The study was approved by the ethics committee of the German Society for Nursing Science (EK-23-018) and it complies with the Declaration of Helsinki. This study is not funded. Each participant provided both verbal and written informed consent to the first author before data collection commenced. During data collection, an initial review of the material is conducted to identify emerging themes within the interviews, enabling a deeper exploration of contrasts between them. Participants were advised that they could contact the interviewer at any time if they required further information or wished to reflect on the interview's impact. Due to the sensitive nature of discussing intimate relationship dynamics, particularly within the context of illness and rehabilitation, strict confidentiality must be upheld. Considering the emotional sensitivity of patients and their partners, the lead researcher undertook specialized training in sensitive interviewing techniques.

Anonymization and Data Security

We will anonymize all participant names, including their place of residence and treatment facility as well as names of workplaces and contact persons. We will manage and store the raw and analytical data (transcripts) and the code list in separate, password-protected data repositories. The data will be stored for 10 years in accordance with the data protection ordinance. No payment or reimbursement of expenses is provided for participation.

Results

The research question has been little explored and, in accordance with qualitative research principles, remains open to new and unexpected findings. The data collection started in June 2024 based on narrative interviews and is actually running. Currently, 15 dyads have been recruited and 7 have been interviewed. The current stage of the project is in work packages 6 and 7 (Figure 2). Due to the extensive procedures involved and the depth of reconstruction anticipated, we expect a sample size of up to 20 dyads. We anticipate that the study will be completed by June 2025, with data analysis concluding in the first quarter of 2025 and publication expected in the third quarter. We assume that patients and their relatives will demonstrate heterogeneity as individuals, as well as in their interactions within the dyad, regarding certain orientations such as coping with illness, motivation for therapy, and coping strategies. Furthermore, we expect that these orientations will manifest dynamically throughout the rehabilitation process and may therefore change over time.

Discussion

Overview

This study aims to enhance our understanding of how the relationships of affected couples evolve over the long term and how these changes impact the rehabilitation process. We propose that the nature of the relationship dynamics between patients and their partners varies based on the individual characteristics

of both the patient and the partner, significantly influencing the rehabilitation experience. These dynamics may affect how patients and their partners interact and adapt to the challenges of rehabilitation. Therefore, it is essential that intervention strategies are customized to the specific types of relationships in order to provide effective therapy.

From a biopsychosocial perspective, it is crucial to involve not only the affected persons themselves but also their social environment in therapy and rehabilitation [27]. The impact of a neurological impairment extends far beyond the individual and touches on the family members and friends. Incorporating health care professionals into the everyday lives of individuals with long-term illnesses signifies a significant shift for both the patients and their partners. Frequent interactions with health care providers, whether through medical appointments or therapies, have a direct effect on patients' health, their level of independence, and the dynamics of their shared lives.

A systematic review conducted by Weitkamp et al [28] suggests that couples dealing with chronic illness benefit from effective stress communication, supportive dyadic coping, and shared appraisals of their situation. We hypothesize that similar strategies will be identified in our study, as couples may use comparable communication techniques to manage stress and enhance mutual support. Furthermore, we expect to gain additional insights into coping strategies, including various communication patterns, and how these influence both the couple's relationship and the rehabilitation process. This variability in coping strategies underscores the intricate ways in which couples adapt to chronic illness. We anticipate that these findings will have implications for therapeutic approaches, emphasizing the importance of recognizing and supporting diverse communication styles and options for action.

Strengths and Limitations

The reconstruction method used in this study promises a significant gain in understanding through an in-depth analysis of the unique life worlds of the dyads. This approach aligns with Flick's [29] advocacy for narrative and reconstructive methods, which are instrumental in revealing deeper insights within qualitative data.

Through nationwide recruitment, we aim to minimize one-sided outcomes and regional disparities in care, thereby enhancing the representativeness of our findings. The study's methodological strengths, bolstered by the application of the documentary method, provide a solid framework for analysis. However, we acknowledge certain limitations, such as the challenges in recruiting same-sex couples and the difficulty in reaching individuals from lower socioeconomic backgrounds. Despite these challenges, we will strive to assemble a heterogeneous sample to increase the study's validity and ensure representation across various societal strata.

Theoretical and Practical Implications

The findings of our study are expected to contribute to the theoretical understanding of couple dynamics in the context of chronic illness and rehabilitation. We hypothesize that the variations in coping strategies will not only reflect different communication patterns but will also emerge from the specific characteristics of patients, their relatives, and the types of relationships involved. This differentiation will enhance our understanding of how various relational dynamics influence the rehabilitation process, thereby supporting existing theories while potentially introducing new dimensions to the discussion. By identifying these nuances, we aim to provide a more comprehensive framework for future research and interventions in this field. We assume that our study will support the principles of RDT by indicating that couples oscillate between change and stability, engaging in a dynamic negotiation process as they adapt to evolving relational and emotional landscapes. The theoretical grounding provided by our engagement with these theories (SI and RDT) offers a robust foundation, allowing for connections to be made with established assumptions in the field.

Enabling a deeper understanding of the interactions between professionals, patients, and their family caregivers could ultimately contribute to an increase in the quality of life of patients and their caregivers. This holistic approach has the potential to increase the effectiveness of rehabilitation by making therapy patient- and family-centered. This could create a more positive outcome in life for all those who are involved. Costs for the health care system could be reduced through effective therapy that also takes into account the mental health of relatives. Furthermore, our results could make it easier for health care professionals to provide care and could be used to support the interaction depending on the patient and the relative type as well as the relationship type.

The results will be published in both a scientific journal and a practice-oriented publication in neurological long-term rehabilitation, reaching a broad readership within the health care sector. This includes health care professionals who support affected individuals and their relatives during various phases of rehabilitation, such as doctors, nurses, physiotherapists, occupational therapists, and speech therapists. A brief summary of the results will also be prepared in patient-friendly language, similar to a patient guideline, and sent to participants upon request.

Due to a further increase in chronic diseases in the coming decades, for example, as a result of environmental, climate, and demographic changes, it is necessary to develop interventions on a physical, psychological, and social level to reduce the burden of chronic diseases [30].

Conclusion

The successful completion of the study will provide recommendations for action for practitioners, and, if possible, will facilitate the development of a treatment concept to improve the care of people with neurological disorders and their caring relatives. A deeper understanding of psychosocial processes in connection with chronic illnesses is of great importance for the development of comprehensive, personalized care strategies.

Data Availability

The datasets generated during this study are not publicly available due to confidentiality and ethical considerations but are available from the corresponding author on reasonable request.

Authors' Contributions

AvB was responsible for the conceptualization and research questions, study design, visualization, and writing of the original draft as well as the ethical approval, and is responsible for the analysis of the data material. EJ supported the selection of the study design (methodology), supervised the research work and the preparation of the ethical approval, and will support the analysis. PK supported the conceptualization of the study design against the background of his nursing science perspective and will support the analysis of data.

Conflicts of Interest

None declared.

Abstract

Background: Integrating algorithm-based clinical decision support (CDS) systems poses significant challenges in evaluating their actual clinical value. Such CDS systems are traditionally assessed via controlled but resource-intensive clinical trials.

Objective: This paper presents a review protocol for preimplementation in silico evaluation methods to enable broadened impact analysis under simulated environments before clinical trials.

Methods: We propose a scoping review protocol that follows an enhanced Arksey and O'Malley framework and PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines to investigate the scope and research gaps in the in silico evaluation of algorithm-based CDS models—specifically CDS decision-making end points and objectives, evaluation metrics used, and simulation paradigms used to assess potential impacts. The databases searched are PubMed, Embase, CINAHL, PsycINFO, Cochrane, IEEEXplore, Web of Science, and arXiv. A 2-stage screening process identified pertinent articles. The information extracted from articles was iteratively refined. The review will use thematic, trend, and descriptive analyses to meet scoping aims.

Results: We conducted an automated search of the databases above in May 2023, with most title and abstract screenings completed by November 2023 and full-text screening extended from December 2023 to May 2024. Concurrent charting and full-text analysis were carried out, with the final analysis and manuscript preparation set for completion in July 2024. Publication of the review results is targeted from July 2024 to February 2025. As of April 2024, a total of 21 articles have been selected following a 2-stage screening process; these will proceed to data extraction and analysis.

Conclusions: We refined our data extraction strategy through a collaborative, multidisciplinary approach, planning to analyze results using thematic analyses to identify approaches to in silico evaluation. Anticipated findings aim to contribute to developing a unified in silico evaluation framework adaptable to various clinical workflows, detailing clinical decision-making characteristics, impact measures, and reusability of methods. The study's findings will be published and presented in forums combining artificial intelligence and machine learning, clinical decision-making, and health technology impact analysis. Ultimately, we aim to bridge the development-deployment gap through in silico evaluation-based potential impact assessments.

Introduction

The recent advent of artificial intelligence (AI) in clinical decision support (CDS) systems furthers the intended purpose of such systems to enhance medical decision-making by using clinical knowledge and other health information [1]. Traditionally, such systems rely on either standard of care or knowledge-based models [2]. AI models' statistical learning capability—iteratively identifying and learning patterns from large volumes of data—facilitates including more information to arrive at an optimal decision recommendation [3,4]. Despite the prevalence of AI-based CDS development [5], adoption has been limited [6,7]. A significant barrier to adoption is the high trust and safety requirement of health care applications that demand evidence on implications to the broader system and the clinical workflows across the care value stream [5,8,9].

The current state of reporting traditional statistical analysis and CDS development predominantly focuses on accuracy, sensitivity, specificity, goodness-of-fit, and other discrimination-related measures [3] that do not precisely measure patient-, provider-, process-, and cost-related outcomes. These metrics may not capture the actual clinical improvements or the broader consequences that may arise when implementing CDS within the clinical workflows. For example, such metrics may be limited or require calibration when considering context-specific tradeoffs in predictive accuracies. Preference may be higher sensitivity than specificity in different contexts, such as early screening. Conversely, an oversensitive screen may result in more resources needed for confirmatory testing [10]. Hence, the ability to simulate the impact of model calibration and thresholding decisions for downstream workflows and eventual outcomes may be beneficial, especially when provider and process resources could render any CDS-based recommendation impracticable.

Traditional assessments of the implications of health technologies, such as algorithm-based CDS, focus on generating clinical evidence through randomized controlled trials to balance assessment scope and feasibility [11]. However, such assessments are challenged by the following: (1) the need for continuous evaluation of impact both in the development stage [12,13] and when such systems are deployed [14,15], (2) the need for more robust evidence that accounts for variations among real-world care pathways—characterized by heterogeneous settings and patient populations [5,9,16,17], and (3) the cost of an expanded scope of assessment when considering a broader health care pathway or system [18] such as in the evaluation of bundled payments in health care pathways and value-based health care [19,20].

In silico methods that simulate real-world care pathways present an alternative to evaluate CDS at preimplementation while approximating real-world care pathway events, behaviors, disease states, and resource constraints. These methods enable an iterative analysis of different clinical workflow scenarios, addressing the need for continuous impact evaluation without significant resource demands and disruptions to ongoing usual care practice [11,21,22]. In addition, such methods allow for the integral consideration of practical constraints [11,23], such as when at-risk patients are correctly identified by a CDS but cannot receive the appropriate downstream interventions due to resource constraints [24,25]. The value of clinical workflow simulations as an alternative is put forward by the recent inclusion of preclinical evaluation of CDS in guidelines for academic research reporting. Specific to AI-based CDS, the development and exploratory clinical investigations of decision support systems driven by AI reporting guidelines strongly endorse the concept of preclinical or in silico evaluation—that is, via computer simulations before the first clinical trial [18]. Vasey et al [21] cite the development of other guidelines, for example, transparent reporting of a multivariable prediction model for individual prognosis or diagnosis–artificial intelligence [26,27] and standards for reporting of diagnostic accuracy study–artificial intelligence [28], that tackle the reporting of AI-based CDS evaluation at the preclinical stage. In addition, in silico modeling has been previously argued to be beneficial in drug discovery [29], surgical systems innovation [30], and biomedical product regulation [10], as it can address the trade-off between scope and resource demands existing in traditional impact assessments.

Evaluating CDS under uncertainty can leverage mathematical models that consider the inherent stochasticity of clinical workflows and systems, such as simulation models [22]. As decisions are often time-sensitive [31], simulations should also be dynamic. Discrete events simulation (DES) and agent-based models (ABM) are stochastic dynamic models frequently used [32]. These simulation models allow context-specific domain nuances to be captured in the model logic as discrete states, actions, and transitions, thereby capturing the unique characteristics and uncertainties that define clinical workflows across care settings and sites. Queueing, Markov, and other stochastic process models [22,33,34] are closely associated with these models. System-level workflow simulations such as those using DES [22] and ABM [35] can model intricate health care dynamics and are commonly applied to model clinical workflows in health service delivery. These methods facilitate comprehensive analyses encompassing patient journey, resource use, and stakeholder interactions, providing insights into operational efficiencies, bottlenecks, and unintended consequences of implementing automated decision-support

interventions. It offers a flexible method to capture the dynamic workflows in which the entities (ie, patients and providers) interact and are exposed to important clinical/process events (ie, admission and clinical decision) while consuming and releasing resources (ie, number of nurses in a hospital ward at a given time interval) [36]. By adjusting the decision thresholds, we can evaluate the CDS' impact using a variety of decision-analytic measures, for example, decision curve analysis [37] to determine the most clinically helpful prediction model.

Given the significance of such in silico evaluation via simulation models, a consolidated knowledge base will help to guide their use in evaluating CDS systems. Current research needs to be more cohesive, with disparate methodologies focusing on narrow facets of health care delivery [38,39]. To support the advancement of workflow-sensitive evaluation methodologies for CDS systems, we propose a scoping review protocol that investigates the following components of in silico evaluation: (1) the use of more pragmatic measures of impact that are relevant to the quadruple aims of health care [40,41], and (2) the simulation modeling paradigm used. Specifically, we propose a review protocol that (1) maps out the state-of-art development and application of in silico clinical workflows to evaluate algorithm-based CDS—both traditional statistical analysis- and AI-based—models and (2) identifies relevant research gaps. To our knowledge, this is the first scoping review on in silico evaluation strategies for AI applications in CDS using workflow simulation methods.

Methods

Overview

We followed the stages in a scoping review proposed in the Arksey and O'Malley framework [42] while considering more recent enhancements [43-45] for each stage. Specifically, we followed the steps of (1) identifying the research question, (2) searching and identifying relevant studies, (3) study selection, (4) data extraction, (5) collection, summarizing, and reporting of findings, and (6) consultation with stakeholders. These are detailed in the succeeding sections.

Stage 1: Identifying the Research Question

This scoping review endeavors to synthesize existing knowledge on the in silico evaluation of algorithm-based CDS systems via clinical workflow simulation methods. High-fidelity workflow simulations offer a pragmatic solution by allowing in silico replication of clinical processes, predicting the behavior of systems, and assessing the potential impacts of new models without risking patient safety or disrupting existing services [46]. To identify the scope of the review, we first conducted a rapid scan [45] of existing academic articles that discuss the evaluation of algorithm-based CDS. This review includes those using standards of care, knowledge bases, or AI to support a clinical decision recommendation [2]. In succeeding sections, these are generically referred to as CDS.

Regular team discussions were conducted to summarize findings and shortlist authors who publish peer-reviewed journal articles in our field of interest. Our study team comprises researchers with collective experience in machine learning model development, conducting systematic review studies, systems optimization research, and medical research and practice. The authors of this protocol—a senior clinician (QZ), a senior data scientist (SSWL), a junior data scientist (MD), and a junior pharmacoepidemiology researcher (YLC)—serve as the initial review team. After several initial iterations, we agreed on the research questions in Textbox 1. Further, we identified a list of concepts and accompanying keywords relevant to our main research question. These are presented in Table 1. Our focus lies in the exploration of simulation methods, particularly their application to clinical decision-making tasks. We aim to examine how these simulation models are developed, implemented, and evaluated. Additionally, we seek to identify gaps within the existing body of literature, specifically concerning the design and assessment of simulation-based approaches in health care.

Textbox 1. Main and specific research questions.

Main research question (RQ):

- What are the proposed in silico potential impact evaluation strategies for clinical decision support (CDS) systems?

Specific RQs:

- RQ1: What are the reported clinical decision tasks and domains that report the use of CDS?
- RQ2: What metrics are reportedly used for evaluating potential impact?
- RQ3: What simulation modeling paradigms are used?
- RQ4: What are the intended objectives of the simulation modeling frameworks used?
- RQ5: What are the gaps in existing literature of in silico CDS evaluation?

Table 1. Concept framework used in searching relevant articles.

Key concepts	Keywords
Clinical decision support models, algorithms, and systems	Machine learning, deep learning, artificial intelligence, reinforcement learning, supervised machine learning, unsupervised machine learning, semisupervised machine learning, self-supervised machine learning, expert system
Objective of the CDS[a] model	Clinical decision support, clinical decision-making, prognosis, diagnosis, screening, triage
Evaluation objective	Validation, potential impact, impact assessment, decision analysis, decision analytics measure, model calibration, model tuning, credibility, cost-benefit analysis
Evaluation strategy	In silico, computer simulation, digital twin, simulation, preimplementation, predeployment, computational simulation

[a]CDS: clinical decision support.

Stage 2: Identifying Relevant Studies

In identifying relevant studies, we first conducted an automated search dated May 2023 of medical (PubMed, Embase, CINAHL, PsycINFO, and Cochrane), open-domain (Web of Science), engineering (IEEEXplore), and preprint (arXiv) academic articles databases using keywords from Table 1 generated during stage 1. Including preprint and engineering databases allows the search to extend to perspectives outside of the medical domain. The arXiv preprint archive was searched to account for more recent articles currently unavailable in peer-reviewed publication databases [47]. Duplicated articles and articles found in the preprint archives that were published will be removed from the pool of potential studies.

We undertook a pilot review on a manageable sample of the more relevant studies to refine the search strategy. The pilot review process allows us to refine our inclusion and exclusion criteria further. The pilot review team comprises at least one senior clinician and a senior data scientist with relevant health care domain experience to guide the construction of search strings—these were refined in a series of team discussions in consultation with a medical librarian. Multimedia Appendix 1 provides details of the source database-specific search strings used for each concept, as shown in Table 1. Differences in search strings are due to discrepancies on what databases can accommodate in a search (eg, wildcard characters may be adapted in some but not in others, and databases may vary in the type of subject heading indexing used). Two junior researchers (MD and YLC) collated the pool of articles identified from these search strings.

Stage 3: Study Selection

A 2-step screening procedure was adopted here—a title-abstract screening followed by a full-text screening was conducted for the articles identified from stage 2. Two reviewers independently screened the articles using the criteria presented in the succeeding paragraphs. The articles' titles and abstracts (ie, step 1 screening) and the full text (ie, step 2) were the basis for screening. The criteria for study selection are continuously revised through regular meetings. The reviewers arrange meetings to resolve any disagreements. The senior reviewers in the study team are consulted to reach a consensus when screening conflicts arise. According to the proposed guidelines for scoping reviews [48,49], we report the article search and screening results in a PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) [50] flow chart shown in the results section.

Our review included the following studies: (1) studies that directly support clinical decision-making specifically for diagnostic, triage, screening, prognostic, and prescriptive purposes; (2) studies that use AI, computer-executed algorithms, machine learning, and traditional statistical multivariate techniques; (3) risk prediction models for a disease condition or a future health outcome; (4) studies that assess CDS models in predeployment stage for its potential impact; (5) studies that propose the use of simulation-based optimization during model development; (6) human studies; (7) experimental or observational studies—including prospective, retrospective, and ambispective studies, clinical trials, pragmatic clinical trials, and validation studies; (8) studies that are published in journal articles, conference proceedings, and preprint archives; (9) studies written in English with no constraints on the year of publication; and (10) risk prediction models for a disease condition or a future health outcome.

We excluded the following studies: (1) studies that do not involve clinical domains as prediction outcomes; (2) studies that focused on the use of AI as therapy (eg, treatment monitoring and glucose control systems); (3) studies that use machine learning, pattern recognition, AI for descriptive analysis; (4) pathological specimen and sensing device signals accuracy-related studies; (5) image segmentation/registration only without classification/prediction with clinical end points; (6) studies that deal with purely system/population level outcomes that are irrelevant to patient-provider interactions; (7) pure qualitative evaluation for clinical usefulness; (8) purely methodological papers on medical data processing (eg, image processing and noise filtering) without specific application domain; (9) studies that use purely ex silico evaluation typically require either a partial or complete deployment of the developed CDS system (eg, randomized controlled trials for actual impact assessment); (10) studies that only use traditional metrics—for example, area under the receiver operating characteristic curve, area under the precision-recall curve, mean squared error, accuracy, sensitivity, specificity, goodness-of-fit, and other discrimination-related measures only—to validate CDS models, systems, and tools, that is, those studies that do not consider broader systems-level usefulness; (11) studies that do not report model development process (eg, proprietary CDS tools or systems) as these do not disclose sufficient information about

underlying technology and algorithms; and (12) studies which report reviews (eg, scoping reviews, systematic reviews, and rapid reviews).

As our primary aim is to exhaustively review the published potential impact evaluation strategies done in silico for CDS, literature or scoping review studies were excluded. No other articles were excluded based on the year of publication. Deduplication was done using Zotero [51].

Stage 4: Data Charting

Overview

Data charting will collect critical information to answer the research question for the articles extracted from stage 3 after the 2-step screening process. An a priori list of coding variables corresponding to this study's concept framework and research questions has been developed (Table 2). Reporting [52,53] and data extraction [54] guidelines related to the concept framework guided the selection of coding variables to be extracted from the screened article database. As studies may or may not conform to these guidelines, and new categories and subcategories may be derived from the literature, the a priori coding variables may change. The emergent categories and subcategories will be checked for co-occurrences (overlapping concepts) and redundancies. Codes with the same concepts will be aggregated and refined to maximize mutual exclusivity and exhaustiveness. Aside from these structured coding variables, we shall also extract general information about the articles as guided by related published review protocols [55-57].

The data charting form will be developed in a shared collaborative Notion.so [58] database with the structure in Multimedia Appendix 1. The form was designed and maintained by an arbiter who ensures it is comprehensive and flexible. The charting process will be initially blinded. As with the article screening, we conducted a pilot charting trial to validate the encoding items. Each researcher can only see their respective chart to facilitate independent charting. An initial charting form is presented in Table 2. Team discussions were held as the team progressed in the charting process to consider other items to extract. At least 2 reviewers will be assigned to each article for validation. Any discrepancies will be resolved together with the entire team for the final determination of the charted codes. After the pilot trial, all articles included from stage 3 will undergo charting, resulting in an encoding database for this review.

Table 2. Data extraction items.

Data extraction broad concepts	Specific items extracted
Characteristics of the studies included	• Publication year • Research location (ie, country) • Data source • Data collection design • Collection period • Patient cohort description
Decision-making objectives and end points	• Objective of the CDS[a] model (ie, triage, diagnostic, prognostic, and prescriptive) • Specific decision-making tasks assisted by CDS • Clinical domains
In silico[b] evaluation metrics	• Specific evaluation metrics • General themes of the metrics (ie, patient, process, provider, and cost-effectiveness outcomes)
In silico evaluation frameworks	• Simulation modeling paradigm • Simulation modeling objective • Simulation parameters (parameters and parameter groups) • Reported reusability • Access to codes and tools used to conduct the simulation

[a]CDS: clinical decision support.

[b]Evaluations via computer simulations of clinical workflows during preimplementation.

Characteristics of the Studies

We include any study that reports the development of an expert system, a computer-aided clinical decision-making tool, or CDS with an underlying rule base or machine learning—including supervised, self-supervised, and unsupervised methods; deep learning; and reinforcement learning. We also include the more traditional multivariate analysis-based CDS such as linear, logistic, and Cox regression approaches to clinical scoring systems and prediction rules [38]. We encode the type of methods or algorithms used, their reported advantages (ie, aside from empirical performance reported), the disadvantages of the method, and their dependencies on data and the population from which the data was collected, as reported by the study authors. We also collected information about where the research was conducted and the year of publication.

Decision-Making Objectives and End Points

Since CDS model outcomes are directly related to its intended task and use, it is necessary to understand the scope of the desired outcomes from the predictions for an objective potential impact assessment. The development and use of clinical rules predate AI-based CDS. The outcomes of these clinical rules are broadly classified into diagnostic, prognostic, and prescriptive

outcomes [52,54,59]. We adopt this same classification for AI-based CDS. Diagnostic outcomes generally predict the risk for a particular condition or disease (based on existing health data) to support early intervention or screening decisions. Prognostic outcomes indicate the future course of an illness or disease, including the likelihood of recovery, quality of life, complications, or mortality. Some CDS studies may prescribe treatment beyond diagnosis or prognosis end points [1,59]. Guidelines for reporting [52,53] and appraisal [54] prediction models mention a comparable taxonomy of CDS outcomes. Another reporting checklist for studies that use AI in medical imaging CDS differentiates the intended use (eg, diagnosis, screening, and staging) with the tools' proposed role (eg, triage, replacement, or add-on) [60]. We shall consider these classifications in our analysis.

In Silico Evaluation Metrics

We explore methods to evaluate CDS' potential impact in silico on clinical workflow operations, patient outcomes, and economic outcomes [5]. Our aims take inspiration from the renewed focus of health care towards the Quadruple Aims, which adds the well-being of care providers as a fourth dimension, in addition to the traditional aims of improved patient experience, better health of populations, and cost reduction [41,61]. This underscores the need to devise workflow-sensitive evaluation methods, for example, considering how CDS sustains service providers' productivity (eg, referral rates as a process metric) within a resource-constrained care pathway. Further, we consider how reported studies propose the measurement of potential impact on patient health beyond the traditional accuracy-related measures [38], such as net benefit [62], realized [24] net benefit, and length of stay [63]. Some studies examine how implementing CDS systems impacts hospital budgets, with related metrics including costs and the incremental cost-effectiveness ratio [64]. More broadly, these metrics may be used to validate potential impact across different periods and study sites; this allows the monitoring of CDS performance consistency and the prompt triggering of model updates when necessary [15].

In Silico Evaluation Frameworks

Simulation modeling is a powerful tool for analyzing complex systems by creating representations that mimic the real world. It allows researchers or decision-makers to study how the system will behave over time prior to the actual deployment. Different simulation methods can be characterized by specific attributes, such as discrete or continuous, static or dynamic, and stochastic or deterministic [32]. A discrete simulation models the state of the system at distinct time points. For example, the number of patients in the waiting room only changes when a patient arrives. In contrast, a continuous simulation models the parameter that changes over time regardless of any triggers that change the state of the parameter. A static simulation models the system only at a specific time point, while a dynamic simulation studies the system's evolution over time. Last, a stochastic simulation involves randomness where simulation parameters can be probabilistic. For example, the patient arrival times may follow a specific distribution. However, a deterministic simulation encompasses parameters that have specific values. For instance, if the simulation sets the number of patients per time interval to 10, the value of such a parameter will stay at 10 throughout the simulation.

Our study focuses on existing research that reports using workflow simulation methods to assess the potential impact before embarking on often challenging and costly actual impact assessment. In silico evaluation can provide a more robust basis for successful implementation trials. As such, we consider studies that evaluate AI tools through an in silico approach without the need for actual deployment. Strategies may use reinforcement learning that optimizes a policy for multiple stages of decision-making (ie, such as machine learning–assisted treatment selection) [65]. Another approach may model a clinical care pathway as a discrete set of states and transitions [25], namely, DES, a popular method in health care workflow simulation to study resource allocation as it incorporates how resources change according to triggering events [36]. Another method, ABM, is particularly useful for modeling the interactions between various entities (ie, health care workers) in a clinical workflow [11]. Studies may also use a retrospective evaluation using cross-validation and decision curve analysis [24,62,66] to measure a decision-analytic score. As data extraction proceeds, we shall consider the more precise taxonomy of the simulation modeling [32] while broadly accounting for other in silico approaches, such as the examples. Other paradigms used will be encoded and reported as they arise.

We further consider the intended purpose of simulation, that is, the simulation modeling objective, which may fall under 1 of the three initial categories: (1) to conduct a straightforward measurement of clinical usefulness metrics, (2) to analyze the sensitivity of outcomes to various workflow parameters and scenarios, and (3) to optimize decision-making capability of CDS via a care pathway simulation.

