonmissingness, calculating the inverse probability of nonmissingness, and using it as a weight in a logistic regression model to compare cessation rates between the two groups.

Results: The Adapt2Quit study was funded in April 2020 and is still ongoing. We have completed the recruitment of individuals (N=757 participants). The 6-month follow-up of all participants was completed in November 2024. The sample consists of 64% (486/757) female participants, 35% (265/757) Black or African American individuals, 51.1% (387/757) White individuals, and

16% (121/757) Hispanic or Latino individuals. In total, 52.6% (398/757) of participants reported having a high school education or being a high school graduate; 70% (529/757) smoked their first cigarette within 30 minutes of waking, and half (379/757, 50%) had stopped smoking for at least one day in the past year. Moreover, 16.6% (126/757) had called the quitline before study participation.

Conclusions: We have recruited a diverse sample of individuals who are socioeconomically disadvantaged and designed a rigorous protocol to evaluate the Adapt2Quit recommender system. Future papers will present our main analysis of the trial.

Introduction

Background

Cigarette smoking is a serious public health problem and the leading cause of preventable disease, disability, and death in the United States [1]. While overall smoking rates have decreased, smoking rates among individuals who are socioeconomically disadvantaged remain high [2-5]. Individuals who are socioeconomically disadvantaged are affected disproportionately from smoking-related diseases [2-5]. Individuals who are socioeconomically disadvantaged may be less likely to try to quit smoking (eg, due to lower self-efficacy and maladaptive beliefs) and are less likely to use evidence-based strategies (such as quitlines).

Computer-Tailored Health Communication via Texting: A Potential Approach

One strategy to engage these individuals is by using computer-tailored messages delivered via texting. Computer-tailored health communication involves the use of computer programs to select the best personalized message for an individual. This form of communication has been effective in enhancing motivation to quit and supporting cessation [6-12]. In a systematic review, computer-tailored messages showed higher cessation rates than nontailored messages (relative risk 1.17, 95% CI 0.97-1.41). Computer-tailored messages work because participants are more likely to engage and carefully process personally relevant messages [13]. Thus, methods to increase the relevance of the message may increase the effectiveness of the smoking cessation intervention. Computer-tailored messages delivered via texting over phones may be particularly attractive for individuals who are socioeconomically disadvantaged. Mobile phone ownership is now nearly universal (95%) [14], and these rates are consistent across socioeconomically disadvantaged groups (less than high school education, 92% and those earning <US $30,000, 92%). The texting app is the most commonly used app on mobile phones [14].

The Adapt2Quit Intervention: Leveraging Machine Learning for Tailored Cessation Support

In our National Institutes of Health–funded trial, we are testing Adapt2Quit, which uses machine learning algorithms (ie, recommender systems) to computer-tailor messages for an individual and deliver them via texting [15]. Recommender systems can be programmed to continuously learn from user feedback and improve personal relevance and customer engagement [15]. Adapt2Quit also includes proactive texting facilitation to the state quitline in which participants are asked if they want to be referred to the quitline, and those who agree are referred to the quitline. Quitlines are programs in the United States that offer evidence-based support (eg, counseling and medications) to individuals who smoke. These individuals can either directly contact quitlines using the number 1-800-QUIT-NOW or be referred by a health care provider or tobacco cessation programs. Although quitlines have been established in all 50 US states, they are vastly underused. The use of texting to promote quitline use could potentially increase quitline use, and thereby increase the effectiveness of the smoking cessation intervention for the participants.

Preliminary Evidence Supporting Adapt2Quit

In our preliminary studies, Adapt2Quit increased engagement and 30-day point-prevalence effectiveness over a standard messaging that randomly selected these messages [16]. In a subanalysis among those who reported lower education (n=49), the average rating of the messages was higher on more days than the average ratings of true comparison messages (77% vs 23%; $P<.01$). This pilot study showed the potential of the Adapt2Quit trial among individuals who are socioeconomically disadvantaged. Since the beginning of the trial, we have completed another randomized controlled trial that tested the machine learning algorithm compared to standard messaging among those who were recruited via social media [17]. In the other trial, there was no significant difference in 6-month point-prevalence smoking cessation (adjusted odds ratio 0.81, 95% CI 0.61-1.08) between the recommender system (146/412, 35.4% of participants with outcome data) and messages tailored by standard messaging based on participants' baseline readiness to quit groups (156/389, 40.1% of participants with outcome data). However, the other trial differs from the current trial being reported in that the messages were delivered via email, it did not target individuals who are socioeconomically disadvantaged, and the system did not facilitate referral to the quitline. Furthermore, another group has evaluated a similar recommender system approach for message selection in a pilot trial for self-reported smoking cessation [18]. However, additional studies testing recommender systems are needed to uncover the potential of these systems for increasing the

effectiveness of computer-tailored smoking cessation interventions.

Theoretical Basis for the Adapt2Quit Intervention

The Adapt2Quit intervention is based on the self-determination theory (SDT). SDT-based interventions support autonomous decisions and are designed to increase intrinsic motivation and self-regulation and they have been shown to improve motivation and cessation outcomes among those who smoke [19-24]. Three innate psychological needs are theorized to promote self-motivation: autonomy, relatedness, and competence [19]. Autonomy reflects the need to engage in behaviors with a sense of choice or personal endorsement [25]. Autonomy support can be provided by acknowledging an individual's unique perspective and offering choice [25,26]. Relatedness reflects the degree to which an individual feels connected to and understood by others. Competence is a feeling of being capable and is akin to self-efficacy, the belief that one can bring about desired outcomes. By supporting autonomy, relatedness, and competence, health behaviors are more likely to be internalized and maintained. Specific examples of how Adapt2Quit supports the SDT are provided in Textboxes 1 [27] and 2. Our aims and hypotheses align with our proposed model, which suggests that relevant personal messages from the Adapt2Quit system will enhance system engagement. This increased engagement is expected to improve internal processes (ie, the SDT constructs measured using the Perceived Competence Scale [PCS]), leading participants to adopt cessation-supporting behaviors (external processes such as quitline and nicotine replacement therapy [NRT] use), ultimately resulting in smoking cessation.

Textbox 1. Examples of mapping the self-determination theory to Adapt2Quit.

- Autonomy: participants can control how often they want to rate the messages with the system. Autonomy increases as the participant's ratings influence the messages they receive, providing an enhanced feeling of control over the intervention. Furthermore, Adapt2Quit facilitates quitline access but does not impose it. Participants are asked if they want to contact the quitline. Only if the participant responds positively, our system will initiate a quitline referral. Autonomy is increased as the participant controls if and when they choose to interact with the quitline. Our messages will focus on persuading the smoker to use quitline.
- Relatedness: in addition to the smoker profile, Adapt2Quit's recommendations are based on feedback from thousands of smokers who previously engaged with the recommender system. Relatedness increases as the system learns and adapts to the ratings feedback of each new smoker. The Adapt2Quit messages database includes peer-written messages [27]. Messages from peers may enhance relatedness because they reflect shared experiences, allowing smokers to more easily identify with the message content [27].
- Competence: Adapt2Quit messages are designed to improve motivation, educate, and increase a smoker's confidence and skills related to smoking cessation. Content includes appropriate strategies and treatments, as cues and reminders to encourage use, which were developed based on current guidelines on smoking cessation. Our pilot showed that Adapt2Quit increased the adoption of cessation-supportive behavior.

Textbox 2. Specific aims.

Aim 1: Adapt2Quit engagement—heterogeneity of Adapt2Quit recommender system engagement

- Hypothesis 1a: among Adapt2Quit participants, those with higher engagement levels (ie, completed more ratings) will have greater scores on the Perceived Competence Scale (PCS).

Aim 2: behavioral processes—internal processes (self-determination theory constructs) and external "processes" or cessation-supportive actions comparing Adapt2Quit and the comparison group (texting facilitation to quitline)

- Hypothesis 2a: Adapt2Quit participants will have greater scores on the PCS than comparison participants.
- Hypothesis 2b: Adapt2Quit participants will adopt more cessation-supporting actions (quitline use and nicotine replacement therapy) than comparison smokers.

Aim 3: effectiveness—6-month smoking cessation in Adapt2Quit versus the comparison group

- Hypothesis 3a: (primary outcome) Adapt2Quit participants will have greater smoking cessation rates (6-month point-prevalence biochemically verified) than comparison participants.
- Hypothesis 3b: (mediation analysis) measured internal and external processes will mediate the effect of Adapt2Quit on smoking cessation.

Paper Objective

This paper describes the protocol and status of our ongoing randomized controlled trial testing the Adapt2Quit intervention among individuals from socioeconomically disadvantaged backgrounds who smoke. Our comparison participants receive the biweekly texting facilitation messages but do not receive the motivational messages recommended by the Adapt2Quit intervention. Our protocol description includes the intervention and comparison system as well as the description of the analyses of the primary and secondary hypotheses listed in the following sections. Since recruitment for our study has finished, we describe the demographics of the participants we have recruited. Our follow-up data collection is in progress.

Methods

Study Design and Setting

This study is a 2-arm randomized controlled trial comparing participants who received smoking cessation text messages selected by the Adapt2Quit recommender system plus a texting

facilitation approach to connect participants to the quitline with participants who received the texting facilitation but no smoking cessation text messages. Study participants were blinded to group assignments. They were recruited from health systems in diverse geographic areas. Recruitment started in April 2020 and was completed in March 2024. Our target sample size was 750 individuals from socioeconomically disadvantaged backgrounds who smoke.

Ethical Considerations

The Adapt2Quit study has been approved by all participating institutions' institutional review boards (IRBs), including Baystate (BH-20-123) and Johns Hopkins (IRB00280942), with the University of Massachusetts Chan Medical School (UMass Chan) IRB (H00018991) being the central IRB. The study is listed in ClinicalTrials.gov (NCT04720625). It is being carried out in accordance with the Helsinki Declaration, and all participants have signed an informed consent form before enrollment in the study. Participants have been informed that they have the right to withdraw their consent at any point during the study, and the reason for their withdrawal will also be documented if the participant so wishes. The participants have received compensation for completing study activities. They received US $25 for completion of baseline, US $25 for the 6-month follow-up, US $50 for completing the carbon monoxide (CO) verification assessment, and an additional US $50 for participation in the qualitative interview. Upon randomization, all patients have been assigned an individual ID number so their data remain anonymous.

Inclusion and Exclusion Criteria

The inclusion criteria were as follows: an individual who smokes, comes from a socioeconomically disadvantaged background, speaks English, who is active in care (having at least 2 clinical visits in the past 2 years), and who has a texting-enabled mobile l phone. We used insurance status to identify participants as socioeconomically disadvantaged [28]. In the United States, people can receive health insurance or health care payment coverage from several sources including through their employer, other private health insurance companies, or through government-supported programs. Individuals who have these government-supported programs are more likely to be from socioeconomically disadvantaged groups. For our study, we used Medicare (a government-funded program for older adults and those with disabilities) and Medicaid (a state and federal program for low-income individuals) to identify individuals from socioeconomically disadvantaged backgrounds. We determined smoking status by asking participants if they had smoked at least 100 cigarettes and their current smoking frequency (Multimedia Appendix 1). Those who responded "yes" to 100 cigarettes and "some" or "every day" were included.

The exclusion criteria were as follows: adults who were unable to consent, individuals who were not yet adults (ie, aged <18 years), prisoners, people with Alzheimer disease, and pilot study participants.

Recruitment

Recruitment was spread over the 3.5 years of the study. Study participants were recruited at urban and rural health care settings across 3 health care systems in the United States (UMass Memorial Medical Center, Baystate Health, and Johns Hopkins University). We used an opt-out recruitment strategy, with some variations between the three sites. At all 3 sites, after obtaining a Health Insurance Portability and Accountability Act waiver, potential participants who met our inclusion criteria in the clinical data warehouse were identified. At the UMass Chan and Baystate Medical Center, an initial invitation letter with a self-addressed, stamped opt-out postcard was sent to those eligible from the local site principal investigator outlining the study's purpose. Johns Hopkins University's site used emailed study invitation letters with instructions to opt-out via email instead of or in addition to mailed letters and "opt-out" postcards for those without an email address. Instructions were provided on how to opt-out by email. At all sites, individuals who opted out or whose email was returned undelivered within 2 weeks were removed from the recruitment list.

Screening, Informed Consent, and Baseline Data Collection

Potential participants were phoned up to 4 times to determine their interest and were screened for eligibility. Before starting the first recruitment call, the research staff sent an automated introductory text message to potential participants who would be called that day. During the phone call, participant eligibility was assessed (Multimedia Appendix 1). Eligible participants were asked to provide informed consent for study participation, were asked to complete the baseline data, and were then randomized to treatment. The screening session, informed consent, and baseline data collection were conducted via Zoom (Zoom Communications, Inc) or by phone.

Once randomized, after completion of the baseline survey (Multimedia Appendix 1), the Adapt2Quit intervention participants received 5 initial motivation messages and were asked to provide a rating. The recruitment staff viewed the rating in real time to confirm whether the participant understood and was comfortable with the system. The staff emphasized the importance of rating their messages to intervention participants. The research staff explained the quitline facilitation process and smoking status texting assessment to both groups and reiterated the importance of completing the ratings to intervention participants. Those randomized to the control group received only the texting facilitation and smoking status but did not receive the motivational messages, and instructions were provided accordingly.

Randomization

Separate randomization tables were created for each site to enhance the balance between the two groups. Participant allocation to study arms was based on a permuted block scheme in which treatment assignments were made within blocks so that numbers assigned to each treatment arm are equal after a block has been filled. Blocks of various sizes (2, 4, and 6) were used in random order to facilitate allocation concealment. As in our prior technology-based trials, we embedded

randomization within the technology [29,30]. After completing the screening, informed consent, and baseline data collection, the research staff entered the participant ID and participant mobile phone number from the survey into a web-based system, which then assigned the allocation based on the randomization table. Using this technique, participants and staff were blinded to allocation during the initial session. The research staff were subsequently unblinded to provide personalized training for the intervention and control groups, as noted.

Intervention and Comparison

Intervention: The Adapt2Quit Recommender System

The Adapt2Quit recommender system uses a machine learning algorithm to select the best message for a participant from a motivational messaging database. We programmed Adapt2Quit to select messages based on the following: (1) the smoking status of the participant and (2) the ratings database (both from prior study participants and current participants) [16,31-33]. We discuss the recommender system components in subsequent sections. The system has multiple components.

Component 1: The Motivational Messages Database

The messages include 261 messages, including 206 expert- and 55 peer-written messages (Multimedia Appendix 2) [27]. We developed the expert-written messages through an iterative group review process guided by theoretical frameworks and existing smoking cessation guidelines [34]. Peer-written messages were written by current and former people who smoke, responding to a web-based survey. Our methods for developing this messaging database and its characteristics have been published [27]. Briefly, the expert messages written by smoking cessation providers and researchers were more "biomedical" (ie, avoidance, behavioral strategies, and health), while peer messages had more "social" and "real-life" content (ie, expectations, money, quality of life, attitudes, and friends) [27]. Our messages were assessed to be readable for someone with at least a fifth grade–level education (Flesch-Kincaid Grade level 5.5). In total, 19.9% (52/261) of the messages were peer messages. Overall, 52.9% (138/261) of the messages provided information about behavioral treatments (eg, substitution and distraction); 39.8% (104/261) contained motivational content, such as reasons to quit; 26.8% (70/261) included health-related information, such as the risks of smoking to physical and cognitive functioning; and 19.9% (52/261) addressed how seeking social support or smoking impacted social interactions with family and friends. Multimedia Appendix 2 lists example messages.

Component 2: Ratings Database

The algorithm uses 2 types of ratings data to generate the following recommendations.

First, ratings from prior study participants. More than 1000 participants have rated our messages using the influence rating question (see definition in the Data Elements, Statistical Analysis, and Power Calculation for Specific Aims section) resulting in 18,920 ratings [16,32,33]. We chose the influence rating question after a pilot test in which we asked participants to rate each message on 4 aspects: influence, emotional response, relevance, and preference [33]. We found that all these aspects were highly correlated. In developing the algorithms for the recommender system, we compared ratings by different user profile characteristics. Of the 20 messages rated most highly by participants with less than a high school education, only 3 messages were rated in the top 20 by college graduate participants. Adapt2Quit considers all these variations for message selection.

Second, current ratings from participants in the intervention group using 2-way texting. Adapt2Quit is also programmed to learn from the explicit ratings of participants receiving the messages. Thus, when a participant is sent a text message, it will be accompanied by a question (see definition in the Data Elements, Statistical Analysis, and Power Calculation for Specific Aims section) asking the participant to rate the text message using the influence ratings question. The participant can choose how frequently they wish to rate the text messages. In addition to improving the system, our participants in the pilot studies noted that rating the messages helped them to cognitively process the messages better and remember their content.

Component 3: Machine Learning Algorithm

In our prior publications, we have described our algorithm development in detail [16,32,33]. For the purpose of this paper, we describe our approach and the functioning of the system in brief. We used a strong generalization protocol that involved completely separating test users from train users, learning a model using all the train users' ratings, freezing all non–user-specific parameters, and finally training the user-specific parameters on a subset of each test user's observed ratings. We evaluated several recommender methods for accurate prediction, including K-nearest neighbors, probabilistic matrix factorization, collective matrix factorization, and the Bayesian probabilistic matrix factorization (BPMF) [33]. In evaluating rating prediction methods, we used a range of standard performance metrics including root mean squared error, Kendall tau-b, and normalized discounted cumulative gain. In all these tests, BPMF was identified as the best single model. For example, comparing the root mean squared error metric between the different algorithms, there was a small but statistically significant gap (P=.01) between the BPMF and other algorithms as determined by a paired t test with Bonferroni correction. The BPMF model estimates a probability distribution over a joint embedding of users and items into complementary latent spaces. The rating of the given user supplies for a given item is approximated by the expected value of the product of the latent user and item factor vectors representing the user-item pair, with the expectation taken over the uncertainty in embeddings.

The intervention participant experience is as follows: during baseline registration, the intervention participant will be asked to rate 5 messages. The recommender system will use these ratings to select the first message. As the intervention unfolds, the participant will be asked to rate each message, and the system will learn and adapt to these ratings [16,32,33]. In the backend, each time the program needs to select a message for an individual, the program sends all the prior ratings provided by the participant and the messages rated by the participant.

The system also sends demographic information of the participant. The algorithm then selects the next messages based on these data from the list of messages that have not been sent to the participant. The algorithm was also programmed to choose only from among those messages that matched the participant's readiness to quit status. All participants will receive a new message every time. When they do not rate the message on a particular day, our system will have the 5 messages rated at baseline and the ratings of the prior participants to fall back upon to pick a new message. Because the machine learning algorithms operate as a black box, in our prior study, we conducted an analysis of our messages to uncover the black box of the algorithms and understand the message selection process and have published our results [35].

Flow of the Intervention

Participants in the intervention group receive motivational messages, texting quitline facilitation, and texting assessment of smoking status.

Motivational messages selected by the Adapt2Quit recommender system including ratings for user feedback. Participants receive daily motivational messages for the first 30 days and every 14 days until the end of the study. As noted, participants were asked to read these messages and provide their ratings. They were able to choose how frequently they rated messages.

For texting quitline facilitation, participants in both study arms were asked (via text message) if they were interested in being referred to the quitline every 14 days or until the participant responded "yes" to this question. We have followed current best practices in SMS text messaging to connect users to the quitline as described in the study by Krebs et al [36], who, after assessing multiple message frames, found that including a self-efficacy frame was the most effective. If participants request to be connected, a member of the study team refers them to quitline via a secure web form provided by the Massachusetts and Maryland quitline. As per their standard protocol, once quitline staff receive notice of participant interest, they proactively call the participant and engage in counseling.

For texting assessments of smoking status, participants were asked, "What is your current smoking status?" every 30 days over a 6-month period.

Comparison

To isolate the effect of the Adapt2Quit recommender system, comparison participants do not receive tailored motivational messages but receive the texting quitline facilitation and the texting assessment of smoking status with the same frequency as intervention participants.

Six-Month Data Collection Procedures

Overview

Six-month follow-up was conducted via telephone using the REDCap (Research Electronic Data Capture; Vanderbilt University) system to collect the data. Participants had the option to complete the REDCap survey on their own, with research staff sending the secure REDCap link by either email or text or mailing a paper survey to the participant. The system is designed to first collect the main outcome data and then branch into any intervention or control-specific questions. This way the staff is blinded to the participants' assignment when the primary outcome data are collected. To maximize retention, participants were asked upon enrollment to provide 2 alternate telephone numbers, their physical and email addresses, and any other contact information, as applicable. All this contact information was used in making multiple attempts to reach participants to complete their follow-up assessment, which includes sending a thank you letter and incentives for completing the 6-month visit. Participants in both groups will receive a US $25 incentive for completion of the 6-month follow-up and an additional US $50 for completing the CO verification assessment. A web-based tracking system was used to automatically alert staff about participants due for the 6-month follow-up measure to facilitate timely assessments.

Qualitative Interviews

After completion of the 6-month follow-up visit, intervention participants will be invited to complete the qualitative interview to deepen the understanding of potential mechanisms and ways to improve the next generation of the Adapt2Quit intervention (Multimedia Appendix 1). We are using a purposeful sampling approach to recruit interview participants (n=30). Purposeful sampling is a technique widely used in qualitative research for the identification and selection of information-rich cases for the most effective use of limited study resources [37]. We will select participants based on the extent of engagement with Adapt2Quit, use of the quitline, and eventual quitting success. Study coordinators will contact participants who agree to be interviewed to complete the audio-recorded qualitative interviews. The interviews will be conducted by phone and will examine a series of topics following the hypothesized path model presented in the research strategy (Adapt2Quit increases engagement, which results in external and internal processes causing the participant to implement smoking cessation–supporting behaviors; Multimedia Appendix 1). Across these topics, our goal is to understand what participants value most and to elicit recommendations for further system enhancement. Interviews are semistructured, allowing for natural conversation with opportunities to explore unanticipated issues, and will be no longer than 30 to 45 minutes in duration. All qualitative interview participants will be asked to provide verbal consent before participating in the interview and being audio recorded. For participation in the qualitative interview, participants will receive US $50.

Data Elements, Statistical Analysis, and Power Calculation for Specific Aims

Data are collected throughout the study at several time points via text-based ratings, quitline use, assessments, questionnaires, and CO readings. Our main outcomes are described subsequently.

Completion of Ratings

Each Adapt2Quit message is accompanied by the influence ratings question as follows: "Please type the number below to indicate whether you agree with this statement—How much does this message influence you to quit smoking"—on a 5-point

Likert scale (strongly disagree to strongly agree). Our program tracks the ratings completed for each participant.

Internal Processes

Perceived competence, a key SDT construct, will be measured using the previously validated PCS [23]. The 4-item scale assesses the participant's feelings of being able to stop smoking permanently ("I feel confident in my ability to not smoke," "I now feel capable of not smoking," "I am able to not smoke anymore," and "I am able to meet the challenge of not smoking"). Responses are scored on a 7-point scale from 1 (strongly disagree) to 7 (strongly agree), and individual items are averaged to create a scale mean. In prior work [23], PCS was reliable (α=.95) at the 6-month follow-up [23]. We will assess PCS at baseline and at the 6-month follow-up visit.

External Processes (Quitline and NRT)

Quitline use is assessed using data collected from the quitline. We will send a list of our users and ask quitline to provide data on these users, such as the number of contacts between the smoker and the counselor. We will use the time to first call completed with the quitline counselor as our primary quitline measure. NRT is self-reported (yes or no).

Six-Month Cessation

Assessment of the 6-month smoking cessation is collected using the 7-day point-prevalence question [38]: "Do you currently smoke cigarettes (smoked even 1 puff in the last 7 days)?" Point prevalence can capture an intervention's delayed effects. A psychometric analysis comparing continuous, prolonged, and point-prevalence outcomes found that point prevalence had the highest concurrent validity [38]. The 7-day window provides an appropriately stringent measure to account for a cross-sectional snapshot. Using the CoVita Smokerlyzer breath CO monitor, participants who self-report quitting at the 6-month follow-up will be asked to complete biochemical verification remotely (the device will be mailed to them) or in person. Because of the variability of the device, participants will be asked to repeat the test 3 times. The average of these values will be used for our analyses [39]. Participants will be classified as tobacco users if their CO measurement is >6 ppm [40]. Participants completing remotely will be asked to conduct the test over videoconference, where our staff will monitor and guide them. To complete the biochemical verification, whether in person or remotely, study participants will receive a US $50 gift card.

Data Analysis

Statistical Analysis and Power Calculations

To preserve randomization, all primary analyses will be on an intent-to-treat basis. Secondary analyses will explore dose-response effects among those with variable levels of adherence to the intervention. All analyses will be 2-sided, and the α error level will be set at .05. We will begin by examining univariate statistics (means, medians, SDs, frequencies, percentages, and 95% CIs) and distributions of the variable of interest. We will examine the balance of participant characteristics by study groups and account for any imbalances in our multivariable analysis. To address sex as a biological variable, we will stratify the analyses by male and female to evaluate whether the mechanisms and outcomes are modified by sex. We will test group differences either using chi-square tests of independence (categorical variables), *Z* test, or a 2-tailed *t* test (continuous variables), or the equivalent nonparametric tests depending on the distribution of the variables. Baseline differences between the intervention and control group will be established based on standardized differences, rather than on tests of statistical significance.

Aim 1: Adapt2Quit Engagement

Aim 1 is analyzed within the intervention group (N=375). Engagement will be defined as the number of daily ratings divided by the total number of rating opportunities (percentage of ratings completed).

Hypothesis 1a

Among Adapt2Quit participants, those with higher engagement levels (completed more ratings) will have greater scores on the PCS. For hypothesis 1a, we will explore the distribution of the PCS at baseline and the averaged PCS scores during follow-up. Furthermore, we will analyze the distribution of engagement. It is likely that these distributions will be nonnormally distributed. In this case, we will transform the distribution into something approximating normality or choose a nonparametric test to assess the correlation between engagement and the PCS. We will generate a generalized linear model with the averaged follow-up PCS score as the dependent variable and engagement as the independent variable, adjusting for demographic characteristics that vary between highly engaged and less-engaged individuals and for baseline PCS measurements.

Power for Hypothesis 1a

We have considerable *power* to detect relatively small correlations for secondary analyses. As a preliminary power estimate, if we assume a normal distribution and α=.05, we have 80% power to detect a correlation coefficient as small as 0.2 with 200 patients. For larger, more meaningful correlations, we have well over 90% power starting at a sample of 375.

Aim 2: Behavioral Processes

Hypothesis 2a

Adapt2Quit participants will have higher scores on the PCS than control participants. To analyze hypothesis 2a, we will first create a generalized linear model where the dependent variable is the averaged PCS score during follow-up (see the section Hypothesis 1a), the independent variable is randomization group, and the baseline PCS score is included as a covariate. Furthermore, to fully use the repeated measures of the PCS, we will develop a random effects interrupted time series model evaluating the change in slope of PCS over time, comparing the Adapt2Quit intervention and comparison group. This will be implemented using a segmented regression to evaluate changes in slope early in the intervention and sustain change over time in the latter months of the 6-month follow-up.

Power for Hypothesis 2a

In a prior smoking cessation study, the mean (SD) of PCS was 4.79 (1.96) [23]. On the basis of these results, for power calculations, we assumed a meaningful difference in the

averaged PCS score to be equal to 1 SD, assumed the mean in control to be 4.79, and set α at .05. To detect a difference of 1 SD, we have 99% power with a sample of 120 participants per group, further demonstrating power for aims 1 and 2.

Hypothesis 2b

Adapt2Quit participants will adopt more cessation-supporting actions (quitline and NRT) than control participants. For hypothesis 2b, the independent variable is again the randomization group. Each dependent variable will be modeled separately. There are several ways to analyze quitline use, including time to first call completed (time from baseline when the first call with the counselor was conducted in a number of weeks) or whether the participant used the quitline and the number of contacts between the patient and counselor. We chose the time to first call completed with the quitline counselor because it matters how quickly the intervention succeeded in motivating participants to call the quitline (if the call happened in the first few days of the intervention or later). The participant may initiate the call, or the counselor can call the participant following a texting referral.

Power for Hypothesis 2b

Analysis and the power calculation for time to first call completed is similar to the hypothesis 3b analysis. The use of NRT will be assessed via self-report at the 6-month follow-up. To analyze NRT use, a dichotomous variable, we will create a logistic model with the use of NRT (yes or no) as the dependent variable and randomization as the independent variable.

Aim 3: Effectiveness

Hypothesis 3a: Primary Outcome

Adapt2Quit participants will have greater smoking cessation rates (6-month point-prevalence biochemically verified) than control participants. For our primary outcome, we will follow recommendations from the Society for Nicotine and Tobacco Research and other experts. While we will attempt to minimize dropout rates loss to follow-up (missing outcomes) in trials such as ours cannot be fully averted [41]. Penalized imputation (missing=still smoking) is not a conservative approach and can be biased (against a group), especially when there is a differential missing between the groups [41]. Thus, the recommended approach is to use inverse probability weighting [42]. In this approach, the first step is to develop a logistic regression model to predict nonmissingness using variables that are found to be different between study participants with and without missing data. The next step is to calculate the inverse probability of nonmissingness and use it as the weight in a logistic regression model to compare the cessation rate between two study groups [43]. Along with inverse probability weighting, we will present penalized imputation and a complete case analysis (limited to those with complete data) as sensitivity analyses. We propose to biochemically verify participants who self-report quitting smoking using a CO meter.

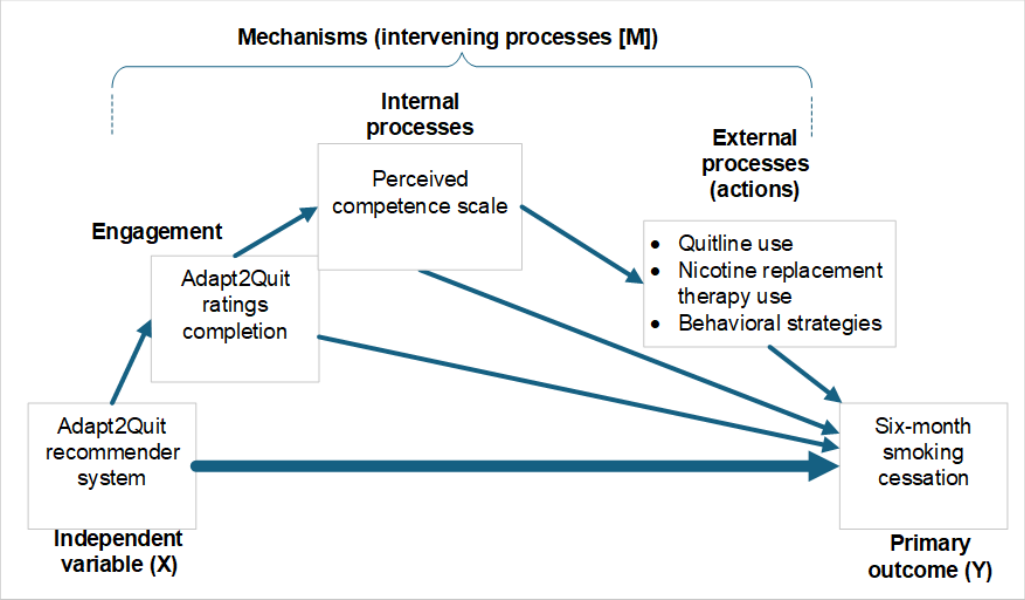
Power for Primary Outcome (Hypothesis 3a)

In our prior National Cancer Institute trial, we observed an absolute 9% difference in the standard messaging versus no-messaging control group [29]. We expect socioeconomically disadvantaged groups to have lower cessation rates than non–socioeconomically disadvantaged groups. Thus, we calculated power using a range of control cessation rates from 7% to 9%. We started at 7%, because it is the estimated rate at which the general population of all individuals who smoke quit without any intervention [34]. On the basis of the recommender enhancements (and further pilot data), we saw an additional marginal difference of 6% at 30 days (even higher for African American individuals who smoke) and expect this difference to continue and expand over time as the recommender system continues to learn and adapt to the individual; however, to be conservative and recognizing the potential difficulty in impacting behavior in this population, we chose to power for a small difference, namely 7%. Although our hypothesis is directional, we have chosen to adopt the commonly used conservative approach of 2-sided tests for all our power calculations. On the basis of a 2-sided chi-square test of equal proportions, α=.05, for all these base rates, we will have 80% power with 600 participants (N=300 per arm). Considering loss to follow-up, we plan to oversample by 25% and thus have budgeted for a total of 750 participants to complete baseline and be randomized. On the basis of our prior experience recruiting from clinical systems, we expect the dropout rate to be lower than the 25% we have assumed in our calculations.

Hypothesis 3b: Mediation Analysis

Measured internal and external processes will mediate the effect of Adapt2Quit on smoking cessation. Adapt2Quit is expected to result in several interconnected processes (Adapt2Quit increases personal relevance, thereby improving system engagement, which results in increasing the external and internal processes, causing the participant to implement cessation-supporting behaviors resulting in smoking cessation; Figure 1). We will explore the pathways using modern mediation and structural equation modeling (SEM) techniques. Mediation occurs when an independent variable (X) leads to a given outcome (Y) through an intervening process (M). In our case, the independent variable is the Adapt2Quit recommender (X), and the outcome will be 6 months of smoking cessation (Y). Perceived competence and adoption of cessation-facilitating behaviors (use of quitlines, use of NRT, and adoption of behavioral strategies) are all potential mediators (M). The mediation analyses will focus on each individual process variable, using the classic mediation principles modified from Barron and Kenny [44]. This approach requires 3 regression models and decomposes the total effect (*c*) of the independent variable (X) into a direct component (*c'*) and an indirect or mediated component (c-c'). Limitations to the modified Barron and Kenny approach include the fact that more complex mediation pathways with multiple steps are not allowed. Thus, we will implement SEM using Mplus as the covariance analysis software. SEM allows for the simultaneous estimation of multiple regression equations representing complex mediation pathways, allowing errors to be correlated across equations. Furthermore, constructs may be represented as latent variables to relax the assumption of no measurement error. An array of diagnostic tests (eg, root mean square error of approximation and comparative fit index) are available to examine model quality.

Figure 1. Hypothesized path model depicting associations among constructs. NRT: nicotine replacement therapy.



Qualitative Interview Analysis

We will transcribe the interviews verbatim and will use the rapid qualitative analysis method to code the transcripts. The rapid qualitative method uses triangulation and iterative data analysis to quickly develop a preliminary understanding of a situation from the insider's perspective [45-47]. In this method, primary topics or "domains" will be taken from the topics addressed in the interview guide to create summary templates. Two research team members will each code at least 10% of the interview transcripts, and coding checks will be completed to ensure interrater reliability. We will use the summary templates to create a matrix to analyze each domain's depth and breadth of data. From these, we will identify study themes and subthemes using the matrix. The research team will collaboratively and iteratively review, discuss, and sort the data to refine the initial themes and subthemes and highlight the most salient quotes. Recordings collected during interviews will be deidentified using subject ID numbers. No identifiable information, such as a full name, will be collected in the recording. Identifiers will be collected separately and will be stored in an encrypted form. Recordings will be transcribed and deidentified. They will be stored in a secured UMass Chan drive specified for the study within the UMass Chan IS regulated environment, where only UMass Chan study staff will have access to them. Recordings, and all other data collected in this study, will be retained and destroyed in accordance with Standard Operating Procedure Human Research Protection-800. Transcripts of audio or video recordings as well as the audio or video recordings themselves will be fully destroyed 6 years from the conclusion of the study period or at the request of the individual to whom that data belongs.

Results

This trial was funded in April 2020 and is currently ongoing. As of May 2024, we had enrolled 757 participants, and 591 (78.1%) of them had completed the 6-month follow-up interviews (Figure 2). We anticipate that data analysis and final manuscript preparation will occur in late 2025. Multimedia Appendix 3 provides the demographic and screening survey responses of 757 participants.

Discussion

Principal Findings

This study protocol describes a randomized controlled trial to test a machine learning algorithm–based, computer-tailored health communication system for smoking cessation. We hypothesized that the intervention will impact mechanisms of action—specifically engagement, competence (a theoretical construct), and adoption of cessation-supportive actions—as well as demonstrate effectiveness in promoting smoking cessation. Our system will test these hypotheses among individuals who are socioeconomically disadvantaged, a group disproportionately affected by smoking.

Because of the potential for wide reach and effectiveness, texting programs (especially texting) have been increasingly adopted in real-world settings worldwide (public health and within health care systems) [48-50]. For example, the World Health Organization has helped establish texting programs for smoking cessation in several countries, including Costa Rica, Tunisia, and India [51]. The US Department of Health and Human Services established a Text4Health Task Force in 2010 to promote health text messaging programs in the United States [48]. In 2017, 55% of state quitlines offered texting programs (up from 20% in 2012) [34,52]. There is now growing evidence that these programs can be effective. An evaluation of SmokefreeTXT (a free evidence-based smoking cessation program offered by the US National Cancer Institute) reported that point-prevalence abstinence for smokers who initiated treatment at completion of the 42-day program was 7.2% (3% at the 6-month follow-up) [53]. Leaders have called for continued innovations to increase the effectiveness of these health messaging programs, especially to increase effectiveness with smokers from socioeconomically disadvantaged backgrounds.

Our study will provide important evidence on whether a more personalized approach using machine learning can encourage quitline use and support smoking cessation, compared to a text-based referral to quitline. In previous papers, we described our pilot studies testing the Adapt2Quit intervention [16,35,54]. Furthermore, our prior large randomized controlled trial compared the Adapt2Quit intervention to a system that delivered messages based on participants' baseline readiness to quit [17]. In that trial, we recruited participants online as well as through referrals from friends and family. In addition, messages were delivered by email rather than by text, as is being done in this trial. The previous study also did not include biochemical verification of smoking cessation. Beyond the potential benefit of computer-tailored messaging, our system aims to actively engage participants with the quitline. Quitlines have proven to be effective in supporting people to quit smoking, yet using a quitline and attending counseling sessions is a significant step for individuals from socioeconomically disadvantaged backgrounds who smoke. Currently, only 2% to 3% of people who smoke use the quitline, with usage rates even lower among individuals from socioeconomically disadvantaged backgrounds [34]. Prior research has shown that it is possible to use a low-intensity intervention such as texting to increase motivation and the use of cessation resources among people who smoke [55].

In addition to our system, one group compared a similar recommender system in a pilot trial to a system that selected messages based on a knowledge base. They compared the message appreciation, engagement with the system, and one's own self-reported smoking cessation status (7-day point prevalence) [18]. Another group developed a recommender system for smoking cessation and promoting physical activity [56]. This group described an experiment they conducted to identify the optimal approach for selecting messages. In addition, a systematic review examined the potential of using another machine learning approach—reinforcement

learning—for similar purposes [57]. Together, these approaches highlight the potential of the use of machine learning approaches to enhance a widely used behavioral intervention: computer-tailored health communication.

Because we have completed recruitment for our study, we also provide the characteristics of our participants. Our recruitment method, using an opt-out strategy at 3 different health care systems, was able to successfully recruit a diverse sample. A third of our sample (265/757, 35%) are Black, and 16% (121/757) self-identified as Hispanic or Latino. There may be several factors for our successes, including that our intervention is a low-intensity intervention using a texting model that is widely available. Furthermore, our procedures for screening, baseline, and follow-up are all remote, which may have reduced barriers to recruitment. Participants in our study indicated higher motivation levels than the general population. This is an artifact of our recruitment strategy that people who are more motivated participate in a study about tobacco cessation. This more representative sample implies that our study findings will be more generalizable to the US population.

Strengths and Limitations

We describe the protocol for a rigorous evaluation of behavioral intervention among individuals from socioeconomically disadvantaged backgrounds. Since recruitment for our study is complete, we also present participant characteristics. Using an opt-out recruitment strategy across 3 different health care systems, we successfully recruited a diverse sample, which has been challenging to achieve for clinical trials. Our fully remote procedures for screening, baseline, and follow-up may have reduced barriers to recruitment. Notably, 35% (265/757) of our sample identified as Black and 16% (121/757) as Hispanic or Latino. This more representative sample suggests that our study findings will be more generalizable to the US population. One limitation is that our participants reported higher motivation levels for quitting smoking than the general population, which is likely due to the recruitment strategy attracting those who were more motivated to participate in a tobacco cessation study. Because we only used insurance status to determine socioeconomically disadvantaged, some participants may not align with all characteristics that may describe socioeconomically disadvantaged.

Conclusions and Future Work

Our project is the first to rigorously test the use of a recommender system for smoking cessation among individuals from socioeconomically disadvantaged backgrounds who smoke. In this paper, we have reported on protocols for conducting a rigorous trial. In addition to our primary analyses for the 3 aims, we will conduct exploratory analyses to assess the heterogeneity of treatment effects across these subgroups, which could yield valuable insights for future tobacco cessation efforts. Our follow-up papers will report on the results of our trial following the analysis plans described in this paper. Future studies will also explore implementing texting interventions in various clinical and public health settings.

Acknowledgments

The Adapt2Quit intervention is funded by the National Cancer Institute (grant R01CA240551), starting in April 2020.

Abstract

Background: Nonmedical use of prescription opioids remains a critical public health issue; 8.5 million people in the United States misused opioids in 2022. Most people obtain prescription opioids for misuse from family or friends. Thus, facilitating secure storage and disposal of opioid medications during and after treatment is needed to prevent medication diversion and subsequent misuse.

Objective: The primary objective of this study is to test the feasibility and efficacy of a novel intervention that uses a persuasive, informational SMS text message reminder system to enhance the impact of secure storage and disposal of unused opioid medications. We hypothesize that the SMS text message intervention will increase secure storage during treatment and disposal of prescription opioids after treatment.

Methods: We will use a 2-arm randomized controlled trial to test the intervention for feasibility and efficacy. Participants (aged 18+ years who have received an opioid prescription in the past 2 weeks) will be randomly assigned to either receive the SMS text message intervention or standard-of-care educational materials. Participants in the intervention will receive 4 SMS text messages related to secure storage and 3 messages related to disposal. All participants will complete baseline, midpoint (day 25), and postintervention (day 45) evaluation surveys. We will test whether receipt of the intervention is associated with two primary outcomes, which are (1) secure storage of prescription opioid medication (locked vs unlocked) and (2) disposal of unused prescription opioid medication (disposed vs not disposed). We will use multiple logistic regression to test the main hypotheses that the intervention will be positively associated with secure storage (locked vs unlocked) and disposal (yes vs no) behaviors, which will allow us to control for demographic variables known to influence the outcomes. This protocol represents the entire structure of the randomized controlled trial.

Results: Recruitment for the randomized controlled trial was launched in April 2024, and data collection was completed in December 2024. The final sample size is 484. Data analyses for the main hypothesis will be completed by May 2025, and the main hypothesis manuscript will be submitted for publication by May 2025.

Conclusions: Results from this study will indicate whether a text message reminder system can increase secure storage and disposal behaviors for individuals who receive opioid medication. This type of intervention has the potential to be integrated into

currently used health care delivery systems, such as prescription pickup reminders at pharmacies. Thus, the intervention is scalable across systems of care, thus expanding the reach of secure storage and disposal programs to prevent prescription opioid misuse.

prescription opioid; storage; disposal; text message intervention; randomized controlled trial; mobile phone

Introduction

Statement of the Problem

Despite efforts in the United States to reduce the number of opioid prescriptions through prescribing guidelines [1,2] and drug monitoring programs [3,4], mortality rates due to the nonmedical use of prescription opioids have remained high since their peak in 2010 [5]. National data estimates that 6.1 million people met the criteria for opioid use disorder and 8.5 million (3%) misused prescription opioids in 2022 [6]. The majority of people obtain prescription opioids for misuse from family or friends, with or without their knowledge [6]. Furthermore, many opioid medications go unused; a meta-analysis of postoperative opioid consumption for acute pain by US adults found that 61% of medications [7] remain after treatment. Unused prescriptions can lead to medication diversion, which is the primary source of prescription opioids for misuse [6]. Facilitating secure storage and disposal of opioid medication during and after treatment is needed to prevent medication diversion.

In an early response to the opioid crisis, the Office of the National Drug Control Policy disseminated a plan that included secure storage and disposal of unused opioid medications as key strategies for prevention [8]. This plan specified the need to educate patients on the proper storage and disposal of prescription medications. The Centers for Disease Control and Prevention recommends that medication is stored out of reach of children and pets and opioid medications should be stored in a locked cabinet or drawer [9]. The US Food and Drug Administration (FDA) endorses multiple methods to dispose of unused prescription opioids when they are no longer needed, including medication take-back days, disposal boxes, mail-back programs, and deactivation kits [10,11]. Currently, the FDA also recommends flushing certain types of medications in the toilet or putting them in the trash if other options are not available [12]. The guidance on flushing unused medications is in contradiction to that provided by the US Environmental Protection Agency [13].

Despite the release of the Office of the National Drug Control Policy plan over a decade ago and guidance on secure storage and disposal from federal agencies [9,10,12,13], evidence suggests uptake of the simple behavior of secure storage and disposal is limited. For example, in a study of a nationally representative panel of 1032 adults who had been prescribed an opioid medication, only 8.6% (n=89) stored their medication in a locked location [14]. Similarly, in a study of 113 patients prescribed opioids for cancer pain, only 15% (n=17) locked their opioids while 36% (n=41) stored opioids in plain sight; however, 73% (n=82) indicated a willingness to store their medications in a locked location [15]. Across multiple studies of individuals prescribed opioids for chronic and acute pain, less than a third reported disposal of unused opioid medications [16-19]. Hence, there is significant room for improvement in opioid medication storage and disposal practices.

There is emerging evidence that a more targeted intervention at medical facilities may enhance the secure storage and disposal of unused opioid medications. Several studies have examined the provision of an educational pamphlet to patients who receive an opioid prescription for acute pain [20-23]. In general, the educational pamphlets contained brief information about nonmedical prescription opioid use and instructions for secure storage and disposal. All studies found statistically significant intervention effects on self-reported storage and disposal of unused prescription opioids [20-23]. That is, a targeted intervention to facilitate secure storage and disposal by patients receiving an opioid prescription improved the uptake of these preventive behaviors. However, the rates of utilization of these practices remained low. Across these studies, secure storage did not improve and 48% (45/86) to 78% (37/170) of patients who received an educational pamphlet still did not dispose of their unused opioid medications, which indicates that additional intervention is warranted.

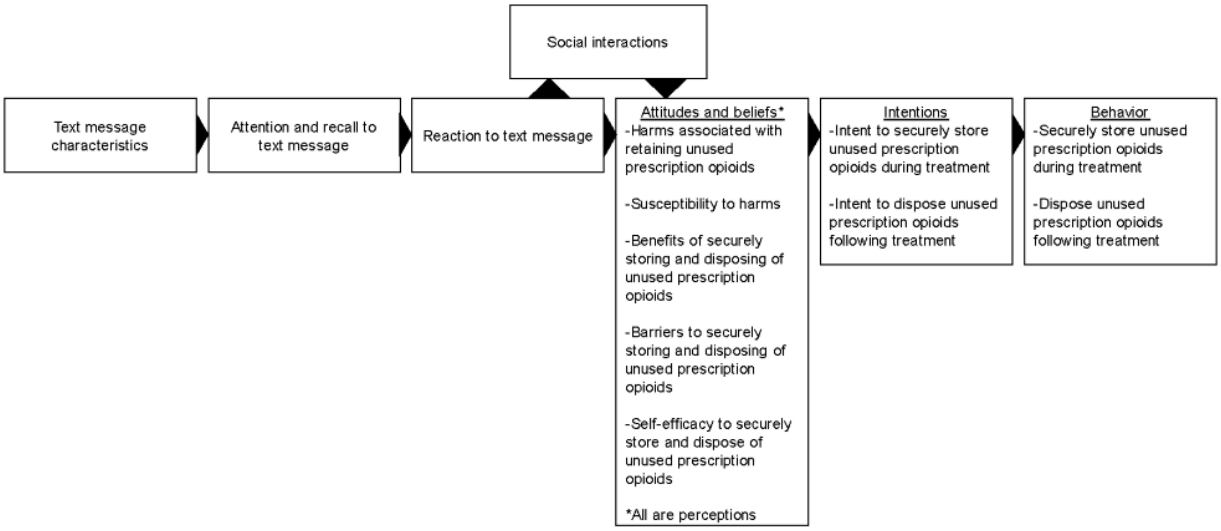
The high prevalence of opioid prescriptions that are not fully used demands an intervention that can scale widely. The widespread adoption and instantaneous nature of mobile phones make them a promising vehicle for economical and systems-based interventions. Almost all (1442/1502, 96%) of US adults have a mobile phone with SMS capabilities [24], indicating that text interventions have the potential to serve as a universal intervention delivery method. Digital health systems have already been implemented in pharmacies. Many pharmacies have established systems that alert patients via text message when medications are ready to be picked up. Patients report that they prefer to receive health information from medical practices via SMS text messages over other forms of communication [25]. Half of pharmacy patrons already use existing pharmacy-based text reminders and smartphone apps [25]. Thus, delivering reminders about the secure storage and disposal of prescription opioids via SMS text messages represents a scalable intervention across systems of care.

Theoretical Frameworks

The study is informed by 2 theoretical frameworks (Figure 1). First, the Message Impact Framework [26] suggests that message characteristics affect the extent to which the message will be

noticed and later recalled. An individual's reaction to the message impacts their knowledge, attitudes, and risk beliefs, which in turn impact intentions and actual behavior. Furthermore, exposure to messages can elicit interpersonal communication and social interactions which further spread and influence individuals' attitudes, beliefs, and reactions to the messages. Second, the Health Belief Model (HBM) [27] posits that messages will generate behavior change if they target perceived barriers, benefits, threats, and self-efficacy specific to the behavior. Specifically, attitudes and beliefs pertaining to perceived seriousness and susceptibility to harms result in the formation of a perceived threat. Along with perceived threats, beliefs about the benefits of and barriers to performing a behavior paired with self-efficacy to do so influence whether an individual will perform the behavior. A cue to action, such as an SMS intervention, serves as a trigger or motivator to perform the behavior, such as securely storing and disposing of prescription opioid medications.

Figure 1. Conceptual framework.



Objective

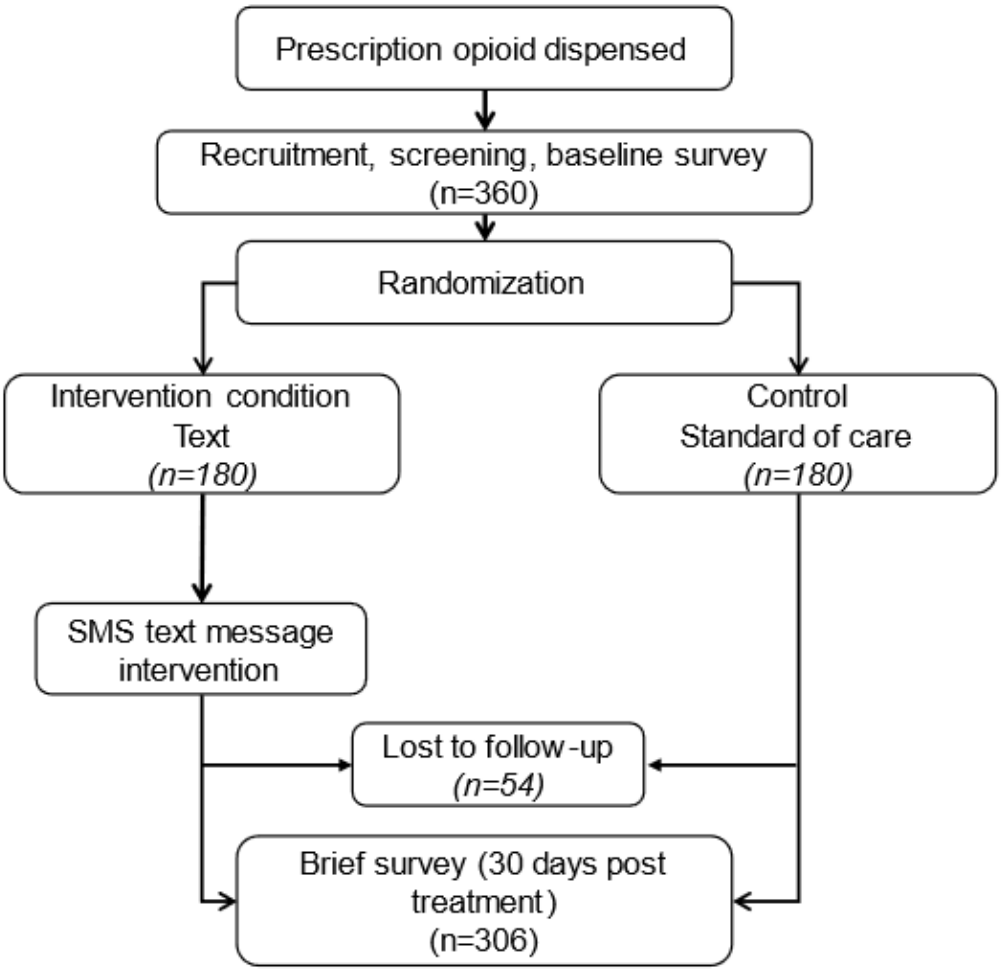
The overall objective of the study is to test the feasibility and efficacy of a novel, evidence-informed strategy that uses a persuasive, informational SMS text message reminder system to expand the impact of secure storage and disposal programs. Our central hypothesis is that the implementation of an SMS text message intervention will increase the secure storage of opioid analgesics during treatment and disposal following treatment.

Methods

Overview

This study uses a 2-arm, single-blinded, randomized controlled trial (RCT) design (Figure 2). Participants are randomly assigned into either the SMS text message intervention condition or a standard-of-care control group. Participants will complete baseline, midpoint (day 25), and postintervention (day 45) evaluation surveys, described further in this study. The primary trial site is Wake Forest University School of Medicine.

Figure 2. Planned randomized controlled trial study design.



Ethical Considerations

This protocol has been approved by the Wake Forest University School of Medicine Institutional Review Board (IRB; IRB00102139).

The consent form will be self-administered on REDCap (Research Electronic Data Capture; Vanderbilt University). Potential participants will review the consent without the assistance of a study team member and will be directed to the study team if they have any questions. In lieu of a signature, participants will be informed that they should "click 'I agree to participate' at the end of the consent form" to provide their authorization to participate in the study. The consent form will use language approved by the Wake Forest University School of Medicine IRB that is designed for readability and includes the general topic of the study, the name of the principal investigator, the principal investigator's contact information, the IRB approval number, and the phone number of the IRB at Wake Forest University School of Medicine. Participants will be reminded that they are not required to answer questions (other than for eligibility), that they can end participation at any time, and that there is no obligation to participate. Given that participants for the RCT may be patients at a participating institution, they will be reminded during the consent process that participation will not impact their treatment or future access to medications.

To recruit participants, we will maintain a spreadsheet that has identifiable information of individuals who have met the study criteria stored electronically on a secured device and IRB-approved cloud system. The purpose of this spreadsheet is to ensure that potential participants are not invited to participate more than once. After ascertaining consent to participate, unique identifiers will be assigned to participants, and identifiers will be stored separately from the data. To minimize the likelihood of a breach in confidentiality, data will be collected and stored in REDCap, a secure web application for building and managing online surveys, and on a secure and encrypted storage system maintained by Wake Forest University School of Medicine IT security.

All participants in the RCT will be provided with incentives following completion of the baseline survey, midpoint survey, and postintervention surveys, in the form of an electronic US $25 Amazon gift card per survey. Participants will be asked if they are willing to upload a photo of their prescription opioid bottle or box for an additional US $5 Amazon gift card. The maximum amount of money that a participant may receive for participation in this study is US $80. Electronic gift cards will be provided via SMS text message to study participants.

Participants

Eligibility

Individuals are eligible to participate if they are 18 years of age or older, able to read and speak English, own a cell phone with the capability of receiving SMS text messages, within 14 days of being dispensed a prescribed opioid medication, and have an opioid prescription that is for 30 days or less.

Sample Size

We plan to enroll 360 participants (n=180 per condition) based on assumptions from an RCT using a text intervention that encouraged parents to vaccinate their adolescent child [28] and an RCT that assessed the delivery of a deactivation product with educational material by medical staff on self-reported disposal of unused opioids [29]. Power calculations based on proportions of vaccine completion for the group exposed to the SMS text message intervention (0.49) and the unexposed group (0.30) [28] indicate a total of 230 participants will be needed to detect a difference in the impact of an SMS text message intervention. Power calculations based on the proportions of disposal for the group who received the deactivation product intervention (0.72) and the unexposed group (0.56) [29] indicate a total of 306 participants will be needed to detect a difference in the disposal of unused opioid medications. We based our sample size on the more conservative estimates [29]. To account for a 15% (12/79) loss to follow-up [21], we plan to recruit an additional 54 participants for a total of 360 participants.

Recruitment

We will use a multimethod approach to recruit participants for the RCT. Potential participants will be identified through the Advocate Health electronic health records. Biweekly, we will receive medical record numbers of Advocate Health patients who were recently prescribed an opioid medication. These individuals will be sent an SMS text message via their Advocate Health MyChart inviting them to participate in the RCT. We will also post flyers in local pharmacies with study information. Participants will be directed to a self-administered consent form programmed in REDCap. If the participant consents to participate, they will complete the self-directed web-based eligibility screener.

Screening and Randomization

If the individual is eligible to participate in the RCT, they will transition immediately from the eligibility screening questions to the baseline survey questions. Following completion of the baseline survey, a study team member will be notified so they can randomize the new participant to study condition. Randomization will occur within REDCap using simple randomization procedures to randomly assign participants to the intervention or control conditions. Randomization will be stratified by biological sex of the participant. An external module has been integrated into REDCap to confirm that each new participant is unique based on their phone number and email address.

Intervention

Procedures (Intervention Condition)

Participants in the intervention group will receive a series of SMS text messages to securely store prescription opioids during treatment and dispose of unused prescription opioids. Twilio will be used to deliver text messages to participants. Twilio is a third-party web service that integrates with REDCap, allowing users to send survey invitations and alerts or notifications to participants as SMS text messages or voice calls. It acts as a conduit between participants' mobile devices and the REDCap project. The intervention will last for 45 days and will start immediately following the completion of the baseline survey. All participants randomized to the intervention study condition will receive 7 identical SMS text messages over the course of the intervention. Participants will receive 4 SMS text messages about storing their medications before the midpoint survey which will take place on day 25 of the research study. SMS text messages about the disposal of unused medications will begin after day 31 of the intervention to ensure that all participants would have completed their treatment regimen. Participants will receive 3 SMS text messages about disposing of their unused medications before the postintervention survey, which will take place on day 45 of the research study. Participants will receive 1-2 SMS text messages about storing and disposing of their unused medications per week, reflecting participant feedback from the first phase of this study, which focused on the development of the SMS text message content (Textbox 1) [29]. The order in which all SMS text messages are delivered will be randomized. The recommendations for storing medications have been endorsed by the Centers for Disease Control and Prevention [9], and recommendations for disposal are currently endorsed by the FDA [10].

Textbox 1. Participant-derived SMS text messages.

Storage messages

- It is your prescription, not theirs. Keep your medication hidden and out of reach.
- Locking up your prescription pain pills could save a life. Keep them in a locked location such as a cabinet or box.
- Your favorite hiding spot could save a life. Keep your pain pills where someone would not look for them.
- Your prescription can become someone else's addiction. Lock up your pain pills.

Disposal messages

- Dispose of your unused medications. You may save the life of someone you love. Dispose in a way that works best for you: Return them to the pharmacy, use a home disposal kit, or mix pills with an undesirable substance and put in your trash.
- Discarding your unused pain pills could save a life. Dispose in a way that works best for you: Return them to the pharmacy, use a home disposal kit, or mix pills with an undesirable substance and put in your trash.
- Your prescription can become someone else's addiction. Safely discard unused or expired medications. Dispose in a way that works best for you: Return them to the pharmacy, use a home disposal kit, or mix pills with an undesirable substance and put in your trash.

Control Condition

Individuals who are assigned to the study control condition will receive the standard of care provided to them from their prescribing physician and dispensing pharmacist. Immediately after completing the postintervention survey, participants will receive information on ways to securely store and dispose of unused opioid medication. This information will be provided in the REDCap survey.

Data Collection and Measures

Evaluation

Participants will complete 3 evaluation surveys. Each evaluation will be delivered via a secure link to a web-based REDCap survey. The baseline survey will be completed directly following study enrollment. A midpoint survey will be sent 25 days after study enrollment, and a final postintervention survey will be delivered 45 days after study enrollment. The baseline survey assesses sociodemographic characteristics, information about the prescribed opioid medication, and past medication storage and disposal behaviors. The midpoint and postintervention surveys ask about how the participant has been storing their opioid medication, if they are still using their opioid medication, if they have disposed of their medication, and their intent to dispose of their medication. Participants assigned to the intervention study condition will provide feedback on the SMS text message intervention in the postintervention survey. Those who were assigned to the control study condition will share what they would like to receive in an SMS text message intervention. All surveys will also query perceptions in alignment with the HBM (eg, perceived barriers, and benefits) [27] about securely storing and disposing of their opioid medications.

Primary Outcomes

We will use 2 primary outcomes based on data from the postintervention survey. Pertaining to storage of opioid medications, participants will be asked, "Where do you usually store your prescribed pain medication?" with response options of (1) in an unlocked box, closet, cabinet, or drawer; (2) in a locked box, closet, cabinet, or drawer; (3) in a purse, backpack, or other carrier; (4) out in the open; (5) other; or (6) unsure where kept. We will create a binary variable for storage of locked (in a locked box, closet, cabinet, or drawer) versus unlocked (all other responses) to test study hypotheses. Related to disposal behaviors, for participants that indicate they had no leftover medications, we will create a binary variable based on the disposal method of the medication (put in the trash, used deactivation product, used a prepaid mail-back envelope, flushed in the toilet, returned them to the pharmacy, or took them to law enforcement agency) versus not disposed (gave them to friend or family member or something else).

Secondary Outcome

For participants who indicate they have medication from their prescription leftover, we will create an intention to dispose variable based on the item "What do you intend to do with your remaining prescription pain medicine?" The binary variable will denote intent to dispose (put them in the trash, use deactivation product, use prepaid mail-back envelope, flush in the toilet, return to pharmacy, or take to law enforcement agency) versus do not intend to dispose (keep them, gave them to friend or family member, or something else).

Other Measures

At the baseline and postintervention time points, we will assess measures derived from the HBM including self-efficacy (eg, I know how to properly dispose my prescription medication), barriers (eg, I do not have access to a locked location where I can securely store my prescription pain medication), benefits (eg, disposing my unused prescription pain medications can stop someone else from taking them), perceived severity (eg, I think there are risks to having prescription pain medication in my home), and perceived susceptibility (eg, I worry about having prescription pain medication in my home). At the midpoint and postintervention time points, we will also assess the SMS text messages themselves using items derived from the Message Impact Framework, including whether the participant felt the SMS text messages grabbed their attention, were easy to understand, and made them think about the risks of having prescription pain medicines in their homes.

Data Management

Before ascertaining consent to participate, we will maintain a spreadsheet stored electronically on a secured device and IRB-approved cloud system that has the name, phone number, and email address of individuals identified via Advocate Health electronic health records who have met study eligibility criteria. This spreadsheet will include the date we contacted the individual and the way in which we contacted them. The purpose of this spreadsheet is to ensure that an individual is not invited to participate more times than approved by the IRB. This spreadsheet will also have a unique identifier, which will be linked to data pertaining to their prescription number, medication list (ie, opioid prescription only), age, gender, and race or ethnicity. We will retain this information for use in the event that they consent to participate in the study. The spreadsheet will be destroyed once recruitment has closed. To minimize the likelihood of a breach in confidentiality, data will be collected and stored in REDCap, a secure web app for building and managing web-based surveys, and on a secure and encrypted storage system maintained by Wake Forest University School of Medicine IT security. Public access to deidentified data will be made public at the conclusion of the study.

Data Analysis

Design and Data Preparation

Analyses will be conducted to assess group differences on the two primary dichotomous outcomes, which are (1) secure storage of the opioid medication (locked vs unlocked) and (2) disposal of unused medication (disposed vs did not dispose). We will use a modified intention-to-treat (ITT) design. While an ITT design minimizes bias and type 1 error, it is often considered a conservative approach that may increase type 2 error [30]. A modified ITT design allows for the exclusion of some randomized subjects in a justified way to achieve the goal of minimizing both type 1 and 2 errors [30]. For this study, we will retain the ITT approach by including all participants regardless of their compliance with the SMS text message intervention. We will modify the ITT approach by excluding participants who do not have outcome data since we will not have a mechanism to assess their storage or disposal behaviors, which could inflate type 2 error if retained in analyses. We will first test for group equivalence in demographic and household characteristics of the participant, diagnosis and treatment, and information about the prescribed opioid (eg, type, number of pills, and duration of treatment). Group differences are not expected in the context of randomization; however, if one of these variables is associated with both a condition and an outcome variable, we will include it as a covariate in subsequent analyses using that outcome. Data will be compiled and screened for integrity, outliers, missing values, and violations of the assumptions of logistic regression. Missing values will be handled in regression analyses using full maximum likelihood estimation.

Statistical Analyses

We will use multiple logistic regression to test the main hypotheses that the intervention will be positively associated with secure storage (locked vs unlocked) and disposal (yes vs no) behaviors, which will allow us to control for demographic variables known to influence the outcomes. We will use a 2-step logistic regression to predict each outcome. In step 1, demographic variables will be entered into the model. We will retain variables significantly associated with the outcome at a significance threshold of $\alpha<.05$. In step 2, the intervention condition will be entered into the model.

Results

Recruitment for the RCT was launched in April 2024, and the first participant enrolled in the study in June 2024. The primary completion date, defined as the date on which the last participant in a clinical study completed the postintervention survey, was in December 2024. The final sample size is 484. Data analyses for the main hypothesis will be completed by May 2025, and the main hypothesis manuscript will be submitted for publication by May 2025.

Discussion

Contributions to the Literature

The overall objective of the study is to test the feasibility of a novel, evidence-informed strategy that uses a persuasive, informational SMS text message reminder system to expand the impact of secure storage and disposal programs. Our central hypothesis is that the implementation of an SMS text message intervention will increase the secure storage of opioid medication during treatment and disposal following treatment. The intervention will be tested with a 2-arm, single-blinded, RCT design. Participants in the intervention group will receive a series of 7 SMS text messages about securely storing prescription opioids during treatment and disposing of unused prescription opioids. The SMS text messages have been developed and refined by end users of the intervention [31].

The status quo is to encourage secure storage and disposal of unused prescription opioids with the implementation of disposal programs [28,29], community-wide awareness campaigns [32], educational pamphlets [20,21], and drug deactivation products [29,33] delivered by medical providers. Current research indicates the need for improved interventions that effectively facilitate secure storage and disposal of unused prescription opioids. Our study adopts an evidence-based intervention strategy, SMS text messages on mobile phones, for a novel purpose—facilitation of secure storage and disposal of prescription opioids. We use a theoretically driven and user-derived messaging delivered in an SMS text message intervention during a critical window of need following receipt of a prescription opioid medication. The findings from the proposed study have the potential to be scalable across multiple systems of care and expand new horizons for medical systems to use existing digital technologies to improve patient care.

Limitations

Several limitations may impact this study. Individuals will be eligible to participate within 14 days of receiving their opioid medications. Thus, individuals with shorter prescriptions may receive SMS text messages about secure storage after they have completed treatment and receive SMS text messages about

disposal after they have already disposed of their unused medication. We will only recruit individuals who have an opioid prescription for 30 days or less, so findings may not be generalizable to patients who have more than a 30-day prescription. We will not be able to control exposure to external messaging about storing or disposing of opioid medications, but we will be assessing self-reported exposure to messaging. While we will be able to track the delivery of all SMS text messages, we cannot assess if they are received or read by the study participants. A systematic, 2-phase approach was used to refine the text messages for the SMS text message intervention using both focus groups and a Qualtrics (Silver Lake) panel [31]. It is possible, but unlikely, that the SMS text messages will not resonate with or be well received by the participants in the RCT. The RCT is being conducted during an election cycle. Participants may be getting more SMS text messages than usual during this period, which may detract from their attention to the study text messages.

Conclusion

Upon successful completion of the study, we will have developed and pretested a systems-level, scalable intervention using mobile technology for the secure storage and disposal of unused prescription opioids, which could be implemented in pharmacies and other medical systems. This contribution is expected to be significant in that facilitating secure storage and disposal of unused prescription opioids should reduce the accumulation of these medications that would otherwise be accessible for nonmedical use. Due to the decreased availability of unused prescription opioids, we would expect to see a decline in the prevalence of nonmedical prescription opioid use and associated consequences. Without the identification of strategies that effectively and universally facilitate secure storage and disposal of unused opioid medications, opioid medications with misuse potential will remain in communities, increasing the likelihood for nonmedical prescription opioid-related morbidity and mortality.

Abstract

Background: Psychotherapy is central to the treatment of mental disorders, highlighting the importance of medical students and residents developing competencies in this area. Chinese medical residents have expressed a strong need for psychotherapy training, yet they are generally dissatisfied with the current offerings. This paper presents the protocol for an evidence-based, well-structured psychotherapy teaching program aimed at medical students and residents.

Objective: This study involves a randomized controlled trial of a 2-day multimodal intensive educational intervention designed to evaluate the effectiveness of a new psychotherapy teaching program for medical students and residents in China. The primary outcomes include participants' knowledge and utilization of psychotherapy, training program acceptability, self-reported self-efficacy, and motivation to apply psychotherapy.

Methods: This 2-arm randomized controlled trial was conducted at Sir Run Run Shaw Hospital. The study aimed to recruit approximately 160 medical students and residents, with about 80 participants in the intervention group and 80 in the control group. Both groups completed a baseline survey before participation, reporting their psychotherapy knowledge, utilization of psychotherapy, self-efficacy, and self-motivation. The intervention group received a 2-day multimodal intensive educational intervention (supervision-based online teaching), while the waitlist control group did not receive any intervention during this period. Both groups were followed up for 8 weeks, completing the same survey administered at baseline. At the end of the study, the control group received the intervention. The primary outcome measure was the change in trainees' psychotherapy knowledge before and after the intervention training. Secondary outcome measures included changes in the trainees' utilization of psychotherapy, self-reported self-efficacy, and self-reported motivation for psychotherapy. Additionally, training program acceptability was assessed. Analysis of covariance was used to analyze the primary outcomes. Pearson correlations and regression analysis explored factors associated with the knowledge score at baseline. The secondary outcomes, including participants' psychotherapy utilization, confidence, and motivation, were analyzed using the same methods as for knowledge. All tests were 2-tailed, with a significance level set at $P<.05$.

Results: A total of 160 participants were recruited and randomized between January 4 and 12, 2024. Baseline assessments were conducted from January 28 to February 1, 2024. The psychotherapy training program for the intervention group took place on February 3 and 4, 2024. Posttraining assessments were conducted starting April 1, 2024. Due to withdrawals, incomplete surveys,

and data loss, we had a total of 113 participants: 57 in the intervention group and 56 in the control group. The amount of data varied across measures. The data analysis was finished in August 2024.

Conclusions: This study aims to evaluate the effectiveness of the multimodal psychotherapy training program for medical students in China. If this brief, cognitive behavioral therapy–based psychotherapy skill training proves effective, the potential mental health impact of its nationwide expansion could be significant.

Introduction

Background

The delivery of psychosocial and psychotherapeutic interventions remains central to the treatment of many patients with psychiatric disorders (eg, obsessive-compulsive disorder, panic disorder, major depression, eating disorders, and addictive behaviors) and psychosomatic disorders (eg, hypertension, bronchial asthma, and rheumatoid arthritis) [1,2]. Cuijpers et al [3] conducted a large-scale network meta-analysis to examine the effects of various types of psychotherapies for adult depression, including cognitive behavioral therapy (CBT), interpersonal therapy, psychodynamic therapy, problem-solving therapy, behavioral activation, life-review therapy, and "third-wave" therapies, as well as nondirective supportive counseling. They found that all types of these therapies were more effective than care-as-usual and waiting list control conditions and that most therapies were more efficacious than placebo. Additionally, most therapies maintained significant effects at the 12-month follow-up compared with care-as-usual. A strong evidence base indicated that several psychotherapy modalities were effective for most mental disorders, whether used alone or in combination, primarily including behavior therapy, CBT, and interpersonal psychotherapy [4,5]. According to a systematic review and meta-analysis, the emotional change processes and mechanisms of psychotherapy were most strongly associated with specific CBT methods, such as fear habituation, emotion regulation and experience, and the habitual reorganization of maladaptive emotional perceptions [6]. Today, CBT is recommended as a first-line intervention for both the acute treatment and relapse prevention of various mental illnesses, including major depressive disorder, and most patients prefer psychological treatment over pharmacologic options [5]. Therefore, medical students in clinical rotations and residents working in psychiatric and psychosomatic departments should be required to develop competencies in psychotherapy, particularly in CBT [7]. However, there remains a significant treatment gap for mental disorders in China [8]. Despite the high prevalence of mental disorders in the country, medical professionals in psychiatric or mental health departments often have a comparatively low capacity to provide adequate care and lack qualified training in psychotherapy. Learning basic psychotherapy skills would benefit medical students, residents, and other health care providers (HCPs), including doctors and nurses, across all departments. These skills can be applied in clinical practice to enhance doctor-patient relationships [9]. A study conducted in Beijing found that after participating in a 2-year psychotherapy training program, medical doctors reported improvements in diagnosing and treating mental illness, as well as in doctor-patient communication and the development of strong doctor-patient relationships. Patients also demonstrated significant improvements in levels of depression and anxiety, the severity of physical symptoms, quality of life, and the patient-rated therapeutic relationship [9]. Therefore, psychotherapy training for medical students, residents, and other HCPs requires greater emphasis.

A narrative review indicated that medical residents in psychiatry have a strong need for psychotherapy training to enhance their competence, yet they generally express dissatisfaction with the current training programs [10]. Therefore, providing evidence-based and well-designed psychotherapy training programs is essential for equipping medical students and residents with a foundational understanding of psychotherapy and the necessary skills for clinical practice [11]. Compared with traditional methods, psychotherapy teaching that emphasizes skill practice and role experience is more popular and effective. For instance, a single-day simulation training program has proven effective in psychiatry for medical students, enhancing their knowledge, communication and interview skills with patients, and confidence in treatment [12]. Despite the critical importance of learning psychotherapy skills during medical school and residency, there is a notable lack of formal evaluation of psychotherapy teaching methods and their efficacy. Given the lack of access to psychotherapy, medical and psychological educators, along with program directors, should design high-quality curricula to teach medical students, residents, and other HCPs the essential knowledge and skills in psychotherapy. These curricula should be evaluated through well-conducted, methodologically robust randomized controlled trials (RCTs) [13].

Aim and Hypotheses

To evaluate the effectiveness of the multimodal psychotherapy training program for medical students in China, well-designed RCTs of psychotherapy teaching programs are urgently needed. The primary aim of this proposed project is to assess the effectiveness of a new multimodal psychotherapy teaching program for medical students and residents in China, which is designed to enhance their psychotherapeutic skills and improve their performance in entry-level clinical settings. The primary

hypothesis was that, compared with a control intervention, the intervention group receiving the psychotherapy teaching program would acquire significantly more knowledge about psychotherapy after training. We also hypothesized that the program would lead to an increase in the utilization of psychotherapy and be associated with improved knowledge in this area. The third hypothesis posited that trainees' self-reported self-efficacy and motivation to apply psychotherapy in clinical practice would increase significantly.

Methods

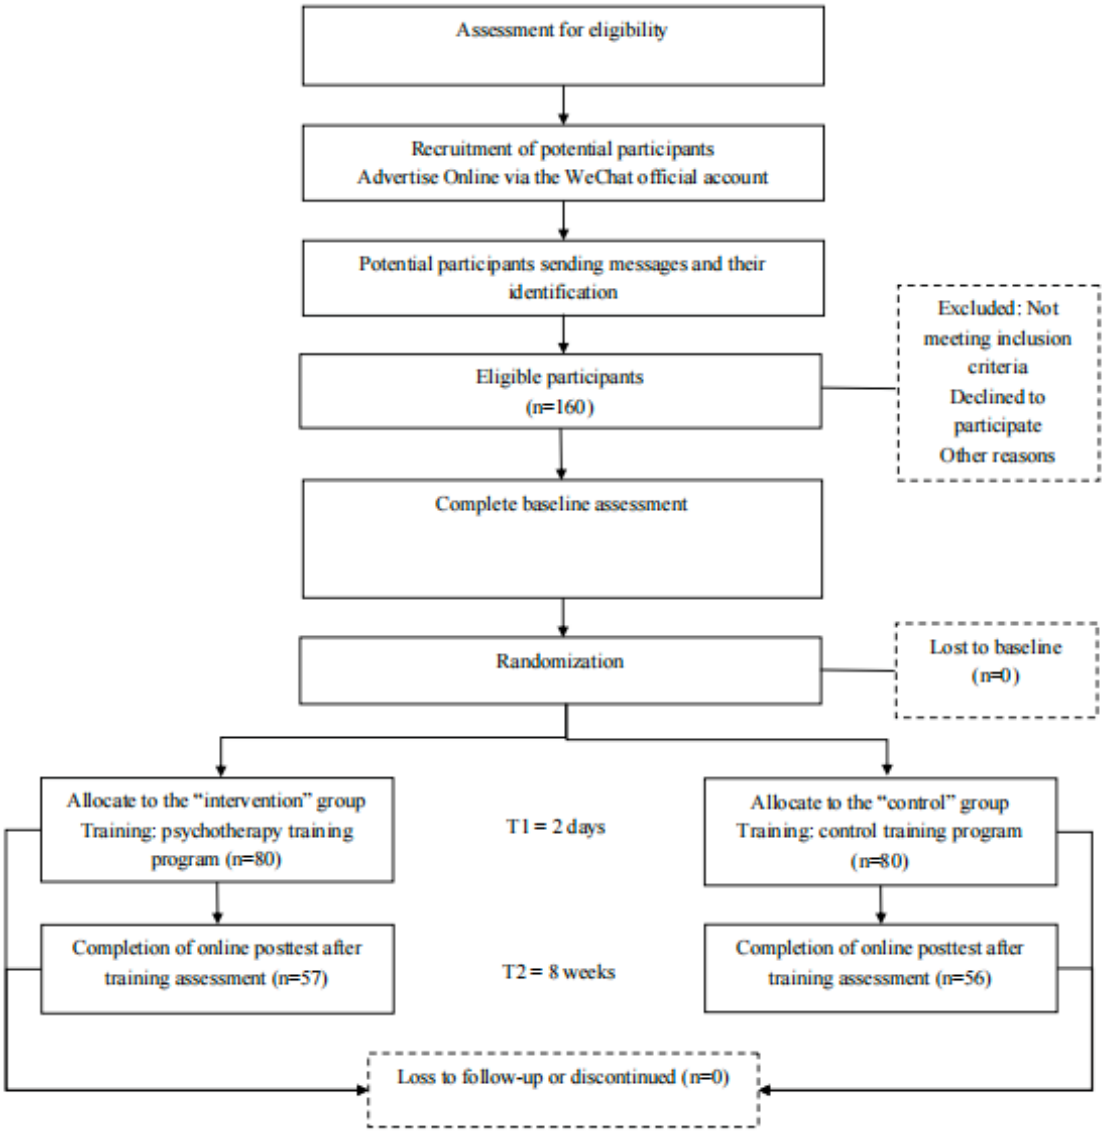
Patient and Public Involvement

Neither participants nor the public were involved in the trial's design, recruitment, or conduct of this study.

Study Design and Participants

This study was an RCT of a 2-day multimodal intensive educational intervention aimed at enhancing the clinical skills in psychotherapy of Chinese medical students and residents. The trial included a waitlist control group, with 8 weeks of follow-up for all participants. A detailed schedule of the study procedures is summarized in Figure 1.

Figure 1. Flowchart study design.



Study participants (n=160) primarily included medical students, residents, and a few other HCPs, such as doctors and nurses, in China. There were no specific restrictions for participants, although most were from Zhejiang University School of Medicine. An overview of participant eligibility criteria is provided in Textbox 1.

Textbox 1. Study inclusion criteria (participants who did not qualify for the criteria were not recruited to participate in this study).

- Medical students, residents, and other health care providers
- Aged 18 years or older
- Expressing an interest in psychotherapy
- Willing to receive randomization
- Willing to provide informed consent to participate in the study

Sample Size and Power Calculation

The sample size was calculated based on the primary outcome using G*Power [14] (version 3; Universität Düsseldorf). As the data were continuous variables and analysis of covariance (ANCOVA) would be used to compare differences between the 2 groups, an a priori analysis selecting ANCOVA as the statistical test was conducted to determine the required sample size. As only a few studies have examined the effectiveness of psychotherapy training for medical students, we were unable to reference effect size or other data as criteria. Therefore, a medium effect size for the primary outcome was estimated preliminarily. It was determined that 128 participants (64 in each group) would be required to achieve 80% power (effect size f=0.25; 1 – β=0.80; α=.05). To account for potential attrition, we aimed to recruit approximately 160 participants (80 in each group), ensuring that the proposed analysis would be sufficiently powered even if 25% of participants in each group were lost to attrition.

Randomization and Group Allocation

This study aimed to recruit approximately 160 participants, with about 80 in each group. The study coordinator randomized participants into the intervention and control groups using a random number generator in R software, maintaining a 1:1 ratio for allocation to the experimental and control conditions. Participants in the intervention group first received the experimental condition, which included the psychotherapy training program after the baseline assessment. The waitlist control group received the control condition, meaning they participated in the psychotherapy training program only at the end of the study. The timeline of the study was as follows: all participants underwent a baseline assessment, the intervention group received the training program, and the control group received a control training program. After 8 weeks, all participants were followed up, and finally, the control group received the intervention training program (Figure 1).

Recruitment

The researchers advertised the program online through the WeChat (Tencent Holdings Limited) official account of the Department of Psychiatry at Sir Run Run Shaw Hospital, Zhejiang University School of Medicine, to recruit potential participants. They encouraged sharing the program details with medical schools and hospitals. Interested individuals could register by sending messages and their identification to the research assistants (Zitang Zhou and Luyao Zou). Research assistants then contacted the respondents to assess their eligibility, explain the study to each participant, and inform them about the allocation to either the control or intervention groups, where they would receive the psychotherapy training program.

Baseline and Posttraining Data Collection

Before randomization, demographic information and self-reported questionnaires were collected from all participants at baseline. This information included participants' sex, age, identity (student, resident, or HCP), education level (undergraduate or graduate degree), department affiliation (psychiatric or nonpsychiatric), and years of psychotherapy-related work. Additionally, outcome measurements were gathered, including trainees' knowledge of psychotherapy, utilization of psychotherapy, self-reported self-efficacy, and self-reported motivation, among others. The questionnaires on psychotherapy knowledge, utilization, and self-efficacy and motivation to engage in psychotherapy were specifically designed based on our training program. Outcome measurements were assessed again 8 weeks after training (Table 1). Data were collected online using WenJuanXing (Questionnaire Star), a Chinese platform that provides professional online questionnaire surveys and data collection for RCTs [15]. The hospital's data monitoring committee oversaw the data collection process, and personal information was deidentified to ensure confidentiality.

Table 1. Schedule of enrollment and posttraining assessments.[a]

Schedule	Baseline	8 weeks after training
Initial approach	✓	N/A[b]
Informed consent	✓	N/A
Eligibility screen	✓	N/A
Randomization	✓	N/A
Intervention/control initiation	✓	N/A
Demographic characteristics	✓	N/A
Knowledge	✓	✓
Self-reported self-efficacy	✓	✓
Self-reported motivation	✓	✓
Utilization	✓	✓

[a]This table illustrates the schedule of enrollment and posttraining assessments. Initial approach, informed consent, eligibility screen, randomization, intervention/control initiation, and demographic characteristics were evaluated and collected only at the baseline timeline. Psychotherapy knowledge, self-reported self-efficacy, self-reported motivation, and utilization were both collected at the baseline and 8 weeks after the training.

[b]N/A: not applicable.

Development of the Psychotherapy Training Program

The psychotherapy training program was primarily developed by an experienced psychotherapist (Tao Pei) and an MD-level psychiatrist (Yanhui Liao), both of whom have approximately 20 years of relevant experience. The details of the 2-day psychotherapy training program are outlined in Multimedia Appendix 1. The program included 2 days of intensive training followed by 8 weeks of follow-up, with guidance on applying psychotherapy in clinical settings.

Intervention

Control Group

After providing consent, participants allocated to the waitlist control group received a message encouraging them to complete all questionnaires from baseline through to the final follow-up at 8 weeks. They were sent messages via WeChat to thank them for their participation and to remind them of the timeline for completing the study. Once they finished the posttraining measurement, a digital booklet of the psychotherapy training program was provided to them via WeChat or as a hard copy upon request. After the trial concluded, participants in the control group were offered the opportunity to receive the psychotherapy training program free of charge.

Intervention Group

All participants in the intervention group received the 2-day psychotherapy training program and were given a hard copy of the program booklet at recruitment. Additionally, supervision-based group meetings were held during the follow-ups at weeks 1, 2, 4, and 8, with each meeting lasting approximately 2 hours. During these follow-up meetings, instructors—including psychotherapists and psychiatrists—were available to answer any psychotherapy-related questions, encourage participants to practice psychological interventions, and provide further information to support the clinical application of psychotherapy.

Outcomes and Outcome Measures

Primary Outcome

Trainees' psychotherapy knowledge was assessed by participants using an 11-point scale (ranging from 0 to 10) before and after the 8-week period (Table 2). At baseline, 160 participants completed the self-reported psychotherapy knowledge questionnaire, and the results indicated a high internal consistency coefficient (Cronbach α) of 0.980 for the scores across the 17 items.

Table 2. Knowledge about psychotherapy.[a]

Variables	Measures (0-10)
Overview of psychotherapy	
Supportive psychotherapy techniques	
Overview of cognitive behavioral therapy	
Beck's cognitive therapy	
Identify automatic thinking and do cognitive conceptualization	
Cognitive conceptualization	
Evaluation of automatic thinking	
Reconstruction techniques for automated thinking1: Socratic questioning	
Reconstruction techniques for automated thinking2: pie charts, continuous spectrum, cost-benefit analysis, behavioral experiments	
Challenge automatic thinking	
Social skill training	
Problem-solving	
Behavioral therapy theory and behavioral conceptualization	
Behavioral activation	
Relaxation training	
Exposure therapy	
Competency structure of psychotherapists and the growth path of cognitive behavioral therapy therapists	

[a]This is the assessment of participants' knowledge about psychotherapy. Each item was rated on a 0-10 scale, where 10 means "knowing very well."

Secondary Outcomes

Training Program Acceptability

Program acceptability in the intervention group was measured using questions designed to assess acceptability, as detailed in Table 3.

Table 3. Questions for assessing the psychotherapy training program acceptability.[a]

Category and questions	Rating
General	
• Overall rating of the program	5=like very much; 4=like somewhat; 3=neutral; 2=dislike somewhat; 1=very dislike; 5=very likely
Appraisal	
• Appraisal of the program—the likelihood of applying the program for patients • Appraisal of the program—the likelihood of recommending the program to other medical students or other health care providers	5=very likely; 4=somewhat likely; 3=neutral; 2=unlikely; 1=not at all likely
Acceptability	
• I would have been able to help patients to deal with mental problems with the program • The program made it easier to communicate and help patients during clinical work • The program disrupted my daily schedule • The program is easy to understand	5=strongly agree; 4=agree; 3=neutral; 2=disagree; 1=strongly disagree
Frequency	
• Frequency of using psychotherapy	1=almost never; 2=sometimes; 3=always

[a]This is the rating of the training acceptability assessment. The last item, "Frequency of using psychotherapy," was rated on a 1-3 Likert scale, where 3 indicates "always."

Utilization of Psychotherapy

The utilization rate of psychotherapy interventions for patients during the 8 weeks of follow-up was assessed using items from Table 4.

Table 4. The utilization rate of psychotherapy.[a]

Variables	Measures (0-10)
Supportive psychotherapy techniques	
Social skill	
Problem-solving skill	
Behavioral activation	
Relaxation training	
Exposure therapy	

[a]This is the assessment of participants' utilization rate of psychotherapy. Each item was rated on a 0-10 scale, where 10 means maximum utilization and 0 means minimum utilization.

Self-Reported Self-Efficacy and Self-Reported Motivation

Self-efficacy and motivation were measured using a visual analog scale on a 10-cm line, representing a continuum from "no self-efficacy or motivation" to "the strongest self-efficacy or motivation" (Table 5).

Table 5. Self-reported self-efficacy and motivation of psychotherapy.[a]

Variables	Visual analog scale
Self-reported self-efficacy	
Confidence in practicing psychotherapy	
Confidence in practicing supportive psychotherapy	
Confidence in practicing cognitive behavioral therapy	
Self-reported m otivation	
Willingness or motivation to practice psychotherapy	
Willingness or motivation to practice supportive psychotherapy	
Willingness or motivation to practice cognitive behavioral therapy	

[a]This is the assessment of participants' self-reported self-efficacy and self-reported motivation. Each item was measured by the visual analog scale on a 10-cm line that represents a continuum between "no self-efficacy or motivation" and "the strongest self-efficacy or motivation.

All secondary outcomes were reported as mean values. According to the baseline measurements of our study, 160 participants evaluated their psychotherapy utilization, confidence, and motivation using self-reported questionnaires. The internal consistency coefficients (Cronbach α) for these 3 questionnaires were 0.950, 0.961, and 0.936, respectively.

Procedures

Figure 1 and Table 1 summarize the schedule for enrollment and posttraining assessments. Participants were evaluated at baseline (0 weeks), before and after receiving the intervention training, and at 8 weeks after training. They were also asked to maintain a daily log of their utilization of the psychotherapy training program, which included activities such as providing emotional support and teaching patients breathing techniques for stress relief. Reminders were sent to participants who did not complete the 8-week posttraining questionnaires.

Withdrawal From the Program

All participants were free to withdraw from the trial at any time without needing to provide a reason. Following the intention-to-treat principle [15], participants who did not respond to the 8-week posttraining assessment were retained in the analysis according to the group to which they were randomized, regardless of whether they received the intervention. Participants who withdrew were excluded from the analysis, and their reasons for withdrawal were recorded. A complete case analysis was conducted, excluding any participants who withdrew at the posttraining assessment point.

Data Analysis

All data were automatically collected via WenJuanXing through a WeChat-based link. The data were downloaded from the WenJuanXing database into a user-specific Excel file. This study did not include interim analyses; data were analyzed only after all had been collected. The trial statistician blinded the intervention assignment in the data using R software (R Foundation for Statistical Computing) and SPSS (2013 release; IBM Corp.).

The primary hypothesis was that, compared with the control intervention, the intervention group receiving the psychotherapy teaching program would significantly gain more knowledge about psychotherapy after training. We also hypothesized that the program would lead to increased utilization of psychotherapy and be associated with improvements in knowledge. The third hypothesis posited that trainees' self-reported self-efficacy and motivation to apply psychotherapy in clinical practice would increase significantly.

Descriptive statistics were used to assess demographic and psychotherapy-related characteristics at baseline. Following normality and homogeneity of variance tests, ANCOVA was used to analyze the primary outcomes. In the ANCOVA model, the dependent variable was the change in the knowledge score. The fixed factor was the group (intervention group or control group), while the covariates included the mean score of psychotherapy knowledge at baseline and years of psychotherapy experience. Pearson correlations and regression analysis (both linear and binary regression models) were used to explore factors associated with the knowledge score at baseline and to assess the increase in psychotherapy utilization in both the intervention and control groups. The secondary outcomes—participants' psychotherapy utilization, confidence, and motivation—will also be analyzed in the same manner as knowledge.