Last, we consider the parameters used to construct the in silico clinical workflow. Specifically, we shall evaluate how patient, provider, process, and cost considerations are represented as simulation parameters. These clinical workflow factors describe the real-world care pathway, including patient condition states, treatment or intervention events, resource availability, duration of events, and many other factors.

Stage 5: Collection, Summarizing, and Reporting of Results

We will collect the data in a table of values corresponding to each variable (ie, column) and each relevant article (ie, row). An analysis of the values extracted will be done to identify sparse- and well-studied themes within and across critical concepts. Frequency and thematic analysis will be used for this analysis [44,67]. Themes combined with the extracted textual information will allow for the study of trends. Univariate and multivariate statistics will be reported as deemed relevant for each type of analysis. Descriptive statistics and charts will be used to describe the characteristics of the included study across the variables listed in Table 2. When appropriate, ANOVA, Kruskal-Wallis, and Pearson chi-square tests will compare trends across different categories. The association of variables based on co-occurrence will also be investigated. Further, the

reusability of any software artifacts or code repositories associated with included studies will be reported according to the claims of the articles' respective authors. The reporting of results will follow the PRISMA-ScR guidelines [50].

Stage 6: Dissemination and Stakeholder Consultation

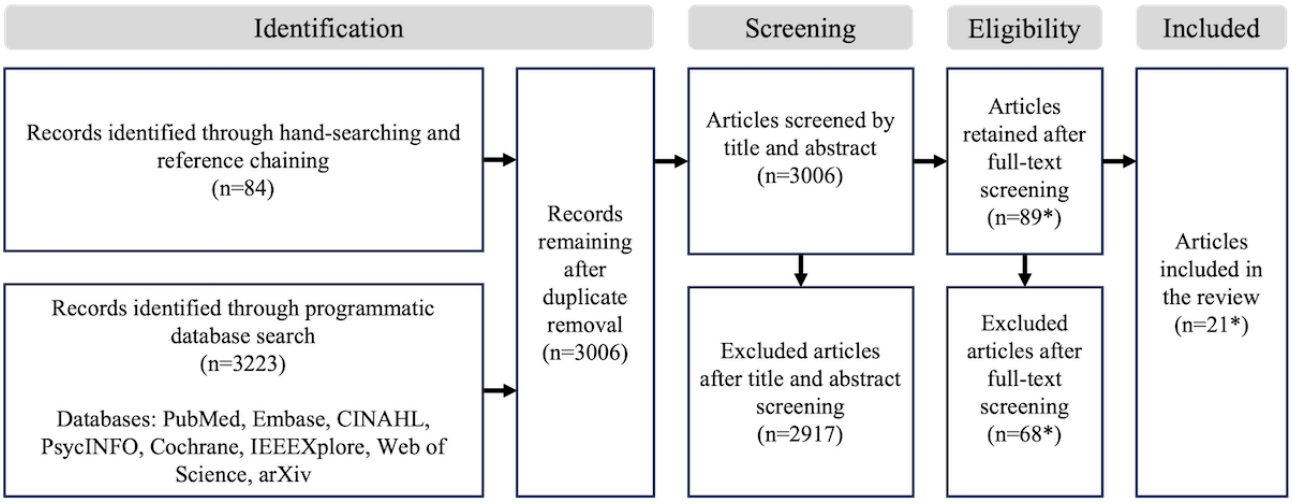
Beyond summarizing the results and findings, we will consider the overall implications of the findings for the in silico potential impact assessment of algorithm-based CDS systems, models, and tools. This scoping review will support the development of a draft framework that will guide clinical workflow simulation modeling for impact assessment, with specific considerations on the model purpose, evaluation scope, objectives, and strategy. This framework will further support the in silico evaluation of proposed CDS studies collected through discussion with potential stakeholders—implementation scientists, modelers, and clinicians conducting. This will also allow stakeholders to provide a higher level of interpretation, domain expertise, and perspective to validate the findings further and support effective knowledge transfer and uptake of evidence to ensure the usefulness of the scoping studies for AI developers and clinical researchers [43].

Results

Our review began with an automated search of selected databases in May 2023. The resulting articles were managed using Zotero [51] and Notion.so [58] for automated article metadata collection and note-taking, respectively. Most of the title and abstract screening were finished by November 2023. However, the review team allows for flexibility as the screening criteria are refined throughout the review. Full-text screening proceeded from December 2023 to May 2024, including hand-searching and reference chaining. Charting was concurrently done with the full-text screening. Analysis and writing of the full scoping review results will be finalized in July 2024. The reporting of this scoping review protocol and results as published literature will be from July 2024 to February 2025.

The current stage of our scoping review yielded the results shown in Figure 1. At the first screening stage, most articles were excluded based on titles and abstracts that did not fulfill the inclusion criteria. Moreover, we also excluded at this stage studies that suggest the development of CDS tools but only perform an evaluation using the area under the precision-recall and receiver operating characteristic curves, accuracy, precision, recall, F_1-score, and other traditional confusion matrix-based scores; further, these were studies that do not attempt to evaluate potential impact and usefulness to its intended clinical care pathway placement [38]. Additional studies were also excluded due to the focus on algorithmic developments in processing medical data (ie, image, text, and structured data). On the contrary, articles that mention usefulness and impact evaluation without providing further details in the title and abstracts were included in the full-text screening.

Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) flowchart. Asterisk (*) indicates data as of April 2024.



In the second stage of the detailed full-text screening (ie, using the full text as the basis), more articles were excluded due to the lack of potential impact and usefulness evaluation. Other articles were excluded as duplicates not detected in the initial automated deduplication based on article metadata. A few articles were also excluded due to unavailable full text, as only extended abstracts were published. As this stage is ongoing and considering that reference chaining may still be conducted based on the screened articles, the final number of relevant articles will be reported along with the scoping review results. As of April 2024, 21 articles are included in the review.

Discussion

Principal Findings

The proliferation of AI models in health care encourages researchers, patients, and providers to use these technologies to optimize the care delivery processes. Yet, only some models are being translated into clinical practice [6]. The ability of data-driven machine learning methods to generalize to different temporal and geographical patient cohorts is challenged by often changing real-world medical data [17]. This demands more robust and adaptive approaches to encourage user acceptance and trust [12,13,16]. Traditional impact assessments based on

pilot implementation for health technology assessment can be resource-intensive with the rapid proliferation of new models [68,69]. The in silico evaluation of algorithm-based CDS provides a resource-efficient framework for estimating novel CDS' potential clinical impact to facilitate the seamless integration of a model into the workflow. Moreover, computer simulations require much fewer resources and have less direct implications for ongoing patient care, allowing for regular and repetitive use throughout the CDS development and maintenance lifecycle. Our review aims to analyze and report the scope of using in silico CDS evaluation in published academic literature. We expect that the results will uncover the clinical decision-making domains where such evaluations are used or, otherwise, underused, how clinical workflows are simulated, the potential impact metrics used to illustrate the usefulness of CDS, and areas where more research is necessary.

Several US Food and Drug Administration–accepted patient simulators [70,71] and other approaches [30,68] that simulate patient characteristics enable an in silico evaluation of patient-level impact and have been proposed to be used at a preclinical stage. These simulators allow the assessment of the response to different treatments by the same patient—which is unlikely in real-world treatment scenarios due to dynamic patient conditions. Comparably, clinical workflow enables simultaneous evaluation of various scenarios using the same patient cohort characteristics, sharing the same validation capabilities and objectives [72,73]. However, clinical workflow simulations encompass a broader perspective, considering the efficiency and effectiveness of treatments and interventions, such as CDS, across the entire care pathway.

In a preliminary collection of included articles, the broader perspective was demonstrated by the accounting for process-related factors. For example, time intervals (ie, door-to-doctor time) between workflow events were considered by Alenany and Cadi [63] as an evaluation metric. Misic et al [23] and Rodriguez et al [74] focused on patient volume and referral rates to evaluate workflow throughput. In addition, other studies simultaneously assess patient outcomes with cost-related outcomes, such as length-of-stay and costs per visit [75], early-stage cancer detection rate and cost savings [76], and intensive care unit length-of-stay and corresponding costs [77]. Yin et al [5] highlighted that in the real-life evaluation of AI applications, the outcomes considered can be grouped into patient, cost-effectiveness, and clinician outcomes. We consider this in our review and propose distinguishing between provider, that is, clinician outcomes and process outcomes [22], expanding the outcome themes into 4 categories.

Furthermore, similar themes can also be applied to categorize clinical workflow factors, that is, parameters, used in the design of an in silico care pathway. Lee et al [35] considered time intervals between events as simulation parameters. Other studies [23,25] used provider-related parameters such as provider effectiveness and carrying capacity. Other studies simultaneously consider patient-, cost-, and process-related outcomes—such as in [35,77]. These parameters are typically based on historically observed data distributions, expert judgment, cited from published literature, or determined from prospective time-motion studies. We will report such a basis for parameter initialization accordingly.

The interplay of multiple outcomes and drivers and the expansion of health care also aim to consider provider well-being, which adds to the complexity of impact evaluation. Different simulation modeling paradigms are proposed to handle such complexity—such as in the DES frameworks used by [25], the ABM done by [35], and state-transition models shown in the microsimulation by Rodriguez et al [74], and in the Markov-based transition model used in [78] evaluating wait time–saving effectiveness of an AI-based CDS. Moreover, dynamic treatment regime optimization is proposed to capture staged treatment scenarios and optimize outcomes [65]. Last, considering cost-effectiveness approaches, decision trees can also be used to capture costs and benefits attributed to a hierarchical decision-making scenario; this is demonstrated by Tsai et al [77] to evaluate an extubation failure prediction CDS.

While extensive literature on the usefulness of simulation modeling and knowledge of the simulation of clinical care pathways as avenues for CDS in silico evaluation still lack consolidation [79], possibly due to the significant context dependencies across different health systems. When translated into a quantitative modeling framework for rigorous, objective evaluation, the diversity, human-centricity, and complexity of clinical workflows pose unique challenges [18]. Addressing these challenges requires interdisciplinary groups familiar with hospital management, clinical context, process nuances, and the availability of necessary modeling capabilities. Despite the prevalence in the reported development and advancements of CDS models, accelerated by the surge in AI methods—studies that reported the extent of clinical and workflow impact through in silico evaluation are still relatively sparse [5,6]. A critical need remains to reassess the current model simulation practices to advance this field. We believe this will expedite the integration of novel CDS system development. To the best of our knowledge, this is the first review that aims to understand CDS system in silico evaluation methods beyond traditional accuracy metrics.

Conclusion

This scoping review follows the framework proposed by Arksey and O'Malley [42] and other recent enhancements [43-45]. We searched 8 medical-focused and general academic domain databases to gather articles from an interdisciplinary perspective. An automated search followed by a 2-step screening process was done to implement the scope of the review. Unlike previous reviews, we will specifically include CDS related to traditional multivariate models and machine learning. In addition, we designed a data charting table based on discussions with the multidisciplinary review team and previous reviews on related topics. This table will guide the data extraction phase, and the items will be flexibly revised along with further study of the included articles. Finally, we plan to summarize our results using descriptive and co-occurrence analyses. For example, the distribution of race and ethnicity of collected patient information—as reported by the included articles—will show how fairness is represented in current AI research in health care. Similarly, an analysis of co-occurring themes (ie, in statistical

analysis methods, CDS decision-making tasks, evaluation metrics, and simulation paradigms) may surface clinical domain-specific and domain-agnostic approaches to in silico potential impact evaluation.

We anticipate our results will be informative about the state-of-the-art in silico evaluation method based on workflow simulation models and the associated outcome metrics and targets. More specifically, our results will describe the characteristics of the clinical decision-making domains being modeled, the relevant measures of impact that are simulated, and how such are captured in clinical workflow simulation. As we also aim to report the reusability of methods cited, our work will serve as a springboard for the reader to find suitable in silico evaluation frameworks, software artifacts, and code repositories. Ultimately, our work is a starting point in developing a unified in silico evaluation framework adaptable to various clinical workflow scenarios.

Limitations

There are several limitations to our approach. First, while some guidelines for reporting may exist, they may need to be revised to cover the variety of studies in our criteria. For example, a transparent reporting of machine learning models developed for diagnosis, prognosis, or prescriptive analytical support is still being developed [27], and conformance to these guidelines may influence the extent and precision of our data charting. Second, a critical appraisal of articles will not be done as we primarily aim to provide an overview of the scope by which in silico evaluation methods have been used. Third, we also included reports from e-Print archives (arXiv), trading off a more exhaustive scope versus the inclusion of non–peer-reviewed articles; an accounting of such articles will be provided in the reporting results. Last, we included only English articles; thus, we cannot extrapolate our findings to publications in different languages. Our findings will add to the knowledge of applications of statistical learning and simulation methods in health care.

Acknowledgments

We want to acknowledge He Yan for her valuable comments on the data charting forms and thank Ginny Chen Zhenzhi for taking on the project management required to move this research forward.

Data Availability

All data generated or analyzed during this study are included in this published article and its Multimedia Appendix files.

Conflicts of Interest

None declared.

Abstract

Background: In Germany, digital transformation and legal regulations are leading to the need to integrate digital technologies into the nursing profession. In addition, to nursing practice, they are also being incorporated into nursing training. Despite comprehensive regulations regarding the use of digital teaching and learning media in nursing education, their specific applicability and implementation vary.

Objective: This study aims to map evidence and identify the main concepts, theories, sources, and knowledge gaps in the use of digital teaching and learning formats in nursing and health care education in Germany.

Methods: The study is planned as a scoping review. The reporting of the study is based on the PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) 2020 guidelines. The sources of information for the review include six bibliographic databases (MEDLINE via PubMed, Cochrane Library, Web of Science Core Collection, ERIC, PROSPERO, and APA PsycInfo). The search results will be presented in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist. The eligibility of studies is based on the population, concept, and context criteria: (1) learners of nursing and health care professions, (2) digital teaching and learning formats, and (3) forms of implementation in Germany since 2007.

Results: The literature search is planned for January 2025. The selection of titles, the coding of the data, and the data analysis are expected to be completed by March 2025.

Conclusions: In Germany, there is a growing interest in integrating digital teaching and learning formats into nursing and health care education. Our scoping review will map applications of digital teaching and learning media in the education of nursing and health care professions in Germany. In this way, the scoping review provides relevant impulses for fields of application and design aspects of digital teaching or learning media for nursing and health care education.

Introduction

Background

The idea of learning with machines is not new. Back in the 1920s, Sidney L Pressey developed a machine that asked a question and offered four possible answers, like the multiple-choice method [1]. Nowadays, digital technologies are used to create and provide learning materials and to support and control the learning process [2]. In this context, the term “e-learning” describes all forms of learning with electronic or

digital media [3]. The introduction of the iPhone in 2007 has been an international milestone in the development of e-learning [3,4]. Mobile devices create the conditions for innovative pedagogical approaches such as flipped classrooms or blended learning, by using modern technologies and various teaching methods to make learning more effective and personalized. In corresponding teaching and learning approaches, the time, place, pace, and scope of learning can be freely chosen [2], giving learners more autonomy and control over their individual learning process. A major advantage of mobile devices is that learners often already possess the necessary technical equipment [5]. The digitalization of nursing and health care education is considered to have particular potential due to the complexity of professional requirements and the constant further development of subject-specific knowledge [6,7]. In addition to the relevance of digital teaching and learning formats in nursing and health care education, there is also a need in Germany to incorporate digitalization into health care professional education. This arises from legal regulations such as § 8 Abs. 8 SGB XI or the E-Health Act, which are intended to promote the digitalization of professional practice and require corresponding skills on the part of nursing professionals. The digitalization of health care professional practice is intended to improve the quality of care and effectively prepare professionals for highly complex care situations, which should ultimately lead to better care outcomes for patients [8-10]. In addition, the topic of digitalization can be found in the new legal foundations of the Act on the Nursing Professions (Pflegeberufegesetz, PflBG), the Training and Examination Regulations for the Nursing Professions (Ausbildungs- und Prüfungsverordnung für die Pflegeberufe, PflAPrV) and the framework curricula and framework training plans. These foundations list forms of digital support for various parts of the nursing process.In this regard, there is a need to develop and integrate digital teaching and learning formats for nursing and health care education [6,11].

Objectives

In Germany, there are increasing efforts to integrate digital teaching and learning formats into nursing and health care education. This fact leads to the question, for which educational content and didactic concepts digital teaching and learning formats are used in nursing and health care education in Germany? Furthermore, which scientific findings are present about the use of digital teaching and learning formats in nursing and health care education in Germany? Thus, our main objectives are (1) digital teaching and learning formats and (2) forms of implementation in the context of learners in the nursing and health care professions.

Methods

Study Design

We conduct a scoping review [12,13] in consideration of published primary sources and reviews. All study designs with the exception of opinion studies, commentaries, editorials, letters to the editor, and pure case reports are considered in order to gain a broad overview of the research field. We operationalize the research question by using the population, concept, and context (PCC) scheme [14]. The population includes learners in the nursing and health care professions, the concept focuses on digital teaching and learning formats, and the context refers to forms of implementation in Germany since 2007. Study reporting is based on the PRISMA-ScR (Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews) [15]. The PRISMA-ScR checklist will be available once the review is complete.

Patient and Public Involvement

Patients and the public are not involved in the design of this protocol. Thus, ethics approval is not required for the scoping review.

Eligibility Criteria

The eligibility of studies is based on the PCC criteria: (1) learners of nursing and health care professions, (2) digital teaching and learning formats, and (3) forms of implementation in Germany since 2007. The scoping review aims to map evidence and identify the main concepts, theories, sources, and knowledge gaps in the use of digital teaching or learning formats in nursing and health care education in Germany. The electronic search is conducted in German and English. Only titles, which are published since 2007 will be included because the iPhone was released for the first time in 2007, which enables new forms of learning and represents an international milestone in the development of e-learning [3,4]. Since this introduction, research into e-learning using mobile devices has increased.

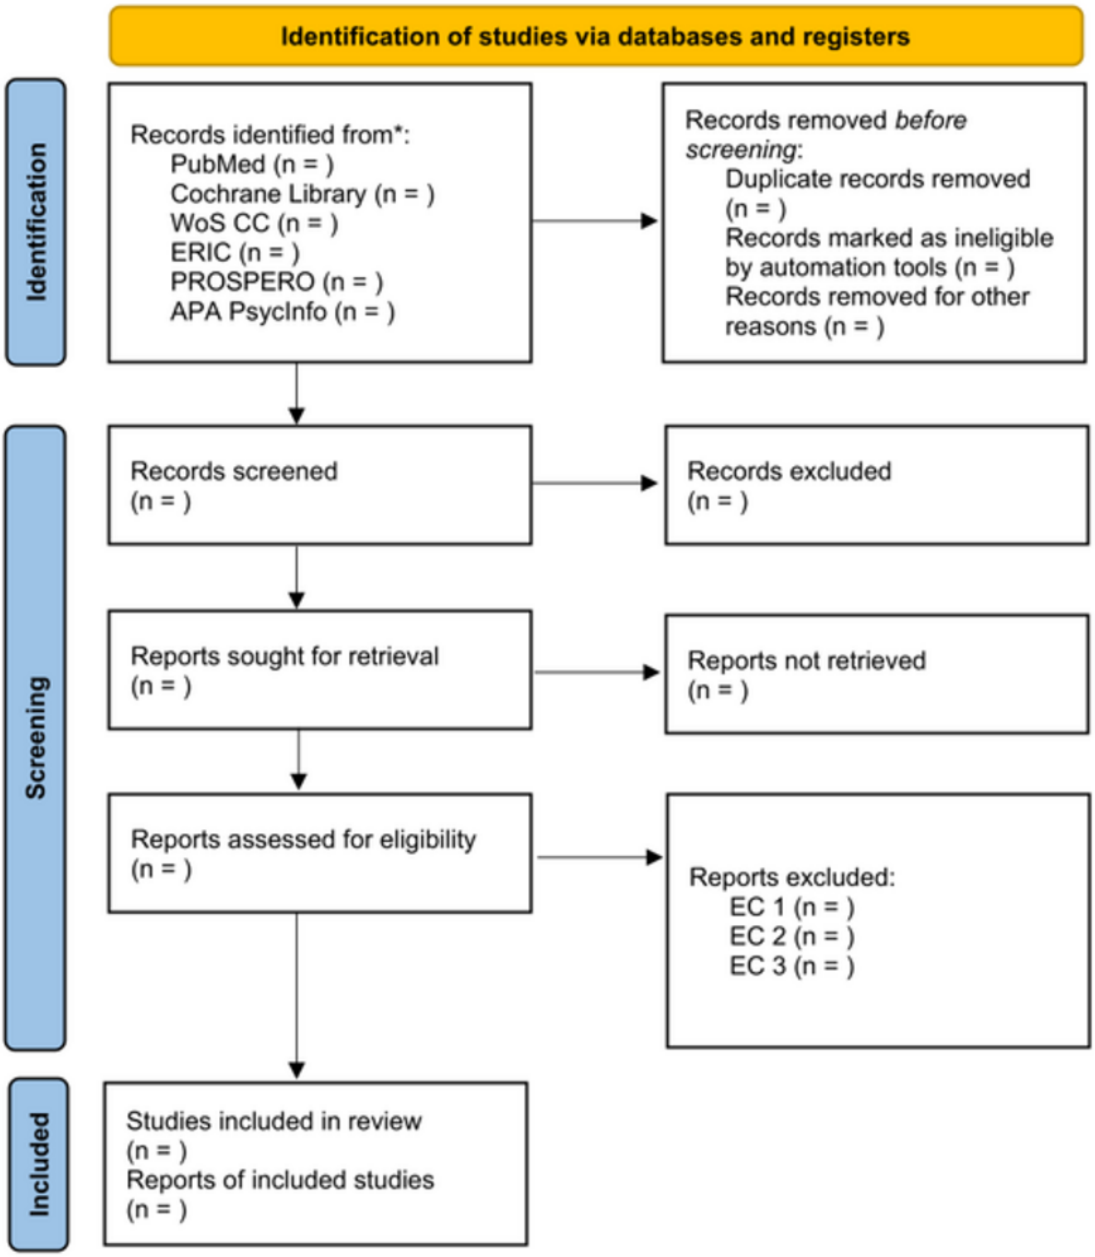
Information Sources

The information sources for the scoping review will include six bibliographic databases (MEDLINE, Cochrane Library, Web of Science Core Collection, Education Resources Information Center [ERIC], PROSPERO, and APA PsycInfo). The starting point will be the search in MEDLINE via PubMed as the central database for scientific studies in the health professions. The PubMed search supports the generation of suitable mesh terms for the research question and is adapted to the databases Cochrane Library, Web of Science Core Collection, ERIC, PROSPERO, and APA PsycInfo [16]. The Cochrane Library provides access to up-to-date and reliable research, which is further complemented by the PROSPERO database as a repository of systematic reviews. ERIC covers the educational discourse on the question and Web of Science Core Collection bundles the vocational education and health care focal points of the question in a database. These focal points are further supplemented and completed by research via APA PsycInfo, which contains peer-reviewed journals, studies, books, and dissertations on learning and teaching methods in health care, including nursing didactics.

Search Strategy

The electronic search strategy will be developed iteratively by the team. The search was based on the PRISMA 2020 statement (Figure 1) [17,18]. The search terms and corresponding MeSH (Medical Subject Headings) terms will be derived to address the two main search topics of the scoping review: (1) digital teaching and learning formats and (2) forms of implementation in the context of learners in the nursing and health care professions.

Figure 1. PRISMA-ScR 2020 flow diagram (source: own illustration, adapted from Page et al [17], licensed under CC BY 4.0 [18]). EC: exclusion criteria; EC 1: lack of reference to nursing and health care education; EC 2: no reference to digital teaching and learning formats; EC 3: no reference to the research question. ERIC: Education Resources Information Center; PRISMA-ScR: Preferred Reporting Items for Systematic Reviews extension for Scoping Reviews; PROSPERO: International Prospective Register of Systematic Reviews; WoS CC: Web of Science Core Collection.



Selection of Sources of Evidence

Two researchers will search in mentioned databases independently of each other using the search strings and will check all studies for relevance and suitability. After screening, two researchers will compare the search results. Any contradictions or inconsistencies in the study assessment will be clarified through discussion. Studies that met the inclusion criteria will be used for the full-text evaluation. This will also be carried out by two researchers. If necessary, we will contact the authors to obtain further information. The study selection will be concluded with a consensus meeting. Afterward, the data for each included study will be extracted by using a self-developed form in Excel (Microsoft Corp). The results of the literature search will be reported in full once the scoping review is complete. A list of included and excluded studies following full-text screening and individual reasons for exclusion will be reported once the review is complete.

Data Charting

We will develop an Excel form for coding and recording all data. Two authors code all data independently of each other. The agreement between the codings is calculated using Cohen κ. If necessary, authors will be contacted to obtain further information. A consensus meeting is supposed to conclude the study selection.

Synthesis of Results

We plan to use qualitative content analysis to form categories in an inductive-deductive alternation [19]. In inductive category

formation, categories are derived directly from the material [20]. Deductive category formation defines the categories before the data analysis [20] and refers to the used PCC scheme. This is categorized into setting, digital teaching, and learning format, as well as application formats. The coded data will be summarized in a table and then synthesized using descriptive statistics (relative frequencies).

Results

The literature search is scheduled for January 2025. We expect to select the relevant studies, code the data, and appraise the studies until March 2025.

Discussion

Principal Findings

Preliminary literature searches have shown that various digital technologies are used in nursing and health care education in Germany, including learning programs, learning platforms [6], and virtual reality technologies [21]. Our scoping review will include a detailed list of such applications once the studies have been selected. We will assess the outcomes of such digital technologies in the context of nursing and health care education in Germany. The most interesting aspect of our review will be application areas and requirements, as well as trends in digital nursing and health care education in Germany.

Comparison to Prior Work

Various digital learning methods have been widely implemented in nursing and health care education. Kimura et al [22] identified interactive online modules and videos as the most frequently used technology-enhanced tools in nursing education. The application period of digital learning formats in nursing and health care training varies [23,24]. Despite the positive associations, the potential of digital teaching and learning is by no means undisputed or proven. For example, the review by Bajpai et al [25] describes a lack of evidence regarding the effectiveness of digital interventions for the training of health care professions. Furthermore, Arkorful and Abaidoo [26] noted potential drawbacks, including reduced interactivity in e-learning environments. Other studies indicated that the achievement of intended learning outcomes through digital teaching or learning media for nursing and health care professions is influenced by variables such as age, training time, and experience of the participants [27,28]. While these findings are valuable, their direct applicability to the German education system is limited, underscoring the importance of examining country-specific implementations of digital education. In this regard, the literature indicates that there are gaps in the implementation of digital media in nursing education [6,29-31]. Our scoping review contributes to this gap by mapping applications of digital teaching and learning media in the education of nursing and health care professions in Germany.

Strengths and Limitations

This protocol has been rigorously developed and the electronic search syntax was iteratively tested and revised by the authors. Scoping reviews, like this study, contain potential biases in the selection of criteria, the search methodology, and the data analysis. Just German and English-language publications in selected databases will be included. The inclusion of other languages, databases, and additional search terms could lead to an increase in literature sources. Especially regarding the background of the heterogeneous study situation, the methodology of the scoping review is relevant to gain a broad perspective of the use of digital teaching and learning media in nursing and health education in Germany. Nevertheless, the possibility of inaccuracies in a combined interpretation exists.

Implications for Practice and Dissemination Plan

Findings from the scoping review could be of interest to various stakeholders, including educational institutions, researchers, health professionals, policy makers, and companies developing digital teaching and learning media. Therefore, the results of the review should be published in a peer-reviewed journal.

Conclusions

Our scoping review maps areas of application of digital teaching and learning methods in nursing and health education in Germany. In addition to the topic areas, the technical implementation methods and the didactic design should also be shown. The findings could be used to establish and expand digital teaching and learning methods in nursing and health care professional educational institutions, especially in Germany.

Acknowledgments

This review was part of the study “Digital Training of Nursing and Health Management” (DigiCare, ESF/14-BM-A55-0021/19). We acknowledge support for the Article Processing Charge from the German Research Foundation (Deutsche Forschungsgemeinschaft [DFG], 491232355) and the Open Access Publication Fund of the Neubrandenburg University of Applied Sciences (Hochschule Neubrandenburg).

Data Availability

This scoping review will be based on previously published data. The datasets generated during or analyzed during this study are available from the corresponding author upon reasonable request.

Abstract

Background: Gender is known to have a strong influence on human health and disease. Despite its relevance to treatment and outcome, gender is insufficiently considered in current health research. One hindering factor is the poor representation of gender information in clinical and health (meta) data.

Objective: We aim to conduct a scoping review of the literature describing gender scores. The review will provide insights into the current application of gender scores in clinical and health settings. The protocol describes how relevant literature will be identified and how gender scores will be evaluated concerning applicability and usability in scientific investigations.

Methods: Our scoping review follows the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines. A title and abstract screening was conducted on PubMed, followed by a full-text screening. The inclusion and exclusion criteria were discussed by a team of 5 domain experts, and a data-charting form was developed. The charted data will be categorized, summarized, and analyzed based on the research questions during the scoping review.

Results: We will report our research results according to the PRISMA-ScR guidelines. The literature retrieval was carried out on June 13, 2024, and resulted in 1202 matches. As of July 2024, the scoping review is in the data extraction phase and we expect to complete and publish the results in the first quarter of 2025.

Conclusions: The scoping review lays the foundation for a retrospective gender assessment by identifying scores that can be applied to existing large-scale datasets. Moreover, it will help to formulate recommendations for standardized gender scores in future investigations.

KEYWORDS

gender score; gender medicine; medical informatics; data integration; gender health gap

Introduction

The interaction of sex and gender plays an important role in the symptoms, diagnosis, therapy, outcome, life expectancy, and generally in the health and illness of men and women [1-3]. Gender includes awareness of diverse sexual orientations and identities and their relevance to daily life, including LGBTQ+ (lesbian, gay, bisexual, transgender, queer, and numerous other gender identities and sexual orientations) individuals. Neglecting

or inadequately considering gender aspects in medical research and practice can have serious consequences for diagnosis, treatment, or risk prediction.

The German Ethics Council defines biological sex by genetic, hormonal, and anatomical conditions or markers, more precisely, by chromosomes, hormones, and internal and external sex organs. Gender, on the other hand, is defined by social attributes, an interaction of biological and psychosocial factors, an individual's social biography, and is shaped by someone's role in society. Psychological attributes determine the individual's self-perception and sexual identity. The sexual identity may differ from someone's physical appearance or biological sex [4]

Despite the known importance of gender in health, such as diagnostic and therapeutic responses, clinical manifestations, and disease progression, gender is currently not sufficiently represented in the health sciences, and sex and gender effects cannot yet be distinguished for most diseases [5]. The work of Vader et al [6], for instance, highlights the importance of gender and shows that gender can be seen as a mediator of sex differences. This particularly concerns chronic diseases with a higher prevalence in women (arthritis, chronic pain, and migraine). The authors even claim, that in these diseases, sex differences would not exist if there was no gender.

To improve the validity and reliability of medical research, it is necessary to encode gender information, in addition to biological sex information. We argue that a systematic gender assessment should be mandatory in future scientific investigations and in particular in clinical and health studies. Adding gender to existing data requires a retrospectively applicable score, ideally suitable for a wide range of applications. Moreover, future health research requires reliable and valid gender scores capable of predicting gender with high accuracy. The scoping review will provide an initial overview of existing gender scores and how they are currently being used in the health sciences. The objectives of this review are (1) to identify and characterize existing gender scores reported in the literature in the health sciences and (2) to systematically assess their applicability to clinical and health research (restricted to selected use cases).

Methods

Design

The scoping review method, as defined by Grant and Booth [7], was selected to provide an overview of the topic and to map the existing literature on the problem. It is well suited because our study deals with heterogeneous methods—covering prospective and retrospective scores, developed using strongly differing approaches—and includes a broad selection of research domains, as all subdomains of health research (eg, psychology and epidemiology) are considered. Furthermore, our review will inform future investigations on the topic [8]. In general, we followed the stepwise approach for scoping reviews described by Mak and Thomas [9] and adapted as many characteristics of the systematic review method as possible [10]. In particular, the review follows the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines [8], and the following steps were carried out: (1) identification of research questions; (2) identification of relevant studies; (3) study selection; (4) data extraction and charting; and (5) collating, summarizing, and reporting the results.

Due to limited resources, the coding of articles was conducted by a single reviewer and based on the database PubMed. It was selected as it is widely used as a standard database for biomedical literature research and is recommended as one of the most important databases for comprehensive systematic reviews [11].

Stage 1: Identification of Research Questions

As outlined in the Introduction section, gender is currently inadequately reflected in most scientific studies. The research questions therefore arose from an initiative to standardize gender encoding in large-scale data collections maintained by the Medical Informatics Initiative Germany (MII; *Medizininformatik-Initiative*) [12] and the Study of Health in Pomerania (SHIP) [13], and to establish recommendations for standardized gender encodings in routine data provided by the Data Integration Center (*Datenintegrationszentrum*) at the University Medicine Greifswald, Germany [14].

The research questions themselves were formulated by 5 domain experts, 3 with a primary background in medicine, 1 with a background in medical informatics, and 1 with a background in medical documentation. The identified and agreed upon research questions for the scoping review are the following: (1) What gender scores exist in medicine? (2) What gender scores are applicable to the SHIP and MII data? (3) How are gender scores currently applied, or are they purely theoretical constructs?

Stage 2: Identification of Relevant Studies

For the first assessment of the topic, a small number of relevant papers [15-17], identified through an initial manual search, were examined to identify keywords and important phrases. Furthermore, literature regarding gender awareness in the medical context [18-20] was examined to identify commonly used scientific terminology regarding gender. While this work defines a gender score as a method for assessing gender, the initial analysis showed that different terminology, such as gender measure or gender index, is used to refer to gender scores in the literature. Therefore, we included these terms in our query and added further terms as synonyms to achieve broad coverage. English language and status as a peer-reviewed article were additional inclusion criteria for our review. Furthermore, we only considered scores applied to adults and excluded scores targeting children.

Based on the extracted keywords, a query was designed to capture the key elements that identify these studies. The query was optimized for recall regarding the initial literature while considering the amount of results. Specifically, the query was designed using Boolean operators, wildcards, proximity search, and a timeline. The time limit was introduced to identify more recent literature and to exclude obsolete research, such as the well-known Bem Sex-Role Inventory [21] which was shown

to be outdated by Donnelly and Twenge [22]. The timeline was determined based on the distribution of articles, which showed that most research on the topic was published in the last 5 years. Throughout the entire review process, secondary literature relevant to our topic was collected. This particularly concerns older scores, which allows for the identification of earlier published literature that is still applied or cited in more recent publications. Although excluded by our initial time limit, we decided to consider them as secondary literature to evaluate if they are still reasonable to apply or obsolete. The final query was executed on June 13, 2024, and is illustrated in Figure 1.