A complete case analysis was performed, excluding any participants with missing information on the posttraining assessment. Additionally, a sensitivity analysis of the missing data was conducted to determine whether the missingness is random. Demographic information and scores for psychotherapy knowledge, utilization, confidence, and motivation at baseline were compared between the complete data group and the missing data group. All tests were 2-tailed, with a significance level set at $P<.05$.

Safety and Adverse Events

Throughout the psychotherapy training program, adverse events were closely monitored. Participants were encouraged to communicate any psychotherapy-related issues or adverse events encountered during their clinical work. We prompted each participant to report any adverse events experienced at each group meeting, and they could also report them at any time. If participants experienced severe adverse events, they were encouraged to seek support from a psychologist or psychiatrist.

We did not anticipate any training-related serious adverse events (SAEs), such as life-threatening incidents, during this trial. However, if any adverse events occur, we will document the SAE, record it on the SAE form, and submit it to the ethics committee of Sir Run Run Shaw Hospital (the principal investigator's affiliation) within 24 hours.

Ethics Approval and Consent to Participate

This study was approved by the ethics committee of Sir Run Run Shaw Hospital, an affiliate of Zhejiang University School of Medicine (2024 Ethics Approval File No. 2024-0066). The trial was conducted in accordance with the Declaration of Helsinki. Participants were provided with informed consent before the baseline assessment. After thoroughly reading and understanding the content of the consent, they received a link to electronically sign their name at the end of the informed consent form and submit it via WeChat. Each participant was informed about the study's purpose, procedures, measurements, potential risks, and benefits before recruitment. Informed consent was then obtained from each participant. Participation was entirely voluntary, and participants could withdraw from the study at any time. Coordinating researchers' contact information was provided to all participants for any inquiries or concerns.

Data Security

The authors utilized the professional version of WenJuanXing, which features high-level security management, alongside an applet on WeChat that ensures the secure and confidential protection of participants' data.

Results

This study recruited 160 participants from January 4 to January 12, 2024. The 2-day training program took place on February 3 and February 4, 2024, and the posttraining assessment was completed on April 1, 2024. Due to withdrawals, incomplete surveys, and data loss, we had a total of 113 participants: 57 in the intervention group and 56 in the control group. The amount of data varies for each measure. Data analysis was completed in August 2024. The results will be published in peer-reviewed journals. If found to be effective, the psychotherapy training program and the accompanying program booklet will be made freely available to the public by the end of the trial.

Discussion

To our knowledge, this will be the first RCT to evaluate the efficacy of a multimodal psychotherapy training program for medical students in China.

The strength of this study lies in its theoretical framework, primarily guided by cognitive behavioral theory. With a large sample size, this RCT evaluates the efficacy of the psychotherapy training program using multimodal teaching methods in China. If effective, this multimodal psychotherapy training program could be applied nationwide, significantly enhancing its potential impact on public health. Its expansion could help HCPs acquire the necessary psychotherapy skills to effectively manage patients' psychological issues.

There are several limitations to this study. First, the effectiveness of teaching and the quality of learning can be influenced by various factors, such as opportunities to implement psychotherapy practice, the intensity of clinical work during the follow-up period (including the impact of holidays), and the availability of continuing education resources. These factors cannot be adequately controlled in this study. Second, the 2-day training will take place at Sir Run Run Shaw Hospital, which may deter participants from other regions of China from attending the program. Third, there are only 2 main instructors (Psychiatrist YL and Psychologist TP) involved in this training program. While both have nearly 20 years of teaching and clinical experience, their individual teaching styles and characteristics may still influence the overall effectiveness of the program. Fourth, although this 8-week training program aims to enhance the acquisition of therapeutic skills, developing proficiency in psychotherapy is likely to be a more prolonged process. Fifth, all measures rely on participants' subjective assessments, which may be influenced by personal biases and expectations of improvement following the intervention training. Lastly, we submitted this protocol to the journal during the recruitment process.

In conclusion, this is the first RCT to evaluate the efficacy of a multimodal psychotherapy training program for medical students in China. If this educational program, which offers brief and short-term psychotherapy skills training, proves effective, its nationwide expansion could have a significant health impact. It provides evidence-based psychotherapy training—primarily in CBT—for medical students, and its dissemination will equip HCPs to better manage mental health issues, such as stress and depression. Therefore, it is crucial to develop effective psychotherapy training that emphasizes basic psychotherapy skills. The results of this training's effectiveness can offer valuable insights for the future development of training programs, enabling them to better meet the learning needs of medical professionals and enhance doctor-patient relationships.

Acknowledgments

The research is supported by the China Medical Board (CMB) Open Competition Program (grant 22-485), the STI 2030-Major Projects of China (grant 2022ZD0211200), and the National Natural Science Foundation of China (grant U22A20302 to YH Liao). The funders had no role in the study design, data collection and analysis, the decision to write the report, or the submission of the paper for publication. We appreciate Dan Han's work as she contributed to manuscript discussion at the beginning stage of manuscript writing.

Availability of Data and Materials

Data sets from this study and the corresponding analysis code will be made publicly available at the conclusion of the study's analyses.

Declaration of Artificial Intelligence Use

Generative artificial intelligence was not used in any portion of the manuscript writing.

Authors' Contributions

YL designed the study, while YL and TP developed the program. YD verified the analytical methods. JT supervised the design of the work and revised the manuscript. All authors discussed and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Psoriasis is an inflammatory disease primarily treated through molecular-targeted therapies. However, emerging evidence suggests that dietary interventions may also play a role in managing inflammation associated with this condition. The Mediterranean diet (MedDiet), prevalent in southern European countries, has been widely recognized for its ability to reduce cardiovascular mortality, largely due to its anti-inflammatory properties. This anti-inflammatory potential has prompted interest in exploring the MedDiet's role in immune-mediated diseases, including psoriasis. Observational studies have indicated potential benefits, such as reductions in the Psoriasis Area and Severity Index. However, there is a need for well-designed clinical trials to address the methodological limitations of these studies and to establish specific dietary recommendations for psoriasis.

Objective: This study aims to evaluate the impact of an intensive dietary intervention based on the MedDiet in patients with psoriasis. The study will assess the effects of this intervention on skin involvement, metabolic parameters, and inflammatory cytokines. In addition, the emotional well-being and quality of life of participants will be evaluated using validated questionnaires. A methodological analysis will also be conducted to enhance the design of future large-scale clinical trials.

Methods: An open-label, single-blinded (evaluator) randomized controlled trial was designed to assess the impact of a high-intensity MedDiet intervention in patients with mild-to-moderate psoriasis. A total of 38 patients will be randomly assigned into 2 groups—an intervention group receiving the MedDiet intervention and a control group receiving standard care. The intervention group will participate in dietary education sessions aimed at adopting the MedDiet over 4 months, with monthly monitoring by experienced nutritionists. Participants will receive 500 mL of extra virgin olive oil per week, along with informative materials, recipes, and weekly menus. In contrast, the control group will receive standard low-fat diet recommendations without nutritionist monitoring. All participants will undergo a baseline visit, a 2-month follow-up visit, and a final visit at 4 months.

Blood tests will be conducted at the beginning and end of the study. This study protocol was approved by the Institutional Review Board of the Hospital Ramón y Cajal (Madrid) in July 2023.

Results: Enrollment concluded in October 2024, with data collection set to finish by February 2025. The findings will be presented at national and international conferences and published in peer-reviewed journals.

Conclusions: This protocol outlines the design of a clinical trial that implements the MedDiet in patients with psoriasis to evaluate its benefits on skin involvement, systemic inflammation, and quality of life.

Introduction

Psoriasis is a common skin disease, affecting between 2% and 4% of the population [1,2]. Its pathogenesis involves a complex interplay between innate and adaptive immunity, with the interleukin (IL)-17/IL-23 axis playing a crucial role. While not all underlying molecular mechanisms have been fully elucidated, current medical treatments primarily target proinflammatory cytokines [3]. In today's era of media, nutrition has become a significant topic of interest among patients with psoriasis. A survey conducted by the National Psoriasis Foundation involving 1206 patients revealed that 89% (n=1073) believed it was important to discuss the role of diet in their disease with their physician, and 86% (n=1037) had attempted dietary modifications. Despite this, only 31% (374/1206) of patients had actually discussed dietary changes with a health care provider [4]. In fact, nutritional approaches play a very important role in the prevention and treatment process of chronic diseases such as inflammatory diseases, autoimmune diseases, cardiovascular diseases, and even mental diseases [5,6].

There is well-established evidence supporting the beneficial effect of weight loss in patients with psoriasis [7]. Dietary interventions that promote weight loss are recognized as valuable therapeutic strategies for reducing inflammation, particularly in obese patients with psoriasis [8]. In addition, the nutrigenomic effects of certain food components have been documented [9]. However, the only firm dietary recommendations currently reflected in most psoriasis guidelines and expert consensus are weight loss for patients who are overweight and obese and a gluten-free diet for those with positive celiac disease serology [10]. Therefore, there remains a need for dietary guidance that offers benefits beyond weight loss, applicable to patients of any body weight.

The Mediterranean diet (MedDiet) refers to the eating patterns typical of the olive-growing regions around the Mediterranean Sea. This dietary approach emphasizes the consumption of fruits, whole grains, vegetables, nuts, seeds, legumes, and olive oil—the hallmark of the MedDiet. It also includes a moderate intake of red wine with meals, seafood, poultry, and fermented dairy products, while limiting red and processed meats, sweets, and other ultraprocessed foods [11]. Growing evidence suggests that the MedDiet may influence the progression and severity of psoriasis [12,13]. In a 2018 cross-sectional study by Phan et al [14], which included 35,735 participants from the NutriNet-Santé cohort, 3557 participants had psoriasis, with 878 classified as severe cases. The multivariate analysis, adjusted for factors such as age, sex, weight, and cardiovascular risk, showed a significantly lower percentage of severe psoriasis cases among those with greater adherence to the MedDiet [14].

Several research groups have designed large-scale dietary interventions to implement the MedDiet in large patient cohorts. The PREDIMED (Prevention with Mediterranean Diet) study [15], which included 7447 patients at high risk of cardiovascular disease, randomly assigned participants into 3 groups—2 groups received Mediterranean dietary advice supplemented with extra virgin olive oil (EVOO) or a mixture of nuts, while the third group followed low-fat dietary recommendations. All groups were closely monitored by nutritionists. The PREDIMED study demonstrated the positive role of the MedDiet in preventing cardiovascular events. Subsequent satellite studies, such as the PREDIMAR (Prevention of Recurrent Arrhythmias with Mediterranean Diet) study [16], which used an entirely online dietary intervention, further underscored the MedDiet's benefits and the feasibility of achieving high adherence to this dietary pattern through a dietary intervention.

The MEDIPSO (Impact of the Mediterranean Diet on Patients with Psoriasis) study, detailed in this paper, was conceived to address the need for more evidence on the relationship between psoriasis and the MedDiet. This proof-of-concept randomized controlled trial, inspired by the PREDIMED study, involves a high-intensity MedDiet intervention in patients with psoriasis. The primary objective is to evaluate the impact of this dietary pattern on psoriasis skin involvement, inflammatory cytokines, and quality of life.

Methods

Study Design

The MEDIPSO study is an open-label, single-blinded (evaluator) randomized controlled trial. This experimental study involves patients with mild-to-moderate psoriasis who are on stable topical treatment, which will be randomly assigned to either a

control group or an intervention group. Patients in the intervention group will receive dietary education focused on adopting the MedDiet, with monthly monitoring by nutritionists experienced in the PREDIMED clinical trial. In contrast, the control group will not receive any active dietary modification interventions.

Both groups will undergo blood tests to assess metabolic parameters before and after the study period, and data on anthropometric characteristics and quality of life will be collected. The study aims to evaluate the effects of the MedDiet on skin involvement, metabolic parameters, and inflammatory cytokines, as well as its impact on emotional well-being and quality of life. In addition, a methodological analysis will be conducted to refine the design for future large-scale clinical trials.

Participants

In total, 38 patients with mild-to-moderate plaque psoriasis and no systemic treatment will be included. Participants for this study will be recruited from among patients who regularly attend dermatology consultations at Hospital Universitario Ramón y Cajal. The inclusion criteria and exclusion criteria are stated in Textbox 1.

Textbox 1. Inclusion and exclusion criteria for the participation in the Impact of the Mediterranean Diet on Patients with Psoriasis study.

Inclusion criteria:

- Psoriasis clinically diagnosed by an experienced dermatologist
- Predominantly psoriasis vulgaris
- Psoriasis Area and Severity Index ≥2 and ≤10 at the time of recruitment
- Stable weight (<5% weight loss or gain) in the last 3 months
- Treated exclusively with topical treatment for psoriasis at enrollment and throughout the study
- Willing and able to follow the study procedure, attend all scheduled visits during the study period, and provide blood samples as indicated in the procedure
- Able to give informed consent
- Willing to implement pregnancy prevention measures throughout the study period

Exclusion criteria:

- Type 1 or 2 diabetes mellitus
- Good adherence to the Mediterranean diet at the time of screening (energy-restricted Mediterranean Diet Adherence Screener score ≥8)
- Language barrier (patients not fluent in Spanish or English) or conditions that make telephone communication difficult (eg, severe hearing loss)
- History of cardiac disease
- Comorbidities that may compromise the implementation of the intervention (eg, cancer, digestive diseases, and so on) or limit survival to less than 6 months
- History or current eating disorder (anorexia, bulimia, etc; screening will be carried out using the Diagnostic and Statistical Manual of Mental Disorders, fifth edition, if indicated)
- Malnourished patients (screening using the Malnutrition Universal Screening Tool, if indicated)
- BMI greater than 40 kg/m^2
- Presenting gout
- Pregnant, planning pregnancy, or breastfeeding
- Use of diuretics at the time of sampling
- Difficulty or inconvenience in changing dietary habits and following the Mediterranean diet (allergies, food intolerances, and special diets)
- Participation in a clinical trial with drugs or dietary intervention in the year prior to inclusion in this study

Sample Size

There are no previous studies specifically evaluating the impact of MedDiet on skin involvement in patients with psoriasis. The only dietary intervention study in psoriasis to date is by Castaldo et al [8], which reported a decrease in Psoriasis Area and Severity Index (PASI) of 7.2 (95% CI –8.7 to –5.6) in a sample of 37 patients. However, this study differs significantly from MEDIPSO in design; it involved a single group without a control group, used a highly aggressive intervention including prolonged fasting periods, targeted only patients with obesity who have severe psoriasis, and excluded other adjuvant treatments, with a longer follow-up period.

In contrast, our study includes a control group, applies a less aggressive dietary intervention, and focuses on patients with mild-to-moderate psoriasis who are allowed to continue their stable topical treatments. Consequently, we anticipate the SD in PASI reduction at week 16 to be much lower, around 1. To

detect a difference of 1 unit on the PASI scale, with an α risk of 0.05 and a β risk of less than 0.2 in a bilateral contrast, we estimate that 19 participants per group (intervention and control) are needed. We assume a common SD of 1 and estimate a loss-to-follow-up rate of 15%.

Randomization

After signing the informed consent, all participants will be enrolled and randomly assigned into either the MedDiet intervention group or the standard-of-care group using closed envelopes. Randomization will be conducted using a computer-generated list created by an independent statistician, who is blinded to the trial and not involved in participant recruitment. The allocation will follow a 1:1 ratio. The recruiter will only open the envelope and learn of each patient's group assignment after the informed consent form has been signed by the patient.

Blinding

The study is single-blinded, as only the investigator evaluating the PASI is blinded. Both the patient, the nutritionists responsible for carrying out the intervention, and the person in charge of follow-up and nonsubjective data collection are aware of the group to which the patient has been assigned.

Roles

The entire dermatology department will be involved in patient recruitment. The principal investigator will oversee initial screening, follow-up, data collection, and the evaluation of side effects. Randomization will be conducted using a sealed-envelope system, with the principal investigator opening the envelopes only after the patient has been enrolled in the study and the informed consent has been signed. This investigator will not be blinded.

The nutritional intervention was fully designed by nutritionists from the University of Navarra, who will implement the intervention with the support of the principal investigator. The nutritionists will also not be blinded.

Evaluation of nonobjective parameters, such as PASI, and data analysis will be conducted by coinvestigators who are blinded to the group assignments.

The Nutritional Intervention

The objective of the nutritional intervention in the MEDIPSO study is to enhance adherence to the MedDiet. A hybrid approach combining remote and face-to-face interactions will be implemented. During the initial visit, when the first blood sample is taken and the patient's data are collected, initial dietary recommendations will be provided along with supportive materials, including instructions on the MedDiet, infographics, sample menus, and recipes. Following this, dietitian-nutritionists with experience from previous MedDiet intervention studies, such as PREDIMED, will conduct monthly telephone consultations with each participant.

During these consultations, the dietitian-nutritionists will assess adherence to the MedDiet and set individualized goals for improvement based on the participant's needs. In addition to the printed materials provided at the first visit, participants will have the opportunity to discuss any questions or concerns with the research team.

Participants in the intervention group will receive 500 mL of EVOO each week, distributed during clinic visits. The goal is to encourage participants to consume at least 4 tablespoons of EVOO daily, using it as the primary culinary fat in their homes as part of the MedDiet.

The dietary recommendations for the intervention will align with the habits defined in the MedDiet according to the Energy-Restricted Mediterranean Diet Adherence Screener (er-MEDAS) scale (Table 1) [17]. Participants will be instructed to follow specific guidelines, including consuming 4 or more tablespoons of EVOO daily for cooking and seasoning; 2 or more servings (200 g per serving) of vegetables per day (with at least 1 serving being raw); 3 or more servings (125 g per serving) of fruits per day (including natural juices); 3 or more servings (60-80 g per serving) of legumes per week; 3 or more servings (150 g per serving) of fish or seafood per week (including at least 1 serving of oily fish); and 3 or more servings (30 g per serving) of nuts per week. Participants will be advised to choose white meats (eg, skinless poultry and rabbit) over red meat (eg, beef and pork) or processed meats (eg, sausages and hamburgers). Regular use of sofrito (a sauce made with chopped tomato, garlic, and onion simmered in olive oil) for cooking, at least twice per week, will also be encouraged. In addition, whole grains (eg, bread, pasta, and rice) should be chosen over refined cereals. The dietary plan will recommend eliminating or limiting the consumption of cream, butter, margarine, carbonated and sugary drinks, baked goods (eg, sweet desserts, cakes, pastries, and cookies), and ultraprocessed foods. The nutritional intervention will not prescribe a specific caloric intake or macronutrient distribution.

Table 1. Energy-Restricted Mediterranean Diet Adherence Screener scale score (the maximum possible score is 17; this was the scale used to assess the adherence to the Mediterranean diet during the study; a score ≤7 was considered to be poor adherence to Mediterranean diet).

Question to be asked to the patient	Criterion to score 1 point; otherwise, 0 is recorded
Do you use extra virgin olive oil as the principal source of fat for cooking?	Yes
How many servings of vegetables do you consume per day? Count garnish and side servings as half a serving; a full serving is 200 g.	≥2
How many pieces of fruit (including fresh-squeezed juice) do you consume per day?	≥3
How many servings of red meat, hamburger, or sausages do you consume per week? A full serving is 100-150 g.	≤1
How many servings (12 g) of butter, margarine, or cream do you consume per week?	<1
How many carbonated and sugar-sweetened beverages do you consume per week?	<1
How many servings (150 g) of pulses do you consume per week?	≥3
How many servings of fish and seafood do you consume per week? (100-150 g of fish, 4-5 pieces, or 200 g of seafood)	≥3
How many times do you consume pastry such as cookies, cake, or sweets per week?	<3
How many times do you consume nuts per week? (1 serving=30 g) per week?	≥3
Do you prefer to eat chicken, turkey, or rabbit instead of beef, pork, hamburgers, or sausages?	Yes
How many times a week do you eat cooked vegetables, pasta, rice, or other dishes dressed with sofrito (a tomato, garlic, onion, or leek sauce simmered with olive oil)?	≥2
Do you add sugar to your beverages (coffee, tea)?	No
How many servings of white bread do you consume per day (1 serving=75 g)?	<1
How many servings of whole-grain bread, pasta, or rice do you consume per week?	≥5
How many servings of refined bread, rice, and pasta do you consume per week?	<3
Do you drink wine? How much do you consume per week? (1 cup=100 mL)	Male 14-21 cups; female 7-14 cups

Study Protocol

The intervention period will last 16 weeks, comprising 3 face-to-face visits for all participants and 2 additional telephone visits for those in the intervention group.

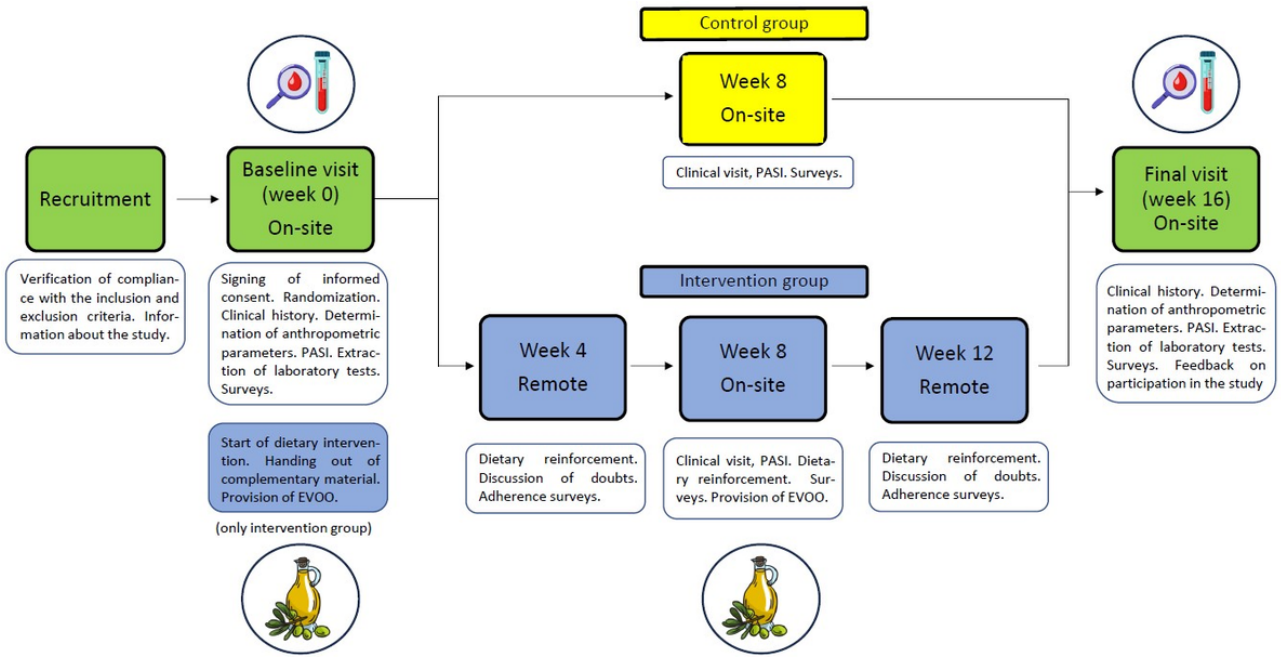
During the baseline visit (visit 1), patients will sign the informed consent, undergo randomization, and have clinical information collected. A complete physical examination will be conducted, and blood samples will be obtained. For patients randomized to the intervention group, this visit will also include the provision of informational materials, the distribution of EVOO, and the initiation of the nutritional intervention.

At week 8, a face-to-face visit (visit 2) will be conducted. The primary objective of this visit is to perform a clinical evaluation to determine if the patient has experienced any clinical worsening that would necessitate the initiation of systemic treatment. If systemic treatment is deemed necessary, the corresponding analytical tests and vaccination protocol will be initiated. This visit at week 8 ensures that participation in the study does not delay the start of systemic treatment if required.

During the final visit (visit 3), clinical information will once again be collected, a complete physical examination will be performed, and final blood samples will be drawn. In addition, feedback will be gathered from the patient regarding their experience in the study, any challenges encountered, and suggestions for improvement. This feedback will be collected through an anonymous, free-response online survey, as well as a brief interview in which the patient can discuss any issues identified during the study with the investigator.

The study protocol is summarized in Figure 1.

Figure 1. Comprehensive overview of the study protocol. As shown, patients in the control group will attend 3 on-site study visits. In contrast, patients in the Mediterranean diet intervention group will attend 3 on-site visits as well as 2 additional remote visits. Participants in the intervention group will receive 4 L of EVOO at weeks 0 and 8 (500 mL per week). Blood tests will be conducted at week 0 and week 16 in both groups. EVOO: extra virgin olive oil; PASI: Psoriasis Area and Severity Index.



Outcomes

The primary outcome is the change from baseline in the PASI at week 16. PASI is the most widely used scale for assessing psoriasis severity and informing therapeutic decisions, with scores ranging from 0 (no lesions) to 72 (severe lesions across the entire body surface) [18].

The secondary outcomes include:

1. Change from baseline in adherence to the MedDiet at week 16: Adherence will be assessed using the validated er-MEDAS questionnaire, which scores from 0 to 17, with higher scores indicating better adherence [17].
2. Change from baseline in anthropometric parameters at week 16: This includes weight, BMI, and abdominal circumference, measured before and after the intervention.
3. Change from baseline in serum inflammatory interleukins at week 16: Levels of various ILs and cytokines will be assessed, including granulocyte-macrophage colony-stimulating factor, interferon gamma (IFNγ), IL-1β, IL 2, IL 4, IL 5, IL 6, IL 9, IL 10, IL 12 (p70), IL 13, IL 15, IL 17A/CTLA8, IL-17E/ IL-25, IL 17F, IL 21, IL 22, IL 23, IL 27, IL 28A/IFNλ2, IL 31, IL 33/NF HEV (mature), MIP-3α/CCL20, tumoral necrosis factor alpha (TNFα), and TNFβ/Lymphotoxin-α (LTA).
4. Change from baseline in metabolic blood parameters at week 16: changes in serum cholesterol, low-density lipoproteins, high-density lipoproteins, lipoprotein A, apolipoprotein A1, apolipoprotein B, fasting serum insulin, hemoglobin, A_{1c} and C-reactive protein (CRP) will be measured.
5. Change from baseline in the impact of the disease on patient's life at week 16: quality of life will be assessed using the validated questionnaire Dermatology Life Quality Index [18]. Change in sleep quality will be evaluated using the Insomnia Severity Index [19] and emotional state changes will be measured using the Hospital Anxiety and Depression Scale [20].

Data Analysis

Once data collection is complete, statistical analysis will be performed using StataIC 17 (Stata Corp). A descriptive analysis of the baseline demographic and clinical characteristics of the patients included in the trial will be conducted. Normality will be assessed using skewness, kurtosis, and histogram plots. Parametric variables will be reported as mean (SD), nonparametric variables as median (IQR), and categorical variables as n (%).

To evaluate differences between the intervention groups, statistical significance will be assessed using the Student *t* test for comparing 2 groups and the ANOVA test for comparisons involving multiple groups, for parametric variables. For nonparametric variables, the Wilcoxon rank-sum test and Kruskal-Wallis test will be applied. Pearson chi-square test will be used for categorical variables. An intention-to-treat analysis will be performed.

Linear mixed-effects models will be used to assess changes in nutritional variables from baseline to follow-up visits. Statistical significance will be determined using a 2-tailed level of significance, with *P* values less than .05 considered significant.

Ethical Considerations

The study protocol (version 2.0; July 10, 2023) was approved by the Institutional Review Board of the Hospital Ramón y Cajal (Madrid) in July 2023 (170/23).

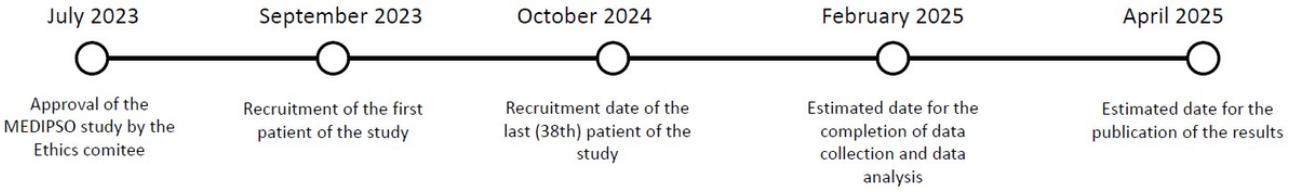
All personal and clinical information of potential and enrolled participants will be coded and used exclusively for clinical trial

purposes. This information will be securely stored in the BioeBank 3.01.0.R26 storage system. Access to this data will be restricted to the investigators involved in this study. No monetary compensation was provided to the participants.

Results

Enrollment concluded in October 2024, with data collection set to finish by February 2025. The findings will be presented at national and international conferences and published in peer-reviewed journals. The estimated study timeline is illustrated in Figure 2.

Figure 2. Estimated study timeline. MEDIPSO: Impact of the Mediterranean Diet on Patients with Psoriasis.



Discussion

Expected Findings

The relationship between psoriasis and the MedDiet has been explored in several cross-sectional studies. Barrea et al [21] conducted a case-control study involving 62 patients with untreated moderate-to-severe psoriasis and 62 healthy controls matched for age, sex, and BMI. This study found that patients with psoriasis were less adherent to the MedDiet than healthy controls. In addition, the consumption of EVOO and fish were identified as predictors of a lower PASI [21]. Similarly, Korovesi et al [22], in a study with a comparable design, reached analogous conclusions and also highlighted the beneficial effect of legume consumption on PASI reduction. Furthermore, Molina-Leyva et al [23] observed a lower severity of psoriasis in patients with greater adherence to the MedDiet, along with a reduction in CRP, a marker of systemic inflammation.

Despite the growing evidence suggesting the potential benefits of the MedDiet in psoriasis, the current evidence remains weak, primarily limited to nonexperimental studies [10]. In an attempt to provide more robust data, Castaldo et al [8] designed an experimental study where an aggressive weight loss was induced through a ketogenic diet followed by a hypocaloric Mediterranean-type diet. Significant reductions in skin involvement were observed, as measured by PASI. Interestingly, no linear correlation was found between weight loss and PASI, suggesting that ketone bodies and other dietary components from both dietary patterns may contribute to the observed anti-inflammatory effects [8]. However, the study's design lacked a control group, making it difficult to attribute the anti-inflammatory effects solely to the dietary intervention. In addition, the study only included obese patients, leaving unanswered the critical question of whether these potential benefits of the MedDiet could also be observed in patients with normal weight.

The molecular mechanisms underlying the potential benefits of the MedDiet on psoriasis severity are not yet well characterized. Beyond psoriasis, greater adherence to the MedDiet has been shown to reduce the severity of other immune-mediated diseases, such as rheumatoid arthritis [24] and inflammatory bowel disease [25]. This observation has shifted attention toward the MedDiet's potential systemic anti-inflammatory effects. Olive oil, a key component of the MedDiet, is rich in monounsaturated fatty acids. Virgin olive oil, in particular, retains all the lipophilic components of the olive, as well as α-tocopherol and phenolic compounds—molecules with strong antioxidant properties—whereas refined olive oil loses most of its antioxidants during the refining process [26]. Supporting this hypothesis, Mena et al [27] conducted a clinical trial demonstrating that patients who followed a MedDiet supplemented with EVOO exhibited a down-regulation of proinflammatory biomarkers associated with atherogenesis, including serum IL-6, soluble intercellular adhesion molecule-1, and CRP [27].

Our study's prospective and longitudinal design offers a valuable opportunity to assess how different inflammatory molecules vary following a dietary intervention specifically in psoriasis, potentially illuminating the molecular mechanisms by which the MedDiet exerts its effects in immune-mediated diseases. A key strength and distinguishing factor of this study compared with previous research is the inclusion of a control group, which enhances the ability to attribute observed changes directly to the dietary intervention. This is particularly important given the frequent use of topical treatments in psoriasis patients, regardless of systemic therapy, and the episodic nature of psoriasis, where spontaneous improvements in severity can occur. In addition, maintaining close contact with a small cohort of patients will enable a thorough evaluation of logistical challenges, which will be crucial for planning future larger-scale multicenter trials.

Several limitations of the study design should be noted. First, this is a unicentric clinical trial, which may limit the external validity of the results. In addition, the interventional nature of the study—characterized by close follow-up and the free provision of EVOO—may mean that the findings are not generalizable to all patients with psoriasis. Furthermore, the MedDiet intervention and follow-up period is limited to 4 months, and the sample size is relatively small, potentially resulting in insufficient statistical power for some analyses. However, these limitations should be viewed in the context of the study's proof-of-concept nature.

Strengths and Limitations of This Study

First, there are no firm dietary recommendations that can be provided to patients with psoriasis. This study is a pioneering effort in implementing the MedDiet in this patient population,

drawing on the expertise of epidemiologists and nutritionists who have specialized in MedDiet interventions, particularly in prestigious studies like the PREDIMED clinical trial.

Second, multiple outcomes resulting from the intervention such as psoriasis severity, cardiometabolic parameters, inflammatory cytokines, and quality of life will be evaluated. In addition, this clinical trial is designed to pave the way for a larger study, involving more patients, multiple centers, and extended follow-up periods.

Third, a possible limitation of this study is the relatively small sample size and the intervention duration of only 4 months, which reflects the proof-of-concept nature of the study.

Finally, the results of the nutritional intervention may not be generalizable to all patients with psoriasis for 2 reasons. First, the study population consists of patients with mild-to-moderate psoriasis who attend dermatology clinics, potentially indicating a higher level of health engagement than the general population. Second, while the provision of EVOO is a strength of the study, it may present a barrier in real-world situations due to the high cost of this product.

In conclusion, the MEDIPSO study was designed to generate high-quality evidence on the relationship between the MedDiet and psoriasis. Through this clinical trial, we aim to explore the anti-inflammatory effects of the MedDiet and their manifestation at both the clinical and molecular levels. In addition, this study is intended to lay the groundwork for future research in this area.

Abstract

Background: Anal fissure is a common proctologic condition that causes significant pain and anguish to patients, significantly impacting their quality of life and well-being. There are various treatment options for anal fissure, ranging from pharmacological agents that reduce anal sphincter tone to surgical interventions for cases resistant to medical management. Ayurvedic treatments have shown potential for the therapeutic management of anal fissure.

Objective: This clinical study aims to analyze the efficacy and safety of murivenna anal infiltration compared to diltiazem topical application in chronic anal fissure.

Methods: This is an open-labeled, randomized, controlled parallel group clinical trial with a sample size of 66 participants to be randomized and allocated in a 1:1 ratio to 2 groups. The intervention group will be treated with murivenna anal infiltration, and the control group will be treated with topical application of diltiazem for a period of 4 weeks. The primary outcome will be the proportion of participants demonstrating complete healing after 4 weeks of treatment. The secondary outcomes will be the proportion of participants demonstrating complete healing after 7 days and 14 days of treatment, change in pain at or after defecation, cessation of bleeding, and any recurrence during the study period. Any adverse events will also be recorded during the trial period.

Results: The project was funded in July 2023, and the study period is 24 months. Participant recruitment started in December 2023. As of August 2024, we have enrolled 50 participants. The data analysis will be complete by June 2025, and the results are expected to be published by August 2025.

Conclusions: High recurrence rates, adverse effects, incomplete healing, and the negative impact on patients' daily activities and quality of life underscore the need for alternative therapeutic options. Ayurveda offers potential for more sustainable relief with fewer adverse effects. Murivenna oil is a time-tested medicated oil effectively used by Ayurvedic physicians for various ulcers of traumatic and pathological origin. This study will provide scientific evidence on the efficacy and safety of murivenna anal infiltration; further, it can be incorporated into the cost-effective management of chronic anal fissure.

Introduction

Anal fissure is a painful tear or split in the distal anal canal. It is a common proctologic condition characterized by intense, prolonged anal pain after defecation, bleeding, and a significant deterioration in the patient's quality of life. The symptoms of anal fissure are a cause of considerable morbidity to the patient. The condition presents with symptoms including severe pain on defecation, which lasts from a few minutes to several hours, bleeding from the rectum, anal discharge, and swelling. If acute, there may be severe pain; the intensity will be comparatively less in the chronic phase. Spontaneous healing of anal fissures is rare due to the reactive spastic contraction of the internal anal sphincter, which diminishes blood flow to the affected area. This constriction impedes the natural healing process, prolonging the duration of symptoms such as pain and bleeding. Therapeutic intervention is often required to alleviate discomfort and promote healing. Various treatment modalities aim to relax the anal sphincter, increase blood flow, and facilitate tissue repair, thereby addressing the underlying cause and promoting resolution of the fissure. Conservative management includes, among other approaches, bulk agents, stool softeners, warm sitz baths, botulinum toxin injections, or topical application of ointments like diltiazem and glyceryl nitrate [1]. New treatment options, such as hyperbaric oxygen therapy to increase tissue oxygenation and induce wound healing, are now being studied [2]. Considerable drawbacks are reported, such as recurrences, toxicity, headaches, and giddiness, while using these external ointments [3]. Surgical treatment is adopted for those cases in which nonsurgical treatment for more than 6 to 8 weeks does not produce desirable results or when there is a recurrence of anal fissure. Surgical treatments include Lord dilatation, lateral internal sphincterotomy, advancement flaps, and fissurectomy [4,5]. Complications of surgical treatments include incontinence to flatus and feces, nonhealing external wounds, abscess, and fistula formation [6]. Miscellaneous novel therapies such as sacral nerve stimulation, autologous adipose tissue transplantation, and posterior tibial nerve stimulation are now being examined as alternatives to lateral sphincterotomy and reliable procedures to avoid fecal incontinence [7]. However, pharmacological modalities are more preferred for treatment of anal fissure, as they are well tolerated, with minimal to no side effects. *Susrutha Samhitha*, a comprehensive Ayurvedic textbook on surgical and parasurgical practices of ancient India, mentions anal fissures as being iatrogenic, and mentions a condition called *parikartika* ("cutting pain in the anus") in the context of *vaidya nimitha bastivyapat* ("indiscretion of the clinician while administering a medicated enema") and *gudakshata* ("ulceration/injury in the anus") in *bastinetravyapat* ("complications due to the enema pipe"). The book further says that this condition should be treated in the same way as traumatic wounds [8]. The *Susrutha* advocates oil irrigation or infiltration to pacify *pitta dosa* (metabolic and biochemical processes that generate heat), which is considered pivotal in the pathology of inflammation and wound formation. [8] *Murivenna* oil is a time-tested medicated oil that treats various exogenous and endogenous ulcers. The drugs used for the preparation of murivenna oil, namely *Aloe vera*, *Pongamia glabra*, *Borreria hispida*, *Asparagus racemosus*, and *Moringa oleifera* are *pittasamaka* (pacifying *pitta*) and *vranavasadana* (ie, they reduce the hypergranulation of wounds). Further, they have been proven to have analgesic and anti-inflammatory properties [9]. Murivenna can potentially help to lessen pain and spasm and promote healing of anal fissures. Further, the anal infiltration process enables the medicine to be retained in the anal canal for an extended period, which can help in reducing increased sphincter tone and associated symptoms.

Hence, this clinical study will compare the effect of murivenna anal infiltration against diltiazem topical application in the treatment of chronic anal fissures. The primary objective of the study is to determine the efficacy of murivenna anal infiltration for healing of anal fissures in comparison with a topical application of 2% diltiazem. The secondary objectives are to determine the safety and efficacy of murivenna anal infiltration for the reduction of pain and bleeding and the prevention of recurrences of anal fissure in comparison with the topical application of 2% diltiazem.

Methods

Study Design and Setting

The study is an open-label, randomized, controlled, parallel group clinical trial conducted at the National Ayurveda Research Institute for Panchakarma (NARIP), Cheruthuruthy, Thrissur District, Kerala, India. The schedule of enrollment, intervention, assessments, and follow-up visits for the study participants is given in Table 1.

Table 1. Schedule of screening, enrollment, intervention assessments, and follow-up in the clinical trial.

Content	Screening	Intervention period					Follow-up period				
		Day 1 (baseline)	Day 8	Day 15	Day 22	Day 30 (treatment end)	Day 60	Day 90	Telephonic follow-up

Study Participants

Inclusion Criteria

Participants of either sex will be included if they are in the age group of 16-65 years, have a chronic anal fissure persisting for more than 6 weeks, are capable of and freely willing to provide written informed consent prior to participation in the study, and comply with the study protocol requirements.

Exclusion Criteria

Individuals with comorbidities, including uncontrolled diabetes mellitus, hypertension, anemia, malnourishment caused by systemic disease, fistula in ano, hemorrhoids, perianal abscess, clinically evident fecal incontinence and anal stenosis/fibrosis, inflammatory bowel disease, tuberculous ulcer, malignancies, HIV, clinically significant renal disease, hepatic disease and cardiovascular disease, psychological disease (eg, anxiety and depression), and active substance abuse will be excluded; participants using medications hampering wound healing will also be excluded. Patients with fissures associated with abscess, drug-induced fissures, fissures resulting from external trauma, fissures located at lateral locations, and multiple fissures will be excluded. Participants using oral calcium channel blockers, having sensitivity to the intervention drugs or calcium channel blockers, with frequent history of headaches, or using drugs such as steroids or nonsteroidal anti-inflammatory drugs, either for fissure or any other unrelated disease or condition, will be excluded from the study. Pregnant and lactating women and participants who have used either of the trial interventions within 30 days prior to the trial's randomization will be excluded from the trial.

Study Intervention

Participants in the intervention group will be treated with anal infiltration of murivenna oil for 4 weeks. The medical team will administer the oil through the anal canal using sterilized rubber tubes attached to syringes at baseline. Either the participant or the attendee will receive education on the procedure and will be asked to perform the procedure on subsequent days until the next visit. The participant should lie down for 15 minutes after completing the procedure. In the first week, the patients will receive anal infiltration of 30 ml of murivenna oil once daily, and for the remaining 3 weeks, they will receive anal infiltration of 20 ml of murivenna oil once daily. During the trial period, participants in the intervention group will receive *triphala choornam* (another Ayurvedic medicine; 10 g) at bedtime as a mild laxative, and the participants will be further advised to perform a sitz bath with triphala kashayam once a day. Participants in the control group will be treated with 2% diltiazem gel for 4 weeks. They will be instructed to apply the gel at least 1.5 cm to 2 cm into the anus in the morning and at night after the sitz bath. During the trial period, participants in the control group will receive lactulose syrup (15 ml) at bedtime as a laxative. Participants in both groups will be advised to consume foods rich in dietary fiber and avoid activities that could cause microtrauma to the anus, such as prolonged sitting or traveling on a bicycle or motorcycle.

The murivenna oil was manufactured at the Good Manufacturing Practices (GMP)–certified pharmacy at NARIP, and the triphala choornam was manufactured by a GMP-certified pharmacy at the Central Ayurveda Research Institute, Jhansi, India, as per the respective standards available in the Ayurvedic

Pharmacopoeia of India [10]. Table 2 lists the ingredients of murivenna oil.

Table 2. Ingredients of murivenna oil.

Serial number	Ingredient	Sanskrit name	Quantity	Part used
1	*Pongamia glabra* Vent	Karanja	384 g	Bark
2	*Piper betle* L	Tambuli	384 g	Leaf
3	*Aloe vera* L	Ghritakumar	384 g	Leaf
4	*Erythrina indica* Lam	Mura	384 g	Leaf
5	*Allium cepa* L	Palandu	384 g	Bulb
6	*Moringa oleifera* Lam	Sobhanjana	384 g	Leaf
7	*Borreria hispida* (L) Schum	Madanaghanti	384 g	Whole Plant
8	*Asparagus racemosus* Wild	Shatavari	192 g	Rhizome
9	Coconut oil	__[a]	768 ml	Oil

[a]Not applicable.

Outcome Measures

The primary outcome will be the proportion of participants who undergo complete healing after 4 weeks of treatment. The secondary outcome measures will include the proportion of participants with complete healing after 7 days and 14 days of treatment, respectively. In the present context, we define healing of the fissures as the disappearance of symptoms and the evidence of fissure re-epithelization, which the investigators will record based on an examination. The investigators will categorize the healing as follows at each follow-up visit: none, partial, or complete.

Another secondary outcome measure will be the mean change in pain intensity during or after defecation. The investigators will ask the participants to record their pain intensity during or after defecation over the last 24 hours using a 100-mm visual analog scale at each follow-up. The investigators will also record how long it takes for participants to experience an improvement in pain intensity and cessation of bleeding, as well as how many participants require analgesics for pain relief. The investigators will advise the participants to log their pain intensity, bleeding status, and any need for analgesics in diary log sheets. The team will issue these sheets on the baseline day, as well as on the 8th, 15th, and 22nd days. Investigators will educate the participants on how to fill out the sheets. The participants will be followed up for 5 months after the intervention period to record any recurrence of anal fissure.

Safety Outcomes

Participant-reported adverse events (AEs) during the trial period will be recorded on every scheduled follow-up visit in a structured format. All AEs during the study will be monitored and appropriate care will be provided. There have been no past reported AEs for murivenna anal infiltration [11]. The predictable AEs for triphala choornam include loose stools, obstipation, change in the sense of taste, nausea, skin lesions, and tiredness [12]. Dizziness, headache, weakness, nausea, or swelling of the hands or feet may rarely occur with the use of diltiazem ointment [13]. Diarrhea, bloating, nausea, vomiting, and stomach pain are reported side effects of lactulose syrup. Rarely reported serious AEs include weakness and irregular heartbeat [14].

Withdrawal Criteria

Participants not willing to continue or who are noncompliant with the study procedures (a minimum 80% compliance is essential to continue in the study) will be withdrawn from the study. Participants developing life-threatening complications or any other severe illness because of another pathology that requires urgent treatment will also be withdrawn from the study. Participants developing serious AEs or treatment-induced AEs requiring hospitalization will be withdrawn from the study. It will be ensured that these participants receive appropriate incidental care or are referred to a higher medical facility if required. The reasons for withdrawal will be recorded in the participant's case record form (CRF). The sponsor and the ethics committee will be informed within 2 working days, and will be provided with proper justification.