Figure 1. PubMed query. The query consists of three parts: (1) terminology expressed for gender score, (2) word expressing that the score was developed, (3) timeline restriction (see stage 2 for further explanation); (ot) matches keywords; (tiab) matches title and abstract; (*) wildcards match different word endings; (~1) this proximity search with distance 1 allows another word between the searched terms (different word endings are automatically included).

```

Stage 3: Study Selection

The obtained results were screened by title and abstract to exclude studies that do not relate to gender scores. Articles that could not be clearly excluded based on title or abstract alone were retained for further examination. The final relevance decision for the remaining articles was based on an examination of the full-text document.

Stage 4: Data Extraction and Charting

We developed a data-charting form that was used to determine eligible data extraction points. The form was based on Gierend et al [23] and then adjusted together with the domain experts involved in this study (see stage 2). It was iteratively optimized and continuously updated throughout the process. The charting form is organized into 4 main sections corresponding to an overview and the 3 research questions. The final data-charting form is illustrated and explained in Table 1. Based on the data extraction points, 1 author critically examined the papers and extracted the relevant data. Initially, more than 30% (7/22) of the publications were randomly double-checked by a second domain expert to ensure high data extraction quality. The 2 reviewers were in full agreement on all reviewed articles. Therefore, the remaining articles are reviewed by a single reviewer throughout the remainder of the review process. Irrelevant papers are removed from the charting form.

Table 1. Summary of data charting.

Section	Description
Section 1: Overview	Summary of the basic publication information
Article metadata	Title, Digital Object Identifier, year of publication (YYYY), keywords
Corresponding author information	Name, research discipline, institute, Research Organization Registry (registry of open persistent identifiers for research organizations)
Publication type	Peer-reviewed or preprint
Study type	Gender score development, use case, or recommendation
Continent	Continents where the study took place or focused on
Funding source	Public, industry, none, or missing
Citation count	Citation count as reported by PubMed and Google Scholar
Objective	Aim or objective of the publication
Methods	The procedures or techniques used to identify, select, process, and analyze information
Summary results	Short description of results
Conclusion	Short description of the conclusion
Section 2: Research questions	Includes the research questions and the required data
What gender scores exist in medicine?	• Necessary variables for the developed gender score • Retrospective or prospective application • Clinical or epidemiological study • Size of cohort • Target variables (feminine, masculine, binary, or continuously) • Model type (statistical model or questionnaire)
What gender scores are applicable to the SHIP[a] and MII[b] data?	• Existence of tool support or executable model • Availability of raw data or code • Reproducibility • Validation • Limitations (eg, restricted scope) • Variable coverage
How are gender scores currently applied, or are they purely theoretical constructs?	• Applicability in other research domains • Practical example of usage • Name and number of used records or databases • Expert evaluation

[a]SHIP: Study of Health in Pomerania.

[b]MII: *Medizininformatik-Initiative* (Medical Informatics Initiative Germany).

Stage 5: Collating, Summarizing, and Reporting the Results

This scoping review aims to summarize recently developed gender scores in health research. The extent of the review is limited to PubMed, the most relevant database for medical research outcomes. We assume that most relevant publications related to health sciences are contained in the resulting dataset. The commonly applied tools for the analytical interpretation of literature such as summary statistics, charts, and figures will be applied to discuss the collected relevant data [24]. We will follow the PRISMA-ScR guidelines [8] and discuss the general interpretation of the results compared to other evidence, the overall aim of the study, effects on practice, and future research, limitations, and recommendations.

Results

In preparation for the scoping review, a search of the database PubMed on June 13, 2024, resulted in 1202 matches. The title-abstract screening step reduced the set to 82 and 30 potentially relevant publications, respectively. It reduced the set of considered papers more than expected. Specifically, our review identified a large number of articles not directly related to the development of gender scores. On the one hand, this is due to the positive trend that gender receives increasing attention in current research. Many articles explicitly consider gender in the form of variables or by applying existing gender scores [25-27]. These articles were matched, as we designed the query to be as inclusive as possible in order not to miss any existing scores or potential extensions of existing scores (including the terms “use” and “used” in our query). On the other hand, in the examined papers the term gender is often used to refer to binary sex categories, for example, girl or boy, female or male, or

woman or man [28-32]. These papers were excluded from our review.

Full-text screening resulted in a final set of 18 papers identified in the scoping review. An additional 4 articles were identified as secondary literature, which were not covered in the timeline of the query but are still relevant in the current literature, as described earlier. A total of 22 studies were included in the review. The described process is further illustrated by the PRISMA-ScR flow diagram [8] in Figure 2. The results will be included into data charting.

We finalized the data extraction process in the third quarter of 2024 and the review will subsequently be concluded by summarizing and analyzing the results in the first quarter of 2025. The scoping review will provide an overview of recently developed gender scores in the literature. The research questions will allow us to select suited gender scores based on quality criteria and underlying research fields. The charting process will further provide information about their quality and retrospective applicability. This will serve as a basis for selecting eligible gender scores for retrospective application to existing data. Furthermore, the identified prospective scores will allow us to formulate recommendations for the inclusion of gender-dependent variables in future investigations, particularly, to incorporate standardized gender scores in investigations performed in the scope of the MII. The review will also reveal potential gaps and limitations of current gender scores, for example, regarding restrictions in underlying cohorts or research fields.

Discussion

Our review investigates the current development and usage of gender scores in health research and aims to assess the applicability of these scores. On the one hand, the insights can help to model gender information in existing data. On the other hand, we anticipate that our data charting will help to identify gender scores that are sufficiently generic and efficient to be implemented on a large scale in future research. Furthermore, our review will provide the basis for future works on the design and development of standardized prospective approaches to gender assessments.

Our review is also a valuable addition to existing scoping reviews that address gender topics. For instance, in 2020 Horstmann et al [33] focused on recently used instruments for the operationalization of sex and gender in health research. Our review identifies gender scores that were recently developed but have not necessarily been implemented yet. We aimed to identify the latest innovations in a very active research field, so we deliberately limited our search to the last 5 years. Indeed,

13 of the 18 articles in our primary result set were published after 2020. Miani et al [34] published an overview of epidemiological aspects of gender scores. Our work, in contrast, includes gender scores from all areas of health research, such as psychology, cardiology, or neurology. Similarly to Horstmann et al [33] and Miani et al [34], we included publications until 2021.

Limitations of this work are that a single reviewer screened titles and abstracts and that our search was limited to PubMed, as explained in the Design section. However, we believe that a major strength of our review protocol is that it addresses all methods of gender assessment and that our data charting covers a wide range of information.

Appropriate consideration of gender aspects in clinical and health studies remains a fundamental issue, and we believe that further work is required to establish the standardized use of gender scores in medical data recording. While our study will provide an overview of existing gender scores, a general, broader awareness of the topic remains of high importance, and solutions need to be found to systematically apply gender scores to clinical and health studies in the future. Therefore, further effort is required to make this topic more present in the scientific community.

Acknowledgments

This work was funded by the German Federal Ministry of Education and Research as part of the projects InkE (01FP23G10A)—Excellence through Inclusiveness in Medicine—and the Network of Data Integration Centers of the University Medicine (D352210009).

Data Availability

We plan to release the generated data persistently on Zenodo.

Authors' Contributions

LS did the conceptualization, data curation, investigation, methodology, visualization, writing of the original draft, and review and editing of the writing. HB and SR handled the data curation, validation, and review and editing of the writing. EK conducted the conceptualization, validation, methodology, supervision, and review and editing of the writing. SS and DW carried out the conceptualization, funding acquisition, methodology, supervision, writing of the original draft, and review and editing of the writing.

Conflicts of Interest

None declared.

Abstract

Background: Workers may be exposed to different infectious agents, putting them at risk of developing occupational diseases. This can occur in many ways, through deliberate use of specific microorganisms or through potential exposure from close contact with biological material. Infection prevention and control measures against biohazards can reduce the risk of infection among workers. During the last few decades, an increasing proportion of workers in Europe have been exposed to infectious biological agents in their workplace. Knowledge gaps on this topic in Europe have limited our understanding of the overall phenomenon in occupational settings.

Objective: This study aims to understand the extent and type of evidence on the epidemiology of occupational or work-related infections caused by bacterial, viral, fungal, and parasitical agents in European countries, the factors affecting their occurrence among workers, and the burden of disease among workers due to occupational risk.

Methods: The review will be conducted following the Joanna Briggs Institute methodology for scoping reviews and the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines. This review will consider studies that include data on the epidemiology of occupational infections, risk factors and determinants, and burden of disease among workers employed in specific occupational sectors in European countries in the period 2010-2023. The search will include MEDLINE, Web of Science, and Scopus databases. Independent reviewers (including GD, SC, AR, PD, and SM) will screen the titles, abstracts, and full texts of the selected studies. Data extraction will be performed using a tool developed by the researchers. The data will be mapped and analyzed according to the type of extracted data.

Results: The literature search through different scientific databases started in April 2024 and is expected to be completed by December 2024. The findings will be extracted using an ad hoc data extraction tool, and relevant results will be presented in narrative and tabular form.

Conclusions: This scoping review aims to provide rigorous evidence to fill the knowledge gap in the epidemiology of occupational or work-related infections in European countries, the factors affecting their occurrence, and the burden of disease in different professional settings. Such findings could improve the understanding of this complex occupational phenomenon in the European context, enabling more accurate and up-to-date surveillance of infections incurred in the workplace.

KEYWORDS

infection; work-related; biological hazard; narrative synthesis; Europe; occupational infection; worker; scoping review; infectious; prevention and control; occupational health; epidemiology; burden of disease; phenomenon

Introduction

Biological agents include a variety of microorganisms, toxins, and allergens that may harm human health. In particular, microorganisms capable of causing infections, such as bacteria, viruses, and fungi, can be pathogenic or can produce diseases that can be transmitted to individuals through various modes of transmission, determining acute or chronic health conditions [1].

In the occupational setting at the European level, prevention and management of all hazards and risks present in the workplace are required to safeguard occupational health and safety for all workers [2]. From this perspective, infection prevention and control measures implemented in the workplace against biological hazards can reduce the risk of infection among workers.

Indeed, employees in different professional sectors may be exposed to a variety of infectious agents, putting them at risk of disease. This exposure can occur in many ways, either through "deliberate use" of specific microorganisms (eg, laboratories and biotechnological industries), through "potential exposure" from processes of activities that require close contact with biological material (composting, recycling, and wastewater recycling), through animal contact (agriculture and food processing), or through contact with humans (health care and education). Globally, the overall annual mortality attributable to occupational infections is estimated at approximately 320,000 deaths, 5000 of which occur in the European Union [3]. However, morbidity from work-related infections could be largely underreported in national and international surveillance systems, possibly because of the lack of distinctive characteristics of work-related infectious diseases compared with infections acquired in nonoccupational settings, thereby making it difficult to establish a causal link between work and disease. Nonetheless, work-related infections may result in significant harm to workers' health, potentially resulting in a high disease burden on the working population. Indeed, experiences in tracking occupational diseases from biological agents are rather different [4], facilitating underestimation of the phenomenon. Indeed, there is often vast heterogeneity between countries in the definition of occupational or work-related diseases or injuries caused by biological agents. The case of SARS-CoV-2 infection among workers is paradigmatic: despite the large literature published on the subject, few countries notify this disease as an occupational accident or injury (eg, China and Italy), while the majority of countries have labeled this event as an occupational disease [5]. In fact, according to the Italian legislation on workers' compensation, cases of infectious and parasitic diseases are included in the category of accidents at work "because the virulent cause is equated to the violent one," which is a required characteristic to identify a work-related injury [6,7].

In particular, during the last few decades, increasing proportions of workers in Europe have been reported to be exposed to infectious biological agents in the workplace [8]. This has increased the need to provide more insight into the appropriate study and assessment of biological risks present in European countries, as well as their potential health effects among the workforce, especially in light of the impact of the COVID-19 pandemic on occupational health. Recent reports from the European Agency for Safety and Health at Work have identified several high-risk occupations for occupational infections (eg, animal-related occupations, waste and wastewater management, health care setting, farming, and traveling for work) and have provided recommendations on the implementation of specific preventive and protective measures in these settings. However, due to limited knowledge caused by the lack of up-to-date information on the ecology of pathogens and epidemiology of associated diseases in the European Union, particularly due to data gaps in monitoring systems for occupational diseases in member countries, it has not yet been possible to reach a comprehensive understanding of the overall phenomenon in all occupational settings [9]. Indeed, in many countries, biological agents are often not considered an Occupational Safety and Health priority, resulting in a reactive rather than a proactive approach to recognizing occupational biohazards and managing the risks to the safety and health of workers.

To understand the available knowledge on this topic, a scoping review will be performed to map the existing literature on infectious diseases in the occupational setting, enabling us to gather evidence on both traditional and emerging occupational biological agents and provide useful insights into their determinants and health impact. The scoping review was chosen as the most appropriate type of review as our aim is to achieve breadth rather than depth in our analysis. Therefore, other types of reviews are not deemed methodologically effective [10].

This scoping review is expected to provide the first rigorous analytical and updated synthesis of research data on the epidemiology of injury or disease due to infectious biological hazards, as well as information on the occupational burden. Stratifying infections according to the type of infectious disease and work task involved could add meaningful information and increase our understanding of the risk factors and corresponding determinants. Indeed, filling knowledge gaps and acquiring high-quality evidence concerning the epidemiology of occupational infections in European countries could be used as the scientific basis for developing and implementing effective preventive programs as well as for informing the activities of Occupational Health Services. This would contribute significantly not only to employers, employees, researchers, and occupational health professionals but also to overall public health.

A preliminary search of MEDLINE, the Cochrane Database of Systematic Reviews, and Joanna Briggs Institute (JBI) Evidence Synthesis was conducted, and 2 published systematic reviews

on the topic were identified [11,12]. However, these 2 systematic reviews did not specifically report data on the prevalence and incidence of occupational infections, definition of risk factors and determinants, as well as direct and indirect burden of disease (eg, economic impact and days absent from work due to ill health). In addition, the most recent systematic review was limited to non–health care workers and covered the period 2009-2020 [12]. Hence, we decided to perform a new review to gather updated evidence on all occupational categories, including health care settings. Furthermore, we decided to restrict the focus of our review to studies performed in European countries, in consideration of sufficiently comparable economic development and diversification, good standards of health care services, including occupational safety and health requirements provisions, as well as similar microorganism ecology, in order to better grasp the updated scientific evidence and possibly reduce confounders and heterogeneity in the subsequent synthesis.

The objectives of this scoping review are (1) to provide a comprehensive and up-to-date synthesis of all studies concerning occupational or work-related infections in European countries; (2) to identify the factors that impact the occurrence of infections among workers; and (3) to quantify the burden of infection among workers in terms of related disabilities, residual working capability, absence from work, and direct and indirect costs generated.

Methods

The proposed scoping review will be conducted in accordance with the JBI methodology for scoping reviews [13] and in line with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines [14].

Review Questions

The review questions of our planned study are as follows:

1. What is the incidence or prevalence rate of infections among workers in European countries?
2. What are the determinants of infection among workers in European countries?
3. What is the burden imposed by infections among European workers in terms of related disabilities, residual working capability, absence from work, and direct and indirect costs?

Eligibility Criteria

Eligibility criteria, defined according to Population, Concept, and Context criteria, are listed in Textbox 1.

Textbox 1. Eligibility criteria defined according to Population, Concept, and Context criteria.

Participants

- Workers employed in specific occupational sectors.

Concept

- Epidemiology of occupational infections, associated risk factors and determinants, burden of impact on health in terms of related disabilities, residual working capability, absence from work, and direct or indirect costs.

Context

- Studies published since 2010, performed in European countries with a common geographical definition of Europe [15].

Types of Sources

- This scoping review will consider all publications that meet the inclusion criteria. This includes, but is not limited to, quantitative, qualitative, and mixed methods studies. Systematic reviews that meet the inclusion criteria will also be considered depending on the research question. If the same data are reported in more than one publication, the primary article or article with the most complete data will be used.
- Analytical observational studies, including prospective and retrospective cohort, case-control, and analytical cross-sectional studies, will be considered for inclusion. Studies not matching the defined Population, Concept, Context criteria, review articles, modeling studies, case series, and individual case reports will be excluded from the review.

Search Strategy

A 3-step search strategy will be followed, as described in the JBI Manual for Evidence Synthesis [13].

An initial limited search of MEDLINE was undertaken to identify articles on the topic of interest. Text words contained in the titles and abstracts of relevant articles and the index terms used to describe the articles were used to develop a full search strategy for MEDLINE (Multimedia Appendix 1). To improve the specificity of the search strategy for injuries and diseases caused by occupational exposure, we adapted the specific filter developed by Mattioli et al [16] to retrieve potentially pertinent citations. The search strategy, including all identified keywords and index terms, will be adapted for each included database and information source. The databases to be searched will include MEDLINE, Web of Science, and Scopus. The reference lists of all included reports will be screened for additional studies. If the full text of a report cannot be accessed, the authors will be contacted. Studies published in English, Italian, French, and Spanish since 2010 will be included.

The second step will consist of a second search of all included databases using the fields, index, and MeSH terms, and all keywords identified during step 1. The databases to be searched will include MEDLINE, Web of Science, and Scopus. An example of the search strategy, including the index and MeSH

terms and keywords and Boolean logic (AND/OR and truncations), is provided in Multimedia Appendix 1.

The third step will consist of screening the reference lists of all the included articles for additional sources. The search strategy will be adapted for each included database and information source.

Study or Source of Evidence Selection

The source of evidence selection will be completed in the following steps. First, all citations identified through the full search of all included databases will be uploaded into Mendeley Reference Manager 2.91.0, and duplicates removed. Second, titles and abstracts will be screened by 4 independent reviewers to assess the inclusion criteria for the review. Finally, the same 4 independent reviewers will evaluate in detail the full text of the selected articles to verify if inclusion criteria are met. Reasons for exclusion of articles that do not satisfy the inclusion criteria will be reported in the scoping review. Disagreements between the reviewers will be resolved by the fifth reviewer or through discussion to reach a consensus. The complete study inclusion process will be reported in the scoping review and presented in a PRISMA-ScR flow diagram [14].

Data Extraction

Data will be extracted from the included studies by 4 independent reviewers by means of a data extraction tool developed by the Authors (Multimedia Appendix 2). The extracted data will include details on the participants, concept, context, study methodology, as well as key findings.

Data Analysis and Presentation

Data analysis and presentation will depend on the data extraction process and potential modification of the data extraction tool; therefore, it will be subject to changes. All changes will be documented in the review. The data will be manually entered into a Microsoft Excel spreadsheet. The data will also include specific details regarding the participants, study methodology, and most relevant findings. If necessary, the draft data extraction tool will be revised during the extraction process, with details on the modifications presented in the scoping review. Relevant results will be presented in tabular form and with a narrative synthesis. Disagreements between the reviewers will be resolved by an additional reviewer or through discussion. All relevant findings will be assessed and discussed by a national collaborative group of researchers from different Italian Universities, Hospitals, and Local Health Authorities.

Results

The literature search through different scientific databases started in April 2024 and is expected to be completed by December 2024. The review will be submitted for publication in 2025.

Discussion

The findings of this review will demonstrate an up-to-date epidemiological picture of occupational or work-related infections in European countries, the factors affecting their occurrence, as well as the burden of disease among different professional settings. Recently published data have shown several professional groups at risk of infection, such as the military, livestock farm workers, dairy producers, abattoir workers, and forestry workers, with the majority of these occupational groups being exposed to respiratory pathogens [12]. This review will add to the currently available evidence, by involving studies performed on all working categories, including health care workers. Such findings could improve the understanding of this complex occupational phenomenon in the European context, enabling a more accurate and up-to-date surveillance of infections caused by occupational exposure. This study is strengthened by the comprehensive and rigorous methodological approach adopted in the search strategy. Moreover, the composition of a national collaborative group, gathering expertise from researchers from different Italian Universities, practitioners, and professionals from reference Polyclinic Hospitals, and Local Health Authorities from different Regions of Italy, provides the unique possibility for multifaceted discussions of the findings, offering multiple perspectives from the different actors implicated in Occupational Health. However, the scoping review will be limited by a reduced resolution on the specific types of infections and work categories, as well as by the lack of a quantitative synthesis. To improve both limitations, further targeted systematic reviews and meta-analyses will be necessary. Nonetheless, this scoping review may serve as a foundational resource to inform policymakers with updated evidence, which can be used to improve the definition of occupational diseases and injuries caused by infectious agents in Italy, but also in different European countries. Furthermore, this updated evidence could provide useful practical insights for Occupational Health professionals, as well as guide future research goals by highlighting understudied professional categories and pathogens, with the aim of reducing possible knowledge gaps.

Acknowledgments

This study is partially supported by the Italian Workers' Compensation Authority (INAIL) in the framework of BRIC 2022: "*Metodologie innovative per la raccolta di informazioni sui casi di tecnopatie da agenti biologici e per l'individuazione dei relativi fattori causali*" (Bando BRIC 2022_ID 22).

Data Availability

The datasets generated during and/or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

All the authors were writing original drafts, reviews, and editing. Conceptualization was performed by GD, SC, AR, PD, and SM. Methodology was handled by GD, SC, and AR. Funding acquisition and supervision were conducted by PD and SM.

Abstract

Background: The rapid evolution of large language models (LLMs), such as Bidirectional Encoder Representations from Transformers (BERT; Google) and GPT (OpenAI), has introduced significant advancements in natural language processing. These models are increasingly integrated into various applications, including mental health support. However, the credibility of LLMs in providing reliable and explainable mental health information and support remains underexplored.

Objective: This scoping review systematically maps the factors influencing the credibility of LLMs in mental health support, including reliability, explainability, and ethical considerations. The review is expected to offer critical insights for practitioners, researchers, and policy makers, guiding future research and policy development. These findings will contribute to the responsible integration of LLMs into mental health care, with a focus on maintaining ethical standards and user trust.

Methods: This review follows PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines and the Joanna Briggs Institute (JBI) methodology. Eligibility criteria include studies that apply transformer-based generative language models in mental health support, such as BERT and GPT. Sources include PsycINFO, MEDLINE via PubMed, Web of Science, IEEE Xplore, and ACM Digital Library. A systematic search of studies from 2019 onward will be conducted and updated until October 2024. Data will be synthesized qualitatively. The Population, Concept, and Context framework will guide the inclusion criteria. Two independent reviewers will screen and extract data, resolving discrepancies through discussion. Data will be synthesized and presented descriptively.

Results: As of September 2024, this study is currently in progress, with the systematic search completed and the screening phase ongoing. We expect to complete data extraction by early November 2024 and synthesis by late November 2024.

Conclusions: This scoping review will map the current evidence on the credibility of LLMs in mental health support. It will identify factors influencing the reliability, explainability, and ethical considerations of these models, providing insights for practitioners, researchers, policy makers, and users. These findings will fill a critical gap in the literature and inform future research, practice, and policy development, ensuring the responsible integration of LLMs in mental health services.

KEYWORDS

large language model; LLM; mental health; explainability; credibility; mobile phone

Introduction

Background

The emergence of generative artificial intelligence (AI) and the rapid evolution of large language models (LLMs) are introducing new complexities and accelerating technological advancements. Our understanding of the inner workings of these systems remains limited. However, there is a widespread rush across all sectors to adopt these technologies, often overlooking the ethical considerations and potential threats to data privacy and confidentiality [1]. The use of LLMs, such as Bidirectional Encoder Representations from Transformers (BERT; Google) and GPT (OpenAI), in mental health research and health care is growing. However, their ability to provide reliable and empathetic mental health support remains underexplored. LLMs have been shown to excel in tasks such as text generation and summarization, but their application in sensitive fields such as mental health requires careful consideration of factors such as ethical concerns, privacy, and model explainability.

As generative AI becomes increasingly integrated into various tools and applications, its presence in our everyday lives grows. The deployment of AI in smartphones, social media, and platforms such as OpenAI's ChatGPT, Google's Gemini, Anthropic's Claude, and Meta's Llama is a testament to this trend. These technological advancements are becoming a staple in our personal and professional spheres, a presence set to expand further. Their influence on our choices is significant and will only intensify in the coming years, potentially impacting our mental health and overall well-being [2].

A recent research study published on the alignment of outcomes of LLMs to human intentions [3] concluded that, based on publicly available users' opinions about their use of LLMs, in general, users tend to trust those LLMs more that demonstrate higher alignment to human intentions. In *Harvard Business Review* [4], the authors of the review "AI can be both accurate and transparent," which was a study to examine the trade-off between accuracy and explainability, tested a wide array of AI models on nearly 100 representative datasets and found that 70% of the time, a more explainable model could be used without compromising accuracy. This suggests that a reliable LLM can be developed and aligned with transparency and social norms. Another study [5] suggested that ethics-based auditing can be a governance mechanism for building and deploying LLMs and potentially bridge the gap between principles and practice in AI ethics. It argues that ethics-based auditing will improve the quality of decision-making, users' satisfaction with privacy and confidentiality at the center, influence laws and policies that govern these systems and minimize human harm.

Given that this technology is still nascent and research into its effects on society is scarce, evaluating its implications and integration into the medical and health care sectors, particularly in mental health support, is essential. It is imperative to recognize and scrutinize this progression, understand its benefits [6] and associated risks, and identify potential measures to prevent and reduce the adverse effects of these technologies on human lives. The ethical dilemmas surrounding the use of these systems, the safeguarding of user privacy and confidentiality, and the accountability of developers remain largely uncharted territories [7]. It can be said that a lot of the published literature and journals either provide general solutions or look into a specific domain, such as applicability or accuracy.

This exploration seeks to shed light on the current state of LLMs, focusing on their reliability and explainability, especially in providing support for mental health. It will try to add more consistent factors that can account for the credibility of LLMs. There is now a growing body of research on using LLMs for mental health care provision [8]. However, it is worth noting that there are very few to almost no studies on the credibility of LLMs, particularly in medicine [9,10] and mental health support. This review intends to address this gap.

Objectives and Research Questions

The study's overall objective is to explore the current state of evidence on the credibility of LLMs by comprehensively reviewing research on credibility factors such as reliability and explainability. A secondary objective is to derive insights into ethical implications for the responsible use of LLMs in mental health support.

To this end, the following research questions will be pursued in the scoping review:

1. How credible are LLMs in providing mental health information and support?
   - What factors influence the reliability of LLMs for mental health support?
   - How credible are LLMs providing mental health information and support?
2. What are the users' perceptions of using LLMs as reliable and explainable sources of mental health support?
3. What ethical implications should be considered for the responsible use of LLMs in mental health support?
   - How can we ensure privacy and confidentiality when users interact with LLMs for sensitive mental health issues?
   - How can we ensure that the shared sensitive information by the user is secure and private?

Methods

Study Design

The PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) [11] will be used as a basic tool, and the Joanna Briggs Institute's (JBI) approach to scoping reviews will be followed [12-14].

Research Strategy and Terms

Information Sources

The selected databases cover a wide range of disciplines relevant to the scope of our review. PsycINFO and MEDLINE focus on psychology and medical research, providing comprehensive coverage of mental health studies. Web of Science ensures multidisciplinary coverage, while IEEE Xplore and ACM Digital Library focus on technological advancements and AI research,

critical for studies on LLMs. These databases together provide a robust and well-rounded search strategy for this scoping review.

Search Strategy

The search strategy will be continuously updated to capture newly published studies during the review period (Multimedia Appendix 1). Monthly alerts will be set up in key databases, and any relevant new papers will be incorporated into the review until the final synthesis phase. An iterative approach will be followed to develop the search strategy. First, search terms used in previous studies and reviews related to the credibility of LLMs in mental health support will be identified. Second, an initial search in MEDLINE via PubMed and ACM Digital Library will be conducted after analyzing text words (title and abstract) and indexed terms, according to JBI methodology. The initial search strategy for MEDLINE via PubMed is given in Multimedia Appendix 1. This approach will use all received search terms in all databases. Finally, the references for all included contributions will be checked. The terms will be adapted to the essential search particulars such as wildcards (*), truncations, and Boolean operators in each electronic database.

For a more precise explanation of the inclusion criteria, the Population, Concept, and Context (PCC) framework will be followed. Textbox 1 shows the most important criteria based on the PCC framework.

The kinds of literature and papers that provide information on at least one research question from the *Objectives and Research Questions* section will be included. Detailed inclusion and exclusion criteria are mentioned below for each review.

Textbox 1. Population, Concept, and Context scheme.

Population

- Mental health practitioners, researchers, educators, students, and adults (age group: 18-65 years)

Concept

- Nonparticipatory, exploratory, cocreation, and co-design

Context

- Exploration of credibility (reliability and explainability) of large language models for mental health support

Types of sources

- Secondary sources, electronic databases, studies published in the last 5 years (2019-2024), studies published in English or that have an English translation available, and full-text papers

Eligibility Criteria

Papers to be included must meet the criteria mentioned in Textbox 2.

Textbox 2. Eligibility criteria.

Study design

- The study must be empirical, exploring the application of transformer-based generative language models in mental health support.

Model type

- The study should involve transformer-based models such as Bidirectional Encoder Representations from Transformers (BERT), GPT-2, or later models designed for generative tasks.

Mental health focus

- The study should address mental health support, encompassing therapy, counseling, or other relevant interventions.

Credibility assessment

- The study should evaluate credibility factors, including accuracy, reliability, explainability, or user satisfaction.

Publication date

- Studies published from 2019 onward are included. We chose 2019 as the starting year for including studies because this marks the beginning of a transformative phase in large language model (LLM) development. In late 2018, BERT was introduced, followed by GPT-2 in 2019, setting the stage for subsequent advancements that significantly impacted the field.

Language

- The study must be published in English or have an English translation to maintain data extraction and analysis consistency.

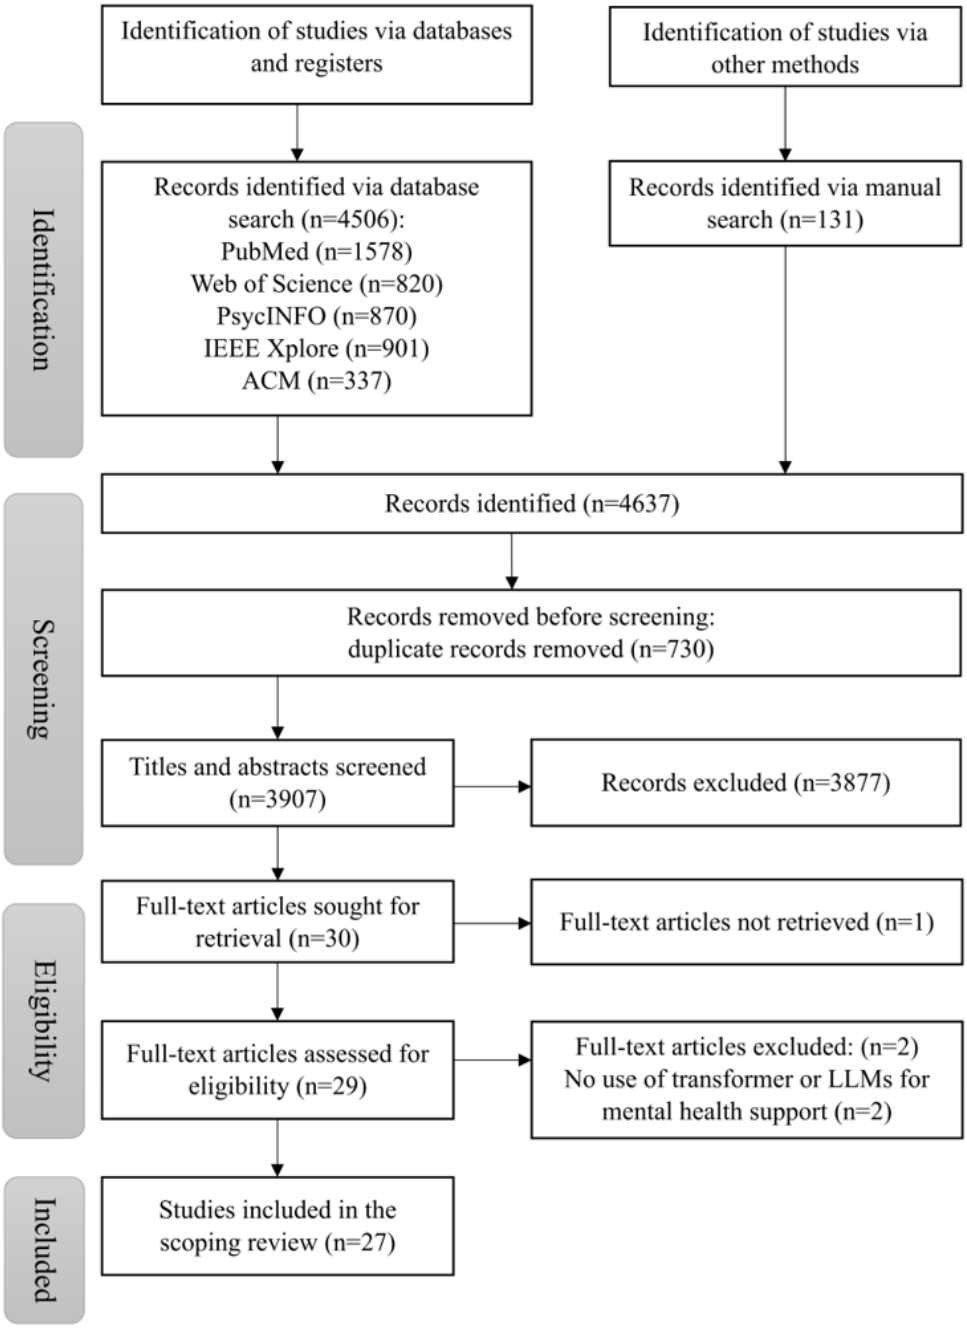
Peer-review or preprint status

- We will prioritize peer-reviewed studies; however, to capture the rapid advancements in this field, we will also include preprint papers from ArXiv and peer-reviewed book chapters. Information from these sources will be presented in a separate table, and interpretations based on these sources will be limited and contextualized regarding the publication status.

Study Selection