Sample Size

The sample size was calculated based on the previous differences in the proportion of participants having complete healing of anal fissures between study groups. In a previously published study, 25% of participants had complete healing of anal fissure by the fourth week of treatment with 2% diltiazem gel, and based on the results of another previously published observational study, we assumed that fissures would heal in nearly 60% of participants treated with the trial intervention [11,15]. A sample size of 30 per group is needed to achieve 80% power with a 95% CI. Adding an attrition rate of 10% results in a sample size per group of 33. Therefore, a total of 66 participants will be enrolled in the trial.

Recruitment

Participants from the outpatient department of NARIP diagnosed with chronic anal fissure will be screened for their eligibility to participate in the clinical trial. Informed consent will be obtained from the participants before screening. Participants eligible as per the inclusion and exclusion criteria will be allocated to one of the study groups based on the randomization schedule.

Randomization and Allocation Concealment

A computer-generated randomization number sequence with block randomization will be created by the study statistician independently of the investigators undertaking recruitment and subsequent visits. The statistician will use Stata (version 16; StataCorp) to generate a random sequence, ensuring that each participant is randomly assigned to one of the study arms in a 1:1 ratio. The assignments will be enclosed in sequentially numbered, opaque, sealed envelopes, which will be opened by the participants at the time of enrollment.

Compliance

Compliance with the prescribed medicines will be monitored through a compliance assessment form issued to the participants on each visit. The participants will be instructed to complete the assessment form after each medicine intake or administration. In addition, compliance will be evaluated by counting the number of containers and tubes returned and the approximate quantity of medications used by each participant. A minimum of 80% compliance is essential for the participant to continue the study.

Concomitant and Rescue Medication

The participants will be instructed to inform the investigators before taking any type of medication apart from the trial drugs. The investigators will record the details of the medications and the reason for taking them in the CRF. If there is any medical emergency, the use of any rescue medication will be permitted, and this medication will be recorded in the relevant section of the CRF.

Data Collection and Documentation

Before conducting this clinical study, the investigators and research team will be uniformly trained on Good Clinical Practice (GCP) protocols, trial-specific processes, and documentation. The research team will collect the information and fill in the details in the CRF (Table 1 provides details) for each visit. All documented data will be checked regularly by the principal investigator (PI) to avoid mistakes and omissions. Any modifications made will be clearly visible, and the corrections will be signed and dated by the PI. The data will subsequently be recorded in an e-format and verified as required; the original CRFs will be archived in order with a search catalog.

Statistical Analysis

All statistical data analyses will be performed using SPSS (version 26.0; IBM Corp). Categorical data will be presented as numbers (percentages) and will be compared using the χ^2 test or Fisher exact test. Continuous variables will be described with either means and SDs for data with a normal distribution or median and IQR for nonnormally distributed data. The within-group analysis will be done using a 2-tailed paired sample *t* test for normal data, whereas the Wilcoxon signed-rank test will be used to compare nonnormal data. Comparisons between the experimental and control groups at each time point will be done using an independent sample 2-tailed unpaired *t* test or Mann-Whitney test for normal and nonnormal data, respectively. $P \leq .05$ will be considered statistically significant.

Monitoring

The monitoring committee set up by the sponsor will conduct on-site or virtual monitoring to ensure adherence to the trial protocol and compliance to GCP and the Central Council for Research in Ayurvedic Sciences Research Policy.

Trial Audit

The regulatory authorities, the institutional ethics committee (IEC), or the funding agency will audit the trial, and the investigators will ensure access to all the documents related to the study for the on-site audit.

Ethical Considerations

The study has been approved by the IEC of NARIP (8/16/23/NARIP/Tech meeting/2511; March 31, 2023) and has been registered prospectively at Clinical Trials Registry - India (CTRI) (CTRI/2023/09/057330). The study will be conducted in accordance with the Indian Council for Medical Research National Ethical Guidelines for Biomedical and Health Research on Human Participants (2017). Written informed consent (in English and Malayalam) will be obtained from the eligible participants before screening. All protocol modifications will be communicated to the IEC and funding agency and corrected accordingly in the CTRI. The CRFs will be stored in a secure area, and the participants' data will be coded to ensure confidentiality. The study participants will be given routine medical care, if required, after the completion of the study period. The study participants will be compensated for any financial losses (eg, loss of wages) with an incidental support of Rs 300 (US $3.49) for each visit.

Results

The project was funded in July 2023, and the study period is 24 months. The participant recruitment was started on December 2023. As of August 2024, we have enrolled 50 participants. The data analysis will be complete by June 2025, and the results are expected to be published by August 2025. The study outcomes will be disseminated through research articles in peer-reviewed scientific journals and presentations at national conferences.

Discussion

This randomized, open-label clinical trial is expected to assess the effect of murivenna anal infiltration compared to topical application of diltiazem in the treatment of chronic anal fissure.

Strength

This is the first randomized clinical trial to evaluate the efficacy of murivenna anal infiltration for chronic anal fissure. The quantitative outcome measures included in this trial will yield valid data for clinical use of murivenna for the treatment of anal fissure.

Limitations

The study is being conducted at a single center, and hence participants from only a single area are included in the trial. The study will apply to countries where Ayurveda is practiced. However, the procedure can be performed by trained persons of other countries provided they have regulatory permission to

use murivenna and triphala choornam. Further, single-pack administrations with a fixed dose of murivenna may be considered for better patient adherence.

Conclusion

If this clinical trial proves effective, medical professionals can consider murivenna anal infiltration as a potential alternative therapeutic option, which may further be incorporated into cost-effective management for chronic anal fissure.

Acknowledgments

The Central Council for Research in Ayurvedic Sciences, Ministry of Ayush, government of India, is funding this study. The funding agency also provided technical support for study design and development of the study protocol. We thank the director and assistant directors of the National Ayurveda Research Institute for Panchakarma, Cheruthuruthy, for their immense support and guidance. We would also like to thank Dr Rabinarayan Acharya, director general of the Central Council for Research in Ayurvedic Sciences, for the support.

Abstract

Background: The increasing development and spread of artificial and assistive intelligence is opening up new areas of application not only in applied medicine but also in related fields such as continuing medical education (CME), which is part of the mandatory training program for medical doctors in Germany. This study aimed to determine whether medical laypersons can successfully conduct training courses specifically for physicians with the help of a large language model (LLM) such as ChatGPT-4. This study aims to qualitatively and quantitatively investigate the impact of using artificial intelligence (AI; specifically ChatGPT) on the acquisition of credit points in German postgraduate medical education.

Objective: Using this approach, we wanted to test further possible applications of AI in the postgraduate medical education setting and obtain results for practical use. Depending on the results, the potential influence of LLMs such as ChatGPT-4 on CME will be discussed, for example, as part of a SWOT (strengths, weaknesses, opportunities, threats) analysis.

Methods: We designed a randomized controlled trial, in which adult high school students attempt to solve CME tests across six medical specialties in three study arms in total with 18 CME training courses per study arm under different interventional conditions with varying amounts of permitted use of ChatGPT-4. Sample size calculation was performed including guess probability (20% correct answers, SD=40%; confidence level of 1–α=.95/α=.05; test power of 1–β=.95; $P<.05$). The study was registered at open scientific framework.

Results: As of October 2024, the acquisition of data and students to participate in the trial is ongoing. Upon analysis of our acquired data, we predict our findings to be ready for publication as soon as early 2025.

Conclusions: We aim to prove that the advances in AI, especially LLMs such as ChatGPT-4 have considerable effects on medical laypersons' ability to successfully pass CME tests. The implications that this holds on how the concept of continuous medical education requires reevaluation are yet to be contemplated.

KEYWORDS

ChatGPT; artificial intelligence; large language model; postgraduate education; continuing medical education; self-assessment program

Introduction

ChatGPT-4 is the latest development in the large language model (LLM) family from ChatGPT. It is said to be trained on more than one trillion parameters, making it one of the most advanced LLMs currently available for generating conversation-style responses to user input. The parameters are the numerical values that determine how a neural network processes input data and produces output data. They are learned from data during the training process, encoding the model's knowledge and skills [1].

Since its launch by OpenAI, the ChatGPT family has stimulated widespread conversation and momentum across different specialties in medicine, as demonstrated by more than 3300 publications related to ChatGPT (or Chat-GPT) indexed in PubMed as of mid-May 2024. Generally, LLMs enable humans to interact and discuss a broad range of topics with artificial intelligence (AI) chatbots. New features of ChatGPT-4 include the acceptance of images as input and the generation of captions, classifications, and analyses, which were not available in earlier versions. Compared to its predecessors, ChatGPT-4 is 82% less likely to respond to inappropriate content requests and 40% more likely to provide factual answers than GPT-3 in internal evaluations [2].

After its success in passing the United States Medical Licensing Examination, performing at a level comparable to that of a third-year medical student [3], these results have been largely confirmed across various medical specialties. Comparisons with different ChatGPT versions and other LLM providers, such as Google, support these findings [3-13]. There are currently two reviews on this topic [14,15], and recent data specific to Germany have been published [16].

In conclusion, there is now a range of data on the use of LLMs in undergraduate education and teaching but less on postgraduate education, such as continuing medical education (CME) [17] or self-assessment programs [4]. Table 1 shows a selection of studies on this topic.

In Germany, CME, which is mandatory for medical specialists, requires earning 250 training points over five years. These CME points can be acquired through further specialization, attending congresses and conferences, and studying medical literature with consecutive answers to specific questions in the text. This approach essentially "credits" the self-study time spent attentively reading a text and then answering questions.

For this study, we decided to use ChatGPT-4 because of its extensive database and ability to enter texts directly. Additionally, the input and operation of ChatGPT are carried out by adult high school students without any prior medical training. This was to differentiate as clearly as possible whether and to what extent LLMs can offer support today. This study aims to provide further insight into whether AI, in the form of LLMs, can support various levels of medical education by correctly answering CME-relevant questions, allowing participants to generate CME credits independently of existing medical knowledge.

Table 1. Data on ChatGPT and postgraduate medical education (continuing medical education or self-assessment programs).

First author	Year	Study	Comparator	Major findings	Conclusions
Sherazi and Canes [4]	2023	Comparative trial	ChatGPT-3.5 versus ChatGPT-4	GPT-4 scored significantly higher than GPT-3.5 on the AUA[a] SASP[b] examinations in overall performance, across all test years, and in various urology topic areas.	Results suggest improvement in evolving AI[c] LLM[d] in answering clinical urology questions. Certain aspects of medical knowledge and clinical reasoning remain challenging for LLM.
Riedel et al [16]	2023	Comparative trial	Performance of ChatGPT on OB/GYN[e] course examinations versus questions from the German medical state licensing examinations	ChatGPT demonstrated consistent and comparable performance across both datasets, providing correct responses at a rate comparable with that of medical students.	ChatGPT has promise as a supplementary tool in medical education and clinical practice, providing efficient and personalized learning experiences and assistance for health care providers.
Noda et al [18]	2024	Comparative trial	ChatGPT-3.5 versus ChatGPT-4 versus Bard (Gemini)	GPT-3.5 and Bard performed similarly while being significantly surpassed by GPT-4. GPT-4's performance was between third- and fourth-year nephrology residents.	GPT-4 outperformed GPT-3.5 and Bard, meeting the Nephrology Board renewal standards in specific years, albeit marginally. The results highlight LLMs potential and limitations.
Ali et al [6]	2023	Comparative trial	ChatGPT-3.5 versus ChatGPT-4 versus user average	GPT-4 significantly outperformed question bank users and GPT-3.5. Increased word count and higher-order problem-solving were associated with lower accuracy for GPT-3.5 not however for GPT-4.	LLMs achieved passing scores on a mock 500-question neurosurgical written board examination, with GPT-4 significantly outperforming ChatGPT.
Watari et al [13]	2023	Comparison study	Chat GPT-4 versus Japanese Residents' performance on GM-ITE[f]	Of 137 GM-ITE questions in Japanese, GPT-4 scores were significantly higher than the mean scores of residents.	GPT-4 demonstrated a tendency to score higher on difficult questions. However, GPT-4 scored comparatively lower on questions testing attitudes toward patients and professionalism requiring an understanding of context and communication.
Guerra et al [5]	2023	Comparative trial	ChatGPT-4 versus ChatGPT, SANS[g] users, medical students, and neurosurgery residents	GPT-4 outperformed ChatGPT exceeding the performances of medical students, neurosurgery residents, and the national average of SANS users across all categories.	GPT-4 significantly outperformed medical students, neurosurgery residents, and the national average of SANS users.

[a]AUA: American Urological Association.

[b]SASP: self-assessment study program.

[c]AI: artificial intelligence.

[d]LLM: large language model.

[e]OB/GYN: obstetrics and gynecology.

[f]GM-ITE: General Medicine In-Training Examination.

[g]SANS: self-assessment in neurosurgery examination.

Methods

Study Design

This is a randomized controlled trial that will be undertaken following the Declaration of Helsinki principles and after approval by the local Ethics Committee of Witten/Herdecke University (S-108/2024, date of approval May 15, 2024) and after registration in a study register (open scientific framework). To obtain representative, comprehensive, and meaningful data, three large German publishing houses (Deutscher Ärzteverlag GmbH, Cologne; Georg Thieme Verlag KG, Stuttgart; and Springer Medizin Verlag, Heidelberg) that offer journals with CME will be evaluated for one volume each of already expired journals (ie, without the possibility of earning credit points) from the fields of internal medicine, surgery, gynecology, pediatrics, neurology, and anesthesiology. The CME tests provided by the publishing houses needed no further adaptation for utilization in the study.

Ethical Considerations

The study protocol which was submitted to and accepted by the Ethics Committee of University Witten/Herdecke (S-108/2024, date of approval May 15, 2024) stated decisively that no monetary or other compensation was to occur. The participant's information was depersonalized by means of not collecting any personal information to begin with, as they were deemed insignificant to the study's results leading to participants enrolling entirely voluntarily. Furthermore, to participate in the study, the students were required to provide a signed informed consent form which all students were given the opportunity to voice concerns and questions and were informed about their ability to revoke their consent without having to provide a reason, while not having to expect any repercussions.

Study Participants

To minimize any influence from prior medical knowledge on the results, adult high school students from North Rhine-Westphalia who are willing to participate will be randomized into three study arms. As high school students can be assumed to be void of relevant medical prior education, the choice to include this group as participants is based on its ability to represent the approximate level of medical knowledge of the general population. The inclusion and exclusion criteria are shown in Textbox 1. It should be emphasized that it is not the high school students who are the participants of the study but the CME course tests to which the methods of the three study arms are applied. Careful considerations were put into the selection of the CME tests screening for images of diseases that students may have deemed disturbing. Such CMEs were excluded. The students were encouraged to voice concerns if the contents of the CME tests resulted in uneasiness. Furthermore, ample opportunity was provided for discussing the students' experiences if deemed necessary by the participants. All these measures aided in minimizing the potential psychological impact of participation in the study. The experience of the participants while attempting to solve the CME tests is not represented in the study's results as they were deemed to exceed the scope of the study. The student's proficiency in the German language was required in the hope of avoiding skewed results based on linguistic incomprehension of the provided literature. The students act purely as "tools," preferably without any medical knowledge of their own.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Aged 18 years or older
- Voluntary participation
- No financial compensation
- German as a native language or at a native speaker level
- Ability to operate ChatGPT or other required software

Exclusion criteria

- Being underage
- Refusal to participate
- Insufficient German language skills
- Inability to operate ChatGPT or other required software

Interventions

This trial is designed as a three-armed randomized controlled trial, including one control arm.

Intervention Group 1: "All-In"

In this group, CME-subject-specific text is entered into ChatGPT-4 first, and then, the questions are answered by ChatGPT based on that input.

Intervention Group 2: "Just Answers"

In this group, questions are answered using only the knowledge available in the ChatGPT-4 database at that time, without entering any subject-specific text first.

Control Group 3: "Search and Find"

Participants in this group were asked to answer the questions using only keywords and common sense without any AI support. As the CME were viewed as digital files, the use of "find in text" of the respective document viewing software was permitted.

The approach to having the CME test questions answered in three study arms aims to uncover significant differences in ChatGPT-4's ability to solve the CME tests, as well as assess the varying time required in the individual study arms.

Data Analysis

Sample size calculation was performed for the hypothesis that CME test results will improve from guess probability (20% correct answers, SD= 40%) to pass level (70% correct answers) with a confidence level of $1–\alpha=.95$, that is, $\alpha=.05$, and a test power of $1–\beta=.95$. Therefore, for an independent-samples, two-sided study, a sample size of at least 18 CME training courses per study arm is needed. Nonetheless, since the CME courses, as our study subjects, can be processed repeatedly using different methods without altering them or the methods, a paired-sample study is possible and preferable. This allows the same CME courses to be used in the three study arms. Although a sample size of 9 for a single-sided paired-sample study would be sufficient (only an improvement in CME test results is expected and desired by applying the study arm methods), we decided to take a conservative route and will work with 18 CME tests that will be run through all three study arms. The CME tests treated were randomly chosen from a large number of available tests. Care was taken to ensure that every high school student completed the same number of tests in each arm of the study so that confounding variables in the students were evenly distributed across the three groups. In addition, none of them would work on a single CME test twice using different methods to avoid learning effects. Together with the reuse of the CME tests in the three study arms (paired study, see above), these measures prevent any bias arising from the high school students

as performing tools or the CME tests themselves as study participants. The AI-supported arms would run through within the shortest possible time and in the correct order so that unwanted training of the AI or the students during the process could be ruled out as much as possible. Statistical data analysis will be performed using the open-source software "R" (R Core Team; 2023). The data is presented as mean ± SD. Since the aim of the study is to identify differences in the percentage test results due to the different approaches in the three study arms, the Student *t* test (1-tailed) or the Mann-Whitney *U* test will be used for the pairwise comparison of means between groups, depending on the normality of the datasets. The Shapiro-Wilk test will be used to check normality. Fisher's exact test was used to assess the independence of categorical variables. Benjamini-Hochberg adjustments of *P* values will be applied in multiple comparisons. Values of $P<.05$ were considered statistically significant.

Results

As of October 2024, we have tested five out of the six students we deemed necessary to examine the 18 CME tests across the three study arms. We are set to terminate the data acquisition by November 2024. The ensuing data analysis is predicted to end in December 2024, enabling us to present our results as early as early 2025.

Discussion

Principal Findings

To present the influence of AI as objectively as possible, we deliberately refrained from using medically trained test participants. This allowed us to identify the pure influence of AI. Depending on the degree of success, it was necessary to determine to what extent AI can be permissible in CME training courses and what conditions or protective measures were to be imposed.

Since its launch in 2023, not only the development of ChatGPT but also its integration into the medical context increased rapidly, as shown by the ever more extensive database versions and the steadily growing number of medical publications [3-6,19-23]. However, as the capabilities of AI increase, so does the responsibility of actual intelligence to use it in the best possible way for the benefit of all without causing harm ("primum nihil nocere"). Even if the use of AI to solve examinations, whether student or specialist examinations, has already been investigated several times, there is still a knowledge gap in postgraduate teaching and its effects. Ethical, social, and above all, legal aspects, also need to be clarified.

AI has the potential to revolutionize various aspects of our lives. In medicine, its strength lies in its wide range of possible applications. However, the use of AI in education, training, and specialization must be clearly labeled, as it presents not only opportunities but also weaknesses and threats, particularly with the use of LLMs such as ChatGPT and related programs [1]. The correct use of AI in postgraduate medical education, especially LLMs, still needs to be explored and discussed.

This study aims to show that medical training tests can be successfully completed by medical laypersons using AI, which raises questions about the continued usefulness of current training programs, potential regulations to prevent misuse, and opportunities to harness AI capabilities in this context. Currently, self-study to obtain CME credits is an integral part of German postgraduate medical education. This study's results may have the potential to influence this practice significantly.

The decision to examine ChatGPT's results in three study arms was based on the hope of being able to compare the results obtained while gaining insight into whether the literature backgrounds of the CME were required to generate significantly superior results.

The rationale behind the choice of medical specialties whose CME tests were analyzed in the study results from ChatGPT-4's ability to merely process text. All the medical specialties we chose to include do not predominantly diagnose based on visual symptoms. However, a new investigation on newer ChatGPT versions, which possess the ability to obtain information from images is underway.

Limitations

This study has several limitations. First, only German CMEs are evaluated. Second, only a minority of specialties were chosen. Finally, we completely dispensed CME with image content, as is usual in radiology, dermatology, or pathology, for example, to avoid changing the selectivity.

How potential biases that result from the data that was used in training the AI tools impacted the results of the study is not derivable, as ChatGPT does not possess knowledge in the classical sense. It is rather the case that lexical data is produced based on prior training.

If knowledge acquired through AI-generated literature is retained differently than medically conventionally attained knowledge is yet to be assessed in future research.

Conclusions

The impact on current on future CME programs should be considered as the certified means of personalizing one's medical education remains scarce. AI could play a role in tailoring continuous education to personalized needs and, for example, adapting the modules based on prior results to target potential individual shortcomings. The role AI could play in medical education provided by university faculties, as well as personalized learning programs surely merits further investigation [24-26].

Acknowledgments

This research received no external funding.

Data Availability

The datasets generated during or analyzed during this study are not yet publicly available as they are yet to be analyzed but can be made available from the corresponding author upon reasonable request.

Authors' Contributions

The conceptualization was a result of cooperation by TS, DG, AB, and CB; the formal analysis was performed by CB, AB, DG, and TS; funding acquisition was accomplished by DG; our methodology was developed by TS, FB, and JE; project administration was supervised by TS and DG; the original draft was written by CB and AB, and it was then rewritten, edited, and reviewed by TS, JE CB, AB, FB, SCT, and DG. Abstract

Background: Clinical trials are known to provide cause-and-effect results and data with low levels of bias. However, a lack of funding for clinical trials, which are considered expensive, means that academic sponsors are rarely able to conduct them. Academic trials are considered highly relevant for the valuable results they provide for clinical questions. This is why initiatives to conduct unfunded clinical trials have been identified as an important issue to pay attention to in future studies. Therefore, we present our initiative through Rogers' theory, which is highlighted in the literature for diffusing innovative change across organizations.

Objective: The purpose of this paper was to describe our case regarding management for conducting a nonfunded nurse-led clinical trial based on our previous low-interventional clinical trial across a specific health organization and with nurses.

Methods: We conducted a low-intervention, nonexternally funded clinical trial using the human and material resources available on site. We managed our trial in a clinical trial unit where there were staff, sources, and ongoing commercial clinical trials. We conducted our trial based on an ongoing commercial trial, and, to do so, we needed behavioral changes. We relied on Rogers' theory, and we identified strengths and barriers to change by analyzing actors' characteristics, perceptions of the situation, motivation, and information. Afterward, we divided the staff according to their characteristics related to innovation and change into permanent staff (research staff with a culture of change) and nonpermanent staff (nursing staff with occasional attendance and resistance to change). First, we preselected only those nurses who were more aware of change (innovators and pioneers) to participate in our trial to avoid a massive rejection, and later, we asked others to join (late adopters). We followed Rogers' phases. For research staff who were aware of the funding, we focused on the "persuasion phase," while for nursing staff, we mixed the "knowledge and persuasion phases" and used pioneers and early adopters as a positive example for other nurses as well as nonfinancial incentives (persuasion). Our trial consisted of different methods of vein cannulation, which was performed in the ongoing commercial trial. Thus, the entire development of our low-interventional clinical trial was conducted without interfering at any point with the parallel commercial clinical trial.

Results: Our management allowed effective conduct of our study, and we met our aims without external funding and without ethical impact during the commercial clinical trial. Costs remained low, primarily because the major expenses were covered by the commercial clinical trial as an inherent part of its design.

Conclusions: Our initiative to conduct a low-intervention clinical trial with no or limited funding was cost-effective. This initiative can be used by researchers with valuable academic research questions who do not have the external funding to conduct studies.

Introduction

Background

Clinical trials are known to provide cause-and-effect results and usually yield high-quality data due to low levels of bias [1]. In addition, clinical trials not only provide the best context for advancing clinical research and health care but also create opportunities to reduce health care costs [2]. Moreover, clinical trials involve key personnel, such as nurses, who can be recruited and trained to carry out a protocol [3]. In the case of clinical research nurses, their ability to work independently has been recognized, but they face practical, ethical, and resource challenges [4]. In particular, the lack of funding for clinical trials, which are considered expensive and involve additional effort (especially investigator-led clinical trials), leads to voluntary activities [5]. It should also be noted that academic sponsors are rarely able to conduct trials without external funding [6]. Therefore, it has become clear that there is a need for increased coordination to ensure that robust research is conducted and to adopt adaptive trial design strategies to respond to the rapidly evolving evidence landscape [7].

Nevertheless, academic trials (ie, trials in which the comparator is usually standard clinical practice [1]) are considered highly relevant due to the valuable results they provide when investigating clinical questions [8]. Academic trials enable comparative data and may lead to changes in practice [5], but researchers in such trials face multilevel challenges, most notably applying for grants and managing funds to pay for participation or study-related injuries [9].

In Europe, between 10% and 30% of clinical trials are conducted by academic or noncommercial sponsors [8], and only a limited number of nurses receive support through funding mechanisms [10] despite evidence showing that trials led by a nurse or physician have noninferior results [11].

Therefore, although our trial is registered at ClinicalTrials.gov (NCT04027218) and our results are published [12], initiatives to conduct nonfunded clinical trials, such as low-interventional clinical trials, have been identified as a major issue to be targeted in future studies [8]. However, implementing initiatives, new ideas, or innovative processes across an organization is challenging. The literature suggests the use of Rogers' curve or Rogers' diffusion of innovation theory to introduce innovation because it applies within and across organizations [13], such as in schools and for teachers [14,15] as well as in health care organizations [16].

Objective

The purpose of this paper was to describe our case of managing the conduct of a nonfunded, nurse-led clinical trial across a specific health organization and with nurses.

Methods

The Field and Study Context

The aim of our initiative was to conduct a phase 4 low-interventional clinical trial without external funding that resulted in low bias, was of high quality, and used available onsite human and material resources.

Thus, we managed our trial in a clinical trial unit where staff and sources were already available. However, up until our trial, almost all clinical trials in this unit evaluated drugs, were financed by the pharmaceutical industry, and involved procedures, particularly venipuncture by nurses, that were performed in the same way.

In other words, the nurses and other research staff in the unit did not participate in a culture of conducting different clinical trials, such as our clinical trial involving medical devices and that proposed changing "the assembly line." In our case, a clinical trial was conducted with different forms of venipuncture, which had previously always been performed using the same technique. This involved changing certain positioning and behavioral barriers.

In the clinical trials unit, there were fixed staff (researchers) and variable staff (nurses). The variable staff consisted of a pool of 20 to 25 nurses who came on occasional days to support the clinical trials but whose main activity was in other hospital departments.

Management and Sampling Access

Rogers' 5 stages of innovation decision-making consist of knowledge, persuasion, decision, implementation, and confirmation information [16]. There are different roles to implementing change. His theory shows that the following roles exist in certain proportions: innovators (2.5%), early adopters (13.5%), adopters (34%), late adopters (34%), and nonadopters (16%). He also considered the minimum threshold for change to be the sum of innovators and early adopters.

Thus, we contemplated the "knowledge phase" for the fixed and variable staff. In the case of workers in the fixed staff component, they were already aware of the problem of obtaining funding to pay employees, so we only focused on the "persuasion phase" as we aimed on getting approval from the director of the unit, who introduced our clinical trial to the fixed and variable staff members.

Another exception had to be made at this stage regarding the expert in blood sample analysis (research staff), as we needed him to analyze our indicators in addition to those that were requested for the unit's trials. Persuasion consisted of suggesting authorship in publications given his interest in his scientific career and the potential for indirect income.

For the variable staff (nurses), we mixed the "knowledge and persuasion phases." We chose to invite only nurses who had the most knowledge or awareness of the change (knowledge) to participate in our clinical trial. In other words, we preselected the nurses (innovators and early adopters) to avoid mass rejection of the trial and to try to allow other nurses to see that a few nurses (innovators and early adopters) had seen this change as a positive step (persuasion). We did not conduct a survey to classify the nurses according to Rogers' roles because we knew the pool of our nurses well and we already knew their positions.

Specifically, to carry out the research, the nurse in charge of this study could not offer any direct payment. We offered to thank the staff in publications, and if anyone wanted to play a more active role in writing manuscripts about this study, they would be positively considered for authorship of articles resulting from the study. The publications are considered professional merit in our country and serve to increase the salary in one's professional career.

Nurse innovators and early adopters agreed to appear in acknowledgements (they did not want to have a more active role) and contribute to the culture and advancement of innovation and research in the nursing profession for colleagues who did not have this insight (late adopters mainly).

In the implementation phase, some nurses (adopters) asked the nurse in charge of the study about the new technique being performed by some collaborating nurses in this study. Therefore, we took advantage of this interest to invite more than one-half of the pool of nurses (adopters and late adopters) to participate in our study. We had a small group of nurses who we knew would not be interested in participating (nonadopters), and they were the last to be invited to participate and declined.

In relation to the fixed staff (research staff), we only focused on the "getting to know" and "confirmation" phases, as they already had knowledge of the project. They were observers, and we only gave them a 20- to 30-minute training on how the study was going to be developed in the unit at the same time a phase 1 clinical trial was being conducted (which was the routine work of the unit) and sought their confirmation to be aligned with the project.

Trial Design

Although our clinical trial protocol was already registered at ClinicalTrials.gov and is freely accessible, we deemed it necessary to provide a brief summary of our trial design so that our management of the field and study context were fully understood.

Study Sample and Eligibility Criteria

Our participants were recruited from the population of individuals who provided written informed consent for the primary clinical trial at the unit (phase 1 bioequivalence study). As shown in Table 1, on the night of first admission (visit 2 in phase 1), participants in the phase 1 bioequivalence study were invited to enroll in our phase 4 clinical trial. They signed the informed consent at that time. Participation in our phase 4 clinical trial was voluntary. We informed participants that this study was a nonfunded study and that no incentive would be provided beyond the payment they received from the phase 1 trial. We also communicated that the potential benefit for them was the expected effective interventions hypothesized in our phase 4 trial (Table 2).

The inclusion and exclusion criteria were the same as those for the bioequivalence trial. In addition, we added 3 criteria for our phase 4 clinical trial that were also compatible with the criteria for the phase 1 trial. These 3 criteria were 6 hours to 8 hours of fasting before vein cannulation, fluid intake limited to ≤500 mL 6 hours to 8 hours before venous cannulation [17], and having been a former participant in a bioequivalence clinical trial at our hospital.

Randomization, Allocation, and Sample Size

Participants were randomized to 1 of 3 interventions and one of the sequences of applying those interventions within 2 periods. Thus, we allocated sequences of 1 intervention and a comparator (1 sequence for each participant).

As Figure 1 shows, randomization was performed at visit 0 of the phase 1 clinical trial after informed consent form was obtained and before participants were screened for inclusion and exclusion criteria for both the phase 4 and 1 trials. As shown in Table 3, we designed 6 sequences.

The study was carried out in the clinical trial unit at our hospital, where bioequivalence clinical trials (phase 1) were performed with groups of 12 participants. Accordingly, we duplicated the 6 sequences used for each group of participants.

Figure 1. Combined fieldwork of the phase 1 and 4 clinical trials. Pk: pharmacokinetics; v: visit.

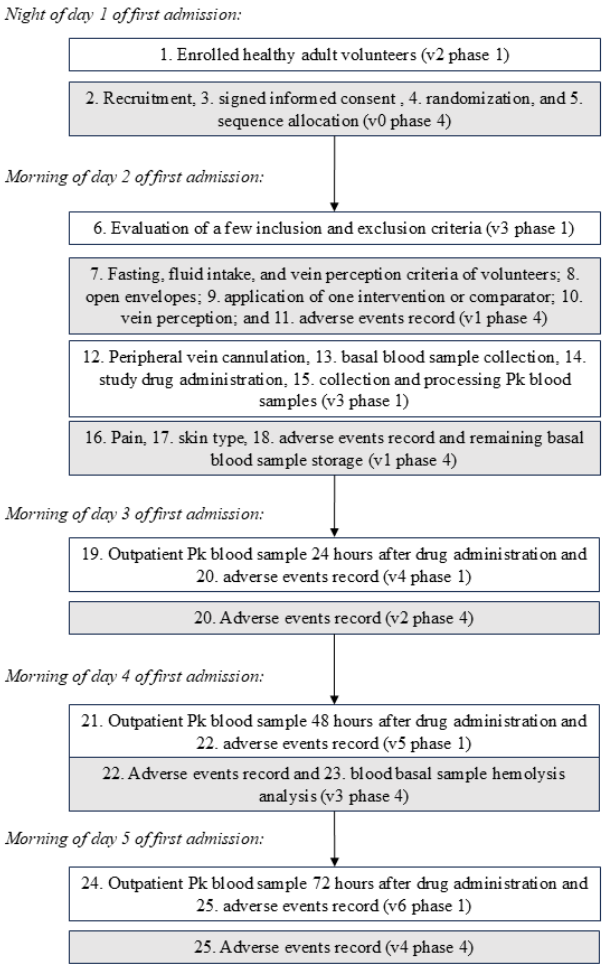

Table 3. Description of the sequences.

No	Sequence	First period	Second period

4	Comparator, dry topical heat	Comparator	Dry topical heat
5	Comparator, high pressure	Comparator	High pressure
6	Comparator, dry topical heat and high pressure	Comparator	Dry topical heat and high pressure

Interventions and the Comparator

Our interventions, given that we designed the additional eligibility criteria, were compatible with the interventions planned in the bioequivalence clinical trial. In the bioequivalence clinical trial, venous cannulation is always performed to obtain blood samples, and we established the following interventions and comparator to avoid interfering with those in the phase 1 trial. First, to apply dry topical heat, 2 bags were heated and placed on each participant's forearm for 7 minutes while an elastic compressor was applied [18]. Second, high pressure was applied via a sphygmomanometer cuff set at 100 mm Hg [19]. Third, for the combined intervention, dry heat was applied followed by pressure per interventions 1 and 2. The 3 interventions had a common comparator (ie, the elastic compressor), which was provided by the hospital and used according to CLSI GP41-A6 guidelines [20], as was performed in the phase 1 clinical trial.

Measures

Vein perception was assessed using the Venous International Assessment scale, which is a validated scale [21]. Vein cannulation was performed using a 20-gauge diameter catheter, and an EDTA K2 blood sample was collected using a Vacutainer blood collection tube (Becton, Dickinson and Company). Pain was assessed using the visual analogue scale, which is validated for acute pain [22]. Skin type was assessed using the Fitzpatrick scale, which has been previously validated [23]. Adverse events were assessed with a severe causality algorithm from the World Health Organization (WHO) [24].

The aforementioned materials are routinely used by nurses in the clinical trial unit and in clinical practice at our hospital. The nurses were familiar with the scales except for the Venous International Assessment scale, Fitzpatrick scale, and WHO algorithm. Therefore, collaborative nurses were trained to administer these tools. We also measured hemolysis in our blood samples, which was performed by an expert who routinely used a NanoDrop 2000 Spectrophotometer (ThermoFisher Scientific) at the unit. Again, we used human and material resources already available in the unit.

Adherence and Monitoring

Our phase 4 clinical trial involved the use of nonharmful interventions. Our interventions delayed vein cannulation by only 7 minutes (heat application), and the data collection did not require extra visits or blood draws. Because our phase 4 clinical trial was a nonfunded study, economic incentives for participants came only from the phase 1 commercial clinical trial. Therefore, the phase 1 trial guaranteed a low dropout rate and adherence to our clinical trial.

According to the low-interventional clinical trial regulations [25], an external monitor was not provided, and the nurse principal investigator conducted the study.

Ethical and Financial Considerations

The research protocol and methodology were approved by the Ethics Committee of the Hospital de La Princesa (Madrid, Spain) under code ECYPVEN-H/17 and registration number 3113.

This was considered a low-interventional clinical trial because "the intervention poses only very limited additional risk to the subject compared to normal clinical practice." We performed our clinical trial based on a phase 1 clinical trial that involved a vein cannulation procedure to ensure participant safety in relation to the same procedure in other clinical trials. Thus, we did not require specific insurance for any potential injury to participants; they were covered by the phase 1 insurance or health system insurance. Data from participants in the phase 1 clinical trial were coded for our study to ensure privacy [25].

Both clinical trial protocols and informed consent forms were in accordance with the Declaration of Helsinki [26]. Specifically, as our clinical trial was concerned with nursing, announcements and information about this trial were made by the nurse who was the principal investigator.

The participants did not receive any remuneration for participation in the low-intervention trial or any other type of compensation.

Furthermore, none of the information appearing in this article allows the identification of data or images of the participants.

We calculated that less than €200 (US $209.50) would be sufficient to cover the overall costs of our phase 4 study, including materials required for our interventions and comparators: 6 pairs of carob seed bags for heat application (4 pairs for use and 2 pairs for backup), 5 sphygmomanometers for pressure application (4 for use and 1 for backup), and 4 timers.

The aforementioned cost overrun was mainly for materials, as the rest of the costs were covered because we used resources from the clinical trials unit where the phase 1 study was conducted.

Blinding

This open study was justified by the complexity of masking interventions (heat or pressure) and operators, as proposed by the CONSORT (Consolidated Standards of Reporting Trials) Statement for Randomized Trials of Nonpharmacologic Treatments [27]. Only the biologist who analyzed plasma sample absorbance was blinded [27].

Results

Our management was effective for conducting a low-intervention study, and we met our objectives without external funding. We conducted a clinical trial in the clinical trial unit of Hospital Universitario de La Princesa (Madrid) during the months of June 2017 and July 2017 with 59 healthy adults who were randomly allocated to 1 of 3 interventions: (1) using dry topical heat for 7 minutes produced by 2 hot seed bags (n=21), (2) applying controlled pressure from a sphygmomanometer inflated to 100 mm Hg (n=18), and (3) combining heat and pressure (n=20). We found that the pressure intervention (n=18) was the most effective for relieving pain, followed by heat (n=21) and the combined intervention (n=20). Furthermore, hemolysis was not significantly affected by any of our interventions, and no serious adverse events occurred [12]. None of the participants dropped out of the study, and a total of 10 nurses who had at least 1 year of experience in the clinical trial unit contributed to the fieldwork of the trial.

Discussion

Main Findings

Our strategy was effective for carrying out a low-intervention, academic clinical trial, as claimed by previous studies. Therefore, we were able to provide an answer to a problem detected in the scientific literature [8].

Our results [12] were consistent with those of previous parallel clinical trials that were funded by (1) a foundation and involved a specific device provided by a manufacturer [18] and (2) a grant [28].

Comparison With Prior Work

Similar to our study sample of 59 participants [8], additional studies have been conducted using 68 participants per group [18] and 36 and 34 participants in 2 groups [28]. In contrast, our study was a crossover, nonfunded study [12]. Although a previous study stated that noncommercial clinical trials recruit fewer participants than commercial trials [1], presumably due to the lack of financial compensation, we could not confirm that statement based on our results.

In addition to the clinical benefits, our results supported our strategy and showed how nurses, who receive relatively little funding (39.4% of total National Institutes of Health funding), can benefit from research funding [29] and lead a high-quality clinical trial without funding. Nurses in a variety of positions are involved in clinical trials, including clinical research nurses (69.7%), research nurse coordinators (17.9%), nurse practitioners (4.4%), and clinical and administrative or program support staff (8%) [30], even if they are not principal investigators [3]. Many are involved in oncology clinical trials [30]. In contrast, our study was conducted with a nurse as the principal investigator [12].

Our trial management was in accordance with the standard framework of Core Competency Domains by the Joint Task Force for Clinical Trial Competency, which consists of 8 domains [31]. Specifically, our study met domains 1 (research design) and 5 (study and site management), which describe a cost-effective, low-interventional clinical trial design and a commercial clinical trial design, respectively. Additionally, domain 7 (leadership and professionalism) [31] was met because our principal investigator was a nurse scientist with a PhD, which the literature highly recommends for research management [3,32].

According to the Rogers' management curve or theory, contextual factors are crucial and, although we were in a suitable environment (clinical trial unit), both the variable and fixed staff had standardized working procedures to reduce variables. Therefore, paradoxically, we agree with other studies [16] that negotiations (persuasion) for the diffusion of innovation are the biggest complication in those environments where there is no routine development of innovative concepts. However, the fixed staff members were easier to persuade due to their professional profile and career and the possibility of authorship in publications or other merits. Furthermore, unlike the aforementioned study, we did not apply the 5 stages of this theory to all variable and fixed professionals, as the latter had a more advanced research and innovation culture.

We also agree with Lundblad [13], as we were able to establish this theory across the health care organization and in a field where work is dedicated to improving research but the traditional theoretical basis does not include diffusion innovation, as in the variable nursing staff. For this reason, we consider our work to be groundbreaking in a collective that is resistant to change [33]; therefore, we could be introducing an innovative initiative according to Rogers' curve.

We also agree with the previous study that less complex innovations (such as our research procedure of vein cannulation) are adopted more quickly than those where the adopter must develop new skills and understanding [16].

Unlike the previous study, we did not conduct an interview to categorize staff profiles according to Rogers' theory, because we believed we knew our pool of nurses (variable staff) and research staff (fixed staff) well and did not need to obtain more information for profile categorization.

We consider that we used the theory adequately, as we were able to conduct our clinical trial and conclude with published results. Furthermore, we agree that this theory is very social, and it depends mainly on two important factors: interpersonal communication relationships and similar actors [13,16]. These were nurse to nurse in our study, rather than doctor or employer to nurse. In our study, the nurses in the pool had very strong rapport and even had a WhatsApp group. Because they asked each other questions through the chat group, they were able to diffuse this innovation. As recommended by Afraz et al [16],

we used the innovators as a factor for promoting diffusion, and we demonstrated that it was effective.

A total of 36.5% of registered clinical trial protocols are sponsored by universities, hospitals, and other academic and nonprofit agencies worldwide [34], although the rate is lower in Spain (ie, 10%-30%) [8]. Noncommercial registered protocols are mainly for phase 4 studies and unmasked, controlled clinical trials. Additionally, only 39.4% of noncommercial protocols registered in ClinicalTrials.gov were published in peer-reviewed scientific journals [8]. However, our nonfunded study was an open phase 4 clinical trial registered in a database and published in a peer-reviewed scientific journal [12].

Additionally, we believe that our nonfunded management benefited from industry-sponsored clinical trials in study design, site selection, quality recruitment support, clinical coordinator centers, and access to study databanks, as Laterre and François [35] proposed that academic and industry trials should be constructive and not opposed.

Controversial statements declare that, compared with commercial studies, academic clinical trials are less restrictive with regards to inclusion and exclusion criteria, have less complex protocols, and have higher external validity than internal validity [1]. Others have reported that methodology clinical trials are as valid as commercial and noncommercial clinical trials; however, blinded and multicontinental trials that are usually conducted by major pharmaceutical companies are still considered superior [34]. Conversely, we believe that academic trials could be as restrictive as commercial trials if they are designed like commercial trials, given that our results were in line with such funded studies [18,28].

Our findings also agree with those of Fuentes Camps et al [8], who highlighted the scarcity of economic resources and suggested that initiatives such as low-interventional clinical trials could fill the void. Our low-interventional management optimizes scientific research by conducting a clinical trial at a cost of approximately €153 (US $186) and without ethical concerns or injury to the participants of the commercial clinical trial.

Clinical trials require specific insurance to cover the potential risks; thus, funding is required [36]. However, clinical trials funded by grants, public institutions [5], or associations [36] usually do not have all their costs met [36]. Therefore, our strategy for a low-interventional trial could be a solution when little or no funding is available. Commercial clinical trials could assume 15% to 22% and 11% to 29% of total costs for clinical procedures and administrative concerns, respectively [5].

Additionally, project management was identified as having a high impact on the total costs of a clinical trial [5] and is usually performed by a coordinator [26]. We agree with the proposal by Bevans et al [30] that a principal investigator who coordinates a single-center clinical trial reduces costs without assuming extra effort.

Contrary to our management, a previous study proposed that a better choice to decrease research costs would be to add a hospital employee to the research team instead of modifying the study design [37]. Although the research question guides the study design [37], we consider that, sometimes, a modified study design could contribute superior benefits from a nonfunded clinical trial for the original or similar research purposes compared with foregoing the study altogether.

As a reflection, if the proposed low-intervention study were to be developed in tandem with a nonfunded study, we consider that, obviously, the benefits of funding and use of resources would be lost. Therefore, when considering the possibility of such studies, one of the main criteria is likely to be that the context or the study on which it is based is funded or standard practice, as is the example of the study proposed here.

It may not be so much a question of whether to obtain funding but rather of making existing funding more efficient and taking advantage of the sometimes scarce resources available for research. We believe that rigorous, relevant, pertinent, and original research can be carried out, even without funding, if creative solutions are devised, such as the one that this article aimed to provide: taking advantage of existing resources to carry out low-intervention but rigorous studies from an experimental point of view. In this sense, would higher quality research be possible if funding was available? It seems obvious that the answer is yes but not in the sense of being rigorous or methodologically robust (which is mandatory when it comes to research). Rather, the answer is related to the sense of opportunity, of deciding what I want to investigate, and when and where I am going to do it. For the rest, we believe that it is even an obligation in the use of resources.

Most of the literature consists of partnership sponsors [10], budgeting [1,5], qualifications of research staff [31], or data contributions from registries [34]. However, a description of a nonfunded, low-interventional clinical trial and its corresponding results was identified for analysis in future research [8]; thus, no comparison is possible in the current article. Therefore, we suggest that our management description can be used for other researchers to conduct a clinical trial without funding or with limited funding.

Strengths and Barriers of the Field and Study Context

According to Rogers' theory, the adoption process depends on the characteristics of actors (such as values, skills, status), situational perception (such as norms, economical aspects), motivation, and information [16]. Thus, adoption depends not only on the individual position, which is conditioned by the collective one, but also on other environmental factors. In our specific noneconomic health care environment, we found strengths and barriers to change.

Regarding strengths, of all the nurses in the hospital, the nurses (variable staff) working in the unit were the most aware of research and innovation. However, the fixed research staff were aware and accepted that additional things were conducted, but they did not collaborate actively; they were only observers.