The saved papers will be checked for duplicates. The open-source app Zotero (Corporation for Digital Scholarship) [15] will be used as a bibliographic tool. Paper screening will be done using the open-access tool Rayyan.ai (Rayyan Systems Inc) [16]. Two independent reviewers will screen all titles and abstracts separately for inclusion or exclusion. Any discrepancies will be resolved through discussions between the 2 reviewers during the screening and data extraction phases. If consensus cannot be reached, a third reviewer will be consulted. This process will ensure reliability and minimize bias by incorporating multiple perspectives and systematic resolution of disagreements. The search results and the study inclusion or exclusion process will be transparently reported in full in the final scoping review, which will be presented in a PRISMA flowchart (Figure 1).

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flowchart. LLM: large language model.



Data Extraction

We will use the literature review matrix method [17] to organize and chart the data extracted from the included research papers. Two reviewers will chart the data independently, continually update the matrix in an iterative process, and discuss the results while all the changes are detailed in the scoping review. After independent extraction, the 2 reviewers will compare their extracted data. Any discrepancies or disagreements will be discussed and resolved through consensus. A third reviewer will be consulted to decide if a consensus cannot be reached. Data extracted will include metrics such as accuracy, reliability, model explainability (eg, explainable AI methods used), user satisfaction scores, and ethical considerations such as privacy and data security measures. Data will be synthesized to address the research questions systematically. The data extraction form will be continually updated in an iterative process as new insights are gained and new studies are reviewed. Reviewers will keep detailed records of any changes to the extraction process and document the rationale. The extracted data will be managed and stored using Zotero for reference management and Rayyan.ai for screening and collaboration. A literature review matrix is given in Multimedia Appendix 2.

Data Analysis and Presentation

To assess the quality of the included studies, we will apply the JBI Critical Appraisal Checklist for Qualitative Research [18]. This tool will evaluate the methodological quality of each study by examining factors such as the clarity of research questions, the appropriateness of the study design, the rigor of data collection, and the credibility of the results. The results of this appraisal will be presented descriptively, helping to

contextualize the findings of the review and ensuring a nuanced understanding of the evidence base. Given the expected heterogeneity in study designs, methodologies, and outcomes, this scoping review will focus on qualitative synthesis rather than meta-analysis. Descriptive synthesis is more appropriate for mapping the broad and varied landscape of LLM applications in mental health support. This will involve evaluating methodological rigor, reporting clarity, and the findings' relevance to the research questions. The results of this appraisal will be presented descriptively, helping to contextualize the findings of the review. The findings will be presented according to the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) checklist (Multimedia Appendix 3). The extracted data will be presented logically and descriptively, including diagrams and tables based on the objectives and research questions of the scoping review. Data synthesis and presentation will follow an inductive approach. A summary description and discussion of the findings according to the research questions, the flowchart, and the entire research process will be provided in text form and described narratively.

Ethical Considerations

Since the data used in the review are collected from secondary sources and primary data are not collected, formal ethical approval is not required.

Dissemination Plan

The findings of this scoping review will be disseminated through various channels, including a peer-reviewed journal publication and presentations at key conferences in the fields of AI and mental health. We also plan to engage with policy makers and health care stakeholders to help inform the development of guidelines and frameworks that promote the responsible use of LLMs in mental health care. This dissemination strategy aims to ensure that the results reach both academic and clinical audiences, as well as those involved in ethical oversight.

Results

As of September 2024, we have completed the initial search, yielding 1578 studies. Out of these, 244 studies were included for title and abstract screening. Full-text screening is underway for 76 studies. Figure 1 shows the PRISMA flowchart, and the PRISMA-P checklist documenting this process is given in Multimedia Appendix 3. The target date for submitting the scoping review is November 30, 2024.

Discussion

Overview

The anticipated findings of this scoping review will focus on identifying and mapping the factors that influence the credibility of LLMs in mental health support. We expect to find evidence related to the reliability and explainability of these models, particularly in the areas of user trust, data privacy, and ethical considerations. These insights are expected to inform future research, policy development, and clinical practice in integrating LLMs for mental health services.

Principal Findings

This scoping review aims to map factors such as model reliability, explainability, and ethical concerns in the context of LLMs for mental health support. These findings will offer a deeper understanding of how LLMs are evaluated for their potential role in sensitive areas such as mental health. We anticipate uncovering gaps in transparency and user trust as key components influencing the integration of LLMs into clinical settings.

Comparison to Previous Work

This review builds on previous work in AI ethics and health care applications, with a particular focus on LLM credibility. Our findings are expected to align with previous studies that emphasize the need for explainability and user trust, but they will also highlight the specific challenges that arise when these models are applied in mental health contexts. Unlike past research that has focused on broader AI applications, this review narrows its scope to LLMs in therapeutic settings, addressing concerns such as misdiagnosis and misinformation.

Strengths and Limitations

The comprehensive nature of this scoping review, using the PRISMA-ScR framework, allows for a systematic exploration of diverse studies across various domains. However, limitations include the exclusion of non-English studies, which may lead to the omission of important research from non–English-speaking regions. In addition, the rapid development of LLM technologies means some newly published studies may be missed, and publication bias could skew the results toward studies reporting positive findings.

Future Directions

This review will highlight the need for further research, particularly in the user-centered evaluation of LLMs within clinical mental health settings. We expect to identify several gaps in the literature, such as the underrepresentation of studies focusing on the impact of LLMs on vulnerable populations. Future work should explore ways to improve model transparency, explainability, and user trust while addressing ethical concerns surrounding the use of LLMs in mental health.

Conclusions

This scoping review addresses a critical gap in the current literature by systematically evaluating the credibility of LLMs in mental health support. By mapping factors such as reliability, explainability, and ethical considerations, this review will provide a comprehensive understanding of how these models can be responsibly integrated into mental health services. The findings will offer valuable insights for mental health practitioners, researchers, and policy makers, helping to shape future studies and ethical guidelines. In particular, the results will inform decisions about the use of LLMs in clinical practice, guiding the development of policies to safeguard user trust and data privacy. Furthermore, the review will serve as a foundation for further research on improving the reliability and transparency of LLMs in sensitive areas such as mental health.

Acknowledgments

This scoping review is conducted as part of the master's thesis of author Dipak Gautam under the supervision of Prof Dr med Philipp Kellmeyer. Data and Web Science Group, School of Business Informatics and Mathematics, University of Mannheim, Germany.

Abstract

Background: Health worker migration from Nigeria poses significant challenges to the Nigerian health care sector and has far-reaching implications for health care systems globally. Understanding the factors driving migration, its effects on health care delivery, and potential policy interventions is critical for addressing this complex issue.

Objective: This study aims to comprehensively examine the factors encouraging the emigration of Nigerian health workers, map out the effects of health worker migration on the Nigerian health system, document the loss of investment in health training and education resulting from migration, identify relevant policy initiatives addressing migration, determine the effects of Nigerian health worker migration on destination countries, and identify the benefits and demerits to Nigeria of health worker migration.

Methods: This study will follow the Joanna Briggs Institute methodology. A search strategy will retrieve published studies from MEDLINE, CINAHL, Embase, Global Health, Academic Search Premiere, and Web of Science. Unpublished studies will be sourced from dissertations and theses. A comprehensive search will involve keyword scans and citation searches. Exclusion criteria will filter out irrelevant studies, such as studies unrelated to the international migration of health workers and non-English language studies. A total of 2 independent reviewers will screen the titles and abstracts and then review the full text. Data will be extracted from the included studies using a data extraction tool developed for this study. The study selection process will be shown using a PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) flowchart. While the traditional risk of bias assessments is not applied to scoping reviews, the quality of included studies will be evaluated based on methodological transparency.

Results: The process of selecting studies will be shown using a PRISMA ScR flowchart, and information gathering will be done through a charting table that has been prepared in advance. We plan to collect data from January 2025 to March 2025 and present the results to examine publication patterns and study details. The final summary is expected to be released by the summer of 2025. It will provide an in-depth look at how health worker migration impacts the health care sector in Nigeria.

Conclusions: This study holds immense potential to contribute to understanding health worker migration from Nigeria and inform policy and practice interventions to address its challenges. By synthesizing existing evidence, the scoping review will guide future research and policy efforts to mitigate the adverse effects of migration on health care systems and workforce sustainability. Furthermore, the results will aid in recognizing deficiencies in the existing literature; this will offer a defined path for specific policy measures and methods to retain health care workers effectively and thus support the sustainability of health care systems.

International Registered Report Identifier (IRRID): PRR1-10.2196/62726

KEYWORDS

training and education; health policy; healthcare workforce; policy interventions; socio-political factors; political instability; workforce capacity

Introduction

Overview

Nigeria is the most populous country in Africa and has one of the largest supplies of health workers on the continent; however, the country has been particularly affected by the migration issue [1]. It is estimated that 20,000 of the 72,000 Nigerian physicians educated in Nigeria were practicing abroad in 2008 [2]. This number represents 28% of the physician workforce trained in Nigeria and is significantly higher than the proportion for any other African country [3]. As a result, Nigeria has a fragile health system that is unable to effectively deliver quality health services to its populace. This includes increased workload for the remaining health workers, decreased access to health care services, and compromised quality of care [4-6]. Furthermore, Nigeria invests substantial resources in training its health workforce, yet many of these trained professionals ultimately migrate to seek better opportunities abroad. Documenting the loss of investment in health training and education due to health worker migration is essential for assessing the economic and human resource implications for Nigeria's health care system [7].

The global crisis in human resources for health has been described as one of the most pressing issues facing the health sector and is now widely acknowledged as a global priority [8]. Addressing the shortage and maldistribution of health workers, including policy dialogue and coordinated action in the area of international migration of health workers, is deemed necessary to avert a long-term global health workforce crisis, which would be detrimental to the attainment of the health-related Sustainable Development Goals and Universal Health Coverage, and ultimately to global health [9]. Policy initiatives have been proposed to address health worker migration in Nigeria, including retention schemes such as offering competitive salaries and benefits, incentive programs like providing opportunities for professional development, and bilateral agreements to regulate the recruitment of Nigerian health workers by foreign countries. Evaluating the effectiveness and impact of these policies is critical for policy makers and stakeholders to develop evidence-based strategies to mitigate the adverse effects of health worker migration [10]. In addition, understanding the effects of Nigerian health worker migration on destination countries is vital for promoting ethical recruitment practices and fostering global health workforce planning. While migration poses challenges for the Nigerian health care system, it also generates remittances, fosters knowledge exchange, and promotes international engagement in health care development initiatives [11].

The migration of highly skilled health workers from developing to developed countries has been cited as contributing to shortages of qualified health workers in many African and Southeast Asian countries. In relation to the Nigerian context, there is evidence that Nigeria has experienced high levels of emigration of health professionals, where the United Kingdom, United States, and Canada are among the leading destination countries [12]. It is important to understand the journeys, distribution, and characteristics of migrant health workers, with the aim of identifying specific policy measures to enhance positive impacts and mitigate negative impacts of migration on health systems in source and destination countries [9,13,14]. In summary, this scoping review protocol seeks to provide a comprehensive overview of health worker migration and its impacts on the Nigerian health care sector. By addressing these issues, the review will inform evidence-based policies and interventions to optimize the management of health worker migration and strengthen the resilience of Nigeria's health care system.

A preliminary search of Campbell's systematic reviews, the Cochrane Database of Systematic Reviews, PROSPERO (International Prospective Register of Systematic Reviews), and Joanna Briggs Institute (JBI) evidence synthesis was conducted. Interestingly, no current or underway systematic reviews or scoping reviews on the topic were identified, highlighting the unique contribution of this study.

Aim and Review Questions

The primary purpose of this study is to establish a better understanding of how migration affects individual developing nations. This understanding will pave the way for new policies that can better manage the recruitment and retention of health professionals, thereby minimizing any negative effects caused by migration. Importantly, this study also holds the potential for positive outcomes, such as increased skill and knowledge within the sector, which can significantly benefit the health care system.

This review will seek to identify the breadth and depth of the available literature, including studies on the causes and consequences of health worker migration, the effectiveness of policy interventions, and the experiences of health workers and their families. This will provide an opportunity to identify research gaps and inform future research and policy decisions. At this preliminary stage in conducting the scoping review, the authors have also found that this type of review is best suited to the resources and time available. Specifically, the review questions are as follows: (1) What factors contribute to the emigration of Nigerian health workers? (2) How does health worker migration impact the Nigerian health system, including its strengths and weaknesses? (3) What effective strategies should be used to promote the retention of skilled health workers within the Nigerian health care system?

Methods

Overview

Following the JBI methodology [15], the study will conduct a comprehensive search across multiple databases to find relevant studies. Data from these studies will be systematically extracted, organized, and analyzed, ensuring a reliable and comprehensive review, with findings presented in a clear and descriptive format.

Search Strategy

The scoping protocol, a detailed plan outlining the methods and search strategy for the scoping review, will initiate with an initial limited search of databases, focusing on analyzing text words in titles, abstracts, and index terms. This will be followed by a comprehensive 2-way search strategy across multiple databases, including MEDLINE, CINAHL (EBSCO), Embase, Global Health, Academic Search Premiere, and Web of Science (Table 1). Unpublished studies will be sourced from dissertations and theses. The search will involve specified keywords (eg, emigration, immigration, and health workers) and free keywords (eg, brain drain and migration). Additional strategies, such as citation and chain searches, will be used to enhance search completeness. Exclusion criteria will filter out studies unrelated to the international migration of health workers or not centered on the Nigerian health care sector. Only English-language studies from an appropriate date range will be considered, aligning with the review's scope and context. Finally, hand-searching of reference lists from relevant primary studies or review articles will be conducted. To address potential publication bias, the review will include measures such as searching for gray literature, unpublished studies, and reports that may contain negative or nonsignificant findings. This approach will help ensure a more comprehensive and balanced understanding of the topic. The scoping protocol plays a crucial role in ensuring the systematic and rigorous conduct of the scoping review, and its adherence will be reported in the final scoping review.

Table 1. Search strategy on databases.

Participant, context, and concept scheme	Number	Search string	MEDLINE (March 28)	CINAHL	Web of Science	Embase	Global Health	Academic Search Premier
International migration AND its impacts on the Nigerian healthcare sector	1	emigration OR immigration OR health workers OR skilled healthcare workers OR health professionals OR healthcare professionals OR healthcare personnel	339,025	119,968	349,710	22,039	12,876	3789
International migration AND its impacts on the Nigerian healthcare sector	2	brain drain OR migration OR healthcare workers	387,827	43,054	851,446	9098	456	1789
	3	#1 AND #2	19,789	11,006		2004	55	2908
Migration AND its impacts on the Nigerian healthcare sector	4	Nigeria OR Nigerian	41,946	7366	4540	455	34	45
Combined	5	#3 AND #4	292	113		23	12	9
Filters	6	English, from 2001 to date (excluding Magazine and book chapters)	33	112		34	33	54

Eligibility Criteria

This scoping review will incorporate the PCC (Population, Concept, Context) framework as a guide, ensuring a comprehensive and inclusive approach. We will thoroughly describe the characteristics of participants, concepts, and contexts alongside our search strategies, data extraction methods, analysis techniques, and result presentation formats. The eligibility criteria, designed to be comprehensive and inclusive, are detailed in Textbox 1. In addition, this review will involve iterative consultations with experts and stakeholders to refine the research questions and inclusion criteria.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria:

- Health workers migration from Nigeria.
- English.
- Studies from 2001 to 2024.
- Conference papers.
- Quantitative and qualitative evidence.
- Gray literature.
- Studies identifying policy initiatives aimed at addressing health worker migration in Nigeria.
- Research mapping out the impacts of health worker migration on the Nigerian health system.

Exclusion criteria:

- Meeting abstracts.
- Editorial materials.
- Book chapters.
- All other languages.
- Studies from 2001 and earlier.
- Studies not related to health worker migration from Nigeria.
- Literature not focused on the effects of health worker migration on the Nigerian health system.
- Articles lacking information on factors encouraging health worker emigration from Nigeria.
- Publications not discussing policy initiatives addressing health worker migration in Nigeria.

Participants

This scoping review will include studies involving health workers who have migrated from Nigeria to other countries. The focus will be on health care professionals, including but not limited to doctors, nurses, midwives, pharmacists, radiographers, and laboratory scientists. In addition, individuals receiving health care services in Nigeria impacted by the migration of health workers will also be considered participants in this review.

Concept

The primary concept under investigation is the migration of health workers and its impacts on the Nigerian health care sector. This includes examining factors contributing to health worker migration, such as motivating factors, as well as the consequences of migration on health care delivery, workforce dynamics, health care access, quality of care, and health outcomes in Nigeria.

Context

The review will consider studies conducted regarding the Nigerian health care sector, including public and private health care facilities, hospitals, clinics, primary health care centers, and community health centers. Equally important, studies focusing on the health care systems of destination countries where Nigerian health workers have migrated will also be included to provide a comprehensive understanding of the context.

Types of Sources

This scoping review will consider a variety of sources, including empirical research studies, policy documents, reports, and gray literature. Gray literature, which refers to nontraditional sources of information that are not published in commercial publications, can include conference papers, theses, government documents, and unpublished research. Specifically, quantitative studies such as surveys, cohort studies, and quantitative analyses of secondary data will be included. Qualitative research using methods such as interviews, focus groups, and case studies will also be considered. In addition, policy documents, government reports, organizational reports, and academic publications addressing the migration of health workers and its impacts on the Nigerian health care sector will be included in the review. For instance, a government report on the brain drain of health workers from Nigeria would be a relevant source for this review.

Study or Source of Evidence Selection

Following the search, all identified citations will be collated and uploaded into EndNote (version 20; Clarivate Analytics), and duplicates will be removed. Following a pilot test, titles, and abstracts will then be screened by 2 or more independent reviewers for assessment against the inclusion criteria for the review. Potentially relevant sources will be retrieved in full, and their citation details will be imported into the JBI System for the Unified Management, Assessment, and Review of Information [16]. Two or more independent reviewers will thoroughly assess the full text of selected citations against the inclusion criteria. Reasons for the exclusion of sources of evidence in full text that do not meet the inclusion criteria will

be recorded and reported in the scoping review. Any disagreements that arise between the reviewers at each stage of the selection process will be resolved through discussion or with an additional reviewer or reviewers. The results of the search and the study inclusion process will be reported in full in the final scoping review and presented in a PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) flow diagram [17]. This process ensures the transparency and rigor of the study selection process.

Data Extraction

To ensure the reliability and consistency of the data, 2 independent reviewers will meticulously extract data from each included study using a standardized data extraction form. The data extracted will include specific details about the participants, concept, context, study methods, and key findings relevant to the review questions. This thorough process guarantees the accuracy of our findings. A draft charting table will be developed as a data extraction tool. This charting table will also serve as the basis for data synthesis, and it will be modified and revised as necessary during the process of extracting data from each included evidence source. The purpose of this table is to provide a structured format for recording the extracted data, ensuring consistency and facilitating the analysis process. The synthesis will follow a narrative, descriptive approach, with identified patterns, gaps, and emerging themes categorized for further analysis. Modifications to the charting table will be detailed in the scoping review. Any disagreements that arise between the reviewers will be resolved through discussion or with an additional reviewer or reviewers. If appropriate, authors of papers will be contacted to request missing or additional data, where required.

Results

The findings of this scoping review will be shared once we finish extracting the data as planned. Our goal is to finalize the data mapping and synthesis by March 2025. The review results will be organized to showcase a thorough overview of the data based on the main themes recognized during the review process. The table for charting will contain information like the publication year and country of the study as well as its objectives and methodology, along with details on the population studied and sample size considered in the research analysis process, including outcomes assessed and intervention duration when relevant. The final summary of results, which will detail the impact of health worker migration on Nigeria's health care system, is anticipated to be released by the summer of 2025. The analysis will be finalized and submitted for publication in the autumn of 2025.

Discussion

Principal Findings

This scoping study will uncover insights into how health workers from Nigeria migrate and how it affects the country's health care system. The results should highlight patterns in what drives their migration, such as reasons and job prospects along with working conditions, while also pointing out the difficulties caused by this shortage of health care workers in delivering services and ensuring access to health care. Furthermore, the review seeks to pinpoint areas where existing research lacks information, which can serve as a basis for studies and policy making decisions to address the consequences of health worker migration.

Dealing with health worker migration challenges is crucial to improving health care delivery. Like countries facing an aging population, Nigeria is also tackling both an aging populace and a scarcity of health care workers, which is straining the health care system [10]. Projections suggest a severe shortage in the health care workforce by 2038, underscoring the urgent need to address health worker emigration as a top priority [13]. This urgency should resonate with policy makers, health care administrators, researchers, and professionals involved in health care workforce management and policy development in Nigeria.

Recent studies on health worker migration in Nigeria shed light on the factors contributing to the departure of professionals from the country. For instance, some studies pointed out that sociopolitical factors such as political instability and insecurity, as well as professional factors like low wages and poor working conditions, are driving health worker emigration [9,14]. The findings underscore the potential of focused interventions to address issues and motivate health workers to remain in Nigeria, instilling a sense of optimism for the future of Nigeria's health care system.

The consequences of health worker migration go beyond workforce shortages; they also impact the quality and accessibility of health care services in Nigeria. For instance, some research studies emphasized how health care delivery is strained and how health inequalities worsen due to the departure of professionals [12,18]. This should underline the gravity of the situation for policy makers, health care administrators, researchers, and professionals involved in Nigeria's health care workforce management and policy development. Moreover, the issue of health workers leaving the country poses challenges to the health care systems' long-term stability and ability to withstand pressures, highlighting the need for measures to retain and develop capacity [7].

Efforts to address these obstacles and encourage health professionals to stay within Nigeria's health care system have been gaining traction. Research conducted by Ossai et al [19] Falase et al [3] emphasized the significance of overcoming hurdles and offering incentives to retain health workers in the country. Furthermore, the World Health Organization's Global Code of Practice on International Recruitment of Health Personnel serves as a guideline for collaboration in tackling health worker migration and bolstering health care systems [20].

In summary, this review aims to focus on the reasons and effects of health care worker migration from Nigeria and sheds light on the challenges faced by the workforce and health care disparities in the country. Drawing comparisons with research will help put the findings into perspective by highlighting trends and new insights discovered. The study's strengths lie in its methodology and thorough analysis of data; however, it may have limitations due to gaps in less-known sources. Moving

forward, efforts should be made towards creating targeted policy recommendations and implementing strategies to mitigate the impacts of migration on the health care system. An effective dissemination strategy guarantees that the research outcomes are communicated to policy makers and experts in the field so they can contribute to solutions.

Strengths and Limitations of the Study

The scoping review is designed to identify the gaps in the literature and recommend strategies for further research in this area. The methods used will provide us with an idea of how much research already exists in this domain and examine how research has been conducted on this topic [21]. In addition, the research team, with its extensive experience in different types of systematic reviews, brings a wealth of knowledge and expertise in this specific field, making it well-equipped to tackle the complexities of this research [21-24].

This review has a few limitations that have been considered when considering the findings. A significant limitation of this review is that the studies identified and included provided very little detail on the health worker's experiences abroad and the impact of migration on the health sector (if they were mentioned). It will, therefore, be difficult to provide a comprehensive account of the health worker migration situation and its impacts on the health sector in Nigeria. Given the limited information available in the literature, it may be necessary to consider broadening the scope of the review in the future. This could involve incorporating nonacademic literature and reports, a step that could potentially provide a more comprehensive understanding of the situation. Another potential limitation is the exclusion of any language other than English, such as French language studies. This is due to the reviewers' lack of proficiency in French, making the use of French language studies a time-consuming process. This may have introduced a language bias.

Given the broad scope of the review, it has been a challenge to frame precise research questions and define specific inclusion criteria. This complexity has made it difficult to assess the relevance of the retrieved studies. Moreover, there was significant variation in the concepts and definitions of health professional and "brain drain" among these studies, a factor that will likely influence the findings once the data is extracted and synthesis is carried out.

Conclusion

This analysis sheds light on the studied topic of health care staff migration and the limited data regarding its extent and effects, despite public worry and ample unofficial publications on the matter. The absence of supporting data has resulted in differing opinions; some term it a "crisis" while others raise concerns. Our scoping review approach has mapped the key concepts and sources, provided an understanding of the existing evidence, and paved the way for a comprehensive follow-up review.

Acknowledgments

The authors thank the librarians from the University of Bradford for their guidance and assistance in this research. This study is being undertaken without external funding. However, a publishing grant from Linnaeus University has been received as part of the University Library's research support. No generative AI was used in any portion of the manuscript writing.

Data Availability

All supporting data will be reported in the manuscript. Any raw data sets supporting the results will be available and presented in the main manuscript or additional supporting files when submitting the systematic review article.

Authors' Contributions

DO contributed to conceptualization, methodology, data curation, writing, original draft, and visualization. EA managed formal analysis, investigation, and visualization. MC handled resources, writing, review, and editing. MSRJ performed supervision, validation, review and editing.

Conflicts of Interest

None declared.

Abstract

Background: In March 2020, the global landscape witnessed widespread upheavals in both socioeconomic and educational spheres due to the onset of the COVID-19 pandemic. With measures imposed to control the virus's spread, educational institutions around the world embraced digital learning, introducing challenges in the adaptation to virtual education. This shift proved especially daunting in resource-limited nations with limited digital infrastructure.

Objective: This scoping review aims to explore the experiences of biochemistry educators during the COVID-19 pandemic, focusing on successful pedagogical strategies used to overcome challenges in remote teaching. The goal is to compile valuable information applicable to health-related undergraduate and postgraduate courses.

Methods: This review considers studies and experiences related to the transition to remote biochemistry education during the pandemic. It encompasses a variety of pedagogical approaches, including online teaching tools, interactive methods, and alternatives to practical laboratory classes. The search spans databases such as MEDLINE, the Cochrane Database of Systematic Reviews, and Joanna Briggs Institute (JBI) Evidence Synthesis, with a focus on identifying systematic or scoping reviews; however, none were identified in the preliminary search.

Results: Starting in February 2022, the scoping review protocol was scheduled for completion by July 2024. From an initial pool of 1171 results, 85 articles were selected, with duplicate verification pending for the subsequent phase of the project. The findings from this review on biochemistry teaching strategies will be communicated using a combination of descriptive narrative, graphical, and tabular formats, emphasizing diverse pedagogical approaches pertinent to the subject. Dissemination will occur through regional and national scientific conference presentations, alongside publication in a peer-reviewed journal.

Conclusions: This review aims to generate innovative pedagogical approaches and pinpoint learning activities, materials, and tools that support social and collaborative learning across various subjects, including biochemistry. Moreover, it will offer perspectives from students and educators on the implemented activities, with the intention of integrating them as supplementary methods to boost student participation, and thereby, improve learning outcomes and skill development.

Introduction

The COVID-19 pandemic, declared by the World Health Organization (WHO) in March 2020, caused significant impacts on both socioeconomic and educational fronts, disrupting the routine of in-person education worldwide [1]. Due to restrictions on people's movement to prevent the spread of the coronavirus, schools and universities shifted to digital learning, which helped prevent 2% to 4% of COVID-19 deaths [2]. Consequently, educators and students were compelled to use digital platforms as universities faced the dilemma of either suspending activities indefinitely or restructuring through online education, with the latter prevailing [3,4]. This transition from traditional to virtual education posed challenges, requiring students and educators to adapt to digital platforms and teachers to develop some level of computer proficiency. In resource-limited countries, the limited digital infrastructure hindered online access, rendering online education less effective [3].

While online teaching tools were already used by various institutions, the widespread shift to this mode of education was abrupt for educators across all levels, from basic to postgraduate courses [4,5]. Therefore, pedagogical strategies had to be rapidly developed to achieve desired competencies through virtual learning without significant learning setbacks [4]. In addition, the need to identify optimal communication tools arose early on to facilitate practical aspects, such as ease of use, compatibility with teachers' and students' computer systems, and avoidance of additional costs for students [5]. This led to the adoption of online meeting programs, such as Microsoft Teams, Cisco Webex, GoToMeeting, Jitsi, and Zoom, on all available electronic devices and required changes in the education system to facilitate the development of students' learning habits and critical thinking; this demanded quick adaptability and creativity from teachers in transitioning from a structured teaching method to an innovative one, especially in medical education [5]. Conventional methods of distance learning often involve prerecorded video lectures and theoretical materials, which may be insufficient to engage students and promote learning [6]. Furthermore, the unavailability of teachers to clarify doubts during and after the class may impede communication and content comprehension, a limitation recognized for several years and accentuated by the COVID-19 pandemic [6,7]. As an alternative to maintaining quality education and direct teacher-student contact, interactive pedagogical tools were used to promote active learning through student participation in online classes [8].

The rapid shift to distance learning during the pandemic presented significant global challenges, as evidenced by Lassoued et al [9], which identified pedagogical, technical, and financial obstacles affecting the quality of education in Arab universities, and by Jalali et al [10], who highlighted similar issues in Iran, where prosthetics and orthotics students faced unreliable internet and a lack of digital competence among both students and faculty, severely impacting the quality of online education. Similarly, Anwar et al [11] in Pakistan and Baticulon et al [12] in the Philippines identified several barriers to effective online learning, including low digital literacy, lack of institutional support, financial difficulties, unreliable internet access, the need for students to manage household responsibilities, and mental health challenges exacerbated by the pandemic, all of which hindered students' ability to engage effectively with online education.

In the field of biochemistry education, specific examples of innovative approaches include the work of Botasini et al [13], who assessed the learning objectives of each practical biochemistry class at the University of Montevideo, distinguishing between those developing skills suitable for remote learning and those primarily requiring hands-on laboratory skills. Gasparello et al [14] replaced applied biochemistry practical classes with a remote activity simulating the use of different techniques for diagnosing SARS-CoV-2, the infectious agent responsible for the COVID-19 pandemic. They suggested continuing this strategy in person, with small groups of students to maintain social distancing. Similarly, Vasiliadou [15] proposed adopting virtual laboratories where practical classes were simulated, allowing students to perform them at their own pace, familiarizing them with health and safety regulations, and providing instant feedback. These virtual experiments could be conducted in groups, promoting social interaction and collaboration among students, crucial in a socially distant situation to facilitate communication and reduce feelings of isolation and loneliness.

Singh and Arya [1] reported the development of new approaches tested on various online platforms with a class of 200 biochemistry students. After using 4 different teaching strategies and analyzing student feedback, they combined these approaches with the flipped classroom method. This involved providing slides, quizzes, and support material links at least 24 hours before delivering a video lecture on a carbohydrate metabolism topic. Students' questions were available to tutors before the online class, and the interactive phase of this hybrid strategy was recorded for students with poor connectivity to answer a related questionnaire later.

Challenges continued to emerge as the need to fulfill educational objectives clashed with the physical distance of students [8,16]. Practical laboratory classes, integral to health professionals' training, posed a particular challenge. Teachers in these disciplines had to address how to teach practical content and skills remotely, leading to the implementation of various alternatives based on available digital tools [16].

As some researchers shared their experiences, such as Thibaut and Schroeder's [17] guide for creating short cases for virtual case-based learning, the value of virtual learning as a complementary tool for the future became evident. In this regard, this scoping review aims to explore different experiences of biochemistry educators during the COVID-19 pandemic, identifying successful pedagogical strategies that engaged students in overcoming challenges posed by this conceptual and abstract discipline. This information can be compiled and used by educators in health-related undergraduate and postgraduate courses. Understanding complex molecular structures, intricate metabolic pathways, and subtle chemical interactions provides profound knowledge of the molecular basis of organism function and, consequently, the development, diagnosis, and treatment of diseases. A preliminary search of MEDLINE, the Cochrane Database of Systematic Reviews, and Joanna Briggs Institute (JBI) Evidence Synthesis did not identify any current or ongoing systematic reviews or scoping reviews on the topic.

Methods

Overview

The research methodology will involve the utilization of the Arksey and O'Malley [18] approach for scoping reviews, comprising the following steps: (1) identify the research question; (2) identify relevant studies; (3) perform study selection; (4) extract and chart the data; and (5) collate, summarize, and report the results. The scoping review methodology will be guided by this framework, and the protocol will follow the relevant PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines [19]. The review protocol was registered in the Open Science Framework [20].

Identify the Research Question

As per Levac et al [21], the research question intended for exploration in this review has been clearly articulated and focused. The question being investigated in this exploratory literature review is "What were the challenges and strategies adopted for remote biochemistry teaching during the COVID-19 pandemic?"

Participants, Concept, and Context Framework for Eligibility Criteria

The inclusion of eligible studies in this scoping review will be guided by the Participants, Concept, and Context framework [22].

Participants

This scoping review will include studies that involve students who participated in biochemistry courses at undergraduate or postgraduate levels, delivered remotely.

Concept

The focus of the study is to analyze the challenges and strategies adopted for remote biochemistry teaching, covering both theoretical and practical approaches, during the COVID-19 pandemic. Studies discussing pedagogical methods, online teaching tools, adaptation of laboratory practices, and other approaches to maintaining the quality of distance education will be considered.

Context

Only studies conducted during the COVID-19 pandemic will be included, as the objective is to explore how biochemistry teaching was adapted and the challenges faced during this specific period. Studies published in any language will be considered.

Exclusion

Duplicate articles, editorials, reviews, conference proceedings, theses, dissertations, and monographs will be excluded.

Identify Relevant Studies

The literature search will be performed from January 2020 to December 2023, during the time period when articles related to tools used for remote teaching during the COVID-19 pandemic were published, in collaboration with a specialized librarian, using an iterative approach. Following the formulation of the question, keywords will be identified ("Teaching"; "Biochemistry"; "Distance Education"; and "COVID-19") that managed to capture articles related to the topic, namely "translational medical research" (Medical Subject Headings terms) and "knowledge translation."

The following databases will be consulted: National Library of Medicine (PubMed), MEDLINE, Scopus, Directory of Open Access Scholarly Resources, Education Resources Information Center, Directory of Open Access Journals, and Google Scholar, through descriptors and their synonyms, according to the Health Sciences Descriptors and Medical Subject Headings, for each item of the strategy (Tables 1 and 2). For the combination of descriptors, the Boolean terms AND, OR, and NOT will be considered.

After conducting the search, the following will be included: studies conducted in English and Portuguese languages, with quantitative and qualitative approaches; primary studies, systematic reviews, meta-analyses, and meta-syntheses; and books and guidelines published in indexed sources that address the established question.

Duplicate articles, editorials, reviews, conference proceedings, theses, dissertations, monographs, undergraduate final projects, opinion publications, consensuses, retractions, editorials, websites, and advertisements disseminated will be excluded.

Perform Study Selection

The citations gathered will be transferred to Mendeley Reference Manager for Desktop (version 2.109.0; Elsevier Ltd.) after the search, and the duplicates will be manually removed. Following this, 2 reviewers (TI and JCA) will independently assess titles and abstracts for eligibility using the Participants, Concept, and Context framework. Full texts of potentially relevant articles meeting the eligibility criteria will be retrieved for the 2 reviewers to scrutinize and compare against the inclusion criteria. In case of discrepancies during any phase of article selection between TI and JCA, resolution will be sought through discussion or consultation with ARdAL, the third reviewer. The final scoping review will feature a descriptive account of the search and study selection process alongside a PRISMA-ScR flow diagram [15].

Extract and Chart the Data

The data from all eligible studies will be extracted and processed through data charting. This process involves extracting information from the selected full-text articles. A Microsoft Excel table will be created for this purpose, encompassing sections, such as title, authors, year of publication, geographic area, study objectives, pedagogical approaches, collaborative learning activities, resources adopted, and summary of findings.

Collate, Summarize, and Report the Results

The characteristics of each identified study will be summarized and described (eg, author name, study location, and year of publication), along with the pedagogical approach used in teaching biochemistry; the learning activities, content, and resources used; and any evaluation by students of the strategies used by their professors.

Results

Initiated in February 2022, the protocol for this scoping review was anticipated to wrap up by July 2024. The research process yielded 1171 results, from which 85 articles were selected. Verification of duplicates has not yet been conducted, and this will be carried out in the next stage of the work.

The outcomes of this scoping review on teaching strategies for biochemistry will be conveyed through a blend of descriptive narrative, graphical, and tabular formats. The presentation will be structured to underscore the various pedagogical approaches relevant to the field. These findings will be shared through regional and national scientific conference presentations, as well as publication in a peer-reviewed journal.

Discussion

Expected Findings

During the COVID-19 pandemic, the teaching of undergraduate and graduate courses in the health care field faced significant challenges [9]. The interruption of in-person laboratory activities and the need for quick adaptation to online teaching were some of the main obstacles [11,12]. Furthermore, the lack of access to laboratories and the disruption of clinical practice affected the development of essential practical skills for students [4].

However, some advantages were identified with the strategies adopted by teachers and institutions during the pandemic [8,17]. For instance, the use of online resources such as prerecorded videos and animated slides allowed for greater efficiency in academic work [1,5]. In addition, engaging in vital scientific activities such as reading articles and preparing presentations, coupled with the flexibility provided by remote learning, which enabled greater student participation, contributed to the cognitive development and enhancement of communication and technological skills of the students [1,4,5].

Considering these observations, continuing remote teaching strategies after the pandemic can bring various benefits [8]. The learning flexibility offered by online classes allows students to access content conveniently and effectively, promoting greater inclusion and expanding access to education [5,16]. Moreover, the possibility of continuous material review facilitates understanding and reinforces learning [1].

It should be emphasized that the use of educational technologies helps students develop essential digital skills for the current and future job market [5]. Therefore, blending educational strategies developed during the pandemic with in-person classes could bring additional opportunities for the improvement of teaching and learning not only in biochemistry but also in other disciplines [6,7].

In addition, this scoping review presents limitations. Specifically, there will be no evaluation of the quality of the studies included. There is a possibility of overlooking pertinent data, given that our search is restricted to published studies exclusively. We have chosen multiple sources and formulated meticulous search strategies to enhance the identification of eligible studies.

Conclusions

The results of this review are expected to bring forth ideas for new pedagogical approaches and identify learning activities, content, and resources that facilitate social and collaborative learning processes, both for biochemistry and other disciplines. In addition, insights from students and teachers regarding the activities developed will be provided, aiming to apply them as additional strategies to enhance student engagement, and consequently, learning and the development of various skills.

Acknowledgments

We would like to thank Zélia Cristina Regis at the Faculty of Medicine of São José do Rio Preto (FAMERP) for her contribution to the development of the research process.

Authors' Contributions

TI, HLGC, ARdAL, and JC conceptualized, designed, and interpreted the data and were the main contributors to writing the manuscript. ABGC, NBGC, VMSB, and DRSS analyzed and interpreted the data. TI, ERdS, NAdASRC, FNFJ, AH, and CM have supervised and revised the final draft.

Conflicts of Interest

None declared.

Abstract

Background: There is a scarcity of data on males' health-seeking behavior, as well as their access to and use of health care services, in Africa. According to some studies, men are less likely than women to seek medical help for issues such as communicable and noncommunicable diseases, depression, substance abuse, physical disabilities, and stressful life events. The study of males' health-seeking behaviors is important, because it allows us to learn about male health, how masculinity encourages underuse of health care services, how this affects males' overall health and well-being, and how cultural values and backgrounds may impact older men's health-seeking behaviors.

Objective: The objective of this review is to assess evidence on how males access and use health care services and their health knowledge, attitudes, and perceptions to identify gaps for targeted, context-specific strategies to improve males' health and outcomes, particularly in Africa.

Methods: The scoping review process will be guided by the methodology frameworks of the Joanna Briggs Institute and Arksey and O'Malley and will follow the Preferred Reporting Items for Systematic reviews and Meta-analysis Protocols Extension for Scoping Reviews guidelines. The following electronic databases will be systematically searched for evidence published between January 2010 and 2023: PubMed, Scopus, Web of Science, African Journals Online, and Google Scholar. Two reviewers will independently screen full texts and chart the data; a third reviewer will be engaged in the event of disagreement between the 2 independent reviewers. The results of this scoping review will be summarized quantitatively through numerical counts and qualitatively through a narrative synthesis.

Results: The electronic database search was conducted between March and April 2023 and redone in April 2024 to include the most recent articles. A total of 114,737 articles were retrieved and 4258 removed as duplicates. After title screening, 337 results remained, and after abstract selection, 140 results remained. As of December 2024, the scoping review was in the full-text screening phase. We plan to complete data extraction, synthesis, and writing of the entire manuscript of the review in January 2025, and then submit it to a journal for peer review and publication in February 2025.

Conclusions: The scoping review results will advance the current knowledge about health-seeking behavior and access to and uptake of health care services among African males. To our knowledge, this scoping review is the first on this topic, and it will identify vital information on the barriers to and facilitators of African males' health care access and uptake. It will also provide information on successful health care programs for males that may be tailored and adopted across different African contexts.

Introduction

The World Health Organization (WHO) defines health as "a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity" [1]. Sustainable Development Goal 3 complements this definition by pinpointing the need for global commitment to "ensure healthy lives and promote well-being for all at all ages" without exclusion [2]. Admirable and essential as these intentions may be, their success is incumbent upon reaching key populations so that the health care requirements of those populations may be fulfilled. Males the world over are one such key population, and they generally underuse the health care opportunities available to them [3-5]. This is concerning, since it is projected that men's health burden will result in men's lifespans being 7 years less than women by 2030. In South Africa, the male health risk and mortality rates are high due to tuberculosis, as well as noncommunicable diseases like diabetes and cardiovascular diseases, all of which are mostly preventable [6]. There are various reasons for men delaying or avoiding seeking health interventions, with some of the most regularly identified ones being a paucity of male-centered interventions, sociodemographic factors, and attitudes toward health services [7-9]. Nonetheless, there is evidence that a shift in males' attitudes is emerging and that they are becoming increasingly willing to access health care. Consequently, there is a drive to not only provide health care services that cater specifically to men and minimize the barriers to their seeking health care, but also to increase research in this field [8]. Our research will thus add to the body of knowledge that is used to fulfill the aforementioned commitment.

"Men" is a broad term; according to the WHO, there are different terminologies, age ranges, and characteristics used to describe the transition from childhood to adulthood for men. Adolescence has been described as the ages of 10 to 19 years and young adulthood as 10 to 24 years [10]. Guided by these clarifications, the age range in our scoping review included all male-related studies involving individuals aged 13 to 17 years as teenagers and those aged 18 years and older as adults. This age range of minors was included due to the fact that the onset of the teenage years is when young people experience "physiological, psychological, and social changes that lay bare the world of sexual experimentation" [11] and the consequences thereof, which may call for health care. This was deemed significant as it could yield a better understanding of males in this population, specifically with regard to their sexual reproductive health practices. Another population that was deemed significant to our study was transgender males, as their health-seeking behavior is currently underresearched, despite their experience of inordinate health risks and challenges [12].

An examination of health policies of 10 low- and middle-income countries revealed that health care priorities in these countries are largely driven by cost-saving measures and the types of disease that are prevalent. This means that health care priorities can differ significantly across geographical areas. Nonetheless, in most sub-Saharan countries, HIV is prioritized, with lymphatic filariasis, syphilis in pregnant or new mothers, human papilloma virus, tuberculosis, and sexually transmitted diseases being other common conditions [13]. What is striking is that not only are none of these conditions unique to males, but some of them are solely female focused. This is concerning because it conveys the impression that particularly male diseases are not a high priority. For example, the incidence of prostate cancer is escalating in West Africa, and treatment is usually delayed for so long that the health outcomes for men with the condition are dismal. Further, men with prostate cancer symptoms either remain ignorant of the disease or are too poor to seek treatment [14]. Equally dangerous are unhealthy lifestyle choices, like smoking and alcohol abuse, which are more prevalent among men, as well as some chronic diseases like diabetes and cerebrovascular disease, two of the main causes of death in men over the age of 45 years: the South African government has recently acknowledged all of these conditions as worthy of being addressed [4]. It is therefore not unreasonable to conclude that improved health literacy targeted specifically at males could help to mitigate their life-threatening health conditions and choices [15].

Apart from the obvious benefits of disease management, males who are inspired and empowered to take control of their own health can inadvertently improve the lives of their families, as well as society in general. Economically, better health would, in the long run, reduce medical costs that would usually be borne by the family and in some part, the government. Socially, healthy men would more likely be able to lead an active life in which they do not feel compelled to avoid health care to preserve their masculinity, nor fear stigmas associated with, for example, mental health conditions or undergoing antenatal HIV screening with their partners [8,16].

But, within the ambit of our study, we first have to ascertain what strategies have the most reasonable chance of uptake to be able to speculate on the benefits of males engaging in health-seeking practices. What has to be borne in mind is that men's health-seeking behavior, which in Africa is influenced by a particularly patriarchal ethos, limited resources, and faith in traditional medicines and cultural superstitions [8,17], may not necessarily match the behavior of males in countries that do not share similar characteristics.

In essence, this scoping review will seek to describe the variations in health-seeking behaviors among males across the African continent, assess their access to and use of health care services, and identify both challenges and facilitators of health care uptake. Additionally, it will explore males' knowledge, attitudes, perceptions, and beliefs regarding their health care needs and available services. The overall goal is to assess the

current evidence on these factors to guide the development of strategies that enhance males' health and improve outcomes across the region. To this end, the primary objective of this scoping review is to map evidence on males' access to and use of health care services and identify gaps for targeted, context-specific strategies to improve males' health outcomes, particularly in Africa.

Methods

Study Design

We will use a scoping review approach to map out existing evidence on males' health-seeking behavior and access to and uptake of health care services in Africa. This will enable us to identify aspects for tailored intervention to improve males' health-seeking behavior. In conducting this review, we will apply the methodological approach and review process of the Joanna Briggs Institute (JBI) [18]. The JBI framework enables an extensive and less-biased synthesis of studies by using comprehensive and transparent methods [19]. The JBI framework synthesizes existing knowledge rather than creating new knowledge [20]. This yields decisions that reflect on the feasibility, appropriateness, meaningfulness, and effectiveness of health behavior [19,20] The Preferred Reporting Items for Systematic reviews and Meta-analyses extension for Scoping Reviews (PRISMA-ScR) guidelines [21,22] will be adhered to in reporting this scoping review. The PRISMA-ScR guidelines are congruent with the JBI approach for scoping reviews, which emphasizes the importance of methodological precision for scoping reviews. We believe that the PRISMA-ScR will improve the reporting of our scoping review [22]. According to the 5 main steps [18], we discuss our review process in the following sections.

Step 1—Identifying the Research Question

The scoping review questions will be formulated according to the population, concept, and context (PCC) approach recommended by the JBI. The PCC framework is suitable when developing objectives and eligibility criteria for scoping reviews [23]. In our study, the PCC inclusion criteria will be useful to guide how the data should be extracted. There is no need for outcomes or interventions of interest to be identified for a scoping review [24] (Table 1).

Based on the PCC framework mentioned above, the research questions we will explore are outlined below:

1. What are the varying health-seeking behaviors among males across the African continent?
2. What are health services for males and how do males access and use health care services in Africa?
3. What knowledge, attitudes, perceptions, and beliefs exist among males about their health care needs and health care services in Africa?
4. What are the challenges and facilitators of health care uptake by males in Africa?

Table 1. The population, concept, and context (PCC) elements in this review.

Element	Description
Population	Males only
Concept	Health-seeking behavior; health care service access, use, and uptake
Context	Africa

Step 2—Identifying Relevant Studies

We will systematically search PubMed, African Journals Online, Web of Science, Scopus, and Google Scholar. The search will include papers with publication years from 2010 to 2023 to better reflect more recent information and current health-seeking behavior among males across the African continent. In addition, government reports available on the websites of departments and ministries of health and associations will be reviewed with a focus on males' access to health care services, knowledge, perceptions, and attitudes regarding health care services, as well as barriers and facilitators to uptake of health services by males. This will help us to identify reports related to males' health-seeking behavior in Africa.

The search strategy will include titles, abstracts, and combinations of keywords, as presented in Multimedia Appendix 1 and Multimedia Appendix 2.

Step 3—Study Selection

After collection of study data from the aforementioned bibliographic databases, 3 reviewers will conduct the review; 2 will perform data selection and database searching and the third will perform quality checking and resolve inclusion and exclusion disagreements between the 2 primary reviewers. The 2 primary reviewers will independently use the inclusion and exclusion criteria to search the titles and abstracts, and they will document reasons for inclusion and exclusion as outlined below. Any discrepancies will be discussed and resolved between these 2 reviewers, but if no conclusion can be reached, the third reviewer will be included in the discussion. Furthermore, the reviewers will independently source full-text versions of articles found to be eligible during the title and abstract screening phase. They will exclude articles without full-text versions available after a conclusive discussion regarding the excluded articles is reached. The searched articles will include male-related studies and include qualitative, quantitative, and mixed methods interventions for males' health, knowledge, attitudes, and perceptions regarding health services for males, as well as access and challenges to use of health care services. Overall, this scoping review will include material that fulfill the criteria outlined in Tables 1 and 2. The exclusion criteria entail studies not conducted in Africa; not including males' health care service access and uptake or health-seeking behavior; and those conducted prior to 2010.

Table 2. The eligibility criteria.

Criteria for study inclusion	Component details
Setting	Only studies from Africa will be considered for the scoping review.
Language	Only English-language studies will be included.
Date	Only studies from the years 2010 to 2023 will be included.
Publication status	All documented studies will be considered and included in the scoping review. This will include only published peer-reviewed articles.
Method	The study will be designed and reported according to the Preferred Reporting Items for Systematic reviews and Meta-Analyses extension for Scoping Reviews. Population, concept, and context will be used as the search strategy approach. Qualitative, quantitative, and mixed methods studies will be included.

Step 4—Charting the Data

Data from the identified eligible studies will be collected and charted. Reviewers will record key themes from each eligible article. The themes will include author, journal, publication status, study duration, year, and demographic information (age, ethnicity, marital/relationship status, employment, residential location [rural or urban], income, and education level), geographical information (country and region in which the study was done), research methodology, and findings included in the synthesis (study design, health-seeking behavior, access, uptake, intervention, main results and outcome, limitations, and other important discoveries; Textbox 1). Microsoft Excel, EndNote, and Rayyan will be used in obtaining the data, saving the search, cleaning the data, screening the data, and charting the data for this scoping review.

Textbox 1. Data chart template (to be expanded during actual review).

Details of elements included in the synthesis

- Author
- Journal
- Publication status
- Study duration
- Year

Demographic information on participants in the synthesis

- Age
- Residential location (rural or urban)
- Ethnicity
- Marital/relationship status
- Income
- Employment
- Education level

Geographic information in the synthesis

- Region where the study was done
- Country

Research methodology and summary findings in the synthesis

- Study design
- Health-seeking behavior
- Access
- Uptake
- Intervention
- Main results and outcome
- Limitation
- Other important discoveries

Other comments, if any

Step 5—Collating, Summarizing, and Reporting the Results

A qualitative and quantitative approach will be used to report and summarize the scoping review. The number and type of eligible studies will be reported numerically, and methods, results, health care services, program, and health-seeking behavior information will be described in a narrative form. Tables and charts will be used to map out the screening process and results. Discussion will be guided by developed themes and study objectives and will include definitions of keywords. The risk of bias will not be assessed, as the scoping review is meant to provide an overview of existing literature about health-seeking behavior of African males and not critically analyze or appraise the selected articles; the limitations of the studies will be noted. Secondary analyses will be performed looking at health-seeking behavior and challenges, knowledge, and stigma regarding access to and uptake of health care services among boys and the transgender population. Analyses will also compare males' health-seeking behavior and service access and use across different regions.

Results

The electronic database search was conducted between March and April 2023 and was redone in April 2024 to include the most recent publications. A total of 114,737 results were retrieved, and 4258 were identified as duplicates. The database was first title screened, and this yielded a total of 337 articles for further abstract screening, which resulted in 140 articles remaining for full article screening. We are currently finalizing full-article screening for the synthesis. We intend to complete the synthesis and initial manuscript write-up in January 2025, for submission for peer review and publication in February 2025.

Discussion

Expected Findings

We expect to substantiate that the burden of disease in males compared to females is high for a plethora of reasons, such as availability of context-specific health care services for males, access by males to health care, and the socioeconomic position of households. Moreover, available evidence has shown that male health-seeking behavior is often delayed, and the uptake of health care services is poor due to barriers such as cultural beliefs, perceptions of masculinity, stigma, gaps in health knowledge, and social and economic factors [25,26]. Based on the limited number of published articles on males' access to and uptake of health care services, especially in Africa, and observations on trends in the proportions by sex of outpatients (ie, there are more females than males) seeking care in primary health care centers [27-30], there is a need for male health care to be taken into consideration. Facilitators like community-based interventions, male-targeted programs, and peer support have been shown to improve male engagement with health care [26]. To our knowledge, this scoping review is the first on this topic, and it will identify key themes and gaps regarding the barriers to and facilitators of African males' health care access and uptake. The scoping review will summarize and discuss our findings, including challenges and facilitators of health care service access and uptake and health-seeking behavior among African males. The results may form the basis for future qualitative research on exploring the health-seeking behavior of African males, quantitative research on barriers to and facilitators of access to and uptake of health care services, implementation research on intervention programs to influence African males to access and use health care services voluntarily, or systematic reviews of programs for working African males to access health care and support systems and increase their health care–seeking behavior. The results may also help policy makers to develop programs and interventions specifically tailored for the needs of males through males' input. The literature synthesis will support the development of evidence-based practices that will address challenges related to males' access to health care services, enhance their health care knowledge, and promote intervention programs to improve uptake, which may result in a decreased burden of disease and mortality rate among males. We expect our main findings to provide insights into what geography-specific health services are available across the African region, as well as provide the latest evidence on the extent of access and uptake, including contributing factors. The results of this scoping review will be disseminated through scientific conference proceedings and presentations, stakeholder meetings, and by publication in a peer-reviewed journal. During the dissemination of findings, stakeholders will be invited to discuss gaps and challenges affecting males' health-seeking behavior and the uptake of health care services to develop context-specific strategies that can be implemented to address the identified gaps and challenges. The dissemination report will also include recommendations for future research, review limitations, and discuss the risk of bias.

Potential Limitations to the Scoping Review

Through this scoping review, we intend to provide a range of information about the health-seeking behavior of males, including their access to and use of health services. However, as we will limit our search to include only published works written in English and implemented in Africa, we are likely to inadvertently exclude relevant programs, thereby skewing the comprehensiveness of the review. Constraints related to the publication type, language, and geographic region will restrict the diversity of the included sources, limiting its applicability across various contexts. Our search strategy did not use the built-in search functionalities of the relevant electronic databases, such as Medical Subject Headings terms for PubMed. Our search strategy might have increased the risk of missing literature. To mitigate this, we constructed a wide range of search terms to ensure a wider reach.

Abstract

Background: Surgical site infections (SSIs) represent one of the most prevalent and significant complications associated with surgical procedures, often leading to prolonged hospitalization and delayed patient recovery. While recent international consensus guidelines have proposed evidence-based strategies to mitigate SSIs, they fall short in addressing the efficient and interdisciplinary implementation of these measures within the operating theater. Consequently, further research is required to identify and evaluate optimal interdisciplinary organizational approaches for the prevention of SSIs.

Objective: This study aims to map the scope, diversity, and nature of research on interdisciplinary strategies aimed at reducing SSIs and to analyze the impact of interdisciplinary on the effectiveness of preventive interventions.

Methods: Using the Joanna Briggs Institute (JBI) methodology for scoping reviews, a comprehensive search will be conducted across databases including Embase (encompassing MEDLINE and PubMed-not-MEDLINE), CINAHL, and the Cochrane Library, supplemented by manual searches of reference lists from included papers. This review targets studies published between 2016 and 2024, aligning with the World Health Organization's 2016 SSI prevention guidelines, which introduced significant advancements in practice and remain the global benchmark. Only studies published in English or French will be considered. Around 5 reviewers independently distributed the included papers for detailed reading and data extraction, while the lead author concurrently and independently reviewed all papers. Inclusion criteria follow the Participants, Concept, and Context (PCC) framework, specifying that the eligible population comprises surgical teams. The primary concept of interest is interdisciplinary strategies aimed at preventing infection risk. The context focuses on adult surgical procedures within the operating room during turnover periods. Studies using experimental, quasi-experimental, preexperimental, observational, case-control, or cross-sectional designs will be included.

Results: From the 1679 papers initially identified, 45 were selected for detailed analysis by 5 reviewers, with the selection process completed by November 2024.

Conclusions: Emerging interdisciplinary strategies demonstrate significant potential in reducing the incidence of SSIs. This initiative forms part of a broader global project focused on codeveloping standardized protocols for preoperative preparation within the operating room to mitigate SSI risks. The findings of this scoping review will serve as the foundation for a subsequent

qualitative survey and a pre-post quasi-experimental quantitative study to evaluate the integration and effectiveness of these strategies in clinical practice. The review protocol will be formally registered in the Open Science Framework (OSF) in 2024.

KEYWORDS

surgical site infection; infection prevention; interdisciplinary strategies; surgical team; operating room; standardized operating procedures

Introduction

Background

The transition to advanced health care technologies is inherently linked to heightened patient safety risks within acute care hospital settings [1]. Operating theaters are environments where multiple risk factors converge, contributing to adverse or severe events. Among these, the risk of infection remains a primary concern and a persistent daily challenge, as infections represent a leading cause of preventable hospital mortality [2]. These infections contribute substantially to morbidity and mortality while also imposing significant additional burdens on health care costs [3]. In Switzerland, surgical site infections (SSIs) are the most prevalent type of health care–associated infection within medical facilities [4].

Adhering to evidence-based practice (EBP) has the potential to significantly reduce infection rates, with the corresponding levels of evidence for SSIs already well-documented in the literature [5]. In the operating theater, the implementation of both standard and procedure-specific precautions is crucial for effective infection prevention [6].

SSIs are nosocomial in nature, occurring after surgical procedures, and primarily influenced by pre-, intra-, and postoperative conditions, host immune response, and surgical cleanliness. Pathogen transmission predominantly occurs through contact, with health care workers' hands serving as a major vector. Effective hand hygiene is paramount in preventing infections, particularly in acute care settings, where it plays a critical role in reducing the incidence of bacteremia, urinary tract infections, SSIs, and ventilator-associated pneumonia [3,7].

Key strategies include maintaining high standards in medical device disinfection, bio cleaning, and surface cleaning to minimize infection risks [8]. Monitoring adherence to disinfection protocols during turnover periods is essential for evaluating interdisciplinary coordination and minimizing contamination risks [9]. Adherence to current guidelines is crucial, given the rapidly evolving nature of EBP, as many practices once deemed acceptable are now considered contraindicated [10,11].

The World Health Organization (WHO) and Society for Healthcare Epidemiology of America (SHEA) recommendations for SSI prevention differ slightly in the level of evidence [2,10]. However, consensus exists regarding key practices, such as appropriate hair removal, surgical hand preparation, the use of alcohol-based skin antiseptics (eg, chlorhexidine gluconate solutions), optimal timing of antibiotic prophylaxis, and effective glycemic control [7,12,13]. Emphasis is also placed on the development of soft skills, the implementation of checklists, adherence to bundled care protocols, SSI monitoring, and providing feedback to operating theater staff members as key strategies for enhancing patient safety [5,12,14,15].

Low compliance with SSI prevention measures persists due to the challenges associated with implementing clinical guidelines effectively. Globally, only 29% of tertiary hospitals across 133 countries have established infection prevention and control (IPC) programs. In Switzerland, according to Swissmedic (2022), 93% of 35 surveyed institutions out of 300 reported deficiencies in critical areas, including procedural adherence, staff training, the presence of hygiene specialists, and cognitive dissonance within operating theater teams.

Operating theaters demand the coordinated efforts of surgeons, anesthetists, technicians, and nurses to deliver high-quality care. Effective IPC depends on robust collaboration, clear communication, cohesive teamwork, and streamlined logistics across various hospital disciplines [16]. The complex and highly technical environment of operating theaters, combined with the diverse professional backgrounds of team members, necessitates effective interprofessional collaboration, particularly in time-sensitive situations [17]. Managing human error in the perioperative period remains a major challenge [18-24].

Interprofessionality emphasizes practical collaboration among skilled professionals, while interdisciplinary focuses on integrating knowledge from diverse academic disciplines to address complex challenges. Both approaches are essential for effective IPC in health care settings.

Although expert guidelines from organizations such as WHO, SHEA, Infectious Diseases Society of America (IDSA), Association for Professionals in Infection Control and Epidemiology (APIC), and American Hospital Association (AHA) provide a strong foundation, they lack sufficient specificity regarding the interdisciplinary applications required for SSI prevention in operating theaters [10]. A preliminary search revealed a lack of recent systematic reviews, underscoring the necessity of investigating and evaluating effective interdisciplinary strategies for reducing SSIs.

Review questions:

1. What are the interdisciplinary strategies to reduce SSIs in the operating theater?

2. What are its characteristics?

3. What improvements have been observed concerning the interventions and their evaluation?

4. Would it be possible to apply a model considering the culture and the local specificities?

Study Aim

This scoping review seeks to map the scope, diversity, and nature of existing research on interdisciplinary strategies for reducing SSIs. The objective is to identify patterns, gaps, and innovations in the literature while evaluating how the integration of diverse disciplinary approaches enhances outcomes in SSI prevention.

Methods

Overview

The proposed scoping review will be conducted according to the Joanna Briggs Institute (JBI) methodology for scoping reviews [25] and the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) [26].