Regarding barriers, we cannot forget that the nursing profession is one of the least sensitive to innovation and only collaborates with economic incentives. Moreover, the fact that it is a variable component makes constancy difficult, both in the introduction of a new procedure and in the acceptance of changes. Although

they were offered recognition in publications or similar, the big barrier was the lack of a direct financial incentive.

Limitations

Our case is not applicable to all commercial trial designs, but it enables the creation of an option of management that can be adjusted according to the study field and commercial trial. Although our strategy could not guarantee the optimum design for ambitious aims, the proposed strategy could make it possible to conduct a nearly optimal study design and, therefore, provide results for research progress.

This article provides a strategy for conducting noncommercial or nonfunded clinical trials by including similar procedures in a funded study in order to reduce budget, personnel, and the cost of providing participants with extra conveniences.

Consequently, another limitation could be that knowledge about research methodology along with change theories or strategies is required. In this study, there was a research nurse with knowledge about change theories for innovation; therefore, we suggest this innovative management to help anyone who has to face a similar challenge.

Conclusion

Our strategy is a cost-effective means of conducting a low-interventional clinical trial with no funding or with limited funding. Furthermore, this strategy can be used by nurse researchers or other researchers to facilitate clinical trial design and site management to provide high-quality results without ethical concerns. Ideally, nurses engaged in care themselves should be able to pose research questions like research nurses, develop them as such, and not be figures with necessarily distinct roles.

Abstract

Background: The impact of adverse childhood experiences (ACEs) has been the focus of most studies for the past decade. There is an indication that developing resilience can help youth overcome these ACEs.

Objective: This article presents a study protocol for a randomized controlled trial (RCT) to investigate the effects of a resilience-building intervention on psychological well-being, coping strategies, stress, quality of life, resilience, resource finding, and resilience among individuals affected with ACEs in Malaysia.

Methods: The is a 2-armed, single-blind, RCT, whereby 50 participants (25 in each group) with ACEs will be randomly assigned to intervention and control groups. The former will be exposed to a resilience-building program (R2), which entails a multisystemic approach to resilience and recognizes the importance of rugged qualities and access to resources among individuals affected with ACEs. The intervention will be delivered via internet-based by a facilitator and broadly divided into 5 sessions, focusing on self-exploration and social support, coping techniques and coping skills, resource finding, spirituality, and resilience building. Meanwhile, the control group participants will not receive any form of intervention. Saliva samples will also be collected from both groups and assessed for salivary cortisol levels. Outcome measures will be assessed during baseline and postintervention using validated instruments. Another follow-up measurement will be conducted 4 weeks later.

Results: The clinical trial has been registered with the Australia New Zealand Clinical Trials Registry. Ethical approval was obtained from the Research Ethics Board at the National University of Malaysia (UKM PPI/111/8/JEP-2021-894). A total of 28 participants have been recruited to the RCT Participant recruitment will be completed by January 2025. The final analysis will be conducted by March 2025.

Conclusions: This is among the first studies to provide evidence in the context of RCTs for resilience-building intervention that combines self-report and physiological measures (ie, saliva and heart blood pressure) among individuals with ACEs. The findings will assist relevant authorities in the health and policy sectors to develop effective strategies for addressing the negative impacts of ACEs on the vulnerable population in Malaysia.

KEYWORDS

adverse childhood experience; resilience; resilience-building intervention; young adults; stress; psychological well-being

Introduction

Background

Adverse childhood experiences (ACEs) are stressful or traumatic events faced by individuals that could have a pervasive impact throughout the developmental stages of their lives through psychological and physiological mechanisms, particularly when the consequences are neglected [1]. ACE can have profound effects on individuals of all ages [2,3]. These experiences may culminate in disrupted development of brain areas that are stress-sensitive [4,5], which are reflected in behavioral alterations.

For example, individuals with ACEs may face challenges with emotion regulation, thereby leading to diverse negative consequences such as difficulties with interpersonal relationships, alcohol, and smoking habits [6,7]. Overall, these events are associated with obesity, depression, suicide, anxiety, heart attack, chronic health problems, chronic obstructive pulmonary disease, asthma, stroke, cancer, and unemployment [8,9]. Apart from emotion regulation, ACE survivors' experience deficits in several domains of executive functions [10], which impact their well-being and psychological health [11]. Evidence suggests that individuals with ACEs, particularly children and young adults, are disadvantaged in terms of coping with increased stress relative to their peers without such bad experiences [12]. Since young adults are still experiencing biological and psychosocial development, the consequential impacts of ACE can be profound during adolescence and young adulthood [12].

Mental health problems are common among children and adults, which are predominantly presented as depression or anxiety and are characterized by frequent comorbidities [13]. Studies have demonstrated that ACEs represent an important predictor of emotional problems [14]. Previous research has documented several underlying events for the association between emotional problems and early ACEs among young children and adults [13,14]. For instance, individuals with a history of early ACEs were more accurate in recognizing threatening stimuli [15], constituting an adaptive response in harmful conditions. Nevertheless, it can heighten the risk of mental health disorders over time [16]. While individuals with ACEs are more likely to adopt maladaptive emotional regulation skills such as disengagement, expressive suppression, and rumination, they are less likely to perform successful activities such as cognitive appraisal [15], thereby leading to early emotional anomalies [16].

Specifically, ACEs also constitute a significant barrier to an individual's capacity for resilience. Resilience depicts the resources, capability, and processes available to a system or an individual to adapt successfully in the face of challenges or adversities [17-19]. Resilience encompasses the factors that facilitate positive adaptation and navigation toward resources to sustain well-being in the context of adversity [16]. Therefore, researchers have developed an interest in resilience intervention as a potential approach to addressing the negative impacts of ACEs [19]. For instance, cognitive behavioral therapy (CBT) has been used in resilience interventions in ameliorating health problems, particularly among adults with a history of ACEs [19-21]. Hence, building resilience in individuals with adversity in the context of psychological intervention offers a new approach to managing individuals with ACEs.

Adverse Childhood Experiences and Negative Consequences Among Children and Adults in Malaysia

ACEs refer to neglect, abuse, and dysfunctional households that may be deleterious to a person's health and well-being. Research conducted in Malaysia has depicted an increasing frequency of child abuse and neglect cases, which are typical examples of ACEs that may impact negatively on physical and mental health [22]. ACEs also contribute to the growing health care expenditure, as the health consequences of ACEs reportedly accounted for 2% of the gross domestic product [23].

Nevertheless, information on the prevalence and negative impacts of ACEs among children and adults in Asia, specifically Malaysia, is scarce due to limited research. A recent study revealed a high prevalence of various ACEs among university students in northeast Malaysia, with a report of emotional abuse, emotional neglect, physical abuse, and sexual abuse occurring in 30.2%, 29.2%, 28.7% and 9.1% of the studied population [22]. High-risk behaviors (HRBs), particularly physical inactivity and community violence were recorded among 39.3% and 54.5% of the students, respectively [22].

Apart from HRBs, depression has been identified as a consistent outcome of ACEs among young adults in Malaysia [24,25]. Young individuals from Shah Alam, Malaysia, exhibited a high level of depression and ostracism, which was associated with ACEs. Early psychological mistreatment such as parental neglect of a child's needs can lead to poor mental well-being [25], externalizing and internalizing problems, as well as anxious and avoidant attachment styles, making it challenging for children to develop a sense of belonging and feeling ostracized [26,27]. Therefore, early life traumatic events and ignorance appear to have strong influences on psychological well-being among this vulnerable population.

Besides the younger population, older adults in Malaysia have also been shown to be affected by ACEs, which may ultimately transit into elder abuse [28]. Furthermore, the risk of elder abuse increased with the cumulative number of ACEs. The results depict how early life adversities play an important role in older adults' victimization. Recognizing the possibility that vulnerability to maltreatment can persist throughout the life course of elderly individuals is critical when attempting to address the problem through emotional and social support.

Resilience-Building Interventions for Individuals With Adverse Childhood Experiences

Resilience is considered to be pertinent in the association between emotional problems and ACEs. Studies have depicted that resilience is a protective factor that can propel an individual to successfully address adverse experiences [29]. Thus, resilience is regarded as playing a protective role in the relationship between emotional disorders and ACE [29-31].

ACEs constitute a public health crisis that requires a wide range of interventions due to their high prevalence and impact on health disparities [31,32]. Resilience interventions are typical examples of CBT that are effective in ameliorating mental health disorders faced by individuals with ACEs [15]. According to Iniguez and Stankowski [33], ACE research has yielded strong evidence to support claims that "resilience resources and well-timed interventions to promote resilience can ameliorate the negative effects of ACEs" [33].

Chandler et al [21] demonstrated the feasibility and efficacy of an empower resilience intervention to enhance resilience and health behaviors among young adults with a history of ACEs. By using a 2-arm pre-post repeated measures design, young adults in the intervention group recorded significantly higher scores for building strengths, creating support connections, and reframing resilience. Meanwhile, a face self-help app designed by Brodbeck et al [34] and based on cognitive-behavioral principles, is currently being tested for its efficacy in promoting resilience and well-being in emerging adults with a history of ACE. MacIsaac et al [35] also evaluated the effects of an innovative, smartphone app-based resilience intervention on first-year university students' self-regulatory skills (ie, emotion regulation and executive functioning), and the mediating role of emotion regulation. After 4 weeks of using the app, students' emotion regulation and depressive symptoms improved significantly, with a faster rate of change in emotion regulation among those with more ACEs. Thus, evidence suggests that app-based resilience intervention can assist young adults with ACE by improving their emotion regulation skills and mitigating depression.

Systematic review findings depict that most interventions for addressing ACEs focused on psychological interventions and mental health outcomes, and cognitive-behavioral therapy has been consistently found to be effective in mitigating the negative impacts of abuse [36]. On the other hand, findings from interventions involving psychological therapies, specific support such as parent training, and broad support interventions are generally inconclusive despite some promising results [36]. In summary, significant gaps exist in the available evidence on interventions for ACEs, with most research focusing on individual psychological effects while neglecting the social pathways which may indirectly influence the negative impacts of ACEs. Several areas such as social relationships, life circumstances and health behaviors are examples of several negative impacts of ACEs that are still under investigation in most intervention research [34-36].

Building upon the global view on ACE research and resilience-building interventions, the Malaysian context must be taken into account in order to develop an effective intervention to address the problem of ACEs among children and young adults. Literature findings from the studies conducted in Malaysia have shown that ACE is a multifactorial problem that requires a multidimensional approach, rather than focusing on one individual aspect [22,23]. Such an approach is well-described in the multisystemic model of resilience developed by Ungar [8], highlighting the capacity of biopsychosocial and social-ecological systems to support external and internal conditions for well-being, as well as improving diverse populations' quality of life. Thus, resilience encompasses the process whereby individuals harness the resources that are necessary for them to function optimally and seek resources to be provided using meaningful approaches, either contextually or culturally [8].

Interventions that emphasize individual change without considering the environmental domain may yield short-term benefits [37]. Hence, intervention should have a dual focus, encompassing personal and environmental change. For instance, a child's resilience is a product of both their capacity to cope effectively under stress and the capacity of their physical and social environments to facilitate positive development. Under conditions of normal stress, individual ruggedness may be sufficient to support well-being; nevertheless, resources become more important and required as the individual experiences greater barriers to functioning. These 2 broad aspects form the foundation of the multisystemic perspective of resilience "R2," which was coined to affirm the need to mitigate both the rugged qualities of individuals and their access to resources) [38].

Research has shown that individuals with more internal capacities such as problem-solving, self-regulation, and positive future orientation are more likely to harness opportunities for relationships and exploit such opportunities for academic or financial success [39,40]. Likewise, higher levels of motivation to execute life tasks and being more optimistic were observed among individuals with better access to external resources [41,42]. These findings reflect the dynamicity of resilience, whereby individuals interact with the world around them to make the best use of available resources despite exposure to adversity or atypical stress.

As highlighted in the reviewed resilience-building interventions for ACEs, while some target the public and common adversities like job burnout [43] and stress [44], others are aimed at specific groups, such as chronically diseased individuals [45], employees returning to work [46], and health care workers [47]. These interventions are delivered using diverse methods, ranging from phone apps to web-based tools or printed manuals, and duration may be as short as single-day workshops to weekly or monthly sessions. However, a recent meta-analysis revealed that such interventions have a small to moderate effect on improving resilience [44,47]. Existing resilience interventions also differ in terms of the targeted protective factors, such as self-efficacy, problem-solving skills, and cognitive flexibility, with most focusing on rugged factors. Only a few interventions consider resources that are external to individuals with ACEs [48]. Accumulated evidence suggests little to no data on interventions that explicitly target both coping strategies and ways of creating better-resourced environments around individuals with ACEs.

Hence, this study will modify and implement an R2 resilience program based on a resilience-building intervention designed with the principles of implementation science [38]. The multisystem aspect of the intervention allows it to focus on multiple systems for the individual's change process and adaptation process around life circumstances. It is a curriculum-based approach that integrates all the well-researched factors and presents equal emphasis on the surrounding environments to the individual [8,38]. Thereafter, the factors and aspects can be modified and implemented into the resilience-building intervention accordingly. This study aims to explore the effects of the resilience-building intervention on mental health, stress, resilience, and resource finding among individuals affected with ACEs in Malaysia.

Methods

Study Design and Setting

This is a 2-armed, single-blinded, randomized controlled trial (RCT) that will be conducted among Malaysian youths with ACEs at the Department of Clinical and Health Psychology, National University of Malaysia. Briefly, the intervention group includes an evidence-based curriculum and components such as emotion regulation, active coping and goal setting, cognitive flexibility, mindfulness-based stress reduction, social support, self-exploration, resources and navigation, and finally, spirituality and religion. Participants in the control group will not receive any form of intervention. The main outcome of this study is resilience among youths with ACE while the secondary outcomes include coping, psychological well-being, quality of life, subjective stress, perceived stress, personal resources, and adult resilience. These variables will be evaluated at baseline and postintervention. Intention-to-treat analysis will also be performed. This clinical trial has been registered with the Australia New Zealand Clinical Trials Registry (trial Id: ACTRN12622000604707).

Sample Size

Sample size calculation was performed using G*power 3.1 software (Heinrich-Heine-Universität Düsseldorf). By assuming a study power of 0.8, 95% CI (α=0.05), and a moderate effect size of 0.25 as recommended by Ferguson (2009), the *F*-test was selected alongside repeated measures ANOVA with in-between interaction, with 2 groups and the number of measurements. Thus, a total sample size of 36 was obtained, reflecting 18 participants per group. We considered a high drop-out rate of 50% as several individuals may be unwilling to participate given the adverse effects of ACEs and confidentiality in sharing experiences with the researchers. Therefore, the sample size was increased to 50, amounting to 25 participants per group.

Eligibility Criteria

The inclusion criteria entail participants aged 18 to 30 years old and an individual who scores more than 4 or higher levels of ACE. This age group spans the young adulthood phase of an individual, and it is considered a significant developmental stage characterized by exposure to unique challenges and opportunities [21]. Meanwhile, the exclusion criteria are individuals receiving any type of intervention, demonstrating any severe psychopathology or psychiatric illness that requires a psychopharmacological approach, and those who had received intervention or therapy consistently in the past. Individuals need to fulfil the criteria to be recruited as mentioned above. Individuals will be recruited through multiple centers and social media platforms

Participant Recruitment and Randomization

The participants for this study are Malaysian youths with ACE, particularly those visiting the Psychological Department at the National University of Malaysia Medical Centre. During the selection stage, participants will be approached by the researcher and seek their consent to participate in the study. Those providing affirmative responses will then be instructed to fill up the self-administered ACE questionnaire.

This assessment period is the screening stage to identify those that fulfil the inclusion criteria. Participants who score four or more of ACE will then be included in a pool of participants and assigned randomly to either the control group or intervention group. Random assignment procedure will be implemented by random allocation software, Research Randomiser [31], to generate numbers and assign participants to an intervention group or control group. Allocation concealment will be performed by a single blinding procedure, whereby the assessors of the outcome measures will be unaware of the specific group the participants belong to. In other words, only the investigator allocating participants to either the control or intervention group will be aware of this information while other assessors are blinded. Table 1 depicts the participant enrolment schedule, time points and assessments to be performed during the study period.

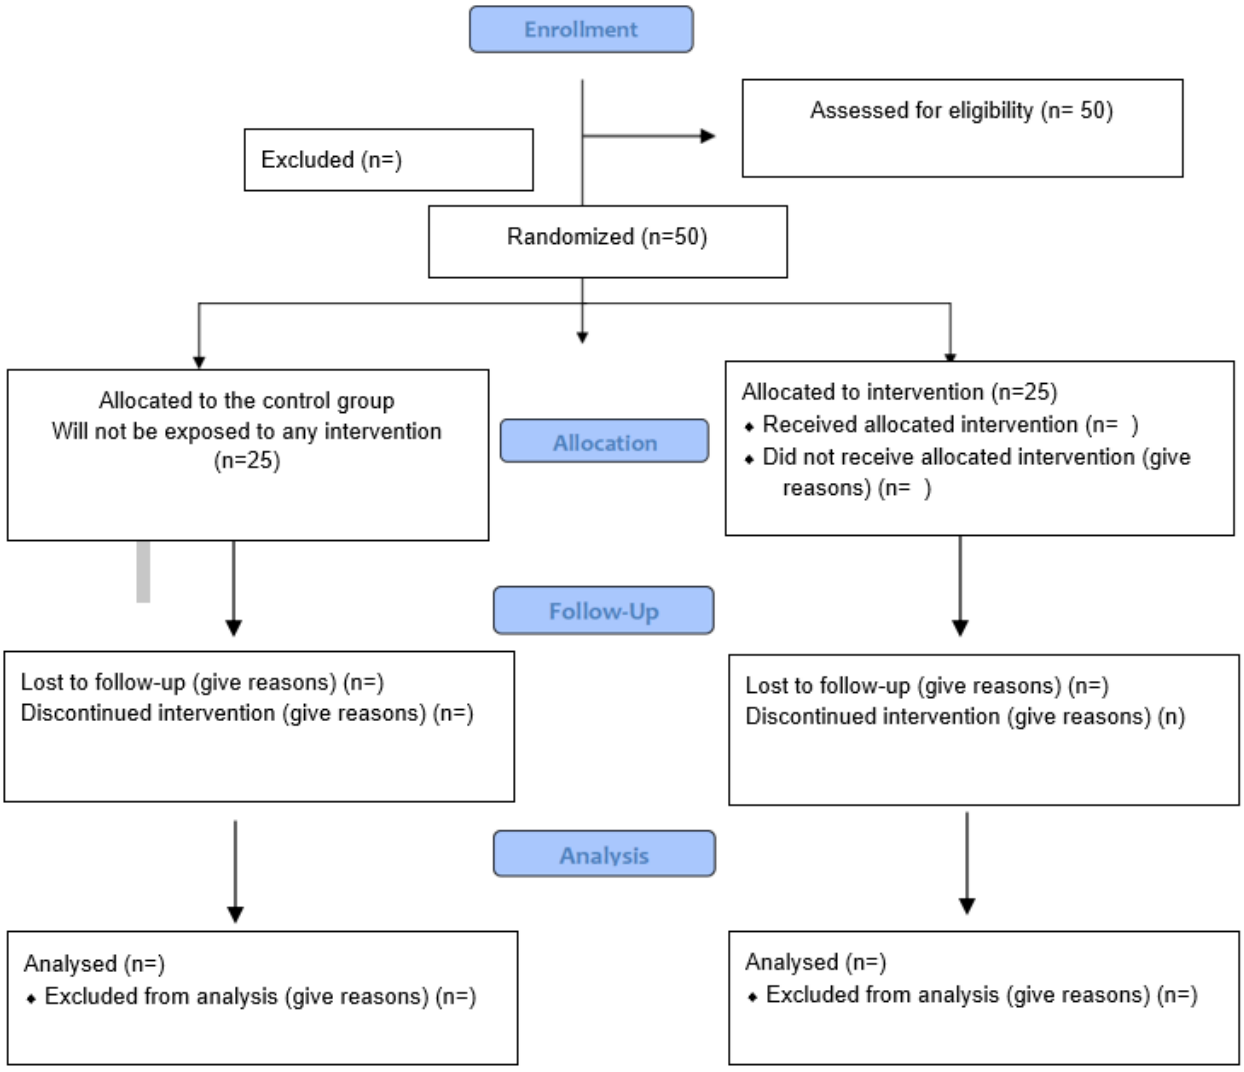
Participants in the control group will receive no intervention, while those in the intervention group will receive five sessions of resilience-building intervention conducted by a trained facilitator. Hotlines, post session, and appropriate resources will be provided for those reporting distress after the intervention. Investigators will be blinded throughout the whole process of randomization and data collection as the whole process is handled by a research assistant (randomization), counsellor, and clinical psychologist (data collection). Under no circumstances will unbundling occur as a research assistant, counsellor, and clinical psychologist are briefed with the standard operating procedure to follow when an incident occurs. The flow diagram is presented in Figure 1.

Figure 1. Consolidated Standards of Reporting Trails 2010 flow diagram.



Contents and Delivery Method of the Intervention

The intervention will be adapted and modified according to the R2 Resilience building program designed by Ungar [20], which comprises 7 principles; help people to navigate, help people to negotiate, think about systems, coordinate services and supports, provide continuous support, be relevant to place and culture, and share responsibility for solutions. These principles will guide the process of modifying the intervention and the principles will be reflected in each session. The intervention will be delivered in 5 sessions.

Session 1 is divided into subsessions entitled “Self-exploration” and “Social support.” The first subsession focuses mainly on building rapport with the participants and helping them explore their coping skills, strengths, weaknesses, and talents. The second subsession emphasizes the importance of social support to enhance a sense of belonging and connection, as well as explore resources relating to social support. Both sessions will be delivered via internet-based with each lasting for 60 minutes.

The second session is also divided into 2 parts, coping technique including cognitive flexibility and grounding technique, and coping skills. The coping technique focuses on participants’ coping strategies and a deeper insight compared with the first session. This section also aims to provide cognitive exercise for preventing catastrophic thinking. As for coping skills, the strategies will be discussed in depth and practiced together with the facilitators. Participants will also be directed to work in pairs and assisted to identify their best coping strategies, either emotion-focused or solution-focused.

The third session comprises 2 parts to familiarize the participant with resource findings and explore their understanding of resilience. First, the facilitator will recap what the participant has learnt in the previous sessions and help identify where they can get help and access the available resources. Such assistance will be tailored for each participant to learn about resilience resources and harnessing them accordingly. In the second part, in-depth discussion will be held with each participant by focusing on past ACEs and how they were able to overcome the experiences, as well as their past resilience resources. Both

sessions will be delivered via internet-based with each lasting for 60 minutes.

The fourth session is also divided into 2 subsessions; (1) what is resilience to you (part II), and (2) spirituality. The first subsession is the continuation of the second part of the third session with the same components as shown in Table 2. Meanwhile, the second subsession entails learning from each other regarding the role of religion and spirituality in addressing past adversities. The last session is the "Resilience-building (wrap-up)," whereby all the intervention components will be reviewed and visualized in the form of a diagram. Each session of the intervention will last for 2 hours (60 minutes for each session, with 15-minute breaks between sessions). Each session will be conducted weekly, week 1 for the first session and week 5 for the fifth session respectively. All sessions of the intervention will be administered via internet-based to each participant by the facilitators.

Table 2. Components of the intervention.

Week	Session	Session	Duration	Mode of delivery	Focus
Week 1	1st session (1A)	Session 1A: Self-exploration	60 minutes	Internet-based	1. Build rapport among students with an ice-breaking activity 2. To help participants explore their coping skills, strengths, weaknesses, and talents
Week 1	1st session (1B)	Session 1B: social support	60 minutes	Internet-based	1. To talk about the importance of social support 2. To foster a sense of belonging and connection. 3. To explore resources regarding social support
Week 2	2nd session (2A)	Session 2A: coping techniques: cognitive flexibility and grounding technique	60 minutes	Internet-based	1. Explore participants' coping strategies (be mindful of labelling participants' strategies). Go deeper from session 1A 2. Cognitive exercise to prevent catastrophic thinking 3. How do you practice cognitive exercise? 4. What is fallacy thinking? 5. Introduce A-B-C and how to practice them
Week 2	2nd session (2B)	Session 2B: coping skills	60 minutes	Internet-based	1. Discuss the strategies in depth and practice them together. (Follow up from Session 2A) 2. Finding allies (participants form a pair and check in with each other) 3. Emotion-focused coping vs. solution-focused coping 4. During a crisis, how do these routines help? 5. Helping the body to feel safe
Week 3	3rd session (3A)	Session 3A: resource finding	60 minutes	Internet-based	1. Review and monitor from the previous session to recap what has been learned 2. To help participants know where to get help and the resources available 3. To help participants learn about their resilience resources and how to tap into them
Week 3	3rd session (3B)	Session 3B: what is resilience to you?	60 minutes	Internet-based	1. How do you survive? 2. What is the meaning of your stories? 3. What are your resilience resources in the past?
Week 4	4th session (4A)	Session 4A: what is resilience to you? part II	60 minutes	Internet-based	1. How do you survive? 2. What is the meaning of your stories? 3. What are your resilience resources in the past?
Week 4	4th session (4B)	Session 4B: spirituality	60 minutes	Internet-based	1. Review and monitor from the previous session to recap what has been learned 2. To learn from each other about the role of religion and spirituality
Week 5	5th session (5A)	Session 5B: eesilience-building (wrap-up)	120 minutes	Internet-based	1. To review and discuss all of the components 2. To draw a diagram with all of the components involved

Intervention Protocol and Fidelity

The intervention will be conducted in Malay or English. It aims to encompass both languages and will be provided according to the participant's native language. Therapists will be trained to follow the protocol and the manual. A recap will be conducted at the end of the session. Dynamic assessment will be used to track the learning progress. Participants will use journaling as a method to practice their skills. In addition, progress and practice will be discussed at the beginning of each session. As for intervention fidelity, journals and progress of group sessions will be collected from mental health professionals after each session to ensure they continue a similar structure for the intervention. The checklist will be prepared for the mental health professional.

Data Collection Instruments and Outcome Measures

Adverse Childhood Experience Questionnaire

The Adverse Childhood Experience Questionnaire (ACE-Q) is a 10-item measure to assess events of traumatic or adverse experiences that an individual experienced before the age of 18 years. The instrument evaluates the individual's exposure to childhood physical, psychological, or sexual abuse, as well as household dysfunction such as substance use, domestic violence, and incarceration. The ACE-10 has been validated among the Malaysian population with an acceptable internal consistency of 0.86 and internal validity ranging from 0.28-0.70 [49].

Patient Health Questionnaire-9

The English and Malay versions of the Patient Health Questionnaire-9 (PHQ-9) will be used in this study to assess depression among youths with ACEs. The instrument has been validated among the Malaysian population by Sherina et al [50] with a sensitivity of 87% (95% CI 71%-95%) and specificity of 82% (95% CI 74%-88%). It was also reportedly suitable as a case-finding instrument in Malaysian primary care clinics.

Brief Coping Orientation to Problem Experienced Scale

The brief coping orientation to problems experienced (COPE) instrument comprises 28 items with 14 broad coping strategies. The Malay version of the instrument was validated by Saiful [51] among secondary school adolescents and was found to be valid and reliable in identifying coping strategies. Specifically, the overall Cronbach α value was 0.83 with the majority of the coping strategies reflecting acceptable internal consistency.

Ryff's Scale of Psychological Well-Being and Quality of Life

The Ryff's Scale of Psychological Well-being (SPWB) and World Health Organization Quality of Life Assessment (WHOQL-BREF) will be used in this study to assess the psychological well-being and quality of life among adolescents with ACEs. These instruments have been validated among the Malaysian population with acceptable discriminant validity, construct validity, and test-retest reliability greater than the threshold value of 0.5 [52-54].

Personal Resources Questionnaire 2000

The personal resources and workability of the participants will be assessed using the Work Ability-Personal Radar (WA-PR) instrument, which has been previously translated into Malay and validated by Hamdan et al [55]. The instrument has adequate psychometric properties and has been validated with acceptable discriminant validity, construct validity, and test-retest reliability greater than the threshold value of 0.5, making it suitable to be used in investigating personal resources and workability levels in the Malaysian population [55].

The Perceived Stress Scale-10

The Perceived Stress Scale-10 (PSS-10) is generally used in assessing stress perception. The Malay version of the PSS-10 has been validated among diverse populations in Malaysia, with the latest being nurses from government hospitals [39]. The instrument revealed acceptable internal consistency with a Cronbach α value of 0.63 and intraclass correlation coefficient of 0.81 (95% CI 0.62-0.91) following a 7-day test-retest reliability analysis. Furthermore, previous studies found significant correlations between the stress component of Depression Anxiety and Stress Scale 21 and the total score and negative component of the PSS-10 (r=0.56-0.61). Therefore, the PSS-10 is considered valid and suitable for investigating stress perception among Malaysian youths, including adolescents [56].

Saliva Cortisol and Blood Pressure Assessment

Each participant will be instructed to provide approximately 2 mL of whole saliva by passive drool, which will be then split into multiple 100 uL aliquots and frozen immediately. One aliquot of each of the 50 participants' saliva will be transported overnight on dry ice to the institutional laboratory. Cortisol analysis will be performed using commercially available immunoassay according to the manufacturer's guidelines (Salimetrics). Meanwhile, participants' blood pressure will be measured objectively with a sphygmomanometer.

Time Points for the Primary Outcomes and Retention

Premeasurements will be conducted at baseline, whereas postmeasurements will be collected after the fifth session as shown in Figure 1. Participants will be given Ringgit Malaysia 50 after the third and fifth sessions of the intervention to ensure they do not drop out of the study. Another follow-up will be conducted 4 weeks after the Intervention.

Data Analysis

All data management and statistical analysis will be conducted using SPSS (version 26; IBM Corp). Data management will be performed by screening for missing data and checking for potential outliers. Descriptive statistics will be used to assess the data normality and to summarize the pre and postintervention scores for each group at different periods. Mean and SDs will be provided for normally distributed data, followed by mixed ANOVA with repeated measures to compare the pre and postintervention mean scores between and within the groups.

The assumptions of ANOVA include randomly collected and normally distributed data, sufficient sample size, homogeneity of variances, and absence of violation and outliers. Levene's test will be applied to test the homogeneity of variance. Mixed ANOVA benefits RCT design as it allows testing for 2 groups across 2-time points. Mixed ANOVA analysis aims to handle

response outcomes conducted on the same experimental unit at a different time or under different conditions [57]. The differential effects of the intervention components will be tested with interactions between the component and time. These analyses will model random slopes and intercepts for participants, explore the fixed effects of the condition, and test the repeated measures over time. This type of analysis is advantageous by accounting for missing values through the maximum likelihood estimation method [57]. Effect sizes will be computed based on Cohen *d*.

In addition, the intention-to-treat analysis will be applied to analyze the participants according to their assigned groups. This analysis includes all participants and ignores noncompliance, protocol deviation, and withdrawal. The intention-to-treat analysis is a complete trial strategy for the design, execution, and analysis of RCT, focusing on the consolidated standard of reporting trial guidelines. Thus, the number of participants in each assigned group will be analyzed by the intention-to-treat principle.

As for missing data, drop-out in this study refers to participants who withdraw actively from the intervention post randomization. All cases of dropouts will be considered in the intent-to-treat samples since they have been randomized and included in the analysis. The extent and pattern of missing data will be assessed, and depending on the results, missing values will be replaced by using multiple imputations. The impact of the imputation of missing values will be further explored by conducting sensitivity analyses.

Criteria for Discontinuing or Modifying Intervention

All the intervention modules were well understood by the participants enrolled in the pilot test; hence, no attempt has been made to review the intervention. Participants have the right to withdraw from the research at any given time if they do not feel comfortable continuing with the study. If the counselor or clinical psychologist reviews and discusses the harm of the participants continuing to participate in the research project, they will advise the participants to drop out of the study based on their professional judgment. A panel comprising counselors, and clinical psychologists will jointly review the case and make a consensus decision.

Data Auditing and Management

The team is required to submit first and second progressive reports to the Research Ethics committee, at the National University of Malaysia as part of the auditing process. Only group data will be reported. Data will be reported collectively; individual data will not be disclosed. Journal and progress of group sessions will be collected from mental health professionals after each session to ensure they continue a similar structure for the intervention. The checklist will be prepared for the mental health professionals.

As for data storage and management, the data will be entered digitally and stored in a Microsoft Excel sheet and Microsoft Word document by the investigator after being collected from mental health professionals. Each dataset will be assigned a code to protect the participants' identity. The encryption of the firewall will help secure and protect the data. A passcode will be generated to protect these documents. The data will be stored in the institution for 5 years, kept confidential and used only for educational purposes.

Standard Operating Procedure to Manage Harm

Counsellors and clinical psychologists will evaluate if any of the participants feel discomfort or express interest in withdrawing from the studies. This assessment will be carried out during the break intervals between each session of the intervention and the follow-up periods post intervention. Participants will be asked verbally if they still feel comfortable and willing to proceed with the intervention. Follow-up and proper redirecting to resources will be practiced with individuals who dropped out of the study.

Protocol Amendments

Any modification to the protocol, an update will be submitted to the Australia New Zealand Clinical Trials Registry and Research Ethics Board, The National University of Malaysia, and related journal publications.

Recordkeeping and Specimen

Consent will be obtained from participants to collect saliva. Data obtained through this study will only be published under group data. No individual data will be identified. The saliva samples obtained will not be kept and discarded right after the cortisol level measurement and analysis. All participants' data and information will be stored for this research as group data.

Ethical Considerations

Ethical approval was obtained from the Research Ethics Board at the National University of Malaysia (UKM PPI/111/8/JEP-2021-894; January 28, 2021). Detailed information on the intervention and recruitment process is provided in the next sections.

Results

This protocol, the informed consent and other relevant documents were reviewed and approved before the conduct of the research. Letters of extension and ethics approval were obtained from the Research Ethics Board at the National University of Malaysia. Amendments will be communicated to investigators, ethics review boards and publishing journals.

By January 2025, a total of 28 participants have been recruited into the study, comprising 14 in the intervention and 14 in the control group. Only 2 participants withdrew from the intervention group mainly due to a change in location and issues relating to data privacy and security. It is expected that participant recruitment will be completed by 30 January 2025. Preliminary analysis is ongoing, and the results suggest improvement in the investigated outcomes among participants in the intervention group across time. Final analysis will be conducted by March 2025, upon completing the data collection.

Discussion

Principal Findings

ACEs are relatively common, trigger substantial suffering and are well-documented as a risk factor for diverse physical and mental health conditions throughout life. While primary prevention is pertinent in reducing ACE, the deleterious short and long-term consequences of ACE can be mitigated by selective prevention.

This study adopted the multisystemic approach to resilience "R2," which recognizes the importance of rugged qualities and access to resources among individuals affected by ACEs. As discussed earlier, the multisystemic model of resilience emphasizes 2 broad aspects, encompassing personal and environmental change [37]. We considered these 2 aspects as pertinent in addressing the consequences of ACEs among young adults in Malaysia, aligning with recommendations from previous studies to approach the problem in a multidimensional manner [8,38]. This study will be the first attempt to adopt an evidence-informed intervention for resilience-building among Malaysians with ACEs. In addition, this research is among the few interventions that explicitly entail both coping strategies and creating better-resourced environments around individuals affected by ACEs.

It is anticipated that the resilience-building intervention will have moderate to strong effects by ameliorating mental health, and stress, and improving participants' resilience and resource finding compared with those in the control group. These expected findings are consistent with the report by Chandler et al [21], whereby a resilience intervention centered around 4 main components (ie, active coping, building strength, cognitive flexibility, and social support) was effective in mitigating the adverse effects of ACEs.

Our intervention is structured into 5 sessions, focusing on self-exploration and social support, coping techniques and coping skills, resource finding, spirituality, and resilience-building. These components are expected to enhance participants' internal capacities such as self-regulation and problem-solving, thereby harnessing opportunities to achieve success in life [39]. By educating them on how to identify and gain better access to external resources, they will be motivated to accomplish life tasks and be more optimistic [42]. These events will assist in building resilience, facilitating participants' interaction with the world around them, and using available resources effectively regardless of being exposed to adversities.

This intervention aims to focus on vital resilience components which are emotion regulation, active coping and goal setting, cognitive flexibility, physical health, mindfulness-based stress reduction, social support, self-exploration, resources and navigation, financial planning, and spirituality and religion. One of the weaknesses of this intervention is that these components will be monitored by informal assessment such as observation, tracking, and recap to ensure participants have learned and acquired the tools and knowledge. It is also difficult to ensure participants from the control group will not receive any form of therapy during the whole duration of the intervention. Hence, the therapist has to check in with the group from time to time to ensure their well-being is taken care of. If needed, the therapist will conduct a post-group counselling session with an individual who is distressed by the intervention. Given that the participants were selected from a pool of individuals obtaining a specific level of ACEs, the findings might not be generalized to the entire population of people with ACEs in the country.

Conclusion

This is the first full clinical trial study investigating resilience-building intervention for youths with ACEs in Malaysia. There are limited studies evaluating the effectiveness of resilience-building interventions combining mental health and physiological responses as outcome measures in Malaysia. Thus, this study conceptualizes resilience from a biopsychosocial-ecological perspective and adapts resilience-building intervention in the Malaysian context. This study aims to develop resilience-building intervention modules specifically for Malaysia, focusing on the process of adapting the modules and modifications according to the Malaysian culture. This will be one of the first studies to provide evidence in the context of RCTs for resilience-building intervention combining self-report and physiological measures (ie, saliva and heart blood pressure) among individuals with ACEs. The findings will assist relevant authorities in the health and policy sectors to develop effective strategies for addressing the negative impacts of ACEs on the vulnerable population in Malaysia.

Acknowledgments

The study has received financial grant support from grant research National University of Malaysia (GUP-2022-054). The grant sponsor is only required to submit a progressive report at the end of the project. It will not involve any of the research activities.

Data Availability and Dissemination Policy

Group data will be available on the Australia New Zealand Clinical Trials Registry. The public will have access to full protocol and group-level datasets. The investigator will publish trial results to participants and health care professionals through publication and data-sharing arrangements on the Australia New Zealand Clinical Trials Registry. The public will have access to the full protocol. Data will be available upon the study's completion.

Abstract

Background: Dementia is a clinical syndrome characterized by a progressive decline in various cognitive domains. Since there is still no treatment for dementia, early diagnosis and prevention are the best approaches. In this context, the cognitive reserve (CR) concept has received considerable attention in dementia research with regard to prognosis. It originates from discrepancies between the degree of brain pathology and clinical manifestations. Acupuncture, as a complementary intervention, has long been widely applied in neurological diseases in East Asia. At the macroscale level, how acupuncture stimulation affects neural activity concerning CR in normal aging and dementia is largely unknown.

Objective: The aim of this study is to investigate the acute neural mechanisms of acupuncture stimulation concerning CR in the normal aging group and the group with cognitive impairment using neuroimaging methods.

Methods: This study is a randomized, placebo-controlled trial. Participants without (n=30) and with cognitive impairment (n=30) will be randomly assigned to the verum or sham acupuncture groups. The verum acupuncture group will receive acupuncture stimulation at acupoints related to cognitive function and gain deqi sensation. The sham acupuncture group will receive superficial needling at nonacupoints not related to cognitive function. Each group will undergo cognitive function tests, functional near-infrared spectroscopy imaging before and after acupuncture stimulation, and an assessment of CR. The primary outcomes will be differences in resting brain activities according to disease status, differences in resting brain connectivity before and after acupuncture stimulation between the 2 groups, and changes in brain activity in relation to the CR index. The secondary outcomes will be brain connectivity or network metrics associated with CR and differences in neural activity between the cognitive task and resting states.

Results: The recruitment began in August 2023; to date, there have been 50 participants, divided into 20 in the group with cognitive impairment and 30 in the unimpaired group. The recruitment process will continue until February 2025.

Conclusions: CR refers to the individual susceptibility to age-related brain changes and pathologies in cognitive impairment, and it is a factor affecting the trajectories of the disease. Although acupuncture is a widely used intervention for various neurological diseases, including dementia, its mechanism associated with CR at the macroscale has not been clearly identified. This study

could contribute to identifying the neural mechanisms of acupuncture stimulation associated with CR using neuroimaging methods and provide a basis for future longitudinal research.

Introduction

Cognitive impairment refers to a generic term in which various cognitive functions, such as memory and executive function, are impaired, and the symptom severity ranges from mild to severe enough to interfere with daily life. Among them, dementia is a clinical syndrome preventing patients from leading a daily life due to the severe decline in several cognitive domains. Alzheimer disease (AD) is by far the most frequent cause of dementia and accounts for up to 80% of all dementia diagnoses [1]. AD symptoms typically begin with mild memory difficulties and gradually progress to severe memory impairment, inducing dysfunctions in daily life [2]. The prevalence and incidence of AD are increasing with an increase in life expectancy, leading to a socioeconomic burden worldwide [3,4].

The concept of cognitive reserve (CR) has received consistent attention in dementia-related research. CR refers to the adaptability of cognitive processes, which helps explain the individual vulnerability of cognitive abilities. It has also been suggested as an active model of the reserve, indicating that dynamic cognitive and functional processes counteract aging-related brain changes or damage [5]. This concept suggests that the brain actively attempts to cope with brain damage, allowing an individual with high CR to better deal with brain pathology. Many studies have shown that CR works differently depending on disease status. In the group without cognitive impairment, participants with high CR showed a slower decline in cognitive function; however, in the AD group, individuals with high CR showed more rapid cognitive deterioration than those with low CR [6,7]. Therefore, CR is considered a factor that modulates the relationship between the neuropathological burden of dementia and clinical symptoms [8,9]. Generally, CR has been measured through proxies, such as years of education, occupational complexity, and questionnaires covering various lifelong experiences.

Various neuroimaging techniques such as magnetic resonance imaging, functional magnetic resonance imaging (fMRI), positron emission tomography, and electroencephalography have been used for the early detection of AD [10]. Although fMRI is noninvasive and has good temporal and excellent spatial resolutions among functional neuroimaging methods, it has inherent limitations such as high cost, immobility due to heavy equipment, and vulnerability to head motion artifacts. In contrast, functional near-infrared spectroscopy (fNIRS) has been suggested as an alternative tool for functional neuroimaging. fNIRS is an optical neuroimaging technique that allows the measurement of changes in brain tissue concentrations of oxyhemoglobin (HbO_2), deoxyhemoglobin (HbR), and total hemoglobin (HbT) within the brain, achieved by irradiating the head with near-infrared (NIR) light [11,12]. This equipment has several practical advantages over conventional techniques represented by fMRI: It has a relatively higher temporal resolution, is noninvasive, cost-effective, lightweight, and easy to handle. It is applicable to cases difficult to fMRI scanning, such as agitated patients, individuals with claustrophobia, and those with pacemakers [13,14]. Moreover, it can be used on patients without moving from the hospital or laboratory, which can be critical for dementia patients with mobility difficulties. With these advantages, it allows us to monitor the alterations in brain function in patients with cognitive impairment in real time and explore neural responses induced by long-term or short-term interventions.

In a recent systematic review of dementia research using fNIRS, its diagnostic and investigative usefulness was evaluated while reviewing 88 studies in the field of dementia [15]. In summary, fNIRS could capture the aberrant hemodynamic responses and a lack of task-appropriate lateralization, often focused on frontal regions, in dementia. On the other hand, inconsistent results were found in prodromal stages. Cognitive decline accompanied by either reduced functional responses or hyperactivity was identified, the latter implying a compensatory response not represented at the dementia stage. However, there have been few fNIRS studies dealing with CR, one of the important factors in cognitive impairment.

Acupuncture has been practiced for thousands of years as an important treatment for a variety of diseases in East Asian medicine [16,17]. It is also being explored in AD research as a complementary and alternative therapy. In a meta-analysis, acupuncture treatment alone showed acceptable efficacy compared to conventional medicine for the management of AD. In addition, in a randomized controlled trial in patients with mild to moderate AD, acupuncture was found to be safe, well tolerated, and effective in improving cognitive function and global clinical status [18]. Specifically, acupuncture has been shown to regulate the release of central neurotransmitters, including acetylcholine and monoamine neurotransmitters [19]. Current neuroimaging studies of acupuncture cover a variety of diseases ranging from pain-related diseases such as chronic low back pain to peripheral and central nervous system disorders including carpal tunnel syndrome, stroke, Parkinson's disease, and dementia [20-24]. Through these, the analgesic mechanism and neuroprotective effect of acupuncture, which are distinct

from sham needling, are consistently elucidated. Among them, a systematic review dealing with 13 AD-related neuroimaging studies found that acupuncture may modulate the default mode network, the central executive, and the frontoparietal networks in the brains of AD patients [24]. However, on the macroscale, the acute neural mechanisms of acupuncture stimulation in relation to CR according to disease status are largely unknown. To identify the neural mechanisms of acupuncture stimulation associated with CR in healthy aging and cognitive impairment patients, rigorous clinical trials such as randomized, placebo-controlled trials with neuroimaging techniques are required.

In this study, our main hypothesis would be that brain networks and brain activations focused on frontal regions would be altered according to the disease status and CR level, and that brain connectivity in the frontal regions would change before and after acupuncture stimulation. Next, we aim to investigate the neural substrates of CR and cognitive function using network metrics. Herein, we present a protocol for a randomized, placebo-controlled, parallel-group clinical trial to explore the acute neural changes after acupuncture stimulation according to CR and elucidate the neural substrates of CR according to disease status by applying fNIRS.

Methods

Trial Design, Setting, and Aim

This study will be a single-center, block-randomized, placebo-controlled, parallel-group clinical trial. The study will be conducted at the College of Korean Medicine at Sangji University. This protocol complies with the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) guidelines [25]. The aim of this study is to investigate the acute neural mechanisms of acupuncture stimulation concerning CR and to identify the neural substrates of CR in the group without cognitive impairment and the group with cognitive impairment using fNIRS.