Search Strategy

A 3-step search strategy will be used for this review. Initially, a preliminary limited search was conducted in MEDLINE (via PubMed) to identify relevant papers on the topic. The text words in the titles and abstracts of these papers, along with the index terms used to describe them, were extracted and cataloged for use as search terms. The second step involves a comprehensive search incorporating all identified keywords and index terms, tailored for each database and information source. Databases to be searched include CINAHL (Multimedia Appendix 1), Embase (Multimedia Appendix 2), MEDLINE (Multimedia Appendix 3), and the Cochrane Library (Multimedia Appendix 4).

The third step comprises a manual search of the reference lists of all included papers to identify additional studies meeting the inclusion criteria. This review focuses on studies published between 2016 and 2024, a period defined by the WHO's designation of SSIs as a global priority and the release of its prevention guidelines. This time frame reflects significant advancements with outdated practices being phased out. Priority was given to studies adhering to these guidelines as no major updates have been introduced since their publication.

Systematic reviews conducted by organizations such as the Centers for Disease Control and Prevention, SHEA, and others broadly align with WHO recommendations, with variations primarily in evidence grading. Additional studies were identified through reference list searches of included papers. Only papers published in English or French were included in the review.

Inclusion Criteria

The Participants, Concept, and Context (PCC) framework was used to guide the identification and selection of studies for inclusion in this review [25].

Participants

The eligible population comprises surgical teams, encompassing all professionals involved in patient preparation within the operating room immediately before surgery. This includes surgeons, anesthetists, anesthetic nurses, registered nurses, scrub nurses, instrument technicians, and nursing assistants. Papers will be included if they address the involvement of at least 3 distinct disciplines [6].

Concept

This review focuses on interdisciplinary strategies for IPC. Interdisciplinary in this context does not merely refer to the diverse characteristics of personnel, such as education or professional roles, but rather to a coordinated framework for joint action, exemplified by standard operating procedures. These interdisciplinary approaches leverage shared mental models and visual triggers to activate synchronization among team members. Such frameworks have been described and validated in other industries, such as task-sharing standard operating procedures used by Airbus in cockpit operations. Papers will be included if they report on at least one interdisciplinary strategy.

Context

The specific context is adult surgical procedures within operating theaters during turnover, defined as the period between the closure of one patient's surgical wound and the incision of the next. This turnover period is critical for infection prevention through measures such as antibiotic prophylaxis and skin preparation. In adult surgeries, turnover often involves high-risk procedures, necessitating robust infection control strategies. Only studies that report interventions during turnover in adult surgical settings will be included; those focusing on pediatric surgery or unrelated contexts will be excluded. A significant body of EBP emphasizes reducing infection risks during this critical transitional phase.

Types of Sources

This scoping review will include experimental and quasi-experimental study designs, such as randomized controlled trials, nonrandomized controlled trials, before-and-after studies, and interrupted time-series studies. In addition, analytical observational studies, including prospective and retrospective cohort studies, case-control studies, and analytical cross-sectional studies, will be considered for inclusion. Publications such as editorials, commentaries, letters, conference proceedings, and gray literature will be excluded as the focus is on identifying effective and validated interdisciplinary models.

Study or Source of Evidence Selection

Following the search, all identified citations will be compiled and uploaded into EndNote 20 (Clarivate), where duplicate entries will be removed. After conducting a pilot test, titles and abstracts will be screened by 2 independent reviewers to determine their alignment with the inclusion criteria. Study selection will involve a dual-review process of titles and abstracts, followed by a thorough analysis of the full text. In cases of discrepancies, a third reviewer will be consulted to reach a consensus. Full-text versions of potentially relevant sources will be retrieved and their citation details will be imported into the JBI System for the Unified Management, Assessment, and Review of Information (JBI) [27]. Around 5 reviewers will independently evaluate the full text of selected citations against the inclusion criteria. Reasons for excluding

sources that do not meet these criteria will be systematically documented and reported in the scoping review. To ensure thoroughness and consistency, all reviewers will collectively read and analyze a subset of the included papers, while the lead author will independently review all included papers to guarantee a comprehensive and unbiased assessment.

Any disagreements among reviewers at any stage of the selection process will be resolved through discussion or, if necessary, with the involvement of additional reviewers. The search results and study inclusion process will be fully documented in the final scoping review and presented using a PRISMA-ScR flow diagram.

Data Extraction

A total of 5 reviewers divided the included papers among themselves for in-depth reading and data extraction, while the lead author independently reviewed all papers in parallel. In cases of confusion or disagreement, the extraction files were compared and discussed with the relevant reviewer to ensure accuracy and consensus. All reviewers used a custom-designed data extraction tool (Data extraction instrument, Multimedia Appendices 5-8; Textbox S1 in Multimedia Appendix 9) to systematically collect data from the studies included in the scoping review.

The data extracted includes detailed information on participants, the concept under investigation, the context, study methodologies, and key findings pertinent to the review question. In addition, general information about each study, as well as its methods, characteristics, and results, will be documented to provide a comprehensive overview. The draft data extraction tool will be adapted and refined as necessary to ensure the accurate extraction of data from each included evidence source. Any modifications made to the tool will be documented in detail within the scoping review. Disagreements among reviewers regarding data extraction will be resolved through discussion or, if required, with the involvement of an additional reviewer. Where appropriate, the authors of the included papers will be contacted to obtain missing or supplementary data.

Results

From the 1679 papers initially identified, 45 were selected for detailed analysis by 5 reviewers, with the selection process completed by November 2024.

The interprofessional perspectives and interdisciplinary interventional components of various strategies aimed at reducing SSIs in the operating theater will be thoroughly detailed. The review will specify whether these interventions were introduced and developed within the framework of a particular implementation model or care concept. In addition, key elements of the triggers synchronization bundle, which facilitate safe organizational practices, proper procedural sequencing, and the delivery of high-quality care, will be highlighted. At the beginning of the year 2025, the identified preventive strategies will be presented through narrative syntheses and summary tables, supplemented by graphs illustrating the distribution of studies and emerging trends related to the scoping review questions. General extraction information will be summarized in a descriptive table (Textbox S1 in Multimedia Appendix 9) and further detailed (Multimedia Appendix 5) for each category. These categories include years of publication, study locations, study designs, sample sizes, and participant demographics. In addition, for the observed interventions, it will be specified whether they fully or partially align with EBP and international recommendations.

Discussion

Overview

We are conducting a comprehensive review of the literature to identify the most effective multidisciplinary models implemented in operating theaters for reducing SSIs. Our objectives are to characterize the key features of these models, evaluate their impact on organizational outcomes, and explore their association with SSI rates. While it is likely that we will identify efficient models, establishing a definitive hierarchy of their effectiveness may be challenging due to the unique characteristics inherent to each surgical specialty. However, several interdisciplinary practices are expected to exert significant influence—either positively or negatively—on the incidence of SSIs.

Our goal is to propose a generalizable model applicable across the majority of surgical specialties, focusing on improving practices and enhancing communication within the operating room to reduce variability. Furthermore, we aim to identify a replicable model suitable for implementation in Switzerland, emphasizing the importance of a collaborative approach adapted to the specific constraints of health care settings.

Evidence-based interdisciplinary strategies have demonstrated effectiveness in reducing SSIs. Research indicates that the successful implementation of care bundles is frequently associated with improvements in process outcomes rather than direct patient outcomes. Nonetheless, patient outcomes consistently show significant reductions in postoperative infection rates when interdisciplinary interventions are rigorously applied [28]. A significant challenge lies in ensuring the consistent engagement of health care professionals, particularly surgeons, in implementing interdisciplinary strategies. The studies reviewed predominantly offer moderate-quality evidence, highlighting the pressing need for standardized approaches and tools to enhance the effectiveness and reproducibility of interventions [29]. However, the concept of interdisciplinary remains underexplored in the existing literature. While support and training programs are frequently emphasized, no singular pivotal factor emerges as decisively shaping the health care system or fostering interdisciplinary collaboration. Notably, critical principles such as decompartmentalization and care synchronization—core components of the cognitive model bundle developed by the Airbus industry to optimize team efficiency—have yet to be systematically identified or applied within this context.

Limitations

This scoping review is restricted to adult patients and the included papers are limited to those published in English and

French, which may result in the exclusion of some relevant evidence. In addition, in several selected studies, the outcome measures are not reported, complicating the evaluation of the interventions' impact on SSI rates. Even when SSI rates are provided, the variability in monitoring methods must be taken into account, as it can influence the interpretation and comparability of results.

Conclusions

Emerging interdisciplinary strategies demonstrate promising potential for the prevention of SSIs and could be effectively replicated in Switzerland through a tailored implementation model. The bundles of care analyzed in this review appear to be robust in structure; however, the quality of interdisciplinary and their implementation in the operating theater remains challenging to evaluate, with adherence to recommended practices consistently falling short of optimal levels. The need for standardization of these bundles is frequently emphasized across studies.

Notably, this review did not reveal significant innovations, underscoring a gap in the literature. It forms part of a global initiative to cocreate a standardized approach to preoperative preparation in the operating room to reduce SSIs. While studies often highlight what should be done, they rarely address how to implement these measures effectively, pointing to an urgent need for innovative and actionable strategies. This presents an opportunity to develop a coconstructed model in collaboration with surgical teams, ensuring its feasibility and effectiveness through evaluation in real-world clinical settings.

Acknowledgments

We thank Dr Rita Nugem for her careful proofreading and valuable advice and the Nurse Directorate of HUG for its support. Open Access funding for this research was provided by the research fund of the Care Directorate at HUG. The doctoral studies for DJ are partially funded by the Geneva University Hospitals.

Authors' Contributions

DJ and SB contributed to conceptualization. DJ, SB, AR, and CD assisted with methodology. SK, CB, AH, AW, SB, and DJ performed data curation. DJ was involved in writing–original draft. SB and AR were involved in writing–review and editing. CD and AR performed supervision.

Conflicts of Interest

None declared.

Abstract

Background: There has been a rapid growth in the literature on the design and evaluation of assistive technologies for people with visual impairments; yet, there is a lack of a comprehensive analysis of the existing literature on the classification of immediate-, short-, medium-, and long-term psychosocial impact of assistive technologies on the quality of life of people with visual impairments.

Objective: This protocol outlines the methodology for a scoping review aimed at identifying and synthesizing the existing literature on the psychosocial impact of assistive technologies on the quality of life of people with visual impairments.

Methods: The review will include primary research studies published in English between 2019 and 2024 that focus on the psychosocial outcomes of assistive technologies for people with visual impairments. Eligible studies will involve participants with visual impairments, of all ages and across various settings, examining psychological (eg, emotional well-being and self-esteem) and social outcomes (eg, social participation and support). Searches will be conducted across 7 electronic research databases: CINAHL (EBSCO), PsycINFO (EBSCO), ACM Digital Library, IEEE Xplore, Scopus, Web of Science, and Google Scholar (first 100 records). Studies will undergo screening and selection based on predefined eligibility criteria, with data extraction focusing on publication details, study design, population characteristics, type of assistive technology, and psychosocial impacts. Results will be summarized using descriptive statistics, charts, and narrative synthesis.

Results: The database search, conducted in July 2024, identified 1145 records, which will be screened and analyzed in subsequent stages of the review process. This protocol outlines the planned approach for identifying, categorizing, and synthesizing evidence. The study findings are anticipated to be finalized and submitted for publication in a peer-reviewed journal by February 2025.

Conclusions: This study will synthesize the recent body of work on the psychosocial impact of assistive technologies for people with visual impairments and recommendations for researchers and designers interested in this research area.

Introduction

Background

Globally, visual impairment affects approximately 1 billion people [1]. Visual impairment significantly impacts people's quality of life, affecting activities of daily living, education, employment, and social interactions [2-4]. The most prominent effects of vision loss are loss of independence and social isolation, leading to anxiety, depression, and other mental health conditions [4]. Due to this, many people with visual impairments

experience low self-esteem and self-efficacy in their mobility and social interaction [5]. Furthermore, the participation of people with visual impairments in leisure activities is low. Where they do, people with visual impairments participate in passive leisure activities (eg, watching television and listening to the radio) rather than actively participating in physical activities, social interaction, and sports in outdoor places [6]. Research shows that people with visual impairments have low mental health outcomes and overall quality of life compared to sighted people [4,7,8].

The World Health Organization [9] defines assistive technology (AT) as an umbrella term for assistive products, systems, and services designed to maintain or improve one's functioning related to cognition, communication, hearing, mobility, self-care, and vision, therefore promoting health, well-being, inclusion, and participation. The European Parliament research report on AT for people with disabilities [10] distinguishes among five types of ATs for blindness and visual impairment: (1) haptic aids (eg, the white cane, the traditional Braille system, embossed pictures, advanced Braille apps, advanced canes, haptic aids for computer use, and matrices of point stimuli), (2) traveling aids (eg, low-technology haptic aids, obstacle and object location detectors, electronic travel devices, assistive apps in mobile phone technology, embedded technologies, and mixed systems), (3) AT for accessible information and communication, (4) AT for daily living (eg, labeling systems, talking readers, tactile and vibrating clocks and alarms, talking kitchen tools, and talking wallets and purses), and (5) phone and tablet apps (eg, magnification apps, color detection apps, money identification apps, object identification apps, scan and read apps, screen reading apps, voice recognition apps, location and GPS apps, and Braille apps).

Mashiata et al [11] classified ATs for visual impairment into four categories: (1) based on portability (eg, nonwearable devices such as smart canes and assistant robots and wearable travel aids such as head-mounted, ear aids, belt-mounted, blind shoes, glasses, and gloves), (2) based on navigation (eg, audio-tactile maps, indoor, indoor-outdoor, and outdoor such as smart city or urban navigation, vehicle detection, airport accessibility, shopping guide, and pedestrian navigation), (3) based on detection (eg, object recognition and obstacle detection, including vehicle detection, pedestrian detection, staircase, and daily life objects), and (4) based on smartphone assistance (eg, digital assistants, mobile apps, including voice maps, voice search, and mobile games).

Over recent decades, disability has stopped being viewed solely in functional terms. Frameworks such as the International Classification of Functioning, Disability and Health and the World Health Organization Quality of Life [12] now emphasize the importance of psychological and social dimensions in understanding and enhancing the quality of life for individuals with disabilities. However, much of the existing research on the impact of ATs has primarily focused on the functional outcomes associated with their use and attributed the poor uptake of these technologies to functional issues [13,14]. Two key points should be raised in relation to this. First, ATs continue to be designed from a biomedical, deficiency-oriented rather than a psychosocial, person-centered approach, failing to effectively fulfill users' needs [15]. Second, researchers have overlooked the role of psychosocial factors in the perception and use of ATs, which may better explain their acceptance and uptake, prompting the development of instruments such as the Psychosocial Impact of Assistive Devices Scale [13] to address this gap.

As with other disabilities, prior research has mainly focused on the functional outcomes of AT and rehabilitation interventions for people with visual impairments [16-18]; yet, there is a lack of a comprehensive review of the literature to understand the psychological and social impact of AT for this population. This review aims, therefore, to comprehensively examine the research investigating the short-, medium-, and long-term psychosocial impact of AT for people with visual impairments.

Objectives and Review Questions

This scoping review aims to answer the following questions: (1) What psychological and social outcomes are associated with the use of ATs among people with visual impairments? (2) What methods and instruments are used to measure the psychosocial impact and outcomes of ATs for people with visual impairments? (3) What are the key trends in the literature in relation to the population characteristics, countries of study, settings, type of ATs examined, impact period, and research methodologies used to assess the psychosocial impact of ATs for people with visual impairments?

Methods

Ethical Considerations

Ethics approval is not required for this study, as human participants were not involved.

Study Design

This scoping review will be conducted following the framework proposed by Arksey and O'Malley [19], which includes six stages: (1) identifying the research question; (2) identifying relevant studies; (3) study selection; (4) charting the data; (5) collating, summarizing, and reporting the results; and (6) consultation. Methodological recommendations from the Joanna Briggs Institute [20] and the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) checklist [21] will also inform the process.

Stage 1: Identifying the Research Question

The primary research question guiding this scoping review is: What are the psychosocial impacts of ATs on people with visual impairments? This question arose from the recognition that while ATs are often evaluated for their functional efficacy, their broader psychosocial impacts have been less explored, despite these impacts potentially being equally or more important in encouraging the uptake and long-term use of these technologies and improving quality of life among users. This scoping review draws from theoretical frameworks such as the World Health Organization Quality of Life framework [12] and Schalock and Alonso's Quality of Life model [22] to conceptualize psychosocial impacts. That is, psychological outcomes refer to the impact of ATs on the mental and emotional state of the individual, including positive feelings (happiness and life

satisfaction), negative feelings (anxiety, depression, and stress), and self-esteem. Social outcomes refer to the impact of ATs on the individual's social interactions, support, and participation in community and societal activities.

Stage 2: Identifying Relevant Studies

An initial limited search was conducted by the research team to inform the development and refinement of the search strategy. A university librarian was also consulted at this stage to help identify the databases and refine the search strategy. The search included variations and combinations of the following key concepts:

- AT ("assistive technol*" OR "adaptive technol*" OR "assistive aid*" OR "assistive equipment*" OR "assistive device*" OR "assistive product*" OR "assistive service*" OR "assistive interv*" OR "sensory aid*").
- Visual impairment ("visual impair*" OR "vision impair*" OR "impaired vision" OR "sight impairment" OR "visual loss" OR "vision loss" OR "vision defect" OR "visual handicap" OR "blind" OR "blindness" OR "low vision" OR "partial* sight*" OR "partial vision" OR "visual* disorder*" OR "vision disord*" OR "visual* disab*" OR "vision disab*" OR "eye disord*").

Next, a full literature search of peer-reviewed journal papers and conference proceedings was conducted across 7 electronic databases, including CINAHL (EBSCO) and PsycINFO (EBSCO), as well as ACM Digital Library, IEEE Xplore, Scopus, Web of Science, and Google Scholar (first 100 records). During the initial limited search, PubMed was considered as a potential database but eventually excluded, as its results heavily targeted biomedical and clinical aspects, which did not align with the focus on psychosocial impacts. Instead, CINAHL was selected for its broader coverage of health care topics and more holistic aspects of care, including well-being and quality of life.

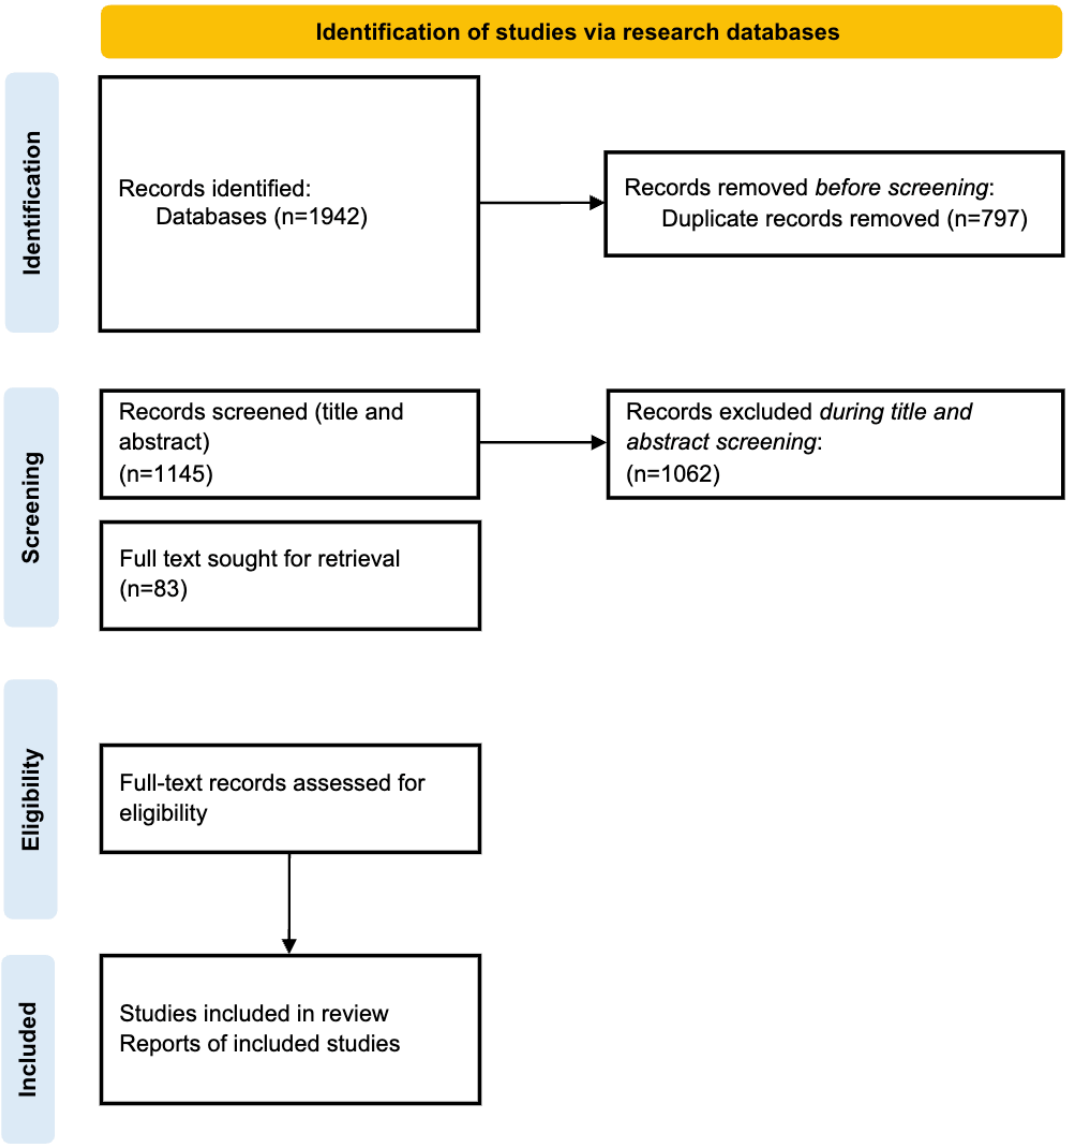
To focus on the most up-to-date literature and to capture the latest developments in the field of ATs for visual impairments, the search was limited to studies published in the past 5 years (2019-2024). Furthermore, the search was limited to studies written in English only. A full literature search was conducted in July 2024, which produced 1942 results.

Stage 3: Study Selection

A systematic approach will be used for study selection. Eligibility criteria have been developed to ensure the relevance and quality of included studies. From a *population* perspective, studies will be included if they focus on people with visual impairments, including children and adults, irrespective of the diagnosis and inclusion criteria used by individual studies. At a *concept* level, studies will be included if they (1) refer to the use of AT by people with visual impairments and (2) focus on the psychosocial impact or outcomes associated with the use of ATs. *Context-wise*, studies conducted in any country or setting, including health care, community, education, and work, and across all age groups will be considered. Primary research, including quantitative, qualitative, and mixed method studies reported in peer-reviewed journal papers or conference proceedings, will be included in this review. Conference abstracts only will be excluded. Secondary research (eg, literature reviews and meta-analyses) and nonempirical works (eg, theoretical papers, conceptual frameworks, opinion pieces, and editorials) may be consulted during the review process but will not be included. The review will only include research that includes the design or evaluation of an AT intervention focusing on impact.

Following the literature search, all retrieved studies will be collated and uploaded into a web-based literature review tool, Rayyan (Rayyan Systems Inc) [23], where duplicates will be removed. A random sample of 25 papers from the overall dataset will be first reviewed for pilot-testing of the source selector criteria. Following this, the reviewers will meet to discuss discrepancies and adapt the criteria based on the insights from the pilot test. Independently, 2 reviewers (RS and MB) will then conduct a screening of titles and abstracts to determine their potential eligibility for inclusion. The full texts of potentially eligible studies will be then retrieved and reviewed in detail for final inclusion. Reasons for excluding sources of evidence at the full-text stage that do not meet the eligibility criteria will be documented and reported in the scoping review. Any disagreements between reviewers (RS and MB) at each stage of the study selection process will be resolved through consensus or by consulting a third reviewer (CH). The search results and the study inclusion process will be reported in full in the final scoping review and presented in a PRISMA-ScR flow diagram (Figure 1 and Multimedia Appendix 1).

Figure 1. PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) flow diagram illustrating the study selection process.



Stage 4: Charting the Data

Data from the studies included in the scoping review will be extracted using a standardized table to ensure consistency and comprehensiveness. The data extraction table will be piloted on a subset of studies and will be revised as necessary. The information to be extracted from each study includes the authors, year of publication, title, source of publication, type of publication, country of study, aim of the study, population and sample characteristics, research design, type of AT or intervention, setting, outcomes, instruments or impact measures, key findings, and the impact period categorized as immediate (less than 1 month), short-term (1 to 6 months), medium-term (6 to 12 months), and long-term (more than 12 months). To ensure the accuracy of the process, a second reviewer (MB) will cross-check the data extracted from at least 25% (n=7) of all included studies. Any discrepancies between reviewers will be resolved through consensus or consultation with a third reviewer (CH).

Stage 5: Collating, Summarizing, and Reporting Results

Descriptive statistics will be used to summarize the overall characteristics of the included studies. These will cover the number of studies, the distribution of studies by publication year, population characteristics, country of origin, study setting, type of ATs examined, impact period, and research methodologies used. Charts and diagrams will also be used to support data presentation. Tables will be constructed to synthesize the psychosocial outcomes reported in the included studies. Tables will detail the methods and instruments used to measure the psychosocial impacts of ATs, including information on specific tools or questionnaires, their reliability and validity, and the context of their app. Additionally, tables will summarize the main findings of the studies included in the review. Furthermore, a narrative summary will accompany the tabular or charted results, providing a description of the literature on the psychosocial impact of ATs on people with visual impairments, including key themes and trends observed. It will also identify gaps in the current body of knowledge, while

recommendations for future research will be made based on the identified gaps or inconsistencies.

Stage 6: Consultation

To expand the relevance and applicability of the findings arising from this scoping review, consultations will be conducted with stakeholders, including AT researchers, policy makers, and users. In particular, AT users will be provided with a summary of findings and invited to provide feedback through a written commentary. Their insights will inform the interpretation of results and the development of recommendations for practice and policy.

Results

This scoping review protocol was submitted to the Open Science Framework [24] on July 17, 2024. The database search was conducted in July 2024, and 1942 records were identified. During identification, 797 records were identified as duplicates and removed. Next, the title and abstract screening was conducted for 1145, of which 1062 records were excluded. Finally, 83 records were included for full-text screening. Data extraction and synthesis, as well as paper preparation, are currently underway. The paper should be submitted in February 2025.

Discussion

Expected Findings

The findings from this scoping review will shed light on the psychosocial impacts of ATs for people with visual impairments. The review will also explore the methods and instruments used to measure these outcomes and will identify key trends in the literature. These findings are expected to inform the development of a global evidence database mapping the impact of AT for people with visual impairments, with a view to extending it to other disabilities and long-term conditions, including other sensory impairments, mental health conditions, neurodevelopmental conditions, intellectual disabilities, and physical disabilities. The database is also expected to serve as a resource for researchers, clinicians, AT developers, policy makers, and other stakeholders, providing accessible and up-to-date evidence on the impact of AT. It is intended to facilitate evidence-based decision-making, support the development of guidelines, interventions, and policies, as well as identify gaps in the current research landscape. Findings will be presented at relevant conferences and shared with stakeholders (eg, disability and health care organizations, AT developers, and policy makers).

Strengths and Limitations

This scoping review is a comprehensive attempt to map the interdisciplinary literature on the psychosocial impact of AT for people with visual impairments. A full literature search of peer-reviewed journal papers and conference proceedings was conducted across 7 interdisciplinary electronic databases, including CINAHL (EBSCO) and PsycINFO (EBSCO) for literature from health care and psychology, as well as ACM Digital Library, IEEE Xplore for human-computer interaction, computing, and accessibility and AT-related literature, and Scopus, Web of Science, and Google Scholar (first 100 records) to include cross-disciplinary literature. The review will follow the PRISMA-ScR checklist that is specific for scoping reviews [21] to ensure a high level of quality and transparency. To this end, the scoping review protocol has been preregistered with the Open Science Framework [24].

One limitation of this scoping review is the exclusion of previous reviews and non–peer-reviewed publications. Additionally, the review only includes research published in English between 2019 and 2024. Due to the limited scope and time constraints of this review, a comprehensive quality assessment will not be conducted. Finally, this review does not include a full literature search on PubMed due to the clinical focus of search results from initial searches.

Acknowledgments

This research has been funded by the UK Research and Innovation Engineering and Physical Sciences Research Council UKRI (UK Research and Innovation) EPSRC (Engineering and Physical Sciences Research Council) ICT (Information and Communication Technologies) Public Engagement Grant (EP/W033674/1).

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

RS, MB, and CH conceptualized the study as a scoping review. MB and CH provided oversight for scoping review protocol development. RS and MB reviewed and edited the protocol, drafted the search strategy, wrote the manuscript, and designed Figure 1. All authors read, provided feedback, and approved the final manuscript for submission.

Conflicts of Interest

None declared.

Abstract

Background: Social determinants of health (SDH) have been shown to be predictors of health outcomes. Integrating SDH screening tools into primary care may help identify individuals or groups with a greater burden of social vulnerability and promote health equity.

Objective: This study aimed (1) to identify the existing screening tools to assess social deprivation in adults in primary care settings; (2) to describe the characteristics of these tools and, where appropriate, their psychometric properties; (3) to describe their validity and reliability in those scales in which validation processes have been conducted; and (4) to identify evidence gaps and provide recommendations for future research.

Methods: This study protocol was structured according to the Joanna Briggs Institute methodology for scoping reviews and reported according to the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines. Furthermore, since not all SDH assessment tools are published as scientific papers, we will use a slightly modified form of the scoping review framework to retrieve specific information about specific tools for screening SDH in primary care contexts. The following electronic databases will be searched by 2 reviewers: MEDLINE (via PubMed), CINAHL Plus, Web of Science, and Scopus. In addition, the following sources will also be searched for gray literature: DART-Europe E-thesis Portal, OpenGrey, and Google Scholar. After the revision of inclusion and exclusion criteria, the titles, abstracts, and full text of the included studies will be separately screened by 2 reviewers. A PRISMA-ScR flowchart will be used to depict the sources of evidence screened, and data charting will be used to gain in-depth knowledge. The findings of the scoping review will be presented in both narrative and tabular formats, summarizing the existing literature on tools used for SDH in primary care settings. A critical analysis will be undertaken to address the variability in tool validation, cultural adaptability, and integration into different health care systems. Finally, key gaps in the existing evidence will be explored, and research priorities will be proposed, emphasizing the need for screening tools that are culturally sensitive, scalable, and easily integrated into primary care workflows. This critically appraised information may be useful for implementing SDH screening tools in primary care settings and may contribute to future research addressing feasibility and validation studies in different primary health care systems.

Results: The study began in July 2024. Data collection is expected to be completed in April 2025, with publication expected in October 2025.

Conclusions: This scoping review will provide a comprehensive and critical description of the available tools aimed at screening SDH in primary care settings. Incorporating these tools into routine care has been recognized as a key strategy for addressing health inequalities, given the growing evidence base on the influence of SDH on health outcomes.

KEYWORDS

social deprivation; social determinants of health; primary health care; social inequality; screening

Introduction

Background

According to the World Health Organization (WHO), social determinants of health (SDH) are the conditions in which people are born, grow, work, live, and age, along with the broader set of forces and systems that shape the conditions of daily life [1]. These determinants include a wide range of factors, such as income, education, employment, working conditions, housing, neighborhood environments, race, and gender [2]. On the other hand, health inequalities are defined as the systematic, avoidable, and unfair differences in health outcomes that can be observed between different groups of people, which are determined by the SDH [3].

In recent years, there has been a growing awareness of the significant impact of SDH on individual and population health outcomes. This has led to a transformation in health care practices and policies with greater recognition of the role of SDH in perpetuating health inequities and in providing a comprehensive understanding of a patient's health [4].

SDH have been shown to be the predictors of health outcomes, including hospital readmissions [5], emergency department visits [6], multimorbidity burden [7], depression prognosis [8], and lower adherence to preventive measures [9,10]. Identifying individuals or groups with a greater burden of social vulnerability or with the greatest disparities in a particular disease can guide future actions to promote health equity [11], implement tailored social interventions, and direct future research [12]. However, despite the clear evidence of the importance of SDH and the need to address its root causes, there are several issues to be considered. First, without multidisciplinary engagement and workflows, along with the availability of social resources for subsequent referral [13], expectations may be raised without solutions being provided, leading to a loss of patient trust. Second, without intersectoral collaboration, long-term strategies, upstream proposals, and public health policies and workflows, we could fall into perpetuating the "fantasy paradigm" [14]—a parallel fantasy world in which proximal, downstream, and easily tackled exposures are posited as potential solutions to health inequalities [15].

Primary care settings are ideal for addressing SDH because they are often the first, and sometimes only, point of contact for patients within the health care system. They are also the place for multiple consultations with a significant social burden, where longitudinal continuity of care is provided and where clinicians are aware of the community health resources [16]. The importance of SDH screening in primary care is underscored by the fact that social needs are often unrecognized in clinical settings, leading to suboptimal care and poorer health outcomes [17]. Therefore, integrating SDH screening tools into primary care is not only consistent with the principles of holistic and patient-centered care but also represents a crucial step toward addressing the root causes of health disparities [18-20].

There is considerable variability in the implementation of SDH screening tools in primary care settings [21]. The absence of standardized screening tools and protocols, along with varying levels of knowledge and training among providers, hinders the ability to identify SDH-related needs and intervene appropriately [22]. Furthermore, the diverse nature of SDH, which covers a wide range of domains and is influenced by individual-, community-, and policy-level factors, poses a significant challenge to the development of comprehensive screening tools [23]. These tools must be sensitive enough to capture the complexity of social determinants while also being practical for use in time-constrained primary care settings. A number of SDH screening tools have been developed and implemented with varying degrees of success. These tools range from brief questionnaires integrated into electronic health records to more extensive assessments conducted through patient interviews [14,21,24]. The development of these tools is often context specific, taking into account the patient population, health care setting, and available resources for follow-up interventions [25]. However, the variability in the content, format, and application of these tools across different health care systems underscores the need for a comprehensive synthesis of available tools aimed at assessing their effectiveness, validity, and feasibility [14].

Primary care providers face numerous barriers to implementing SDH screening, including time constraints, lack of training, and uncertainty about how to address identified needs [17,26]. There are also concerns that screening may reveal problems that providers are ill-equipped to deal with, leading to increased stress and workload without a clear pathway for patient referral and intervention [14]. Without collaboration between sectors such as social work or community resources in SDH screening and subsequent referral, primary care clinicians alone may not be able to cope [26]. Therefore, an important aspect of evaluating SDH screening tools is to consider not only their ability to identify social determinants but also their integration into care processes, the availability of resources to address identified needs, and their impact on patient outcomes [27].