The participants will be divided into 2 equal groups: the verum acupuncture group (study group) and the sham acupuncture group (control group). After each group is confirmed to participate in the study through screening (visit 0), fNIRS scanning and acupuncture manipulation will be conducted at visit 1. Cognitive function assessments, including the Korean version of the Mini-Mental State Examination (MMSE-K) and Montreal Cognitive Assessment (K-MoCA), will be conducted during screening. At visit 1, each participant will be measured twice using fNIRS (first and second scan) before and after acupuncture stimulation. Finally, CR marker assessment, such as the Cognitive Reserve Index Questionnaire (CRIq), will be conducted through interviews in visit 1. The period between visit 0 and visit 1 will not exceed 1 week. Participant recruitment was initiated on August 22, 2023, and the study is scheduled to continue until February 2025. The flow chart is illustrated in Figure 1, and the overall procedure is presented in Table 1.

Participants and Recruitment Strategy

Eligibility Criteria

The inclusion criteria for healthy controls (the group without cognitive impairment) are as follows: (1) males and females aged ≥19 years without cognitive impairment (MMSE-K≥24, K-MoCA≥23); (2) participants without severe neurological, organic dysfunction; and (3) participants or authorized surrogates who voluntarily sign the informed consent.

The inclusion criteria for the group with cognitive impairment are as follows: (1) males and females aged ≥60 years showing cognitive impairment (MMSE-K<24, K-MoCA<23) or diagnosed with mild cognitive impairment (MCI) or dementia with a clinical dementia rating<3; (2) participants or authorized surrogates who voluntarily sign the informed consent; and (3) participants who can complete this study.

The exclusion criteria for healthy controls (the group without cognitive impairment) are as follows: (1) participants with other brain disorders, alcoholism or drug abuse, neuropsychiatric disease, or taking psychiatric medicines, and severe organic dysfunctions inducing cognitive impairment; and (2) participants with any other reasons that may be considered inappropriate by the researcher.

The exclusion criteria for the group with cognitive impairment are as follows: (1) severe dementia patients with a clinical dementia rating of 3; (2) patients with other brain disorders such as cerebrovascular disease and epilepsy; (3) patients with cognitive impairment induced by another primary disease; (4) patients with severe organic dysfunctions; (5) patients presenting alcoholism or drug abuse, with neuropsychiatric disease or taking psychiatric medicines; and (6) patients with any other reasons that may be considered inappropriate by the researcher.

Enrollment, Randomization, and Blinding

Recruitment will be conducted through advertisements on websites and public announcements. Promotion through local communities is also under consideration. The recruitment of participants with cognitive impairment will be promoted through cooperation with community dementia care centers. In this study, in accordance with the recruitment of the participants, the effect of age on brain function will also be investigated; therefore, recruitment in the group without cognitive impairment will not be restricted to older adult participants.

Stratified block randomization will be performed according to sex. Both groups will be assigned in a 1:1 ratio to the study and control groups by applying a block size of 4. Randomization will be conducted using a computer-generated allocation list by an assigned researcher not involved in the assessment or intervention. Participants will be blinded to the type of

intervention used. The practitioner will not provide clues regarding allocating information to the participants during the study. Blinding will be maintained until the end of the study. Participants will be asked about their experience of blinding after the end of the study.

Sample Size

In this study, the number of participants has been determined statistically. In our hypothesis, the significance level (α) and power (1–β) will be set to 5% and 80%, respectively. Then, an effect size will be calculated using an estimated value of the variability in the MMSE-K and K-MoCA scores based on the literature [26]. As a result, the number of samples came out to be about 10-15 for each group (study or control group) to satisfy the criteria of the normal deviates of significance level and power in the healthy controls and patient groups. The anticipated dropout rate was set to 10%. A similar number of subjects (i.e., 10–15 subjects in each group) can be found in the previous neuroimaging studies [27-29].

Study Procedures

All participants will be subjected to measurement of vital signs (blood pressure, pulse rate, and temperature), demographic information, and medical history (past, present, and family). Cognitive function assessments (MMSE-K and K-MoCA) will also be performed during visit 0 (screening). Eligible participants who meet the inclusion and exclusion criteria will receive the schedule for visit 1.

At visit 1, the investigator will check the participant's vital signs and changes in medication, perform 2 fNIRS scans before and after acupuncture stimulation, and assess the level of CR using CRIq. For medications, the investigator will check for changes but will not specifically allow or restrict certain drugs. According to stratified randomization, the participants will be assigned to 2 acupuncture stimulation groups. Acupuncture stimulation will be performed by a Korean medicine doctor with >3 years of clinical experience. fNIRS scans consist largely of 2 main parts: a 5-minute resting state scan and a task scan of working memory.

Cognitive Function Assessment

The investigator will assess 2 cognitive function tests: the MMSE-K and K-MoCA. The MMSE-K is a 30-point questionnaire consisting of 12 questions that are widely used in clinical and research settings to measure cognitive impairment [30]. The K-MoCA is an extensively used 30-point cognitive assessment tool that effectively differentiates MCI [31]. The evaluation of each assessment will be conducted by an investigator blinded to the assigned group.

Measurement of Cognitive Reserve

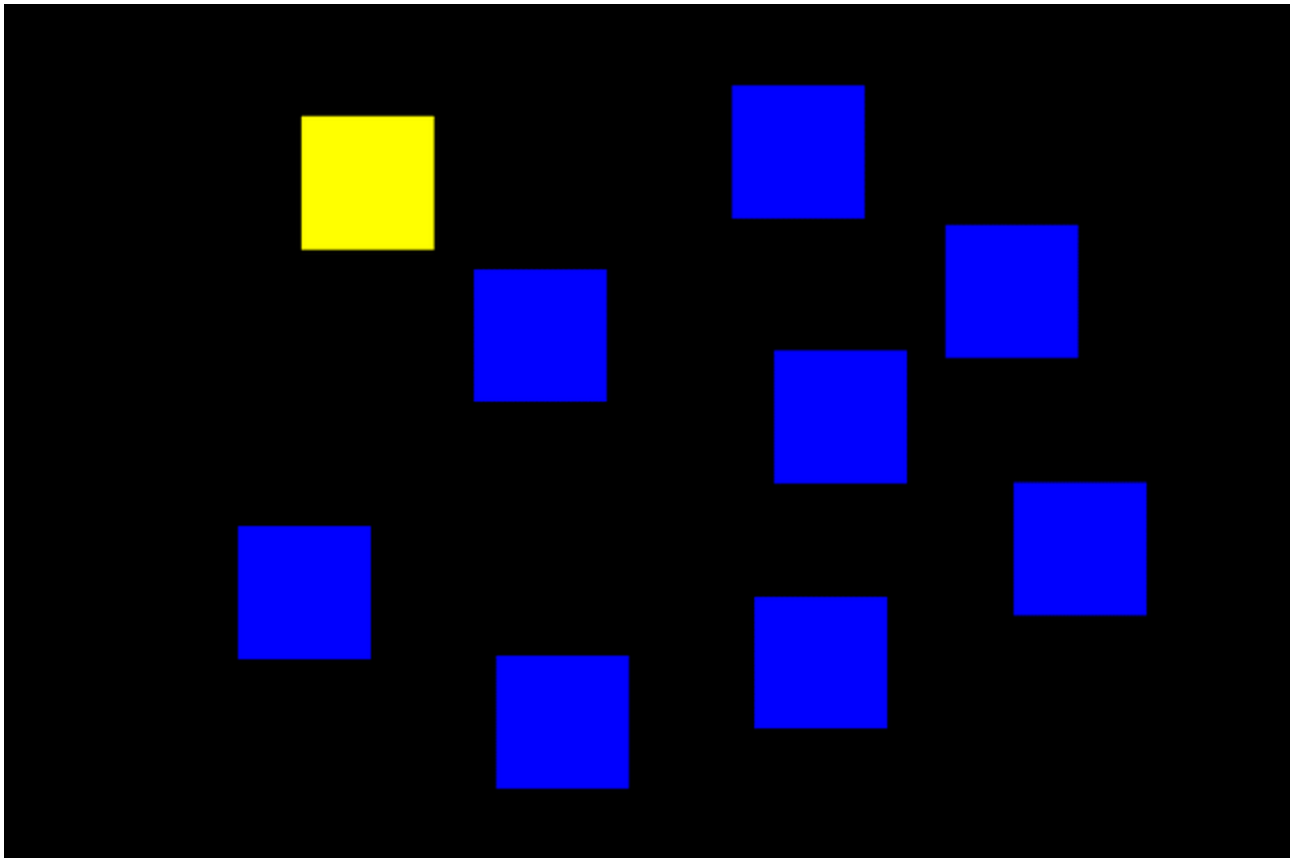
CR assessment will be conducted using the CRIq questionnaire [32]. It includes demographic data and items categorized into 3 sections: education, working activities, and leisure time; each item returns a subscore. It evaluates the CR of an individual by compiling the information associated with the individual's entire adult life. The quantification of CR will be calculated as the sum of all domains, and the subscore of each domain will also be applied in further correlation analysis. Depending on the mean value of CRIq, it will be dichotomized into the high CR and low CR groups. The investigator will also assess the participants' bilingualism. The evaluation of each assessment will be conducted by an investigator blinded to the assigned group.

fNIRS Imaging

For this experiment, fNIRS equipment (NIRSIT, OBELAB) will be used. fNIRS is a portable near-infrared neuroimaging device that measures hemodynamic variations in cerebral blood by irradiating the cerebral cortex with a near-infrared laser. The equipment irradiates the wavelengths of 780 and 850 nm of laser, which is harmless to humans. It contains 48 channels that can cover the frontal regions of the brain, allowing the quantification of ΔHbO_2, ΔHbR, and ΔHbT in that area. Based on this, the analysis applied in fMRI, such as graph theory analysis and general linear model analysis, can be used.

The fNIRS scans will be conducted before and after acupuncture. The scan consists of 2 parts: a resting state and working memory task scan. The resting-state fNIRS scan lasts for 5 minutes, during which the participant is asked to look at the monitor screen and remain comfortable. The task fNIRS scan is performed while conducting a Corsi block tapping task, a cognitive task related to working memory [33]. This experiment requires participants to tap a spatially separated sequence of up to 9 identical blocks in the same order in which they are presented. The sequences start simple, using 4 blocks, and become more complicated using a maximum of 6 blocks (Figure 2).

Figure 2. Presentation of Corsi block task.



Interventions

In the study group, verum acupuncture stimulation will be conducted for 15 minutes by stainless steel acupuncture (0.25 mm×40 mm, Dongbang acupuncture) on acupoints, which are known to be associated with cognitive functions in previous studies (Baihui [GV20], Sishencong [EX-HN1], Taixi [KI3], Zusanli [ST36], Hegu [LI4], and Taichong [LR3]), and deqi sensation will be induced [24,34,35]. The needle will be lifted and thrust approximately 30-50 mm and twisted and rotated at approximately a 90°-180° angle 60 times/minute (60 Hz). The manipulation will then be performed at 1-minute intervals to maintain the amount of stimulation and achieve deqi sensation. A questionnaire on deqi sensations will be implemented.

For the control group, superficial needling acupuncture (depth of needling: 1-2 mm per nonacupoint) will be performed for 15 minutes using stainless steel acupuncture (0.25 mm×40 mm, Dongbang acupuncture) on nonacupoints. Nonacupoints, which are not related to cognitive function, would be approximately 1 cm away from the acupoints of the study group. The needles for sham acupuncture will remain in place. In the case of superficial needling, manipulation techniques and induction of deqi sensation will not be achieved.

Superficial needling can be a subtype of minimal acupuncture [36]. We thought that the characteristics of acupoints, depth of acupuncture stimulation, intensity of the stimulation, and deqi sensation would all be determinants of acupuncture stimulation. Therefore, we selected minimal acupuncture that lacks these features as a sham control. This type of sham acupuncture has been applied in various studies, including Bell's palsy, migraine, and chronic musculoskeletal pain syndrome, for a long time [37-40].

Outcome Measures

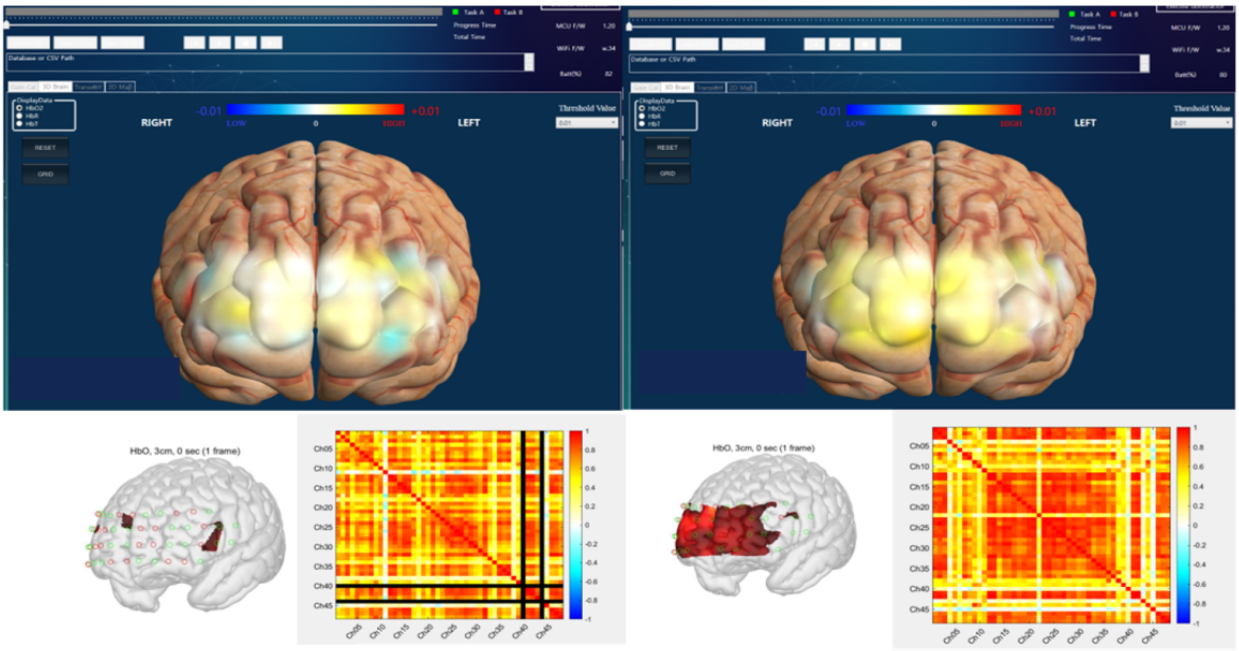
This study aims to explore the immediate neural mechanisms of the acute response to acupuncture stimulation associated with CR in normal aging and disease status and identify the neural substrates of CR.

The primary outcomes will be as follows: (1) differences in brain activation and resting-state brain connectivity according to disease status (the groups with vs without cognitive impairment); (2) differences in brain activation before and after acupuncture between study and control groups (verum acupuncture vs sham acupuncture); and (3) differences in brain activation according to CR (high CR group vs low CR group).

Secondary outcomes are brain connectivity or network metrics (graph theoretic metrics) associated with the CRIq index, differences in brain activity between working memory tasks and resting states, and network metrics associated with cognitive function scores (MMSE-K, K-MoCA).

The brain connectivity matrix will be obtained as Pearson correlation between 48 channels using time-series data during the scan period (Figure 3). Network metrics, including the index of efficiency, clustering coefficient, and centrality, can be calculated using the connectivity matrix by the Brain Connectivity toolbox in MATLAB 2023b (The Mathworks).

Figure 3. Resting-state brain connectivity matrix before acupuncture stimulation (A) and after acupuncture stimulation (B).



(A) Before acupuncture stimulation (B) After acupuncture stimulation

Data Collection, Monitoring, and Dropout Criteria

Data Collection and Adverse Events Monitoring

Demographic information (age, sex, height, and weight), medical history, and concomitant medication will be collected for each participant at the start of the study. Researchers will record blood pressure, body temperature, respiratory rate, and pulse rate in visits 0 and 1. All adverse events will be fully reported in case report forms, and the association between the adverse events and intervention will be evaluated as not related, possibly related, or related. Severity will be evaluated as mild, moderate, or severe. When severe adverse events, including death, life-threatening events, and the need for hospital admission, occur, the investigator will suspend all or part of the clinical trial and notify other investigators and the Institutional Review Board within 24 hours.

Dropout Criteria

The participants will be excluded in the following cases: severe adverse events occur; difficulty proceeding with the trial due to adverse events; the participant or a legal representative wants to stop the trial; the participant withdraws consent to join the trial; the participant fails to finish the interview or the fNIRS scan; and progression of the trial is considered inappropriate by the principal investigator.

Statistical Analysis

Only data from participants who completed the fNIRS scan, cognitive function test, and measurement of CR will be contained in the statistical analysis. All categorical data are presented as frequencies or percentiles and will be analyzed using the chi-square or Fisher's exact test. All numerical data will be presented as the mean and standard deviation and analyzed using an independent *t* test or Wilcoxon rank-sum test. Preprocessing and analyses of fNIRS data will be performed using MATLAB and the NIRSIT analysis tool.

A two-sample *t* test will be performed to compare the brain activations and connectivity between the groups with and without cognitive impairment. A paired *t* test will be conducted to compare the brain activations and connectivity before and after acupuncture stimulation. The CR values from CRIq will be applied for correlation analysis in the form of continuous variables or divided into binary groups (high and low CR) by mean values for subgroup analysis. Since the expression of CR may appear differently depending on the disease status, a subgroup analysis will be conducted by dividing the healthy control and the patient group. Mixed model analysis will be adjusted to determine the interaction effect of intervention and CR in both groups. Pearson correlation will determine the CR-related brain connectivity or clinical score–related metrics. If there is a significant age difference between 2 groups, the age factor will be added as a covariate in the analysis to adjust the effect of age as much as possible.

Statistical significance in fNIRS imaging would be explored using uncorrected and corrected levels (false discovery rate and family-wise error). At the uncorrected level, uncorrected $P<.001$ will be used, and at the corrected level, $P<.05$ will be applied.

Data Management

The investigators will collect and record the medical information in each participant's case report form. All study data, including all patient confirmations, all original signed informed consent forms, and detailed original records, will be retained by the study institution for 3 years after the end of the trial.

Quality Control

Important protocol modifications must be reported to the IRB. The approval period of the trial is 1 year, and after 1 year,

regular reports must be submitted to the IRB, and re-approval should be obtained. Before the beginning of the trial, all investigators involved in the intervention will be trained in the process of the trial. In total, 2 independent research assistants will check the data and case report forms to avoid mistyping or errors during the trial. There is no plan for early termination of the study before February 2025. If the target number of participants is complete, additional recruitment may proceed depending on the research funding status.

Ethical Considerations

The trial will be performed in accordance with the Declaration of Helsinki. This trial has been approved by the Institutional Review Board of Sangji University (1040782-230426-HR-04-112). The protocol has been registered with the Clinical Research Information Service of the Republic of Korea (number KCT0008719), one of the WHO ICTRP Primary Registries. Written informed consent will be obtained from each participant or their legal representative. All data will be anonymized, and the identification information of all documents will be recorded according to the identification code. The information will be kept confidential in a locked place. Participants in this study will be paid a small compensation fee, approximately 50,000 won (equivalent to approximately US $30), for participation in the study.

Results

The recruitment and enrollment of the study began in August 2023, and to date, there have been 50 participants, divided into 20 in the group with cognitive impairment and 30 in the unimpaired group. Within the group with cognitive impairment, 16 participants (80%) had dementia and 4 subjects had MCI. The percentages of female participants in the group with cognitive impairment and the group without cognitive impairment were 70% and 57%, respectively. Ongoing recruitment is in progress. The protocol version used in this study is V.1.0 (2023.06.12). This study will continue until February 2025, after which the communication of final results will be made in accordance with the CONSORT checklist.

Discussion

Overview

Dementia affects an estimated 57 million people worldwide, and AD is the most common dementia-inducing disease [41]. The neuropathologic hallmark of AD is extracellular amyloid beta deposition and neurofibrillary tangles consisting of phosphorylated tau protein [42]. Although various therapeutic drugs are being developed with the advancement of medical technology, there is no definitive treatment for AD. Therefore, early diagnosis and prevention are important for cognitive impairment disorder.

At first, CR originated from the observations of the mismatch between the pathological degree of brain damage and clinical symptoms. In a postmortem study, there were neuropathological alterations comparable to dementia; however, the participants had no symptoms of dementia in their lives [43]. In this context, CR is considered a factor mediating the relationship between the neuropathology of the disease and clinical manifestation and has clinical importance as a prognostic factor of the disease trajectory [44]. There are several CR surrogate markers, including years of education, occupation, leisure activities, composite scores, questionnaires, and residual methods using imaging markers. This study applies a CRIq, which consists of subscores of lifelong education, occupation, and leisure activity as the main CR proxy.

Acupuncture has been used to treat several neurological diseases in East Asian countries. Several studies have revealed the effects and mechanisms of acupuncture in MCI or AD using neuroimaging methods. Moreover, studies applying fNIRS have reported the neural mechanisms of acupuncture manipulation in patients with MCI and healthy participants [45,46]. However, there have been no studies on the neural mechanisms of acupuncture stimulation in relation to CR.

This randomized, placebo-controlled clinical trial aims to investigate the neural substrates of CR in both the normal group and the group with cognitive impairment and explore the neural mechanisms of acupuncture stimulation in relation to CR using fNIRS. The potential significance of this research lies in elucidating the connection between acupuncture and CR, thus providing insights into the therapeutic possibilities for cognitive impairments. We expect to contribute to identifying neural mechanisms of acupuncture stimulation in cognitive impairment in relation to CR. This study could provide a basis for further study about the long-term effects and mechanisms of acupuncture treatment in cognitive impairment.

Innovations and Limitations

This is the first study to identify the association between CR, an important factor related to the prognosis of dementia, and acupuncture stimulation. The application of the neuroimaging method (fNIRS) can provide new insights into the neural mechanisms of complementary medicine in the field of convergence research. This randomized, controlled trial can contribute to elucidating the genuine neural response to the acupuncture stimulation. However, as a cross-sectional study, it is not possible to identify the long-term effect of acupuncture treatment on cognitive impairments and explore the longitudinal neural mechanism of acupuncture treatment. Additionally, to ensure the reliability of the data, we still further expand the sample size.

Conclusions

This study will provide data on the neural substrates of acupuncture stimulation associated with CR as well as brain network alterations depending on disease status. More importantly, if the acute neural mechanisms of acupuncture stimulation are identified, the results could serve as a basis for the long-term effects of acupuncture treatment on cognitive impairments. This study could provide a scientific foundation for further clinical application of acupuncture as a complementary medicine for cognitive impairments, which induce a high socioeconomic burden.

Abstract

Background: Childhood obesity frequently persists into adulthood and is associated with an increased risk and earlier onset of cardiovascular disease in later life. Behavioral change strategies have been proposed as the first-line weight management approach for children and adolescents with obesity. Nonpharmacological interventions, such as traditional Chinese medicine (TCM) auricular acupressure treatment and intermittent low-carbohydrate diet (ILCD), are increasingly being investigated in the young obese population. However, there is limited high-quality evidence about effectiveness and safety in weight control and reducing cardiometabolic risk in the pediatric population.

Objective: This study aimed to compare the effect of cardiometabolic risk reduction between TCM auricular acupressure treatment (TAAT) and ILCD in children with overweight or obesity with gastric-heat and dampness-obstruction syndrome.

Methods: This is a randomized controlled trial. Eligible participants are children with overweight or obesity and enrolled at the obesity clinic of the department of TCM at a tertiary children's hospital. Eligible participants must meet the following criteria: (1) be aged between 6 and 18 years, (2) be overweight, and (3) have gastric-heat and dampness-obstruction syndrome. Recruited children will be randomized 3:1 to receive either TAAT or a self-administered ILCD for 1 month: 150 in the TAAT group and 50 in the ILCD group. The primary outcome is the change in body weight from the beginning of treatment to the end of 1 month. Secondary outcomes included body weight, waist circumference, waist-to-height ratio, BMI, blood pressure, body fat content, indexes of liver and renal function, indexes of glucose metabolism, gut microbiota, and TCM syndrome scores at the end of 1 month and 3 months, respectively. Primary statistical analyses were conducted using the intention-to-treat strategy. A generalized linear model was used to compare the difference in weight change between the groups, with the baseline body weight as the covariate, to obtain the estimate of the mean difference in body weight change and its 95% CI, using Gaussian for family function and identity for link function.

Results: The study protocol was approved by the institutional ethical committee and registered on ClinicalTrials.gov on May 5, 2023, before recruitment. Recruitment began in June 2023 and is expected to be completed by December 2025. As of November 2024, we have enrolled 112 participants.

Conclusions: This randomized controlled trial will provide evidence on the treatment effects and safety of TAAT versus ILCD among children with overweight or obesity with gastric-heat and dampness-obstruction syndrome, in reducing body weight and

improving cardiometabolic risks. Exploratory aims include potential underlying mechanisms of the 2 kinds of interventions, based on biosamples.

Introduction

The Report on Cardiovascular Health and Disease in China (2022) [1] shows that cardiovascular disease is the leading cause of death among urban and rural residents in China, which is mainly caused by hypertension, dyslipidemia, diabetes, overweight or obesity, physical inactivity, inappropriate diet, and metabolic syndrome. It is important to note that obesity, especially abdominal obesity, is a direct risk factor for cardiovascular disease. Unfortunately, obesity can persist from childhood and adolescence into adulthood [2,3]. Obesity in children and adolescents is a global health issue [4], with China, India, the United States, Indonesia, and Brazil being the top-ranked countries, each estimated to have more than one million children with obesity in 2030 [5].

First-line treatments for obesity should be supported by behavioral change strategies [4]. Family-based interventions that address diet, physical activity, sedentary behavior, and sleep quality are recommended. However, the weight loss effect is not ideal and is difficult to maintain. Although evidence for pharmacotherapy and bariatric surgery as supplemental therapies is emerging, they are not recommended for weight loss in children [6]. In fact, safer and more acceptable nonpharmacological interventions, such as traditional Chinese medicine (TCM) and TCM auricular acupressure treatment (TAAT), are increasingly used.

The earliest known mention of TAAT dates back to Huang Di Nei Jing (circa 100 BC) [7,8]. Currently, auricular therapy is widely used in clinical settings for pain relief, epilepsy treatment, improving sleep quality, and obesity [9-11]. This approach offers the advantage of individualized treatment based on the dialectical theory of governance. TAAT has been found effective on children, adolescents, and adult obesity [12-14]. The study found that auricular acupuncture stimulation clearly modulates the feeding-related hypothalamic neuronal activity of experimental (both hypothalamic and dietary) obese rats. The results suggest that auricular acupuncture stimulation may not reduce appetite but is more likely concerned with satiation formation and preservation [15]. However, high-quality clinical evidence is lacking. According to TCM, obesity is located on the spleen and stomach, followed by the liver and kidney. TCM identifies several syndrome types of obesity, including gastric-heat and dampness-obstruction syndrome, spleen-deficiency and dampness-stagnation syndrome, liver-qi stagnation syndrome, and spleen-kidney deficiency syndrome [16,17]. Among these, gastric-heat and dampness-obstruction syndrome is the most common type [18]. In order to ensure the sample size is attained, the gastric-heat and dampness-obstruction syndrome has been selected for inclusion in the study. In addition, the choice of a single syndrome in preference to multiple options ensures comparability in the evaluation of efficacy between groups.

Numerous studies have demonstrated the effectiveness of low carbohydrate diets (<50 g per day or <10% energy from carbohydrates) in combating obesity [19], deemed feasible and acceptable [20,21]. Our previous research has shown that the intermittent low carbohydrate diet (ILCD) was effective in improving weight-related outcomes in children and adolescents [22]. However, the efficacy needs to be further investigated, and long-term effects are uncertain. So far, there are currently no randomized controlled trials comparing the effectiveness between ILCD and TAAT. At the same time, our secondary aim is to explore the mechanistic differences between the 2 nondrug interventions. Therefore, this study aims to assess whether TAAT as the experimental arm is more effective than ILCD as the control arm in improving the cardiometabolic risk in children with overweight or obesity with gastric-heat and dampness-obstruction syndrome.

Methods

Objective and Trial Design

This is a randomized controlled superiority trial that aims to compare the effects of TAAT versus ILCD in reducing the cardiometabolic risk in children with overweight or obesity with gastric-heat and dampness-obstruction syndrome. Participants were allocated in a 3:1 ratio to either an auricular acupressure treatment group or a control group. The TCM clinicians were aware of the allocation but did not participate in the following research. Conversely, the outcome observers were blinded about the allocation.

Recruitment and Study Setting

Eligible participants were recruited by a pediatrician at the obesity clinic of the Department of TCM in Children's Hospital of Fudan University. All participants were required to provide written consent before intervention.

Participants Eligibility Criteria

Eligible participants must meet the following criteria: (1) be aged between 6 and 18 years, (2) be overweight [23], and (3) have gastric-heat and dampness-obstruction syndrome [16].

Overweight or obesity with gastric-heat and dampness-obstruction syndrome was defined as follows:

(1) The "Expert Consensus on Diagnosis, Assessment, and Management of Obesity in Chinese Children" states that BMIs between 85% and 95% were classified as overweight, while those above 95% were classified as obese for children of the same gender and age [23].

(2) The "Pediatrics of Traditional Chinese Medicine" framework [16] outlined the conditions that must be met for the gastric-heat and dampness-obstruction syndrome, which include (1) dizziness and heaviness in the head, (2) thirst, (3) rapid digestion of food and polyorexia, (4) heaviness of limbs, (5) fatigue body and lack of strength, (6) a red tongue, (7) greasy fur, and (8) a slippery pulse. It is important to note that conditions (7) and (8) must be satisfied, while conditions (1) to (6) must be satisfied at least 3 conditions.

Participants who met any of the following exclusion criteria were excluded: (1) having hereditary obesity or obesity caused by endocrine disorders, such as Cushing syndrome, primary hypothyroidism, and hypothalamic obesity; (2) currently being enrolled in other clinical trials or having participated in another clinical trial in the past 3 months; (3) self-administration of oral weight-loss medications or other forms of meal replacements; and (4) having serious organic diseases of the heart, liver, kidneys, or brain, or infectious diseases or psychiatric disorders.

Interventions

Experimental Group (TAAT Group)

Specialized TCM clinicians conducted TAAT following a standardized procedure. The location and operation of the ear acupoints followed the guidelines outlined in the "National Standard of the Peoples Republic of China for Nomenclature and Location of Auricular Points (GB/*t* 13734-2008)." In addition, all TCM clinicians had received specialized training to ensure a comprehensive understanding of the auricular acupressure intervention program and to standardize the procedures performed by different clinicians.

The study selected the following ear acupoints for acupressure treatment: Shenmen (TF4), Xiaoping (TG2), Endocrine (CO18), Stomach (CO4), Mouth (CO1), and Subcortex (AT4) (refer to Figures 1 and 2) [24]. The acupressure was administered using an opaque patch with Vaccaria seed. Participants were instructed to apply pressure for 1 minute before and after meals each day, for a total of 2 to 3 days per week. They were followed weekly and received a 3-course treatment, with 1 course per month.

Figure 1. Location of the subcortex (AT4).

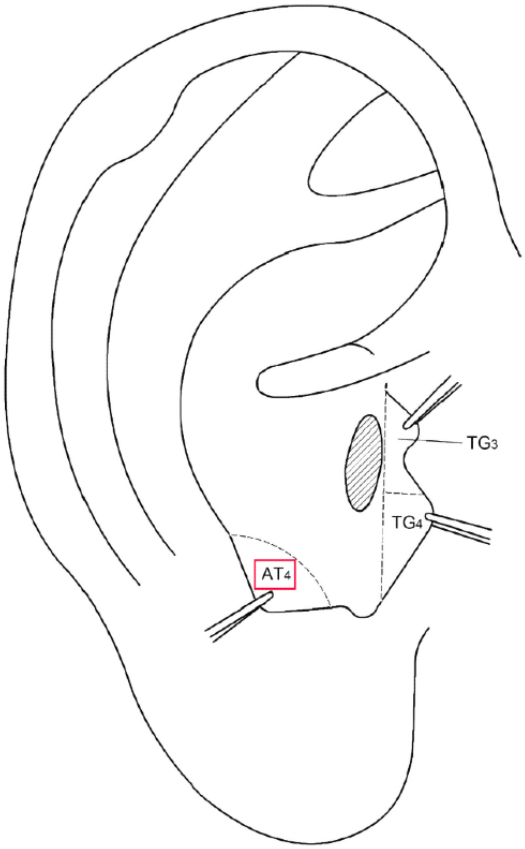

Figure 2. Location of the shenmen (TF4), Xiaoping (TG2), endocrine (CO18), stomach (CO4), mouth (CO1).

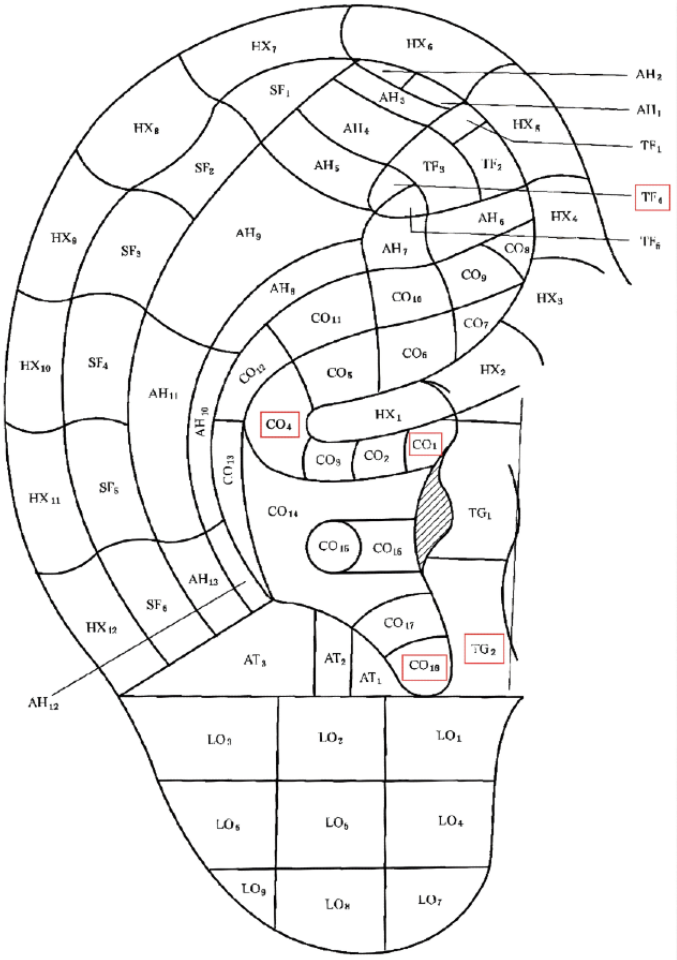

Control Group (ILCD Group)

Participants were required to limit their daily carbohydrate intake to 50 g or less, while their dietary calorie intake was not restricted for nonconsecutive 7 days of 2 weeks, corresponding to 14 days in a month. On the remaining days, participants should maintain their normal diet. The intervention period lasted for 1 month, followed by a 2-month follow-up period [20].

Follow-Up Period

First, a WeChat group was created for parents of participants to facilitate communication and monitoring about diet and exercise recording, as well as scheduling follow-up appointments. Second, adherence to the study interventions were uniformly assessed in both groups at each visit. Third, if participants missed any visits, investigators would contact them directly by telephone to encourage continued participation and evaluate barriers.

The research assistant attempted to establish contact with the missed participants. A dropout participant was defined as someone who had not been reached for 3 months. If participants decided to withdraw before completion, all collected data would be remained for analysis.

Outcomes

Primary Outcome

Change in body weight from the beginning of the treatment to 1 month.

Secondary Outcomes

Secondary outcomes included body weight, waist circumference, waist-to-height ratio, BMI, blood pressure (BP), body fat content, glucose metabolism, blood lipid levels, liver and kidney function, composition of gut microbiota, and TCM syndrome score, and were assessed at the end of 1 month and 3 months, respectively.

Measurement

Anthropometry

Including the measurements of weight, height, waist circumference (WC), and BP. These measurements should be taken by the same person, using the same instruments, at the same time of day. Each measurement should be taken 3 times in a row, and the average of the 3 values should be used.

(1) **Weight measurement:** The participant should be weighed in light clothing and preferably with an empty bladder. They should also remove shoes, heavy jewelry, and watches. The electronic weight scale should display 0.0 before the participant stands on it. The participants should stand with their feet

together in the center and their heels against the back edge of the scales. The participant's arms should be hanging loosely at their sides and their head should be facing forward. The weight measurements were recorded in kilograms and were accurate to 0.1.

(2) **Height measurement:** Height should be measured using a stadiometer with the participant standing barefoot and with feet together. The head should be positioned level with a horizontal Frankfurt plane, which is an imaginary line from the lower border of the eye orbit to the auditory meatus. Any hair knots or braids that may interfere with the measurement should be untangled. The press plate should be in contact with the head with moderate tightness. The height measurements were recorded in centimeters with an accuracy of 0.1.

BMI was a widely used tool for assessing the risk of overweight and obesity in individuals. It was calculated using the following equation:

(3) **Waist circumference measurement:** The measurement should be taken while the participant exhales. WC was measured by placing a tape measure around the waist, 1 cm below the navel, with the participant standing and arms naturally at their sides. Record the data in centimeters with an accuracy of 0.1.

Waist-to-height ratio had emerged as a surrogate for abdominal obesity that also takes into account body size and allows the same cut of across age and gender [25]. It was calculated using the following equation:

(4) **Blood pressure measurement:** BP was measured on the right arm using the CONTEC08A electronic sphygmomanometer (CONTEC Medical Systems Co). The participant should be seated in a quiet room for 3-5 minutes before measurement, with the back supported and feet uncrossed on the floor. The right arm should be at heart level, supported, and uncovered above the cuff. The correct cuff size should be used. The bladder length should be 80%-100% of the circumference of the arm, and the width should be at least 40%.

Body Fat Content

Body composition was measured by determining the body fat percentage using the LUNAR dual photon X-ray dual-energy X-ray absorptiometry equipment (General Electric Company). Dual-energy X-ray absorptiometry was a medical imaging technology that used low dose radiation for a whole-body scan to provide accurate measurements of fat percentage. The equipment was operated by qualified professionals.

Venous Blood Tests

The tests were conducted after a 10-hour overnight fast to avoid any influence of diet on the test results. The tests included glucose metabolism, blood lipid levels, and liver and kidney function. The remaining blood samples were stored in a –80°C refrigerator for further testing. The operators conducting the tests possessed professional qualifications.

TCM Syndrome Score

"Pediatrics of Traditional Chinese Medicine" listed a number of TCM symptoms in obesity with gastric-heat and dampness-obstruction syndrome: (1) dizziness and heaviness in the head, (2) thirst, (3) rapid digestion of food and polyorexia, (4) heaviness of limbs, (5) fatigue body and lack of strength, (6) a red tongue, (7) greasy fur, and (8) a slippery pulse. Each item was scored on a scale of 0-2, with 2 points for obvious symptoms, 0 points for nonsymptomatic, and 1 point for symptoms that are between obvious and nonsymptomatic. The total syndrome score was obtained by adding up the scores for each item. A qualified clinician performed the score evaluation.

Gut Microbiota Test

Stool samples were collected using Boyou nucleic acid storage tubes (Shanghai Biotechnology Corporation) and stored in a laboratory refrigerator at –80°C. To study intestinal flora diversity, the 16S rDNA target region would be amplified, and information on intestinal microbial diversity and community composition will be obtained by detecting sequence variation and abundance of the target region. The operators possessed professional qualifications.

Dietary and Exercise Data

Diet and exercise data were recorded by the children and their families, but they were educated by qualified clinicians before recording [26,27].

(1) **From the baseline to the first month:** The weight of the food was measured using an electronic scale before and after each meal, and photographs were taken as well. Participants were required to wear sports watches every day, including during sleep, but not while bathing, swimming, or in other special cases. Dietary data included the type and weight of the foods consumed, while exercise data included step count, calorie consumption, resting heart rate, sleep duration, and exercise type. All data was meticulously recorded daily in the "Diet and Exercise Handbook."

(2) **From the second month to the third month:** The method and content remained unchanged. Dietary and exercise data were recorded on Thursdays, Fridays, and Saturdays during 1 week, and distributed at the beginning, middle, and end of the month, rather than every day.

Participant Timeline

The participant timeline was shown in Table 1, following the Standard Protocol Items: Recommendations for Interventional Trials (SPIRIT) diagram [28].

Table 1. Schedule of enrollment, interventions, and assessments for the trial. t1, preinclusion assessment; t0, baseline; t1, intervention for one 1 month; t2, intervention for 3 months.

[d]TCM: Traditional Chinese Medicine.

Sample Size

The primary outcome was the change in body weight from baseline to 1 month. The sample size calculation was based on the difference in weight change between the 2 groups: the TAAT group and the ILCD group.

Our pilot data from 12 patients revealed a weight loss of 1.9 kg after 4 weeks of TAAT and a weight reduction of 1.4 kg after 4 weeks of ILCD, with an SD of 1.1 kg. We assumed a 0.5 kg difference in weight reduction between the 2 arms, power of 0.80, a 2-sided α of .05, and a sample size ratio of 3:1, a minimum sample size of 150 for the TAAT group and 50 for the ILCD group were required, respectively. Assuming a dropout rate of 15%, the trial enrolled at least 240 participants. The “test for 2 means module” of the PASS 16.0 software was used.

Recruitment

The estimated period for recruitment, intervention, and data collection would take probably 30 months to complete. Eligible clients attending the obesity clinic at the Children’s Hospital of Fudan University were invited to participate in the study through collaboration with TCM clinicians. The time required for participant recruitment and baseline assessment was approximately 30 to 45 minutes.

Randomization and Blinding

Participants were randomly assigned to either the experimental or control group through a simple randomization process generated by the R Language (version 4.2.2; R core team). This process was designed by the clinical trial unit of the Children’s Hospital of Fudan University and follows a 3:1 allocation ratio.

The study coordinator, who was not involved in data collection, performed the allocation. The randomization list was kept strictly confidential. Allocation was done by the study coordinator in a sequentially numbered fashion using identical, opaque, sealed envelopes. The recruiting clinicians were blinded to study group allocation and did not have access to the allocation sequence.

Eligible participants were enrolled by trained clinicians. The study coordinator independently assigned participants to either the intervention or control groups. Outcome observers were blinded. The analysis team received aggregated data obtained for the control and experimental groups. Study participants

could be blinded, but they were scheduled for separate follow-up dates.

Adverse Events and Assessment of Safety

After participants provided informed consent and enrolled in the study, any adverse events were collected and recorded until the end of the study period. Adverse events that occurred after consent was signed, but before receiving the study intervention was reported as not related to our intervention. Any serious adverse event that occurred would be reported to the principal investigator and documented.

Data Management and Monitoring

Trained clinicians were input data onto a paper-based clinical research form designed by the research team. Once data collection was complete for each participant, it would be entered into an electronic database with built-in checks to ensure completeness. Data monitoring has occurred periodically throughout the study. We used access to create a database, and 2 investigators independently performed dual data entry twice. Once verified, the database was saved appropriately. After confirming the accuracy of the database, it was locked and submitted to an independent statistical team for analysis.

Statistical Analysis

Primary statistical analyses were conducted using the intention-to-treat strategy. Sensitivity analyses were performed using per-protocol set analysis.

Analysis of Primary Outcome

The primary outcome in this study was the change in body weight from baseline to 1 month. A generalized linear model (GLM) was used to compare the difference in weight change between the groups, with the baseline body weight as the covariate, to obtain the estimate of the mean difference in body weight change and its 95% CI, using Gaussian for family function and identity for link function.

Analysis of Secondary Outcomes

GLM was used to obtain differences in effect sizes and their 95% CI for continuous variables between groups. Categorical variables were described in absolute numbers (percentages) and GLM was used to obtain differences in effect values and their 95% CI, using logistic for family function and logit for link function.

Statistical analyses were conducted using Stata 16.0 software (StataCrop). All statistical tests were 2-sided with a significance level of α=.05. Differences were considered statistically significant at P<.05.

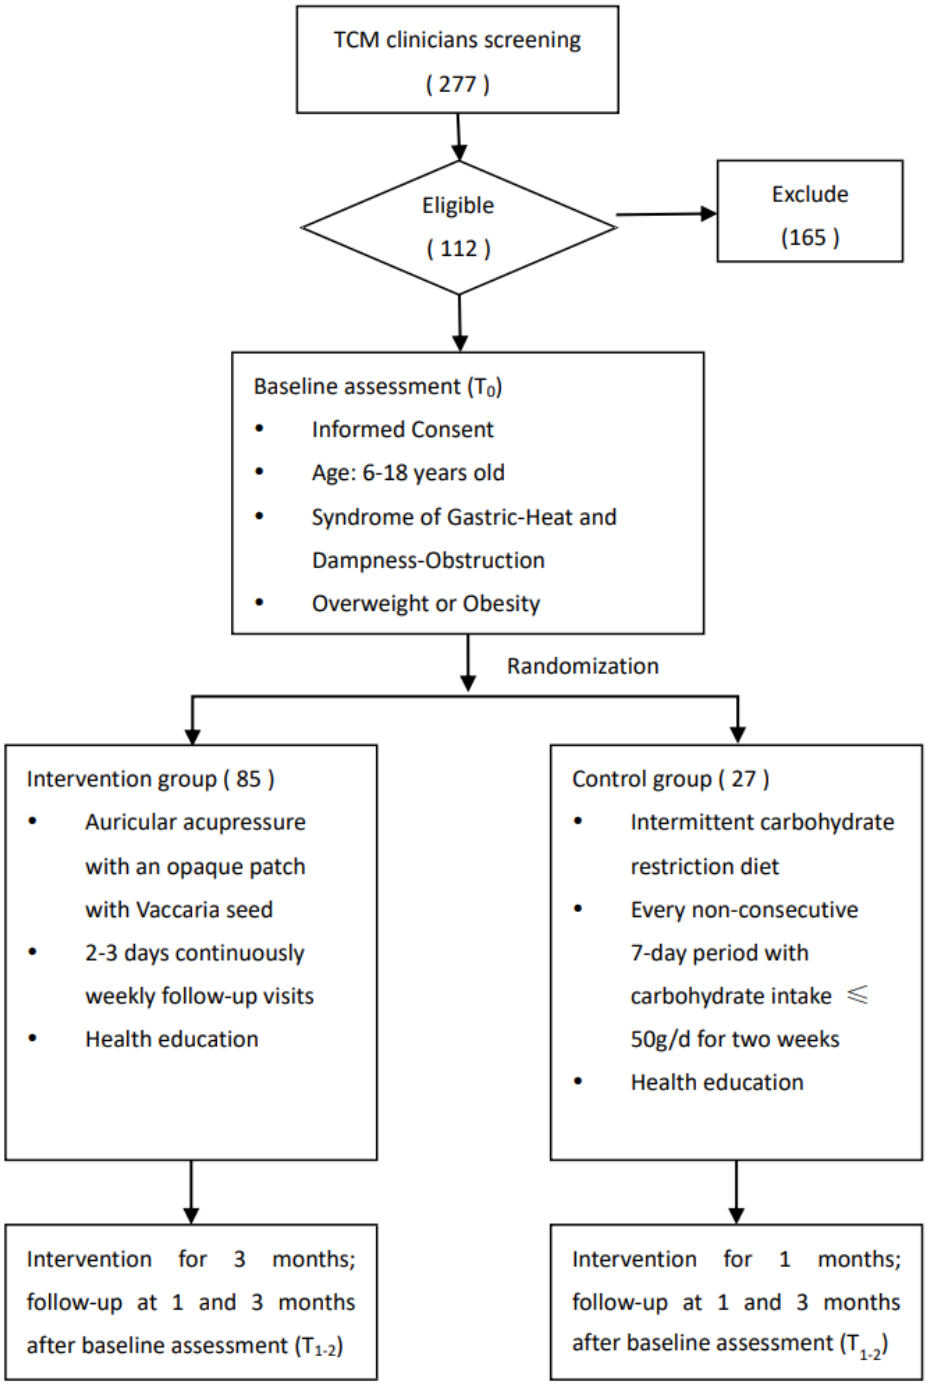
Ethical Considerations

This study has been approved by the Medical Ethics Committee of the Children's Hospital of Fudan University and will be conducted in accordance with the approved guidelines and regulations of the participating institution (approval number 2021 [.350]). This trial was conducted in accordance with the current version (AP_IDR_2.0) of the protocol, which has been registered at ClinicalTrials.gov. Informed written consent was obtained from all patients before inclusion in the study. As the involvement of the patients were voluntary, the study could be stopped at any time. All records that contain names or other personal identifiers were stored separately from study records identified by code number. The identification of participants in any images of the manuscript or supplementary material was impossible. For example, the researchers provided the necessary recording materials and sample collectors. The intervention method did not entail additional costs for the participants; thus, no compensation was required.

Results

The protocol was registered on ClinicalTrials.gov (NCT05847478) on May 5, 2023. The current protocol is version 2.0, dated February 28, 2023, which is the final version as approved by the institutional ethical committee. Recruitment started in June 2023 and is expected to be completed in December 2025. By November 2024, we had enrolled 112 participants (Figure 3).

Figure 3. Flowchart of the study. TCM: traditional Chinese medicine; T0: baseline; T1: intervention for 1 month; T2: intervention for 3 months.



Discussion

Anticipated Findings

It is hypothesized that TAAT will prove superior to ILCD in controlling body weight through this clinical trial. In addition, it is anticipated that the mechanistic differences between the 2 nondrug intervention methods will be elucidated. This study will be the first randomized controlled trial to investigate the effect and safety of TAAT compared with ILCD for overweight or obesity and other cardiometabolic risk factors. Previous studies on the effects of auricular treatment have mainly focused on adolescents and adults [12,14]. A study was conducted as a randomized controlled trial to examine the effects of auricular acupressure on obesity improvement in children. However, this trial had a small sample size and did not take into account the impact of diet, exercise, and lifestyle on body weight [15]. Consequently, there is a lack of high-quality clinical trials on the effects of TAAT in children with obesity, although we found some clinical evidence of this approach in children. Furthermore, the participants' gut microbiota will be studied in order to explore the underlying mechanisms of the 2 different interventions.

All participants in this study are patients from the Department of TCM and seeking TCM intervention. As one of the treatment methods in TCM, previous studies have shown that TAAT is effective in reducing body weight, WC, and body fat mass

[14,29]; therefore, we did not consider a blank control group, instead, using an ILCD, according to its effect indicated in recent randomized trials [30,31].

TAAT appears minimal side effects, including the pain caused by local noninvasive stimulation that can be tolerated by most children [32]. As participants are recruited from the obesity clinic of the Department of TCM, randomization is set in a 3:1 ratio, allowing that needs of more participants are satisfied.

Maintaining compliance remains challenging to the young population. To ensure better compliance, we use methods such as regular reminders and random checks. To avoid bias, the outcome observer is unaware of the grouping of the participants.

In conclusion, we will evaluate the efficacy and safety of the TAAT in losing weight and improving the cardiometabolic risk of overweight or obese children with gastric-heat and dampness-obstruction syndrome. The results of this study will lead to an update of the consensus on TCM intervention for obesity. However, given the limitations of the intervention time in the experimental design, it is hoped that in future clinical trials, the intervention and follow-up time will be extended in order to obtain a long-term evaluation of the intervention effect.

Conclusion

We conducted a pragmatic randomized controlled trial to investigate the effect and safety of TAAT compared with ILCD for overweight or obese children comorbid with at least one cardiometabolic risk factor. Furthermore, our study will investigate the participants' differential responses of gut microbiota and serum biomarkers to examine underlying mechanisms. The protocol of our study will provide methodologic information and obtain interesting evidence from children for the 2 kinds of nonpharmacological interventions.

Acknowledgments

We thank all the patients and doctors who participated in this study. The funding agency had no role in the study design, data collection, data analysis, data interpretation, writing of the report, or the decision to submit the report for publication.

This study was supported by grants from the Shanghai Municipal Comprehensive Hospital Integrated Traditional Chinese and Western Medicine Special Project Funding (project number ZHYY-ZXYJHZX-202111).

Abstract

Background: Colles fracture, a common wrist injury, often requires surgical intervention. After surgery, patients may experience persistent pain and reduced wrist function, potentially resulting in long-term disability. In clinical practice, traditional Chinese medicine practitioners frequently use Ru-Yi-Jin-Huang-Saan (RYJHS) to treat such patients in Taiwan. RYJHS is a traditional Chinese herbal formula with a history spanning centuries, primarily used topically for the treatment of bone fractures and the promotion of healing. However, there is currently a lack of substantial clinical evidence supporting its efficacy in the management of postsurgical Colles fractures. To the best of our knowledge, there are no studies evaluating the clinical effectiveness of RYJHS.

Objective: This study aims to investigate the therapeutic potential of RYJHS in postsurgical Colles fracture cases. An additional objective is to provide an alternative treatment option for postoperative patients unable to take anti-inflammatory and pain relief medications.

Methods: This is a protocol for a randomized, double-blind, placebo-controlled trial. A total of 100 postoperative patients with Colles fracture, aged 20-80 years, will be recruited for this study. They will be randomly assigned to either the experimental or control group in a 1:1 allocation ratio. Both groups will receive standard postoperative Colles fracture treatment. The primary outcome measure will assess wrist functional recovery using the Patient-Rated Wrist Evaluation score. Secondary outcomes will include C-reactive protein levels and ultrasound measurements of wrist swelling. All of these examinations will be assessed at baseline, 3 days after surgery, and 6 days after surgery. In addition, the Dyshidrotic Eczema Area and Severity Index will be used to monitor for adverse skin reactions.

Results: This protocol was registered at ClinicalTrials.gov on December 6, 2022. It was performed in accordance with the approved guidelines and regulations of the participating institutions. Recruitment began in May 2023, with data collection expected to conclude in May 2025. Study completion is expected in December 2025.

Conclusions: This is the first protocol discussing the assessment of the therapeutic efficacy and safety of topical traditional Chinese medicine in patients after fracture surgery. The protocol will establish an integrated care model combining both traditional Chinese medicine and Western medicine for postsurgical fracture cases.

Trial Registration: ClinicalTrials.gov NCT05638360; https://clinicaltrials.gov/ct2/show/NCT05638360

Introduction

Distal radial fracture is the most common fracture clinically and is approximately one-sixth of cases in emergency departments in the United States [1]. Studies on the Taiwanese population have shown that the prevalence of Colles fracture was 10.2-14.5 per 10,000 people [2]. This situation causes huge losses to the social economy, as well as decreased school attendance, lost work hours, care needs, and permanent disability [3]. In the Western world, closed reduction and cast immobilization are the first choices of treatments in most cases of distal radius fracture [4]. However, surgery intervention is the first choice in Taiwan. Unfortunately, pain and swelling after surgery may hinder rehabilitation and the regaining of hand function, such as postponed recovery of range of motion, daily function, and muscle power [5]. To control pain and swelling, physicians often use ice packing [6], opioids, nonsteroidal anti-inflammatory drugs (NSAIDs), and steroids [7-9]. Some studies reported that these drugs can have the risk of addiction, lead to respiratory restriction, delay fracture wound healing, raise the risk of osteoporosis, and raise glucose levels [10-13]. Since internal medicine has side effects, external medicine should be used to reduce swelling and relieve pain after the operation.

Traditional Chinese medicine (TCM) has been used to treat fractures for thousands of years. In animal studies, TCM extracts have been shown to accelerate bone healing and prevent delayed fracture healing and nonunion [14]. Other studies have also shown that TCM inhibits the inflammatory response in osteoarthritis rat models [15,16]. Until now, there has been no published study on the application of TCM in the treatment of postoperative fractures. However, TCM for external application has been widely used to treat swelling and pain after fracture. Therefore, we have designed an experiment to verify the curative effect of the external application of TCM in fracture surgery.

Ru-Yi-Jin-Huang-Saan (RYJHS) is a TCM herbal patch composed of a fixed blend of TCM ingredients combined with water. It is traditionally applied to relieve swelling and pain in the early stages of musculoskeletal injuries, attributed in TCM theory to its heat-clearing and swelling-reducing properties. Modern pharmacological studies also confirm its antibacterial, anti-inflammatory, wound-healing, and hemostatic effects [17,18]. As recorded in the classic TCM text, *The Golden Mirror of Medicine*, RYJHS is prescribed for conditions such as furuncles, carbuncles, traumatic wounds, mumps, contact dermatitis, lower limb edema, mastitis, and cellulitis. An animal study also demonstrated that RYJHS significantly accelerated fracture healing, notably enhancing collagen formation and bone cell metabolism [19].

The primary components of RYJHS include *Trichosanthis radix*, *Rhei radix et Rhizoma*, *Phellodendri cortex*, *Curcumae longae rhizoma*, *Angelicae dahuricae radix*, *Magnoliae cortex*, *Glycyrrhizae radix et Rhizoma*, *Citri reticulatae pericarpium vetum*, *Atractylodis rhizoma*, and *Arisaematis rhizoma*. Pharmacological research highlights the various therapeutic properties of these components (given in Table 1). For example, *Trichosanthes kirilowii* extract has been shown to accelerate wound healing and possesses antibacterial and anti-inflammatory effects [20-22]. *Rhei radix et rhizoma* inhibits inflammation via NF-κB inactivation [23], and *Phellodendri cortex* has both anti-inflammatory and antibacterial properties [24,25]. Curcumin, the active component in *Curcumae longae rhizoma*, exhibits antioxidant, antimicrobial, and wound-healing effects through growth factor induction [26]. Studies on *Angelicae dahuricae radix* highlight its antinociceptive and anti-inflammatory activities [27]. *Magnoliae cortex*, rich in magnolol, is noted for its anti-inflammatory and antimicrobial activities [28-38]. *Glycyrrhizae radix et rhizoma* has shown anti-inflammatory effects through inhibition of PGE2, TXB2, and LTB4 [39], along with antimicrobial properties [40-42]. *Citri reticulatae pericarpium vetum* offers significant antioxidant and anti-inflammatory benefits [43-46]. *Atractylodis rhizoma* demonstrates antifungal, antibacterial, antioxidant, and anti-inflammatory activities [47-50], while *Arisaematis rhizoma* has been found to have anti-inflammatory and analgesic effects [51,52].

Table 1. The proportion of Ru-Yi-Jin-Huang-Saan (RYJHS) and the efficacy of its ingredients.

Latin crude drug name (English name)	Plant part	Proportion	Efficacy
Trichosanthis radix (Trichosanthes root)	Root	25%	Wound healing, antibacterial, and anti-inflammatory effects
Rhei radix et rhizoma (Rhubarb)	Root and rhizome	12.5%	Anti-inflammatory effect
Phellodendri cortex (Phellodendron bark)	Bark	12.5%	Antibacterial and anti-inflammatory effects
Curcumae longae rhizoma (Turmeric rhizome)	Rhizome	12.5%	Wound healing, antioxidant, radical scavenging, antimicrobial, and anti-inflammatory effects
Angelicae dahuricae radix (Dahurian Angelica root)	Root	12.5%	Antinociceptive and anti-inflammatory effects
Magnoliae cortex (Magnolia bark)	Bark	5%	Anti-inflammatory and antimicrobial effects
Glycyrrhizae radix et rhizoma (Liquorice root and rhizome)	Root and rhizome	5%	Anti-inflammatory and antimicrobial effects
Citri reticulatae pericarpium vetum (Aged tangerine peel)	Peel	5%	Antioxidant and anti-inflammatory effects
Atractylodis rhizoma (Atractylodes rhizome)	Rhizome	5%	Antifungal, antibacterial, antioxidant, and anti-inflammatory effects
Arisaematis rhizoma (Jackinthepulpit tuber)	Rhizome	5%	Anti-inflammatory and analgesic effects

Further research indicates that RYJHS can alleviate inflammatory pain without causing sensitization [53]. Clinically, it is used to manage conditions such as phlebitis [54], osteoarthritis of the knee [55], gout, diabetic foot ulcers [56], and herpes zoster.

However, despite the numerous studies mentioned above, there is still a lack of clinical research on RYJHS. This study aims to evaluate the efficacy and adverse effects of using RYJHS on Colles fracture after surgery.

Methods

Study Design

The study is a randomized, double-blind, placebo-controlled trial design based on SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) reporting guidelines (Multimedia Appendix 1) [57], and the results will follow the CONSORT (Consolidated Standards of Reporting Trials) guidelines [58]. Our research project is scheduled to recruit patients from May 1, 2023, to April 30, 2025. All postoperative patients with Colles fracture will be recruited through referrals from orthopedic physicians at Changhua Christian Hospital. Researchers will screen and select participants based on specific inclusion and exclusion criteria.

In this study, all participants are randomly assigned using a computerized block randomization schedule. We randomly generate a pool of 100 patients, who are assigned to sequentially numbered opaque envelopes. The treatment allocations are balanced within each group, with each group containing 50 patients. Researchers and patients are both blinded to the treatment allocation, with the exception of the statistician responsible for the randomization process. The two groups in the study consisted of the experimental group receiving RYJHS treatment and the control group receiving a placebo.

Study Settings and Participants

All participants undergo standard medical treatment after surgery and are involved in the efficacy assessment of RYJHS external application. Figure 1 shows the study's flowchart. Both groups apply a patch plaster on the back of the wrist without wounds (avoiding the suture of the fracture operation). Figure 2 shows the site of the medication application. The experiment group apply the RYJHS plaster, while the control group apply a placebo plaster. The patch is applied twice a day, for 6 hours each time, with a 6-hour break in between, repeated for 3 days, completing one course of treatment. Patients undergo two courses of treatment, with the first course completed during hospitalization, and the second course completed 3 days after discharge.

CRP: C-reactive protein; DASI: Dyshidrotic Eczema Area and Severity Index; ORIF: open reduction and internal fixation; PRWE: Patient-Rated Wrist Evaluation; RYJHS: Ru-Yi-Jin-Huang-Saan.

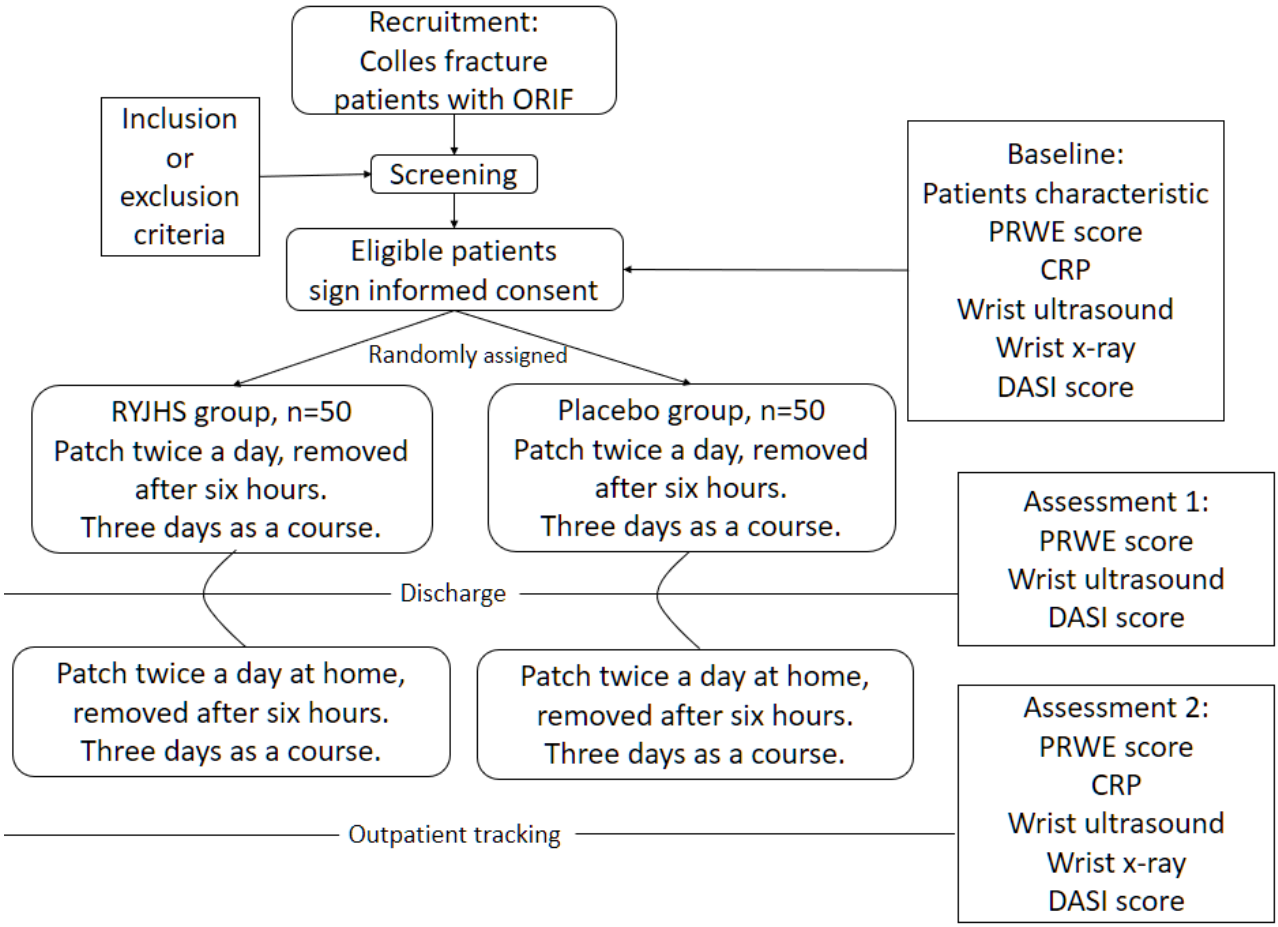

Figure 2. Applying Ru-Yi-Jin-Huang-Saan (RYJHS) plaster on Colles fracture after surgery. (A) The surgical incision site. (B) The site of the RYJHS plaster on a Colles fracture after surgery.

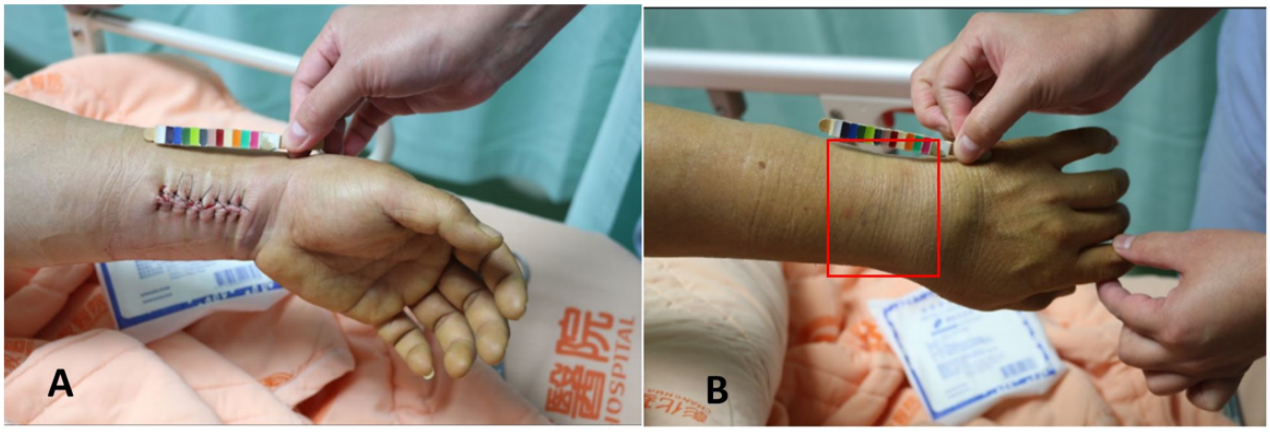

Inclusion Criteria

To be eligible for our study, patients must meet the following criteria: be 20-80 years of age, have a Colles fracture (Frykman classification type I-VI) [59] diagnosis that has been treated with open reduction and internal fixation (ORIF) surgery, and provide informed consent either personally or through their family members.

Exclusion Criteria

The following exclusion criteria will be applied: age older than 80 years or younger than 20 years; inability to comply with experimental procedures or complete questionnaires; presence of wounds on the back of the wrist; allergy to the herbal patch before; use of other Chinese herbal topical medicine after fracture; pregnancy; cancer; stroke; and systemic diseases such

as severe anemia, thyroid disease, and poorly controlled diabetes.

Sample Size Calculation

Our study closely resembles the design of phase-2 studies in clinical trials, which aim to assess the effectiveness of drugs in participants with specific conditions or diseases. We used G*Power (Heinrich-Heine-Universität Düsseldorf) to estimate the necessary sample size for our study, taking into account repeated-measures ANOVA within-between interactions with a medium effect size of f=0.25 and α level=.05. To achieve a statistical power of 0.95, we calculated a total sample size of 86 [60]. To account for potential dropouts and satisfy our inclusion criteria, we will enroll 100 individuals who have been admitted to our orthopedic care ward and diagnosed with Colles fracture after surgery.

Study Medication

RYJHS is a common TCM plaster that has been used for more than 500 years. RYJHS is composed of 10 herbs: *Trichosanthis radix*, *Rhei radix et rhizoma*, *Phellodendri cortex*, *Curcumae longae rhizoma*, *Angelicae dahuricae radix*, *Magnolite cortex*, *Glycyrrhizae radix et rhizoma*, *Citri reticulatae pericarpium vetum*, *Atractylodis rhizoma*, and *Arisaematis rhizoma* (given in Table 1). This herbal formula is a fixed prescription announced by the Department of Chinese Medicine and Pharmacy. The RYJHS used in our study is manufactured by Kaiser Pharmaceutical Co and meets the requirements of Good Manufacturing Practice. It has also been issued a drug certificate. The placebo powder, which uses computer color-matching technology in the color simulation of RYJHS [61], is also produced by Kaiser Pharmaceutical Co. Both RYJHS and the placebo are prepared by mixing 13 grams of powder with 23 mL of water, which is then evenly spread onto a cotton cloth and covered with gauze for later use. The aforementioned procedures are all carried out by the same experienced technician, as given in Figure 3.

Figure 3. Preparation of Ru-Yi-Jin-Huang-Saan (RYJHS) plaster. (A) Spread the paste onto a cotton cloth and (B) cover with gauze.

Outcome Measurements

In this study, we will gather data from each participant including their gender, age, affected hand and dominant hand, Patient-Rated Wrist Evaluation (PRWE) score, C-reactive protein (CRP) levels, wrist ultrasound results, wrist x-ray images, and Dyshidrotic Eczema Area and Severity Index (DASI) score. Patients who have undergone Colles fracture surgery are required to be evaluated, and data will be collected before the trial, as well as 3 days and 6 days after topical medication application. The participant timetable of enrollment, assessments, and treatments is given in Table 2. The primary outcome is the PRWE score, which is used to assess wrist function recovery. The PRWE score, collected via a questionnaire, was developed in Canada for patients with wrist problems to express their pain and level of function [62]. The secondary outcomes are CRP level and wrist imaging records, which are used to demonstrate the degree of inflammation and swelling reduction. In addition, the DASI score is used to monitor any allergic or adverse events that may occur at the application site [63].

[a]D_x: number of days into the experiment.

[b]Not available.

[c]PRWE: Patient-Rated Wrist Evaluation.

[d]CRP: C-reactive protein.

[e]DASI: Dyshidrotic Eczema Area and Severity Index.

[f]If a patient has any side effects during the experiment, they must be recorded immediately.

Statistical Analysis

We will conduct statistical analyses using the SPSS software (version 22; IBM Corporation). Descriptive analyses will be performed on demographic data using frequencies and percentages to characterize the sample. Categorical variables will be compared using chi-square tests, while continuous variables will be compared using 2-tailed *t* tests. We will use repeated-measures ANOVA to determine if changes in wrist function (the dependent variable) are due to the interaction between the "type of treatment" (RYJHS) and "time" (measurement time). Multiple regression will be used to assess the impact of latent factors on primary outcomes (wrist function) and secondary outcomes (swelling and inflammation), adjusting for all possible covariates. Regression models will be performed in different outcome groups to compare the effects of different treatments (RYJHS intervention vs placebo).

Ethical Considerations

Approval for this trial (protocol ID 221006) was granted by the Institutional Review Board of Changhua Christian Hospital (CCH) on November 25, 2022, following the principles outlined in the Declaration of Helsinki. The study protocol has also been registered on ClinicalTrials.gov (NCT05638360). Individuals interested in participating will be required to provide written informed consent before the study's initiation. They will receive comprehensive information about the study, including procedures, potential benefits, and risks, excluding specific details regarding the RYJHS medication. Participants are free to withdraw at any time without any impact on their future medical care.

Data collected will be anonymized to protect participants' privacy, and all information will be kept confidential according to institutional data protection policies. No direct compensation will be provided to participants. The results of this research will be disseminated through publication in a peer-reviewed journal and presented at scientific conferences.

Results

The protocol was registered on ClinicalTrials.gov (NCT05638360) on December 6, 2022. Patient recruitment commenced in May 2023, with the first patient enrolled on June 15, 2023, and is projected to continue until April 30, 2025. As of December 2023, a total of 32 patients have been enrolled. Data analysis and report preparation are expected to be completed by the end of 2025.

Discussion

Expected Findings

The primary clinical treatments for Colles fractures, such as closed reduction, casting, percutaneous fixation, external fixation, and ORIF, generally yield positive functional outcomes.

However, both percutaneous and external fixation have reported a higher risk of infection, while percutaneous fixation has been shown to have a higher rate of soft tissue injuries [64,65]. Besides, the ORIF procedure including local dissection, reduction, and the insertion of plates or screws results in a higher incidence of tendonitis, tendon irritation, or tendon rupture [66,67]. In Taiwan, the routine conventional treatment for Colles fracture is ORIF surgery. However, operations often result in soft-tissue and lymphatic vessel damage. As a result, patients may experience heat, pain, redness, and swelling after the operation. The discomfort disrupts their willingness to undergo rehabilitation. Prolonged swelling can also affect the range of motion, hand function, muscle strength, and outward appearance of these patients [68]. Therefore, resolving pain and swelling is a significant problem for patients with Colles fracture after ORIF surgery.

The most common method of relieving swelling is ice packing. Ice packing can reduce swelling, capillary permeability, and delivery of inflammatory substances [69]. Besides, ice packing can decrease nerve conduction velocity, increase pain threshold, and provide analgesia [70]. However, many studies have reported that ice packing not only delays wound healing but also has a higher risk of cold injury [71,72]. Besides, pain management is also a concern for patients who undergo ORIF surgery. Physicians often prescribe opioids; NSAIDs; or a combination of opioids, NSAIDs, and steroids for pain management [73]. However, due to the potential side effects, these medications raise concerns for patients with diabetes, hypertension, gastrointestinal disorders, impaired liver function, or impaired kidney function.

There are several limitations in this study design. First, during the patients' hospitalization, patients were assisted by nurses who ensured regular medication application. However, it may be challenging to confirm whether the patients continued to apply the medication on schedule after discharge. Therefore, it might be necessary to use phone reminders to engage caregivers in assisting with regular medication application. Second, theoretically, the closer the topical medication is applied to the lesion, the more effective it is likely to be. However, due to concerns about postsurgical wound infections, the application of topical medication needs to be avoided on the site of surgical incision. Therefore, for the purpose of this experiment, only the uninjured area on the back of the wrist can be selected for topical medication application. Finally, the inclusion criteria for the trial of Colles fracture did not encompass comminuted fractures; thus, the efficacy of RYJHS may not be evaluated in patients with severe Colles fractures.

This study represents the first randomized, double-blind, placebo-controlled trial to investigate the efficacy of RYJHS for postoperative Colles fractures. RYJHS, with its natural ingredients known for anti-inflammatory and antibacterial properties, could serve as a noninvasive adjunctive therapy to reduce postoperative complications and enhance functional recovery. Its application aligns with patients' increasing interest in integrative medicine options that minimize reliance on pharmaceuticals. Future directions include exploring RYJHS's active ingredients, assessing formulation efficiency, and developing a more accessible application method, which may strengthen RYJHS's role as an adjunctive treatment for Colles fractures.

Conclusion

This randomized, double-blind, placebo-controlled trial aims to provide robust evidence of the efficacy and safety of RYJHS as a topical adjunctive treatment for postsurgical Colles fractures. With the potential to reduce inflammation and aid functional recovery, RYJHS could offer an alternative, nonpharmaceutical option for managing postoperative complications in patients with Colles fractures.

Acknowledgments

The authors sincerely thank all patients who participated in this study and health care workers not listed in the paper. This study was supported by China Medical University Hospital, Taiwan (DMR-110-007, DMR-111-197, DMR-HHC-111-1, and DMR-112-003). This work is financially supported by the Changhua Christian Hospital Special Research Project (112-CCH-IRP-070). No additional funding has been received.

Data Availability

Since this protocol does not contain any data, it will be provided after analysis and published in a journal upon trial completion. Data can be made available upon the author's request.

Authors' Contributions

Lien-Cheng Lin contributed to conceptualization, validation, visualization, writing-original draft and steering the primary author. WHW handled resources and writing–review and editing. WKC performed methodology and formal analysis. JLG assisted with data curation and project administration. RCY handled investigation and software. PCH and Lun-Chien Lo contributed to funding acquisition, supervision, and writing–review and editing.

Conflicts of Interest

None declared.

Abstract

Background: Chronic heart failure has high morbidity and mortality, with approximately half of the patients dying within 5 years of diagnosis. Recent additions to the armamentarium of anti–heart failure therapies include angiotensin receptor-neprilysin inhibitors (ARNIs) and sodium/glucose cotransporter 2 inhibitors (SGLT2is). Both classes have demonstrated mortality and morbidity benefits. Although these new therapies have morbidity and mortality benefits, it is not known whether rapid initiation is beneficial when compared with the conventional, slower-stepped approach. Many clinicians have been taught that starting with low-dose therapies and gradually increasing the dose is a safe way of intensifying treatment regimens. Pharmacologically, it is rational to use a combination of drugs that target multiple pathological mechanisms, as there is potential synergism and better therapeutic outcomes. Theoretically, the quicker the right combinations are used, the more likely the beneficial effects will be experienced. However, rapid up-titration must be balanced with patient safety and tolerability.

Objective: This study aims to determine if early addition of ARNIs, SGLT2is, β-blockers, and mineralocorticoid receptor antagonists (within 4 weeks), when compared with the same therapies initiated slower (within 6 months), will reduce all-cause mortality and hospitalizations for heart failure in patients with stable heart failure with reduced ejection fraction.

Methods: This is a single-center, randomized controlled, double-arm, assessor-blinded, active control, and pragmatic clinical trial. Adults with stable heart failure with reduced ejection fraction and idiopathic dilated cardiomyopathy will be randomized to conventional sequencing (the control arm; over 6 months) of anti–heart failure therapies, and a second arm will receive rapid sequencing (over 4 weeks). Study participants will be followed for 5 years to assess the safety, efficacy, and tolerability of the 2 types of sequencing. Posttrial access and care will be provided to all study participants throughout their lifespan.

Results: We are currently in the process of obtaining ethical clearance and funding.

Conclusions: We envisage that this study will help support evidence-based medicine and inform clinical practice guidelines on the optimal rate of sequencing of anti–heart failure therapies. A third placebo arm was considered, but costs would be too much and not providing study participants with therapies with known morbidity and mortality benefits may be unethical, in our opinion. Given the post–COVID-19 economic downturn and posttrial access to interventions, a major challenge will be acquiring funding for this study.

Introduction

Background

The current management of heart failure with reduced ejection fraction (HFrEF) has been revolutionized by the emergence of novel classes of drugs, namely, angiotensin receptor-neprilysin inhibitors (ARNIs) and sodium/glucose cotransporter 2 inhibitors (SGLT2is) [1,2]. With landmark clinical trials [3-6] demonstrating the efficacy of the latter drugs, there has been a paradigm shift in initiating and sequencing optimal anti–heart failure therapy and a concomitant reevaluation of the evidence base that guides conventional heart failure management. The American Heart Association heart failure guideline supports the rapid titration of guideline-based therapies every 1-2 weeks, with the goal of achieving target doses [7]. However, the European Society of Cardiology does not contain a timeline for the initiation of guideline-based heart failure therapy [8]. Pharmacologically, it is rational to use a combination of drugs that target multiple pathological mechanisms, as there is potential synergism and better therapeutic outcomes. Theoretically, the quicker the right combinations are used, the more likely the beneficial effects will be experienced. However, rapid up-titration must be balanced with patient safety and tolerability.

Sacubitril and valsartan, β-blockers, mineralocorticoid receptor antagonists (MRAs), and SGLT2is are disease-modifying agents that are used as combination therapy and are now regarded as a foundational therapy for HFrEF [1,2]. The conventional approach to initiating and optimizing HFrEF therapy reflects the sequence in which drugs were developed and trialed over the past 40 years [1]. Clinicians initiate therapy with an angiotensin-converting enzyme inhibitor or angiotensin receptor blocker, followed by a β-blocker, then an MRA, then a neprilysin inhibitor, and, finally, an SGLT2i. Each drug required up-titration to the target dose, or the maximally tolerated dose, before initiating another class of drug, with a treatment period usually spanning >6 months [1].

This approach is limited by several clinical misconceptions and assumptions: first, the most efficacious anti–heart failure therapies were developed first. The counterargument is exemplified by the fact that digitalis has been used in clinical practice for 200 years, yet it is no longer considered a key therapeutic agent. Second, drug efficacy is only achieved at maximum target doses [1]. However, studies have demonstrated morbidity and mortality reduction with the use of low-dose anti–heart failure therapy in HFrEF, with maximum target doses adding only a smaller clinical benefit. Third, the efficacy and safety of individual anti–heart failure drug class were assessed in clinical trials that required patients to be receiving all background therapy at target doses. However, most trials were conducted with patients receiving subtarget doses of anti–heart failure therapy [2].

Initiating drugs over a 6-month period is undesirable for several reasons. Practically, target doses of anti–heart failure therapy are infrequently achieved due to patient factors (nonadherence, perceived adverse effects, and costs), drug factors (adverse effects and frequency of dosing), physician factors (clinical inertia and limited time), inadequate patient follow-up, and a lack of perceived benefit of higher drug doses. Furthermore, there is a strong evidence base suggesting that the use of each of the foundation drugs has demonstrated morbidity and mortality reduction within 30 days of therapy initiation [1,2,9].

The aim of this study is to determine if early addition of ARNIs, SGLT2is, β-blockers, and MRAs (within 4 weeks), when compared with the same therapies initiated slower (within 6 months), will reduce all-cause mortality and hospitalizations for heart failure in patients with stable HFrEF.

Rationale

The use of ARNIs and SGLT2is in low- to middle-income country settings is limited by high cost and accessibility. Despite the strong body of evidence supporting the safety and efficacy of ARNIs and SGLT2is, these agents are not yet included in the South African Essential Drug List. ARNIs and SGLT2is are available to private funders, yet access is limited as costs are only partially reimbursed by medical insurance schemes. Furthermore, SGLT2is have not yet been approved for heart failure by the South African Health Products Regulatory Authority, and use within clinical practice is predominantly off-label. Donations by the pharmaceutical industry have enabled limited access to ARNIs and SGLT2is in the public sector.

The challenge in this regard is maximizing access and rationalizing the use of ARNIs and SGLT2is while canvassing for widespread cost-effective rollout in the public sector.

The data on ARNIs and SGLT2is from high-income country settings suggest that morbidity and mortality reduction is achieved early in the clinical presentation of heart failure [1,2]. There, however, remains a paucity of data on the safety and efficacy of these drugs in sub-Saharan Africa.

Within sub-Saharan Africa, the main driver of heart failure remains hypertension, with ischemic heart disease emerging as a key etiology. There, however, is a growing cohort of young patients with idiopathic dilated cardiomyopathy with HFrEF who are often suboptimally medically treated with minimum prospects of receiving heart transplants. In our opinion, such a group of patients would ideally benefit from ARNIs and SGLT2is. Data from key clinical trials have demonstrated the use of ARNIs as de novo therapy in patients presenting with heart failure [3,10,11]. The latter trials have argued against the use of angiotensin-converting enzyme inhibitors or angiotensin receptor blockers upfront with a transition phase to ARNI therapy, as there would be merely a delay in using the most effective therapy with a concomitant risk of sudden cardiac death.

The rapid initiation of anti–heart failure therapy described above seems rational in a high-income country setting where drug monitoring and assessment of adverse reactions are facilitated by the ease and rapidity of access to health care facilities [1,2]. However, in low- to middle-income country settings, the infrequent and irregular access to health care facilities limits instituting the rapid initiation algorithm for heart failure therapy. Furthermore, there is a lack of robust data and randomized controlled trials comparing rapid initiation versus a slower, phased initiation of heart failure therapy [1].

Study Objectives

Primary Objective

The primary efficacy end point is the composite end point of all-cause mortality and hospitalization for heart failure.

Secondary Objectives

Secondary end points include death from cardiovascular causes (eg, cardiogenic shock, myocardial infarction, tachycardia, or brady-arrythmia), improvement in the 6-minute walk test, improvement in the New York Heart Association functional class, improvement in symptoms as per the Kansas City Cardiomyopathy Questionnaire, trans-esophageal echo-determined ejection fraction (chamber dilatation, left ventricular systolic function, global longitudinal strain, and speckle tracking), and N-terminal prohormone of brain natriuretic peptide levels. Adverse drug reactions will also be collected and analyzed.

Definitions

Heart Failure

Heart failure is defined as a “clinical syndrome consisting of cardinal symptoms (eg, breathlessness, ankle swelling, and fatigue) that may be accompanied by signs (eg, elevated jugular venous pressure, pulmonary crackles, and peripheral edema). It is due to a structural and/or functional abnormality of the heart that results in elevated intracardiac pressures and/or inadequate cardiac output at rest and/or during exercise” [7].

Reduced Left Ventricular Ejection Fraction

Reduced left ventricular ejection fraction is defined as an ejection fraction ≤40%, that is, those with a significant reduction in left ventricular systolic function [8].

Methods

Proposed Novel and Rapid Sequencing

The proposed algorithm for initiation of anti–heart failure therapy comprises of 3 steps once clinical euvolemia has been achieved with diuresis [2].

Step 1 is the concurrent initiation of treatment with a β-blocker and an SGLT2i. β-Blockers are pertinent in the treatment of HFrEF, especially in the context of reducing sudden cardiac death. Evidence has demonstrated reduced hospitalization for heart failure with the use of SGLT2is. The early diuretic effect of SGLT2is may attenuate the early risk of worsening heart failure when β-blockers are initiated [2].

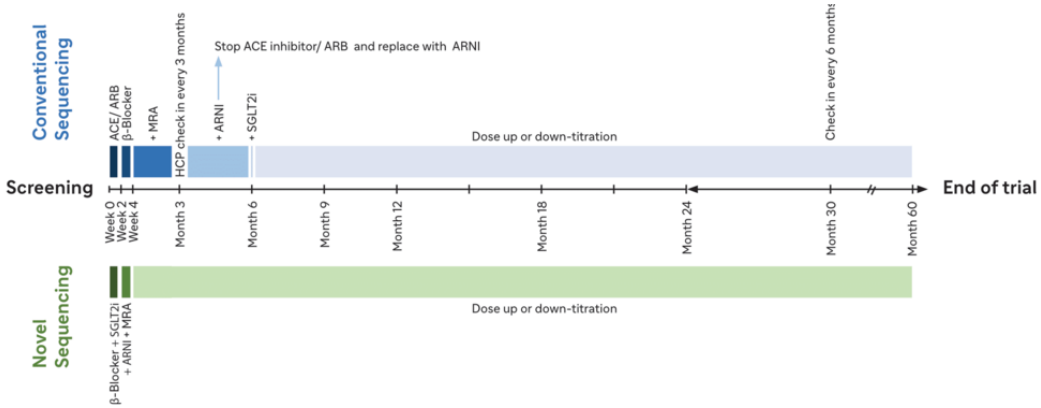
Step 2 comprises of the addition of an ARNI (sacubitril and valsartan) within 1-2 weeks of step 1. The presence of hypotension (systolic blood pressure <100 mm Hg) warrants evaluation of blood response with an angiotensin receptor blocker before switching to an ARNI [2].

Step 3 is the addition of an MRA, within 1-2 weeks of step 2, depending on the serum potassium and the presence and degree of renal impairment. ARNIs and SGLT2i may improve renal function and potassium homeostasis, thereby permitting the use of MRAs. In patients with hypotension, MRAs may be used as step 2 [2].

The above algorithm represents a generic approach and may be individualized to specific scenarios. Patients with decompensated heart failure are a subgroup that require greater caution when initiating anti–heart failure therapy. β-Blocker therapy should only be initiated in the hospital after discontinuation of intravenous therapy for several days and the patient is clinically euvolemic, defined as the absence of rales and ascites and the presence of minimal peripheral edema [2].

In the appropriate patient, treatment with all 4 foundational treatments may be achieved within 4 weeks, with subsequent dose up-titration. This strategy increases the probability that highly effective therapies will be implemented in a manner that reduces mortality and hospitalizations and enhances the tolerability of subsequently administered treatments [1]. Figure 1 shows the proposed study flow diagram, which contains the novel and conventional sequencing approaches. A key difference is the rate at which therapies are added, with the novel sequence arm having patients on all the efficacious therapies initiated within 4 weeks.

Figure 1. Study flow diagram. ACE: angiotensin-converting enzyme; ARB: angiotensin receptor blockers; ARNI: angiotensin receptor-neprilysin inhibitors; HCP: health care professional; MRA: mineralocorticoid receptor antagonists; SGLT2i: sodium/glucose cotransporter 2 inhibitors.



Study Design

This is a prospective, double-arm, randomized, assessor-blinded, and pragmatic clinical trial. The study will take place at a single site, that is, Tygerberg Hospital, Western Cape, South Africa.

Selection of Patients

Study participants will be adults with idiopathic dilated cardiomyopathy who consent to participate in the study. Patients will be free to withdraw at any time. The recruitment period will be 1 year.

Study participants will be randomized to the study arms by using a computer-generated randomization sequence.

Inclusion, exclusion, and withdrawal criteria are listed in Textbox 1.

Textbox 1. Selection criteria (inclusion, exclusion, and withdrawal criteria).

Inclusion criteria

- All patients aged <18 or >50 years who fulfill the clinical criteria for idiopathic dilated cardiomyopathy with reduced ejection fraction
- New York Heart Association Functional class II-IV

Exclusion criteria

- Aged >18 years or <50 years
- Unable or unwilling to provide informed consent to undergo any of the recommended investigations or to participate in the study
- Acute coronary syndrome, bypass graft surgery or other major cardiac surgery, stroke, or transient ischemic attack ≤90 days from visit 1
- Acute decompensated heart failure
- Systolic blood pressure ≥180 mm Hg or <100 mm Hg
- Estimated glomerular filtration rate <30 mL/min/1.73 m^2
- Serum potassium level >5.4 mmol/L
- History of angioedema

Withdrawal criteria

- Patient decision to leave the study
- Adverse drug reactions

Selection of Investigators

This study will be conducted at a tertiary-level public hospital's department of cardiology. Investigators will be the authors of this publication and other staff based at Tygerberg Hospital.

Statistical Considerations

Sample Size

We determined that a target number of 248 primary outcome events would provide a power of 80% to detect a 30% lower relative risk of the primary outcome in the novel sequencing arm than in the conventional sequencing arm at a 2-sided α level of .05. Assuming an incidence of the primary outcome of at least 50% over 5 years in the conventional sequencing arm and a dropout of 10% per arm, we established a planned enrolment of 584 patients (292 per study arm).

Analysis Population

The analysis population will include all study participants included in the study. This is an intention-to-treat analysis and even participants who have withdrawn, or dropped out, from the study after randomization will have their data analyzed.

Statistical Methods

Patient demographic and clinical profiles will be described using the statistical software SAS (version 9.4; SAS Institute). Continuous variables will be expressed as an absolute number, with associated percentage, mean, SD, median, and range where applicable. Clinical assessment of response to heart failure therapy will be performed using the Kansas City Cardiomyopathy Questionnaire, New York Heart Association functional classification, 6-minute walk distance, and hospital admission for heart failure. Objective measures of therapy response will be ascertained by serial N-terminal prohormone of brain natriuretic peptide levels and 2D echocardiography. Echocardiographic features of response to therapy will be characterized according to left ventricular ejection fraction as determined by the Simpson biplane method, global longitudinal strain, and speckle tracking.

Associations between outcomes and indicator variables will be explored through logistic regression. Where appropriate, indicator variables and specific outcomes will be investigated individually through a univariate analysis. Where significant, variables will be entered into and controlled for in a Cox-proportional hazards regression model. Adjustment for confounding will be performed by a competing risks analysis and propensity score matching (Table 1).

Table 1. Statistical methods.

Outcome measures	Hypothesis	Measure	Time points	Analysis methods
Primary end points	The intervention will reduce the outcome from baseline to 5 years.	—[a]	—	—
All-cause mortality	Rapid sequencing of anti–heart failure therapy will reduce all-cause mortality.	All-cause mortality (binary)	End of trial	Cox proportional hazards regression
Hospitalization	Rapid sequencing of anti–heart failure therapy will reduce all-cause mortality.	Hospitalized for heart failure (binary)	End of trial	Cox proportional hazards regression
Secondary end points				
Deaths (from cardiovascular causes)	Intervention will reduce cardiovascular-related deaths	Cardiovascular mortality (binary)	End of trial	Chi-square test
6-minute walk test	Improvement in distance walked in 6-minutes	Distance in meters (continuous)	Baseline and end of trial	✓
NYHA[b] functional class	Improvement in dyspnea	Functional class 1, 2, 3, and 4 (ordinal)	Baseline and end of trial	✓
KCCQ[c]	Improvement in symptoms of heart failure	Questionnaire (ordinal)	Baseline and end of trial	✓
Trans-esophageal echo	Improvement in ejection fraction	Ejection fraction measured in percentage (%; continuous)	Baseline and end of trial	✓
NT-pro[d] and BNP[e] levels	Reduction in levels	Concentration units (pg/mL; continuous)	Baseline and end of trial	✓

[a]Not applicable.

[b]NYHA: New York Heart Association.

[c]KCCQ: Kansas City Cardiomyopathy Questionnaire.

[d]NT-pro: N-terminal prohormone.

[e]BNP: brain natriuretic peptide.

Ethical Considerations

This study will be conducted in accordance with the principles laid down by the 18th World Medical Assembly [12]. Study participants' data will be deidentified of names and surnames and identifying information. An application for ethical approval will be submitted to the Stellenbosch University Research and Ethics Committee. The study will be performed in accordance with local regulations, including local data protection regulations and requisite hospital and Provincial Department of Health Approval. Posttrial access and care will be provided to all study participants, throughout their lifespan.

Results

We are currently in the process of generating funding. If funding is obtained, we will apply for ethical clearance and requisite permissions.

Discussion

Principal Findings

This study aims to determine if rapid sequencing of anti–heart failure drugs with proven morbidity and mortality benefits would be superior to slower titration of these therapies.

We chose a composite end point to reduce the sample size, as a larger sample size would result in greater costs and reduce the feasibility of the study. Given the high mortality and frequent hospitalizations for heart failure, we included both events in the combined primary efficacy endpoint.

Intuitively, it makes sense to ensure that the most efficacious heart failure therapies are initiated as soon as possible. Given that the therapies have varied modes of action, we hypothesize that if they are started together as soon as possible, they would have greater benefits than starting them later. Combination therapies are likely to target different pathophysiological aspects of heart failure and thus improve clinical outcomes. Issues with rapid initiation may potentially include hypotension and other adverse effects. We will guard against hypotensive events by starting with the lowest possible dose and stopping the drug if the patient becomes hemodynamically unstable. Furthermore, study participants are required to be euvolemic before rapid sequencing so that we do not worsen patients' heart failure and thus limit hemodynamic instability and decompensated heart failure. It is a standard clinical practice to ensure euvolemia before titration of anti–heart failure therapies. Euvolemia is usually achieved by loop diuretics [8].

We chose a relatively young group of patients so that underlying issues such as ischemic heart disease are less probable and would not serve as confounders. Furthermore, this group of patients may benefit from the increased life expectancy as compared with the older group.

The public health sector in South Africa has resource constraints. Often, there are not enough clinicians to adequately manage the patients. Thus, doing trials in this setting is challenging. However, given the proven safety and efficacy of ARNIs, SGLT2is, and MRAs, and their widespread use in high-income countries, we envisage limited problems. Furthermore, making these novel therapies available to a vulnerable population would serve as a motivation for clinicians who work in this setting. The setting is a teaching and training facility, and having exposure to these novel therapies will grow the expertise and skills of health care practitioners. Furthermore, we envisage reducing the complexity of the study by using a pragmatic study design so that we can integrate the trial into routine clinical practice in the department of cardiology. This will reduce the administration burden while also resulting in the collection of safety, efficacy, and tolerability data. We feel that the trial would not add to the administrative burden of the clinicians, as we will not ask them to do any work beyond what they usually do in the clinic. Furthermore, a separate designated individual will collect and analyze the data, so that clinicians will not be burdened with this task and not impinge on their demanding clinical work.

Posttrial access and posttrial care are contentious issues [13]. In this study, we plan to provide both posttrial access and posttrial care because it is, in our opinion, ethically justified. Given that the newer therapies are efficacious, safe, and tolerable, it would be unkind to stop the therapies after the trial is completed, as the study participants would not be able to procure the therapy privately because of their limited financial resources. The provision of posttrial care would also increase the cost of the study, but we will continue to provide posttrial care in our cardiology clinic at no cost to the study participants.

We hope to acquire funding from the manufacturers of ARNIs, SGLT2is, β-blockers, and MRAs, as the data generated from this study have the potential to inform clinical practice guidelines. Given the high costs of doing such trials, we hope companies will assist if they are only providing the drug and not covering the other clinical trial costs like investigator fees, protocol development, manuscript writing, and statistical analysis, and so on. The study has dual objectives of generating of evidence while also providing patients with access to highly efficacious and premium therapies for heart failure.

Given that both study groups will receive the same therapies, we do not pitch drugs head-to-head, as we feel that the combination of drugs with proven mortality and morbidity data would be most likely to have synergistic effects and further reduce morbidity and mortality. This approach is also more likely to generate funding as all companies can contribute to financing the study, not with the risk of their products being negatively affected by head-to-head trials that show one drug being superior to another drug.

We have tried to create a "win-win" situation by generating data to inform clinical practice guidelines and providing access to novel therapies in resource-limited settings. The research can help with master's and PhD degrees, given the rich dataset generated.

Limitations

The study is proposed to use one study site in the Western Cape of South Africa, which may not be reflective of the demographics of the South African population. Due to the nature of the study and means of intervention, implementation of a

placebo-controlled arm will not be possible but is nonetheless cited as a limitation.

Conclusions

Recent additions to the armamentarium of anti–heart failure therapies such as ARNIs and SGLT2is have demonstrated morbidity and mortality benefits. Earlier use of such therapy within patients with stable HFrEF may impact patient outcomes. This study will provide important data to support evidence-based medicine and will help inform clinical practice guidelines on the optimal rate of sequencing of anti–heart failure therapies.

Acknowledgments

We are grateful to Novartis for paying the article processing fee.

Data Availability

The dataset will be made available upon written request.

Conflicts of Interest

PN was sponsored by Novartis for online attendance at European Society of Cardiology (ESC) Congress 2022 and received drug sponsor for a phase IV clinical trial from Sandoz, a subsidiary of Novartis. PN was previously employed as a Medical Manager by Boehringer and was responsible for preregistration medical activities related to empagliflozin. KH was previously employed as Medical Director by Boehringer and was responsible for preregistration medical activities related to empagliflozin.

Abstract

Background: Rhino-orbital-cerebral mucormycosis (ROCM) is the most common (45%-74%) mucormycosis in India. With contemporary medical care, ROCM has a mortality rate of 40%-50% and 70% of survivors are left with residual defects. Recently, several cases of mucormycosis in people with COVID-19 have been increasingly reported worldwide, from India, due to immune dysregulation caused by SARS-CoV-2. To reduce the high mortality rate and residual defect in most survivors under the guidelines of the Ministry of AYUSH, the Government of India recommended homoeopathy as an add-on therapy to maximize the effectiveness of standard treatment in conventional therapy.

Objective: This study aimed to evaluate the role of existing homoeopathic treatment as an adjuvant therapy in patients with COVID-19–related ROCM and enhancing the survival of the patients hospitalized due to COVID-19 infection and to access the initial treatment response and duration required for significant or complete recovery in patients receiving adjuvant treatment.

Methods: This superiority, randomized controlled clinical trial would include two parallel comparator groups A and B. Group A would be the experimental group and would receive homoeopathic treatment along with the standard line of treatment as per investigational medicinal product (IMP) and group B would be the control arm and would receive standard line of treatment as per IMP along with identical placebo. Allocation would be 1:1 through randomization. Based on the inclusion and exclusion criteria, 36 participants per arm would be screened. Participants would be assessed clinically twice a day and magnetic resonance imagery or endoscopy cum-biopsy would be assessed on days 1, 14, and 28. Laboratory investigations may vary as per demand of disease conditions.

Results: In India, the COVID-19 pandemic, particularly during the second wave, resulted in a surge of mucormycosis cases among patients with COVID-19. At the time this protocol was being developed, there was a significant spike in mucormycosis cases in India, particularly in Mumbai (June 2021). However, by the time the Central Council for Research in Homoeopathy obtained the necessary approvals and ethical clearance for the study, the incidence of mucormycosis had drastically declined (September 2021). As a result, the study was not initiated and registered. The authors feel it is their ethical responsibility to share the reviewed protocol with the medical community as a reference for future work.

Conclusions: This study aims to evaluate the role of existing homoeopathic medicines as an adjuvant therapy in managing COVID-19–related ROCM, potentially contributing to the use of homoeopathy as an evidence-based medical approach. The protocol can also serve as a valuable resource for clinicians and researchers addressing mucormycosis cases unrelated to COVID-19,

particularly in immunocompromised patients. It would help ensure preparedness, whether or not sufficient evidence is available, in the event of a future health emergency.

Introduction

Immune dysregulation induced by SARS-CoV-2, along with the extensive use of glucocorticoids and immunomodulatory drugs like tocilizumab, has heightened the risk of secondary bacterial and fungal infections in patients with COVID-19 [1-3]. Recently in past, India experienced a significant surge in mucormycosis cases, caused by a group of molds known as mucoromycetes, commonly found in the environment. These molds release spores that are easily aerosolized and dispersed [4]. The most frequent genera causing infections in humans include *Rhizopus* and *Mucor* species, along with others like *Apophysomyces*, *Rhizomucor*, *Cunninghamella*, *Lichtheimia*, *Cokeromyces*, and *Saksenaea* [5]. *Rhizopus oryzae* is the most prevalent species, responsible for nearly 60% of human mucormycosis cases and about 90% of the rhino-orbital-cerebral mucormycosis (ROCM) form [6]. The primary mode of infection is through the inhalation of fungal spores.

Both *Aspergillus* and *Candida* have been identified as the primary fungal pathogens involved in co-infections among patients with COVID-19 [7]. Prolonged hospitalization, with or without mechanical ventilation, is also a contributing factor to these types of fungal infections [8]. Studies suggested that COVID-19 infection is associated with the destruction of β-cell of the pancreas [9,10]. A history of corticosteroid use for treating COVID-19 was found in 76.3% of mucormycosis cases, with remdesivir use in 20.6%, and tocilizumab in 4.1%. The most commonly affected organs were the nose and sinuses (88.9%), followed by rhino-orbital involvement (56.7%), and the ROCM type (22.2%) [8]. Uncontrolled hyperglycemia and the onset of diabetic ketoacidosis are often linked to corticosteroid use. COVID-19 infection can lead to endotheliitis, endothelial damage, thrombosis, lymphopenia, and reduced CD4+ and CD8+ lymphocyte counts, which increase susceptibility to secondary or opportunistic fungal infections [8]. Mucormycetes can invade blood vessels and spread to the brain and other organs through the bloodstream, leading to disseminated infections [11]. Diagnosis of ROCM should include early radiological imaging with a magnetic resonance imaging (MRI) of the paranasal sinuses (PNSs) and the brain with contrast, and confirmation can be made through fungal staining or culture from properly collected specimens [12].

ROCM is the most common form of mucormycosis in India, accounting for 45%-74% of cases. Complications of ROCM include blindness [13] cerebral infarction, cerebral abscess, cavernous sinus thrombosis, and intracranial hemorrhages [14]. The disease progresses rapidly and has a poor prognosis if not diagnosed early. Early detection, aggressive management of the underlying condition, surgical debridement, systemic and local antifungal treatments, and hyperbaric oxygen therapy significantly improve prognosis and survival rate [15]. The standard treatment for mucormycosis involves correcting diabetic ketoacidosis or other metabolic disturbances, daily irrigation and packing of the affected orbital and paranasal areas with amphotericin B, along with intravenous amphotericin B therapy [16].

Staging of ROCM

Stage 1 of ROCM has involvement of the nasal mucosa and subdivision 1a is limited to the middle turbinate, 1b involves inferior turbinate and ostium of the nasolacrimal duct, 1c involves nasal septum, and 1d involves bilateral nasal mucosal involvement.

Stage 2 of ROCM has involvement of paranasal sinuses and subdivision 2a involves only 1 sinus, 2b involves 2 ipsilateral sinuses, 2c involves more than 2 ipsilateral sinuses and palate or oral cavity and 2d has involvement of bilateral paranasal sinuses, the zygoma and mandible [17].

Despite all efforts in the conventional line of treatment, ROCM has a mortality rate of 40%-50% and 70% of survivors are left with residual defects [18]. To reduce the high mortality rate and residual defect in most of the survivors, Ministry of AYUSH, Government of India [19] has recommended homoeopathy as an add-on therapy to maximize the effectiveness of the standard line of treatment in conventional therapy. It is a well-established fact that homoeopathy is helpful as an adjuvant therapy along with the standard line of treatment for treating various disease conditions where conventional medicine has its own limitations [20].

In various research studies undertaken on various fungi, in vitro models showed that homoeopathy medicine could prevent the growth of the fungus. Prajapati et al [21] showed that showed that homoeopathic drugs, namely *Zingiber officinale*, *Holarrhena antidysenterica*, *Terminalia chebula*, *Allium cepa*, *Caesalpinia bonducella*, *Eucalyptus globulus*, *Ruta graveolens*, and *Thuja occidentalis* have significant antifungal activity against human pathogenic fungi *Aspergillus niger* whereas Gupta and Garg [22] revealed that homoeopathic medicines Mezereum 1000 potency showed maximum inhibition of growth of Candida albicans.

Hence, this study is intended to evaluate the role of homoeopathy as an adjuvant therapy in COVID-19–related mucormycosis and to enhance the survival of the hospitalized patients with ROCM. Due to the decline in COVID-19 cases in September 2021, the period when approvals could be sought,

the study was deemed unfeasible and had to be canceled. The authors consider it their ethical responsibility to share this reviewed protocol with the professional community as a resource for further research applicable to mucormycosis cases not specifically linked to COVID-19 infection. This initiative aims to ensure preparedness with evidence, regardless of its availability if similar emergencies arise in the future. Thus, we present this protocol to the community in hopes it would be used for immunocompromised or diabetes-related mucormycosis in individuals.

Objectives

Primary Objective

The primary objective is to evaluate the role of adjuvant homoeopathy in addition to the standard treatment of patients with COVID-19–related ROCM through standard parameters in respective conditions.

Secondary Objective

This study also aims to enhance the survival of the patients hospitalized due to COVID-19–related mucormycosis.

Methods

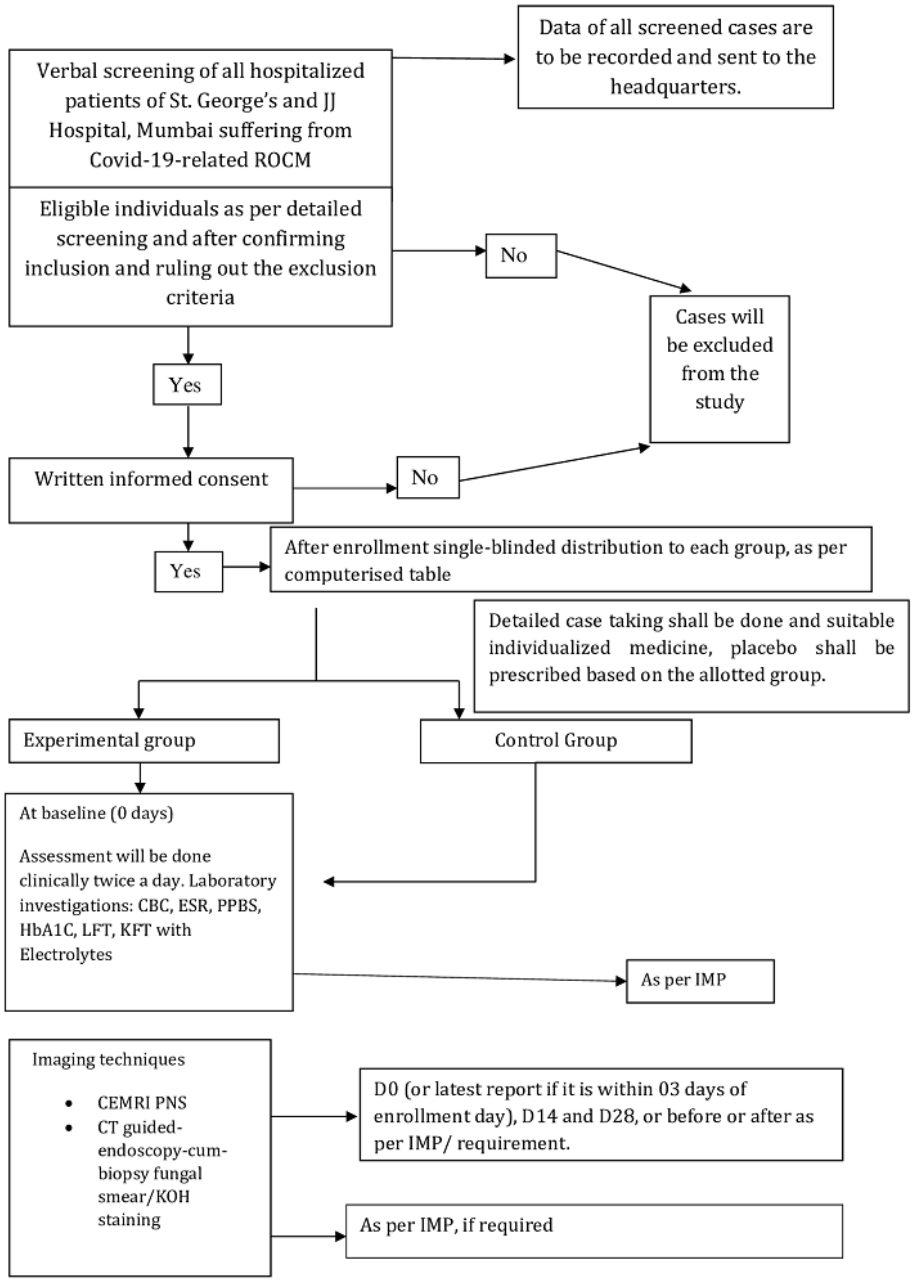
Study Design

The study is a superiority, single-blind, randomized controlled trial (RCT) with 2 groups: group A (experimental) and group B (control). Group A would receive homeopathic treatment in addition to the standard treatment for COVID-19–associated mucormycosis, as recommended by the Investigational Medicinal Product or Fungal Infections Study Forum (IMP or FISF; Multimedia Appendix 1) [23]. Group B would receive conventional treatment per the same guidelines, along with an identical placebo. Participants would be randomly assigned to either group in a 1:1 ratio using a computerized random number generator.

The trial would be planned to be conducted in a hospital setting, with informed consent obtained from patients admitted for the treatment of COVID-19–related mucormycosis. The study duration is 3 months, with an extension if needed to complete the required sample size. Patients with stage 1 or 2 COVID-19–related ROCM would be enrolled and randomized based on the trial's inclusion criteria. Both groups would receive the same auxiliary care, with dose repetition following the same pattern in both groups.

Participants would be assessed clinically twice a day, and MRI or endoscopy with biopsy would be performed on days 1, 14, and 28, with variations depending on the disease progression. The study protocol adheres to the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) 2013 guidelines, as illustrated in Figure 1.

Figure 1. Flow diagram of study design. CEMRI PNS: Contrast-Enhanced Magnetic Resonance Imaging of Para Nasal sinus; CBC: complete blood count; CT: computed tomography; ESR: erythrocyte sedimentation rate; HbA1c: hemoglobin A1c; IMP: investigational medicinal product; KFT: kidney function test; KOH: potassium hydroxide; LFT: liver function test; PPBS: postprandial blood sugar; ROCM: rhino-orbital-cerebral mucormycosis.



Study Setting and Duration

This RCT was planned for the St. George's and JJ Hospital, Mumbai, which was the hospitals of Sir JJ Group of hospitals, and had a common Institutional Ethics Committee. An informed consent of the patients admitted in the inpatient department for treatment of COVID-19–related mucormycosis planned to be taken before inclusion. Duration of the study would be 3 months and maybe extended if the desired sample size is not achieved.

Eligibility Criteria

The eligibility criteria are shown in Textbox 1.

Textbox 1. Eligibility criteria.

Inclusion criteria

- Both male and female participants aged 18 years or older and confirmed cases of COVID-19–related rhino-orbital-cerebral mucormycosis (ROCM) diagnosed as stage 1 and stage 2 (Multimedia Appendix 2) by potassium hydroxide staining (KOH staining) or magnetic resonance imaging (MRI) or biopsy would be included in the study. MRI would show Mucosal thickening with T2 hypointense components at T2W images, nonenhancement of involved mucosa or soft tissue at postcontrast T1W images, Marrow edema and enhancement of adjacent bones and skull base at fat-saturated T2W and postcontrast T1W image [24]. A hyperintense lesion extending from paranasal sinus along orbital apex into intracranial structures and narrowing or slow flow in the ipsilateral internal carotid artery in the vicinity of mucor invasion seen in T2W [25]. KOH staining or microscopy and biopsy of affected area would show nonseptate or pauci-septate, ribbon-like hyphae (at least 6-16 µm wide), and vessel occlusion [26].

Exclusion criteria

- ROCM at stage 3 and 4 (Multimedia Appendix 2) presenting with bony erosion, cerebral vascular invasion, invasion into the cranium, orbital apex or cribriform plate of the ethmoid bone, cavernous sinus (II-VI cranial nerve palsies) and diagnosed cases of pulmonary, cutaneous, gastrointestinal, advanced disseminated mucormycosis, pregnant and lactating women, cases where progression to death is inevitable and imminent within the next 24 hours according to the clinical team irrespective of the provision of treatments would be excluded from the study.

Intervention

Preparation of Study Intervention and Placebo Materials

Homoeopathic medicines to be used in the trial are known pharmacopeial preparations. As no new remedy is proposed to be investigated, there is no potential risk due to intervention. Intervention medicines would be administered orally. The medicine would be repeated depending on the potency and complaints of the patient in accordance with the principles of homoeopathy. Once the improvement sets in, placebo would be continued till the main medicine continues to act. The placebo (30 CH) would be identically prepared using only purified water, and pharmaceutical-grade ethanol, without glycerin or any medicinal active component.

Details of Intervention

The intervention would be a homoeopathic medicine which would be given as pills medicated with an ultradiluted homeopathic remedy. As a basic rule, increased dilution is proportionate to increased therapeutic power and no side effects. Owing to the nanoparticle nature of the drugs particles in serial dilutions above the Avogadro constant [27], homoeopathic intervention does not have any safety issue since inception. As the medicines used for this trial are already in use for decades and therefore, practical safety of medicines is well-established, this trial would be phase 3 trial and further validate the efficacy of these medicines, specifically in ROCM.

Through patient information sheet, patient would be duly informed about equal chances of receiving placebo or homoeopathic medicine, depending on the group she or he's allotted, and then consent would be taken. Furthermore, patients would be getting standard care of conventional medicine in both groups, and, therefore, would not be at risk. A detailed history and examination would be gathered from the already available information of the patient in the admission records at hospital. The patients randomized into experimental group would be interrogated by the homoeopathic physician only for the additional information required from homoeopathy perspective. Daily recording of the administered dose would be recorded and also captured in the case record form developed by the homoeopathy team, which would be having content other than, and in addition to the standard form, which would be filled at the hospital. If there is any change in dosage or prescription of medications during the study period, that would be mentioned with reason in the prescription chart. If these medicines are stopped, that too would be recorded with reason.

The patients assigned to the placebo group would be given placebo in the form of similar looking homoeopathic pills of size 30, dispensed with the 30% V/V dispensing alcohol. The prescribed medicine would be changed if no change in the next scheduled laboratory investigations or patient reports to be clinically unwell, even after at least 3 doses of the prescribed medicine.

In either arm, no patient would be devoid of conventional management as per IMP at any given point of time. Till the end point of the study in hospitalized patients, if required to enquire about well-being of the patient, phone call may be done in both groups and it would be considered as a phone follow-up.

FISF recommendations on Treatment of COVID-19–associated mucormycosis [23] (Multimedia Appendix 1) would be followed for regime of medication under standard care of intervention, which includes 3-6 weeks of amphotericin B therapy, followed by consolidation therapy for 3-6 months, strict control of hyperglycemia, steroids for lifesaving purposes in patients with COVID-19; abuse or misuse or untimely use to be avoided, judicious immunomodulating drugs, surgical debridement of the infected tissues, and regular monitoring through clinical, radio-imaging, and microbiological assessment.

For Homeopathic Intervention

As the condition is immunocompromised, very acute and progressive in nature, the homoeopathic medicines would be recommended in low potency and in frequent repetition. Medicine will be repeated in the following instances (Textbox 2).

Textbox 2. Condition where medicine would be repeated.

Repetition of medicine:

- If improvement stops, repeat the same medicine in the same potency.
- If no further amelioration occurs even after repeating the medicine in the same potency or improvement lasts for a very short period, give higher potency of the same medicine.
- If there is too short relief of symptoms (lasting for a few hours and diminishing further on subsequent repetition of the doses), reassess the case and observe.
- If the medicine remains appropriate after reassessment, it should be administered in a next higher potency.
- If no further amelioration occurs, reassess the case and prescribe the indicated remedy.
- If aggravation is quick, short, and strong with rapid improvement of the patient, discontinue the medicine and prescribe placebo.
- If the appearance of new symptoms is observed, and if the symptoms are not of a serious nature, wait till the new symptoms pass off. Then select another indicated remedy after reassessing the case.
- In case of serious symptoms, change the medicine and check for safety end point.

Withdrawal of a trial participant:

- If the patient worsens, and mucormycosis expands beyond the range of inclusion criteria.
- If the patient is in need of ventilator support.
- If the participant is unwilling to continue or turns noncompliant.

Outcome Measures

Primary Outcome

The following changes would be observed in MRI contrast:

1. Mucosal thickening with reduction in Transverse Relaxation time T2 hypointense components at T2-weighted (T2W) images.
2. Infiltration of mucosa/soft tissue at postcontrast T1-weighted (T1W) images.
3. Marrow edema and enhancement of adjacent bones and skull base at fat-saturated T2W and postcontrast T1W image.
4. Hyperintense lesion extending from paranasal sinus along orbital apex into intracranial structures and narrowing or slow flow in the ipsilateral internal carotid artery in the vicinity of mucor invasion seen in T2W.
5. Staging of Code Mucor as per Guidelines for the Diagnosis, Staging and Management of ROCM in the setting of COVID-19 pandemic [17]. The absence of stage 1 would be considered as cured and progression from stage 1 to stage 2 or stage 2 to stage 3 or 4 would be considered as worse outcome.

Secondary Outcomes

The median survival rate of the patients would be assessed in both the groups during hospitalization.

Participant Timeline

Each patient would be followed up for 28 days. Participant would be followed up every 4 hours, or sooner, as per the case and would be asked a few questions as per case recording form, before commencing the treatment. Participants would be requested to be available on phone for follow up by the doctor on day 14 and day 28, in case they are discharged from the hospital before day 14 of the illness.

The following variables would be clinically assessed in every follow up:

1. Nasal stuffiness
2. Nasal discharge
3. Foul smell
4. Epistaxis
5. Facial pain
6. Facial edema
7. Dental pain
8. Malaise
9. Fever

Sample Size

Based on the computation of sample size, literature, and expert opinions and assuming a type 1 error of 5% and type 2 error of 20% with a power of 80%, it was estimated that there would be 36 participants each in the intervention and control group, with a total of 72 participants. This could be escalated based on attrition due to loss in follow-up. If this loss to follow-up is considered at 25%, a total of 45 participants have to be enrolled in each group, with a total sample of 90 for the study.

Randomization and Blinding

The study participants were planned to be recruited from St. George's and JJ Hospital, Mumbai. The recruitment would be based on the inclusion criteria. The participants would be allocated to either intervention or placebo groups as per the randomization sequence generated by using GraphPad (GraphPad Software) by Dotmatics (Insightful Science) software. Coded or prenumbered identical containers would be used for allocation concealment. The principal investigator (PI) at Central Council for Research in Homoeopathy (CCRH) headquarters would be involved in the sequence generation process and allocation concealment procedure. The PI would label the interventions as per the randomization codes, which would be handed over to the site PIs. The site PIs would enroll

participants and randomly assign participants to interventions. The only trial participants interventions would be blinded. To ensure the quality of blinding the packaging for both the interventions and placebo would be identical in odor, color, size, and taste. The unblinding would be done by the PI at CCRH headquarters at the end of the study. If severe adverse events would be reported by the participants during the trial, unblinding may be performed per Data and Safety Monitoring Board (DSMB) or ethical committee recommendations. The reason for urgent unblinding should be well-documented.

Screening and Enrollment

All the participants would be voluntarily invited to the study and then required to sign an informed consent form containing information on the regulatory authorities and the related procedures, including laboratory investigations and subsequent randomization after enrollment. Enrollment of the participants would be based on inclusion criteria. The hospital must maintain a log register that records all the details of the screened participants and the reasons for exclusion. After enrollment the participants would be randomized and allocated to the intervention or the placebo arm as per the generated randomization sequence using GraphPad by Dotmatics software.

Data Collection Methods

Considering the critical importance of COVID-19–related ROCM, data from the trial participants would be collected extensively. The following documents below would be developed and retained.

1. Case record form of COVID-19–related ROCM.
2. A database that stores the above information for each patient with the subsequent observations by the physician at every visit.
3. Reports of all laboratory investigations to help physicians understand efficacy of diagnostic tools or interventions.
4. All data pertaining to homoeopathy, like case taking, repertorization chart, and prescription decisions would be maintained.

Assessment and Data Analysis

Potassium hydroxide staining and Contrast-Enhanced Magnetic Resonance Imaging (CEMRI PNS) would be used for diagnosis and staging of ROCM. However, for assessment of the progress of the condition, following parameters would be evaluated on days 14 and 28:

1. CEMRI PNS impression
2. Code Mucor staging
3. Clinical assessment
4. Laboratory parameters

The participants would be assessed clinically twice a day and the laboratory parameters complete blood count, erythrocyte sedimentation rate, fasting blood sugar, postprandial blood sugar, hemoglobin A_{1c} levels, liver function test, and kidney function test with electrolytes would be assessed on days 0, 14, and 28. These tests would be repeated as many times as required as per Institutional Management Protocol, which is essentially based on FISF guidelines. However, the assessments would be done only on the fixed days, as mentioned above.

CEMRI PNS would also be done on day 1 (or latest report if it is within 03 days of enrolment day), day 14, and day 28, or before or after as per IMP or FISF requirement Multimedia Appendix 3.

Follow-Ups

Each patient would be followed up for 28 days. Participants would be followed up daily as long as they are hospitalized; in case of discharge before this follow up period, they would be followed up telephonically on day 14 and day 28.

The following variables would be clinically assessed in every follow-up:

1. Nasal stuffiness
2. Nasal discharge
3. Foul smell
4. Epistaxis
5. Facial pain
6. Facial edema
7. Dental pain
8. Malaise
9. Fever

The case would be said to be completed when there is either recovery of the participant as per the outcome parameters, followed by discharge from the hospital, or has advanced in the form of advanced disseminated mucormycosis or death of the patient.

Data Analysis

The study center would send a weekly report as per weekly report proforma on case recruitment to headquarters either by fax or email every week. The DSMB would assess the research data regularly. The conclusion report on completion of the study (after 3 months) is to be submitted to Headquarters as per concluding report proforma.

Withdrawal Criteria

The participant would be withdrawn from the study if the condition of the participants worsens and the mucormycosis expands beyond the inclusion criteria (safety end point), participants require ventilator support, it suggests a severe respiratory condition, possibly due to complications from mucormycosis or other underlying health issues, or participants become unwilling to continue or become noncompliant in the RCT and request the site PI to withdraw them for the RCT would be withdrawn from the study. Every participant can withdraw from the trial anytime for any reason and without prejudice.

End Point

A case would be considered complete when the participant either recovers based on the defined outcome parameters and is discharged from the hospital within or before 28 days. Safety end points include advanced disseminated mucormycosis and patient death.

Statistical Analysis

Data collected would be compiled on to a Microsoft Excel worksheet and would be subjected to statistical analysis using

an appropriate package like SPSS (IBM Corp) software. Descriptive statistics like frequency and percentage of categorical data, mean (SD) of numerical data in each group or subgroup would be depicted. Frequency and percentage of various categories in each group or subgroup would be compared using chi-square test. Normality of numerical data would be checked using Shapiro-Wilk test or Kolmogorov-Smirnov test. Depending on the normality of data, statistical tests would be determined. For a numerical continuous data following a normal distribution, inter group comparison (2 groups) would be done using *t* test, else a nonparametric substitute like the Mann-Whitney *U* test would be used. Intra group comparisons for a numerical continuous data following a normal distribution would be carried out using paired *t* test (for 2 observations) or repeated measures ANOVA for >2 observations, else a nonparametric substitute like Wilcoxon signed-rank test (for 2 observations) or the Friedman test for >2 observations would be used. Frequency and percentage of various responses in each time interval would be compared using the chi-square test or McNemar test. Having set the α error at 5%, β error at 20%, and power at 80%, $P<.05$ would be considered statistically significant (Multimedia Appendices 4, 5, and 6).

Data Monitoring and Management

Project Monitoring and Reviews

Record of each enrolled case is also to be electronically maintained and this electronically maintained record is to be sent to headquarters through email to the study coordinator at CCRH headquarters as soon the case is enrolled for verification of the case record with annexures. Concerned authority shall do on-site monitoring at 1-month interval till completion of the study.

Quality Control

A centralized workshop would be organized for the investigators (to be involved in specific study) to ensure standardization and quality control. A periodical review would be conducted at all the sites for quality assurance. A random subset of records from each site would be evaluated for quality control. Investigators would be asked to bring all medical records for selected subjects to the data analysis workshop. Information in the medical records would be compared with the data on the case report form to assess completeness and accuracy of reported data.

Harms

Homoeopathic medicines which shall be used in the trial are known pharmacopeial preparations. As no new remedy is proposed to be investigated, there is no potential risk due to intervention.

Auditing and Inspecting

The study center would send a weekly report as per weekly report proforma on case recruitment to headquarters either by fax or email every week of the month. The DSMB would assess the research data regularly. The conclusion report on completion of the study (after 3 months) is to be submitted to hqrs. as per concluding report proforma.

Ethical Considerations

Protocol Development

This is carried out in consultation with experts of St. George's and JJ Hospital, Mumbai and then subsequently reviewed by Dr V Shankar Kumar, Consultant ENT Surgeon Apollo Spectra Hospitals, Chennai and Dr Sushil Kabra, Department of Pediatrics, AIIMS New Delhi before it was submitted to ethics committee.

Human Subject Ethics Review Approvals or Exemptions

The study protocol shall be in accordance with the latest revision of the Helsinki Declaration on human experimentation and Good Clinical Practices India. Although medicines proposed to be used during the study are known homoeopathic pharmacopeial preparations, necessary clearance of the Ethical Committee shall be obtained before undertaking the study. The Scientific Advisory Board and the Central Ethics Committee of the CCRH have approved the study protocol and the amendments (1-29/2021-22/CCRH/Tech/Post-covid Mucormycosis/887; July 15, 2021). The investigator must meet the study requirements as specified in the protocol. Protocol amendments are possible only in exceptional cases (eg, where the health or well-being of the participant is affected) and only after authorization by the Scientific Advisory Committee (SAC) of the Council. If there is any modification in the protocol, an addendum of the same shall be circulated to all the investigators after due approval of SAC and EC. The investigator shall update the protocol by attaching the addendum of the amendment to the already circulated protocol. In case of any administrative or technical amendments, which do not affect the health of the participant, agreement of all the concerned shall be made. These changes shall also be justified in writing and all those concerned are to be informed.

Informed Consent

Individuals aged 18 years or older would be considered eligible for consent. The site PI would obtain voluntary consent from the participants before the screening test after explaining the study. The participants would be provided with the participant information sheet describing the study details and would voluntarily sign the consent form if they agree to take the intervention.

Privacy and Confidentiality

The investigator would inform the participants that all trials results recorded would be treated in strict confidence. During documentation and analysis, the participants would only be identified by their subject code and unique identifier number. The confidentiality of the participants' personal data would be maintained as per data protection regulations.

Compensation Details

CCRH would provide insurance cover in the trial for the said study duration, according to the terms finalized under clinical trial cover with the identified insurance firm.

Protocol Violation

If the patient stops taking the intervention medication on their own, this would be considered as protocol violation. So, these participants would not be considered for per protocol analysis.

Declaration of Interest

No conflict of competing interest of the PI or site PI, or any other member of the investigation team.

Access to Data

The access to data would be restricted for analysis and interpretation only by CCRH and other collaborating organization, as and when involved. For all purposes, the data would remain strictly confidential, and anonymity would be assured through the best possible means.

Ancillary and Posttrial Care

The participant would be provided with all ancillary care during the study and other ancillary techniques. Besides, she/he would be provided with regular outpatient department care, even after the study is over.

Dissemination Policy

The investigators would communicate trial results to participants, health care professionals, the public, and other relevant groups (through publication, reporting in results databases, or other data sharing arrangements) after completion of the study. However, no information based on unjustified claims, or the findings of interim analysis would be communicated in any form.

Results

India faced a significant impact from the COVID-19 pandemic, with 44,587,307 confirmed cases and 528,629 deaths reported as of January 17, 2023, according to the World Health Organization [28]. The second wave placed tremendous strain on the nation's health care system, resulting in severe shortages of drugs, vaccines, ventilators, and oxygen. During this period, there was a notable increase in mucormycosis cases among patients with COVID-19, leading the government to classify it as a notifiable disease under the Epidemic Diseases Act of 1897 on May 20, 2021 [29]. To address the high mortality rate and long-term complications experienced by many survivors, the Ministry of AYUSH, Government of India, recommended homoeopathy as an adjunct therapy to enhance the effectiveness of standard conventional treatments. The CCRH developed a protocol to incorporate homoeopathy as an additional therapy for treating COVID-19–associated mucormycosis. However, when this protocol was created, there was a significant number of mucormycosis cases in India, particularly in Mumbai (June 2021). By the time CCRH obtained all necessary approvals and ethical clearance for the study, the incidence had decreased dramatically (September 2021), resulting in the study not being initiated or registered. The authors believe it is their ethical duty to share this reviewed protocol with the medical community as a reference for future research.

Discussion

Principal Findings

This study was conceived during the exponential increase in Mucormycosis cases in India since March 2021. This opportunistic infection was being observed in patients with severe COVID-19. Globally, the prevalence of mucormycosis varied from 0.005 to 1.7 per million population in 2019-2020. Its prevalence in India was 0.14 per 1000 population. In May 2021, the cases peaked to 11,717 cases of mucormycosis across 18 states of India [24]. ROCM is extremely fatal with mortality rates ranging from 85%-93%, despite the best treatment in immunocompromised patients [30]. Patients with poorly controlled diabetes mellitus are the primary group at risk for developing ROCM. Other recognized risk factors worldwide include diabetes-associated ketoacidosis, hematological malignancies, solid organ or bone marrow transplants, surgeries, trauma, neutropenia, protein-calorie malnutrition, autoimmune diseases, chronic kidney disease or renal failure, HIV infection, deferoxamine therapy, and corticosteroid therapy [31]. ROCM typically starts in the paranasal sinuses and then spreads to adjacent structures, such as the orbit and neurocranium. Most reported cases are from Iran (26%), India (22%), China (17%), and the United States (15%), regions where diabetes prevalence is significantly increasing [32]. Chavda et al [33] state that mucormycosis affects the nose, eyes, and brain and is a potentially fatal intrusive fungal infection that frequently affects immunodeficient individuals.

In conventional treatment, surgical and pharmaceutical interventions are key to treat mucormycosis, thus necessitating a multidisciplinary approach team of otolaryngology, ophthalmology, neurosurgery, and infectious disease specialists in a facility setting. Intravenous antifungal pharmacotherapy is the first line of treatment, amphotericin B deoxycholate and posaconazole or isavuconazole being the 2 antifungal agents recommended for the primary therapy of mucormycosis [34]. However, the scope of treatment in limited in this condition, and resulting side effects are known. Chakraborty et al [34] have reported side effects from liposomal amphotericin B, which include fever, chills, nausea, vomiting, loss of appetite, headache, and some serious side effects which include swelling or pain at injection site, muscle or joint pain, unusual tiredness, weakness, muscle cramping and signs of kidney problems (such as a change in the amount of urine or painful urination) and so on after infusion of the drug, which, in turn, causes hindrance to continue the required conventional treatment [17]. Sachdeva et al [35] states that hepatotoxicity and nephrotoxicity are well-known serious side effects of intravenous Amphotericin B and posaconazole treatment. Pal et al [36] reports palatal, facial soft tissue necrosis, loss of vision, and invasion of soft tissues of the infratemporal fossa, orbit or palate through neurovascular structures as complications of ROCM.

Due to limited scope of conventional medicine, side effects that are serious or interfere in the treatment, advance complications and poor prognosis with high mortality rate, the authors felt a need of exploring the usefulness of alternative system of medicine to complement the standard line of treatment for

COVID-19–related ROCM. The authors have had a successful experience of providing adjunct homoeopathic treatment in severe cases of COVID-19 before planning this RCT, which, is now reported [37]. Planning this RCT, thus, seemed to be a step in the right direction.

The evidence for similar studies in the past in homoeopathy sector is limited. The literature was, therefore, looked up for role of homoeopathy in fungal studies, instead. A study on dermatophytosis and its management by homoeopathic medicines reports successful reduction in the NRS and DLQI scores, thus suggesting it as a feasible integrative treatment option for tinea infections [38]. An in vitro study on antifungal activity of homoeopathic medicines against plant fungus *Aspergillus niger* observed that homoeopathic medicines with various potencies (6C to CM) had a significant antifungal activity, compared with the controls, which is bavistin (Carbendazim) and ethanol (Dispensing alcohol 90%) [39]. A case series by Roy et al [40] reports positive effect of homoeopathic medicines against dermatophytosis. Furthermore, a pilot study by Sherr et al [41] reported that homoeopathic medicine Bacillinum had a potential to improve long term tinea status and reduces the chances to relapse as compared with the standard treatment for tinea and homoeopathy can be used as an alternative to standard treatment care. Other in-vitro studies have also reported homoeopathy medicines to have worked effectively against the growth of different forms of fungus [21,22].

There was, however, no study reported so far to assess the role of homoeopathic medicines in mucormycosis. Hence, to the authors' knowledge, this protocol was a first with the aim to evaluate the efficacy of homoeopathic medicines as an adjuvant in the treatment of COVID-19–related ROCM. However, with the decline in COVID-19 cases in September 2021, which was the time when the approvals could be sought, the study had to be called off due to nonfeasibility reasons. The authors feel this as their ethical duty to share this reviewed protocol with the profession as a reckoner or source of further work for the clinicians or scientists alike, in a more generalized manner, which is to say, in the cases of mucormycosis not particularly resulting from COVID-19 infection. This would help in being prepared with the evidence, or the lack of it, should such an emergency situation arise in future. We, thus, share this protocol with the community with the hope that it may be adopted for mucormycosis cases that are generally seen in immunocompromised individuals.

Conclusion

This study aimed to evaluate the role of existing homoeopathic medicines as an adjuvant therapy in managing COVID-19–related ROCM, potentially contributing to the use of homoeopathy as an evidence-based medical approach. The protocol can also serve as a valuable resource for clinicians and researchers addressing mucormycosis cases unrelated to COVID-19 infection, particularly in immunocompromised patients. It would help ensure preparedness, whether or not sufficient evidence is available, in the event of a future health emergency. The authors have tried to adopt universally acceptable, standardized parameters for determining the improvement, with secondary parameters intended for evaluating the survival rate of the hospitalized patients besides other parameters that have been selected for assessing initial treatment response through laboratory and imaging techniques. A planned outcome of the study includes comparing the time required for significant or complete recovery between patients receiving adjuvant treatment and those in the control group. The authors welcome future studies based on this protocol and would be pleased to see their work advanced by fellow professionals.

Acknowledgments

Dr VK Gupta, Chairman of the Scientific Advisory Board of the Central Council for Research in Homoeopathy (CCRH), and Dr LK Nanda, Chairman of the Special Committee on Clinical Research at CCRH, along with their respective committees, are acknowledged for granting technical approvals. Additionally, reviewers Dr V Shankar Kumar, Consultant ENT Surgeon at Apollo Spectra Hospitals, Chennai, and Dr Sushil Kabra, Department of Pediatrics at the All India Institute of Medical Sciences, New Delhi, are thanked for their valuable comments that enhanced the protocol during its development. The funding authority was the Central Council for Research in Homoeopathy under the Ministry of AYUSH.

Data Availability

No data are associated with the protocol as the study could not be initiated because mucormycosis cases started declining.

Authors' Contributions

RB and HK conceptualized the study. JS planned its conduct and methodology under the guidance of HK. JS and TG developed the protocol and contributed in final manuscript writing. All authors agreed with the final version of the manuscript.

Conflicts of Interest

None declared.