Rationale for a Scoping Review

To avoid duplication of effort, a preliminary search conducted in July 2024 revealed that although several approaches to

synthesizing the literature on the use of tools to screen for SDH in clinical settings had been published [17,21,28] or were in progress (Parry et al [29]), many of the known tools had not been published in scientific papers and could only be found on institutional websites or through references to their use in the scientific literature (eg, EPICES score [30]) or book chapters. Therefore, several approaches to synthesizing the existing literature were considered, and scoping was found to be the most appropriate for the needs of this study according to the reasons for deciding to undertake a scoping review proposed by Arksey and O'Malley [31], namely that the use of SDH screening tools in primary care is an emerging issue, and different tools have been proposed because the generalizability across countries and primary care systems may not be possible, so mapping these tools is of scientific interest. In addition, a standard systematic review would leave out numerous tools that have not been published in traditional databases of the scientific literature, such as websites of health institutions, books, and so on. Therefore, suggesting lines of research and methodologies can be of scientific interest.

Study Aims

Our overall aim is to explore the literature describing the usefulness of SDH screening tools for adults in primary care settings. To achieve this, we will address the following specific objectives: (1) to identify existing screening tools for assessing social deprivation in adults in primary care settings; (2) to describe the characteristics of these tools, such as country, year of publication, and items included; (3) to describe their validity and reliability in those scales that have undergone validation processes; and (4) to identify evidence gaps and provide recommendations for future research.

Methods

Overview

In reviewing the existing literature, several approaches were considered, and a scoping review was found to be the most appropriate for the requirements of this study. Therefore, this study protocol was structured according to the 5-stage framework by Arksey and O'Malley [31]. In addition, the scoping review will be conducted according to the Joanna Briggs Institute methodology for scoping reviews [32] and reported following the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines [33]. Furthermore, because not all the SDH assessment tools are published as scientific papers, we will use a slightly modified form of the scoping review framework outlined by Peters et al [34] to retrieve specific information about specific social deprivation screening tools in primary care contexts.

Identifying the Research Question

Some differences can be observed between these two approaches [33,34]. In essence, both approaches can be complementary, as the former is a checklist for reporting a scoping review compatible with the Population, Concept, and Context framework that we have chosen to describe the research question of our review (Multimedia Appendix 1). Our population will consist of adults (aged 18 years or older); our concept of SDH tools is understood as the conditions in which people are born, grow, work, live, and age, and the broader set of forces and systems that shape the conditions of daily life [1]; and as a contextual framework, the tools should be applicable to primary care settings.

Identifying Relevant Studies

The search strategy has been developed in collaboration with the research team and the participant librarians, adapting the PRISMA-ScR guidelines for literature search [35] to a scoping review. Two reviewers (JM-A and VM-V) independently searched the following electronic databases: MEDLINE (via PubMed), CINAHL Plus, Web of Science, and Scopus. The search strategy included terms related to the following descriptors, combined using Boolean operators: (1) SDH, (2) measurement tools, (3) validation studies, and (4) primary health care. All retrieved records will be imported into Mendeley (Elsevier) software, and duplicates will be removed. Textbox 1 provides the search strategy for the MEDLINE database as an example.

Textbox 1. Search strategy in MEDLINE.

Concept

- (tool [Title/Abstract]) OR ("questionnaire"[Title/Abstract])) OR ("scale"[Title/Abstract])) OR (measurement[Title/Abstract])) OR ("test"[Title/Abstract])) OR ("measure"[Title/Abstract])) OR ("assessment"[Title/Abstract])) OR ("index"[Title/Abstract])) OR ("indexes"[Title/Abstract]) OR ("score"[Title/Abstract]) OR (screening[Title])

AND

Social determinants of health

- (poverty[Title/Abstract]) OR (poverty[MeSH Terms])) OR (socioeconomic status[Title/Abstract])) OR (low socioeconomic status[Title/Abstract])) OR (low socioeconomic status[MeSH Terms])) OR (Social Deprivation[MeSH Terms])) OR (Social Deprivation[Title/Abstract])) OR (Social Vulnerability[Title/Abstract])) OR (Social Vulnerability[MeSH Terms])) OR (Social Determinants of Health[Title/Abstract])) OR (Social Determinants of Health[MeSH Terms])) OR ("social class"[MeSH Terms])) OR (social determinants[Title/Abstract])) OR (socioeconomic factors[MeSH Terms])) OR (socioeconomic factors[Title/Abstract])) OR (deprivation[Title/Abstract]) OR (drivers [Title]) OR (Social Drivers of Health [Title]) OR (social needs[Title])

AND

Validity

- (validity [Title/Abstract]) OR (Feasibility Studies [MeSH Terms] OR (Feasibility[Title/Abstract])) OR (applicability[Title/Abstract])) OR (screening[Title/Abstract])) OR (validation[Title/Abstract])) OR ("validation studies as topic"[MeSH Terms])) OR (health outcome predictor[Title])

AND

Context

- (Primary Health Care [Title/Abstract]) OR (Primary Health Care[MeSH Terms])) OR (primary care[Title/Abstract])) OR (Family Practice[Title/Abstract])) OR (Family Practice[MeSH Terms])) OR (general practice[MeSH Terms])) OR (general practice[Title/Abstract])) OR (clinical setting[Title]) OR (outpatient [Title]) OR (ambulatory [Title]) OR (Internal Medicine[Title])

The search strategy and index terms will be adapted for each electronic database or information source.

In addition, several approaches will be used to search the gray literature, understood as materials and research produced by organizations outside of traditional academic publishing. First, we will search the DART-Europe E-thesis Portal for access to dissertations and OpenGrey, a system for information on gray literature in Europe. We will also search using keywords in Google Scholar, and the first 200 results sorted by relevance will be screened for suitability according to the recommendations of Haddaway et al [36]. Furthermore, a supplementary search of the reference lists of studies selected for inclusion in the review will be conducted to identify additional relevant studies. This will be followed by a systematic citation search using CitationChaser [37] to compile studies citing the papers selected for inclusion. If further information is required regarding the studies of key papers, the authors will be contacted accordingly. Finally, an iterative approach will be used to search the websites of health institutions in the main countries that have implemented health policies related to social inequalities in health. Mendeley will be used as reference manager software.

Study Selection

The identified studies will be transferred to the web-based version of the Rayyan Systematic Review Tool [38] for further processing. Rayyan is a web-based tool designed to facilitate the screening process, which is a critical component of any systematic review. As recommended, two authors (JM-A and VM-V), after agreeing on a framework for screening papers according to the research objectives [33], will independently carry out the title and abstract selection of studies. Full papers will be obtained if the literature meets the inclusion criteria or if a decision cannot be made from the title or abstract alone. The review authors will resolve disagreements by consensus-based decision and, if necessary, by discussion within the group. In addition, we will record the specific reasons for the exclusion of each study.

For our scoping review, the inclusion criteria are given in Table 1. However, we will be aware that a reflexive process of the inclusion and exclusion criteria will be undertaken during the screening process, which will serve to consolidate the criteria [34].

Table 1. Inclusion and exclusion criteria based on the Population, Concept, and Context framework.

Scope parameters	Inclusion criteria	Exclusion criteria
Population	Adult participants (including older adults)	Pediatric population and adolescents
Concept	Screening tools for SDH[a] that include more than one dimension of SDH and screening tools with social deprivation indexes	Screening tools for only one dimension of SDH (eg, screening tools for only food insecurity)
Context	Primary care settings	Other specialty or emergent care setting
Types of evidence	Full-text papers of empirical research studies (eg, validation studies, randomized controlled trials, and observational studies), study protocols, full-text conference proceedings, papers written in English, documents retrieved from institutional websites, and PhD dissertations	Reviews[b], abstracts, posters, and papers for which we cannot obtain the full text or which are not written in English

[a]SDH: social determinants of health.

[b]Although systematic reviews will not be selected for inclusion, the studies included in these reviews will be reviewed to evaluate their possible inclusion in the scoping review.

Critical Appraisal

As scoping reviews are primarily aimed at identifying and exploring the existing literature on a topic, it has been stated that a quality assessment is not applicable [34]. In our case, as the methods used to develop the SDH screening tool may not always be standardized, conducting a quality assessment is likely to be unsuccessful. However, a critical review assessing their ability to be incorporated into care processes, their relationship to the availability of resources to address identified needs, and their impact on patient outcomes will be included in the *Results* and *Discussion* sections.

Charting the Data

A PRISMA-ScR [33] flowchart will be used to depict the sources of evidence screened, the assessment of documents' eligibility (which may include tools extracted from institutional documents, not just papers), and the tools included in the review, along with reasons for exclusions at each stage.

The data charting is specific to scoping reviews and differs from the data extraction processes commonly used in other types of research synthesis designs, where data extraction is a more structured process often including statistical procedures. In contrast, data charting in scoping reviews is a more comprehensive approach that incorporates narrative information to describe details about how, why, and where the study was conducted [39]. Accordingly, a consensus-based, data-charting form will be used by the 2 reviewers, who will independently extract the data, discuss the results, and iteratively update the data-charting form. This data-charting table will include descriptive variables (year of publication, study design, setting, target population, and data source) and information about the aims and structure (dimensions, items, and procedures for completing the questions) of the tool and setting characteristics.

Ethical Considerations

Ethical approval is not required for this review as it involves the analysis of publicly available empirical studies and the production of secondary data.

Expected Outcomes

Following the publication of this protocol, the search for SDH screening tools, removal of duplicates, and study selection will take place (estimated time: 2 months). The findings of this scoping review will be presented in both narrative and tabular formats, summarizing the existing literature on tools used for SDH in primary care settings. The narrative summary will describe the scope and nature of the identified screening tools including their structure (domains, number of items, and how the information should be obtained [eg, questionnaires and digital platforms]) and the contexts in which they are applied. The integration of these tools into clinical workflows, as well as any evidence of their effectiveness in improving patient outcomes, will also be considered.

Critical Analysis

Overview

The results will include a critical analysis of the strengths, limitations, and usability in primary care settings of the screening tools. This analysis will address the variability in tool validation, cultural adaptability, and integration into diverse health care systems. Potential biases or limitations in the implementation or outcomes of the tools, such as insufficient training of health care providers or limited follow-up on identified needs, will also be concerns to be discussed.

Research Gaps and Priorities

Key gaps in the existing evidence, such as social determinants not included in the tools, concerns about age or gender underrepresentation, and limited follow-up analysis of the usefulness of SDH screening on health outcomes, will also be critically examined. Finally, based on these findings, research priorities will be proposed, emphasizing the need for screening tools that are culturally sensitive, scalable, and easily integrated into primary care workflows (estimated time to complete these tasks: 6 months).

Dissemination of the Results

To ensure that the insights resulting from this review reach a variety of stakeholders, such as health care practitioners, policy makers, and academics, the findings will be disseminated using several dissemination strategies including reporting results in open-access journals and scientific conferences. In addition, stakeholders will be engaged at every stage of the review process to facilitate the adoption and implementation of evidence-based screening tools in clinical settings, thereby increasing their impact on health equity (estimated time: 6 months).

Results

The study began in July 2024. Data collection is expected to be completed in April 2025, with publication expected in October 2025.

Discussion

Principal Findings

This scoping review will provide a comprehensive and critical description of the available tools aimed at screening SDH in primary care settings. Incorporating these tools into routine care has been recognized as a key strategy for addressing health inequalities, given the growing evidence on the influence of SDH on health outcomes. Nonetheless, the absence of a comprehensive review makes it difficult for health care practitioners to select the most appropriate tools for their context and patient populations.

The importance of identifying and addressing the social needs of the patients attending health care settings has been highlighted by Gottlieb and Fichtenberg [40], and some scientific contributions have previously addressed some issues related to the implementation of SDH screening tools in clinical settings, such as the coverage and economic evaluation of these tools [41], the evaluation of interventions linking social and medical care [42], the barriers to the implementation of SDH in electronic health records [43], and its integration in nonspecific clinical settings [44]. In addition, a report from the US Preventive Services Task Force alerted on the importance of considering SDH in the recommendations of preventive interventions in primary care [19]. However, a catalog of currently available screening tools, their scope, structure, and dimensions is lacking. Furthermore, this review will assess the contextual elements such as resource accessibility and stakeholder involvement (patients, practitioners, and health care providers) that influence the implementation and effectiveness of these technologies in primary care. This review will map the body of literature to identify potential gaps and areas for additional research, including tool validation in varied populations, tool influence on clinical outcomes, and tool integration into larger care systems.

Including SDH screening tools for children in this review might seem to make our review more coherent, but it would greatly increase the complexity of the review. The tools for children and adults are very different. Overall, measuring SDH in children should emphasize developmental needs, relationships with caregivers, and early life conditions, whereas measures for adults tend to focus more on employment, social deprivation, and cumulative social conditions, as well as focus on the individual rather than indirectly asking the caregiver about the child's health [45]. Therefore, a review of SDH in the pediatric population requires a synthesis study, probably with a different methodological approach, focusing exclusively on this topic.

A key strength of this protocol lies in its systematic approach, which adheres to the current methodological frameworks for scoping reviews. This ensures that the review process will be transparent and reproducible, while allowing a broad range of study designs and inclusion settings. However, a limitation of this review is the potential for missing unpublished or non–English-language studies, which may result in an incomplete understanding of the global landscape of SDH screening tools.

Conclusions

This scoping review will provide a valuable synthesis of the available SDH screening tools applicable in primary care and identify critical gaps in the existing literature. This review will provide insights into the implementation of these tools, while identifying areas for further research, including validation in diverse populations. Ultimately, this work aims to support the integration of SDH screening into routine care, contributing to efforts to reduce health inequalities and improve patient outcomes.

Acknowledgments

This study was funded by the Research Network on Preventative Activities and Health Promotion (RD12/0005/0009) to VM-V. Additional funding was obtained from the Foundation for Biosanitary Research and Innovation in Primary Care (FIIBAP).

Authors' Contributions

JM-A and VM-V contributed to the conceptualization. JM-A and VM-V developed the methodology. JM-A, AEM, HMM, and VM-V performed the investigation. JM-A, VM-V, and AEM managed writing–original draft preparation. NJO, IDLMH, FSV, ACM, HMM, and SC handled writing–review and editing.

Conflicts of Interest

None declared.

Abstract

Background: The study of supercentenarians (individuals aged 110 years or older) offers valuable insights into aging, longevity, and the factors contributing to exceptional lifespans. These individuals often exhibit extraordinary cognitive and physical performance, which can inform strategies to improve the health of the general population. Research on centenarians (individuals aged 100 years or older), semi-supercentenarians (individuals aged 105-109 years), and supercentenarians covers themes like genetic factors, microbiome, inflammation, diet, lifestyle, and psychological aspects. These studies often focus on various aspects of extreme longevity, using varied objectives and methodologies, highlighting the need for a comprehensive synthesis to map the breadth of research and identify gaps in understanding this demographic.

Objective: This scoping review aims to map and synthesize existing evidence on the determinants of extreme longevity, focusing on individuals living beyond 105 years. This review seeks to categorize genetic factors associated with semi-supercentenarians and supercentenarians; explore the range of socioecological factors contributing to their longevity; and identify common themes such as health, functional capacity, cognition, mental health, behaviors, social support, quality of life, personality traits, environmental factors, and religiosity. Additionally, it aims to examine and describe the methodologies and assessment tools used in studies on extreme longevity and provide an overview of global demographic trends and patterns among supercentenarians, including geographic distribution, gender prevalence, and socioeconomic characteristics.

Methods: This scoping review follows the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) 2015 guidelines and the Population, Exposure, and Outcome framework. It includes observational and interventional, quantitative and qualitative studies on supercentenarians and semi-supercentenarians. Data will be sourced from databases like Scopus, PubMed, ProQuest, PsycINFO, and The Cochrane Library. The selection process involves abstract and full-text screening by two independent reviewers, with data extraction focusing on study characteristics, participant demographics, interventions or exposures, and key findings. A thematic analysis will identify patterns across various themes

Results: As of October 2, 2024, five databases were searched, yielding 844 studies. After removing duplicates, 706 studies remained. Following the first and second screening stages, 135 studies were found to be eligible. The study is expected to be completed by the end of February 2025.

Conclusions: By synthesizing evidence, this study will understand the global scope of supercentenarians, describe the main themes of research interest, and identify gaps. The findings are expected to contribute significantly to the body of knowledge on longevity, informing future research and public health policies. This scoping review aims to enhance the understanding of factors promoting healthy aging and extreme longevity, benefiting broader public health initiatives.

KEYWORDS

supercentenarians; semi-supercentenarians; extreme longevity; genetic factors; socioecological factors; health determinants; aging research; scoping review; cognitive performance; data collection methods

Introduction

The study of supercentenarians—individuals who have reached the remarkable age of 110 years or older—holds immense scientific interest. These exceptional individuals provide valuable insights into aging, longevity, and the factors contributing to their remarkable lifespans. Limiting illness—both in duration and the number of individuals affected—becomes more critical as human longevity increases. Studying healthy humans with exceptional lifespans is meaningful in discovering clues to improve the general population's health. Centenarians (individuals aged 100 years or older), semi-supercentenarians (individuals aged 105-109 years), and supercentenarians (individuals aged 110 years or older) are excellent models for the study of healthy longevity. According to research, this aged population surprisingly maintain extraordinary cognitive and physical performance [1].

These studies provide valuable insights into various aspects of supercentenarian aging and use a variety of methodological frameworks for evaluating the determinants of extreme longevity. Currently, there exists a wide range of studies that investigate exceptional lifespans from diverse perspectives. Sebastiani et al [2] discussed genome sequencing in supercentenarians, revealing common and rare genetic variants that may contribute to exceptional longevity. Franzke et al [3] looked into "DNAging" and discovered that supercentenarians exhibit improved DNA repair and antioxidant defense mechanisms compared to younger cohorts. Santos-Lozano et al [4] discovered that both genetic and environmental factors are attributed to exceptional longevity in centenarians and supercentenarians. Some studies discussed morbidity in supercentenarians and found that cognitive and physical function decline is delayed in supercentenarians [5], while other studies investigated other factors contributing to super longevity in supercentenarians such as diet and lifestyle [6,7].

This scoping review aims to comprehensively synthesize the existing evidence to understand the determinants that contribute to extreme longevity in individuals living beyond 105 years, as well as the methodologies used for data collection.

This scoping review's main objectives are as follows:

1. To map and categorize the existing evidence on genetic factors associated with extreme longevity in semi-supercentenarians and supercentenarians;
2. To explore and synthesize the range of socioecological factors, including lifestyle behaviors, environmental exposures, and social support systems, that are associated with achieving extreme longevity;
3. To examine and describe the methodologies and assessment tools used in studies investigating extreme longevity; and
4. To provide an overview of global demographic trends and patterns among supercentenarians, including geographic distribution, gender prevalence, and socioeconomic characteristics.

Methods

Approach

This scoping review follows the Population, Exposure, and Outcome framework [8] and the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) guidelines published in 2015 (Multimedia Appendix 1) [9]. The population and outcome are as follows:

- Population: Semi-supercentenarians (aged 105 years or older)
- Exposure: Genetics and socioecological factors
- Outcome: Supercentenarian (aged 110 years or older)

Eligibility Criteria

Study Characteristics

This scoping review will include quantitative and qualitative studies in which supercentenarians and semi-supercentenarians are the focus of the study, including observational research (case-report, case-series, cross-sectional, case-control, and cohort studies) and interventional research (quasi-experimental studies and randomized controlled trials).

Types of Participants

This scoping review will target studies in which groups or subgroups of participants comprise male or female individuals aged 105 years and older.

The exclusion criteria will be studies involving participants younger than 105 years as the primary focus.

Setting and Time Frame

In this scoping review, articles will be screened initially without any time restrictions. Additionally, there will be no limitations on the study settings.

Report Characteristics

Only peer-reviewed studies with full-text availability in English will be included. There will be no restrictions on the date of acceptance or publication. Regarding publication status, only articles that are either published or in press will be considered.

The exclusion criteria will be articles not available in full text, non–English-language studies, and non–peer-reviewed studies (eg, gray literature)

Information Sources

Our sources of information will be limited to electronic databases. An electronic search will be performed through Scopus (including Scopus Secondary literature), PubMed, ProQuest, PsycINFO, and The Cochrane Library (Cochrane Database of Systematic Reviews, Cochrane CENTRAL, and

Cochrane Methodology Register). Additionally, the reference lists of primary studies included in the review and the reference lists of relevant, previously published reviews will be reviewed.

Search Strategy

The search syntax used in the different databases is shown in Table 1.

Table 1. Search syntax.

Database	Search query	Filters
Scopus Articles	TITLE-ABS-KEY (*supercentenarian* OR semi*supercentenarian) AND (LIMIT-TO (DOCTYPE , “ar”) OR LIMIT-TO (DOCTYPE , “no”) OR LIMIT-TO (DOCTYPE , “cp”) OR LIMIT-TO (DOCTYPE , “sh”) OR LIMIT-TO (DOCTYPE , “le”) OR LIMIT-TO (DOCTYPE , “ed”))	Articles, notes, conference papers, letters, and editorials; excluded reviews and book chapters
PubMed	“supercentenarian”[Title/Abstract] OR “semi*supercentenarian”[Title/Abstract] OR ((“Centenarians”[MeSH[a] Terms] OR “Centenarians”[All Fields] OR “centenarian”[All Fields]) AND “Centenarians”[MeSH Terms])	None

[a]MESH: Medical Subject Headings.

Details of the search records, such as the date of the search, database, keywords, number of studies identified, and the number of eligible studies, will be appropriately documented. The authors will follow the adapted PRISMA-P guidelines to report the screening results.

Study Records: Selection Process

The results from the database search will be entered into Zotero (Corporation for Digital Scholarship), where duplicate records will be removed. Abstract and full-text screenings of the studies will be conducted by two independent reviewers using the eligibility criteria as a guide. Any disagreements among reviewers following abstract screening will be resolved through discussions to reach a consensus. However, a third reviewer will be involved to address discrepancies at the full-text screening stage.

Data Extraction and Coding

Data extraction will be done through systematic categorization of information from the included studies. The information will be categorized into predefined fields to ensure uniformity and consistency. The extracted data will include the following categories:

- Study details: Title, author(s), year of publication, journal, and geographic location
- Study design: Observational (eg, case-report, case-series, cross-sectional, case-control, and cohort studies) or interventional (eg, quasi-experimental studies and randomized controlled trials) studies
- Study population: Demographics (age, gender, and socioeconomic background) and sample size
- Factors analyzed: Genetic determinants, socioecological factors (eg, lifestyle behaviors, environmental influences, and social support), and health outcomes
- Methodological details: Data collection methods, assessment tools, and analytical approaches
- Type of data: Quantitative, qualitative, or mixed methods

The extracted data will then be coded and classified into themes based on the study’s objectives and reported findings. Uniformity will be maintained by using a standardized data extraction template and regular discussions among reviewers

to resolve ambiguities and discrepancies during the coding process.

Data Synthesis

Thematic analysis will be conducted to synthesize findings from included studies, following the 6-phase framework by Braun et al [10]. This process includes familiarizing with the data, generating codes, identifying and reviewing themes, and producing the final synthesis. Themes will focus on age validation, demographics, health, functional capacity, cognition, behaviors, social support, quality of life, personality traits, environmental and genetic factors, and religiosity. Themes will be identified inductively to allow for novel insights while remaining aligned with the review objectives.

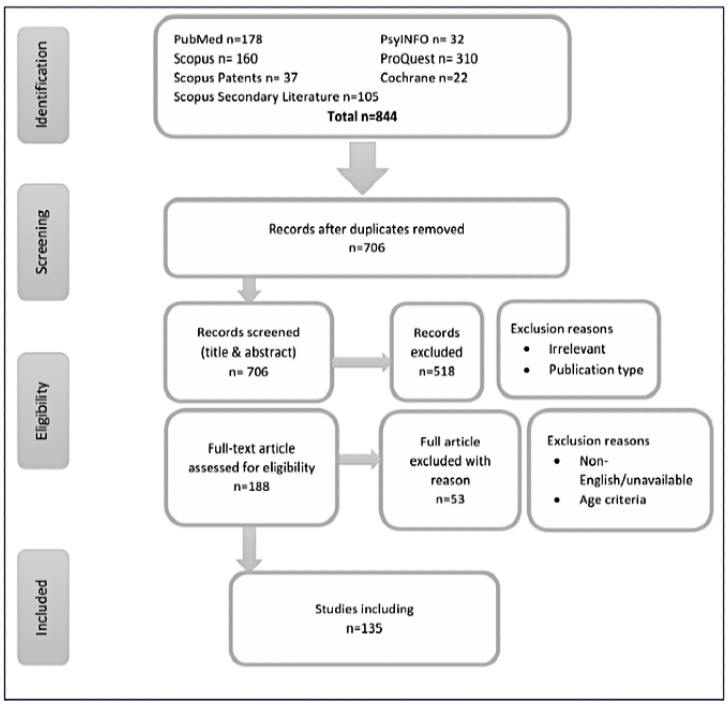
Reflexivity will be ensured through regular team discussions and documentation of assumptions to minimize researcher bias. Confirmability will be achieved by using two independent reviewers for coding, with discrepancies resolved through discussion or a third reviewer. Dependability will be ensured through a standardized coding process and team reviews of the thematic framework.

Credibility will be supported by providing detailed descriptions of themes. Transferability will be addressed by detailing the contexts and characteristics of the included studies and discussing broader implications for aging research.

Results

As of October 2, 2024, five databases were searched, and 844 studies were retrieved. After eliminating duplicates, 706 studies remained. Following the first stage of title and abstract screening, 518 studies were excluded and 188 studies remained. The remaining studies were subjected to full-text screening against the eligibility criteria, which resulted in eliminating 53 studies, leaving 135 studies to be included (Figure 1). The study is expected to be completed by the end of February 2025.

Figure 1. PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow chart.



Discussion

Expected Findings

The study of semi-supercentenarians and supercentenarians is extremely valuable in shedding light on healthy aging and longevity [11]. Scholars have studied various areas and numerous factors suspected to contribute to extreme longevity. A study on Italian centenarians and supercentenarians used a multidimensional approach (genetic, demographic, and phenotypic characteristics) to better understand the complex interactions underlying longevity [12]. Other research concentrated on cognition and dementia. Recent research has identified the transcription factor *REST* as an important factor in extreme longevity and cognitive activity [13], while others found that supercentenarians show particularly mild neuropathological findings and thus exhibit remarkable resilience to age-related cognitive decline and dementia [14]. Genetic factors were also studied. A study found strong genetic components to longevity, with siblings of centenarians having significantly higher chances of reaching 90 years [15]. Psychosocial factors, including demographics, personality, and socioeconomic resources, were also found to significantly impact the health and quality of life of centenarians [16]. These are a few studies among many that contribute to the broader discussions on aging theories. On the other hand, more than 25 landmark centenarian and supercentenarian studies have been conducted by specialized organizations across different geographical regions, using diverse methodologies and data collection approaches [17-21]. Given the extensive research on semi-supercentenarians and supercentenarians, this scoping review will serve as a valuable resource for mapping the genetic and socioecological factors associated with individuals aged

105 and older. It will also identify and summarize the methods and assessment tools used to study the key factors contributing to extreme longevity.

A total of 135 studies has been included, reflecting a diverse body of research. However, the wide range of topics, methodologies, and findings highlights the need for a comprehensive synthesis to consolidate existing evidence and identify gaps for future investigation. This review provides an overview of current research on extreme longevity while pinpointing areas that require further study. This scoping review sets the foundation for future standardized research protocols in longevity studies. Additionally, the findings of this study will have important implications for aging-related health care strategies and interventions. Understanding the genetic and socioecological determinants of extreme longevity can lead to personalized health interventions that aim at promoting healthy aging. Policy makers and health care providers can use this evidence to design lifelong healthy behaviors programs and improve social and community support systems for older adults. The findings of this study will contribute to the body of literature on semi-supercentenarians and supercentenarians, inform future studies and interventions, and guide policy makers in the field of aging and public health.

Study Limitations

This scoping review has limitations that need to be acknowledged. There is a risk of selection bias. This scoping review only includes peer-reviewed, full-text articles in English, which may narrow the findings by excluding relevant studies published in other languages or in gray literature. Moreover, there is difficulty in making direct comparisons due to significant methodological differences, particularly in how longevity determinants are defined and the assessment tools used. Lastly, this scoping review as a study does not establish causal relationships between genetic, socioecological factors, and extreme longevity. Instead, it serves as a foundation by identifying gaps, trends, and inconsistencies in the existing research. It provides insights that can guide future longitudinal studies (which track individuals over time) and experimental research (which tests specific interventions) to better understand the causal mechanisms behind extreme longevity.

Abstract

Background: The use of artificial intelligence (AI) technologies in radiography practice is increasing. As this advanced technology becomes more embedded in radiography systems and clinical practice, the role of radiographers will evolve. In the context of these anticipated changes, it may be reasonable to expect modifications to the competencies and educational requirements of current and future practitioners to ensure successful AI adoption.

Objective: The aim of this scoping review is to explore and synthesize the literature on the adjustments needed in the radiography curriculum to prepare radiography students for the demands of AI-assisted health care environments.

Methods: Using the Joanna Briggs Institute methodology, an initial search was run in Scopus to determine whether the search strategy that was developed with a library specialist would capture the relevant literature by screening the title and abstract of the first 50 articles. Additional search terms identified in the articles were added to the search strategy. Next, EBSCOhost, PubMed, and Web of Science databases were searched. In total, 2 reviewers will independently review the title, abstract, and full-text articles according to the predefined inclusion and exclusion criteria, with conflicts resolved by a third reviewer.

Results: The search results will be reported using the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) checklist. The final scoping review will present the data analysis as findings in tabular form and through narrative descriptions. The final database searches were completed in October 2024 and yielded 2224 records. Title and abstract screening of 1930 articles is underway after removing 294 duplicates. The scoping review is expected to be finalized by the end of March 2025.

Conclusions: A scoping review aims to systematically map the evidence on the adjustments needed in the radiography curriculum to prepare radiography students for the integration of AI technologies in the health care environment. It is relevant to map the evidence because increased integration of AI-based technologies in clinical practice has been noted and changes in practice must be underpinned by appropriate education and training. The findings in this study will provide a better understanding of how the radiography curriculum should adapt to meet the educational needs of current and future radiographers to ensure competent and safe practice in response to AI technologies.

KEYWORDS

artificial intelligence; machine learning; radiography; education; scoping review

Introduction

Radiography is arguably one of the most technologically advanced health care disciplines, encompassing various technologies that continuously evolve with advancements in computing power and human knowledge [1,2]. Although the use of technology has always been extensive in the profession, recent technological advancements have focused on incorporating complex machine learning algorithms, which have led to a change in clinical protocols that affect patient outcomes and radiography practice [3-5]. Artificial intelligence (AI) technologies play an increasingly important role in clinical radiography with applications such as scheduling patients, image interpretation and reporting, vetting of examinations, patient positioning, image generation and reconstruction, radiation therapy dosimetry, and image postprocessing [4,6-8]. As the number of AI applications increases in clinical practice [9], it is postulated that the practitioner role may change and expand, and these new roles will require modifications to the competencies and educational requirements of current and future practitioners [4].

The increasing integration of AI technologies in radiography practice raises significant questions about the influences of AI technology on radiography practice and the subsequent ways in which radiography education may be required to change. Recent reviews have explored AI's current and potential applications in radiography practice [5] and examined the AI educational programs available to radiography staff globally [1]. Furthermore, research undertaken in the United Kingdom, Africa, and the Middle East exploring AI topics linked to education in radiography has focused on equipping practitioners for successful AI adoption [10] as well as the perceptions and attitudes of students and practitioners [11-16]. These conversations illustrate that there has been increasing exploration of various facets of AI in radiography, indicating that the emergence of AI technologies will continue to shape the future of radiography and radiography education.

Opinion statements and discussion pieces argue for the inclusion of AI education in undergraduate radiography curricula and appropriate education for current practitioners [3,4,17]. In addition, recommendations were made that higher education institutions must ensure that radiography curricula provide educational opportunities for patient-centered care in relation to AI integration to ensure competent and safe practice [2,3,6]. With increasing automation in clinical tasks, patient-centered care will gain more importance, highlighting the need for academic curricula to prioritize patient-centered care [2,4]. The evolving landscape of radiography, marked by the increasing integration of AI, raises important questions about how to best prepare future radiographers. Therefore, mapping the existing literature on the way that radiography education may need to change because of the integration of AI technologies in clinical practice is needed to grasp the current state of knowledge on the topic for future educational considerations. The aim of this scoping review is to explore and synthesize the literature on the adjustments needed in the radiography curriculum to prepare radiography students for the demands of AI-assisted health care environments.

Methods

Overview

The review will follow the Joanna Briggs Institute methodology for scoping reviews because it uses a rigorous and logical approach to scoping reviews [18,19]. The methodological guideline delineates 6 steps to map the extent of the literature on the research topic. These include (1) defining the research question, (2) developing the inclusion and exclusion criteria, (3) describing the search strategy, (4) searching the literature, (5) data extraction, and (6) analyzing the evidence and presenting the results [19]. The scoping review protocol is registered on the Open Science Framework [20]. The PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) reporting guidelines and checklist [21] will be used to report the results (Multimedia Appendix 1).

Step 1: Defining the Review Question

The research question that will guide the scoping review is "How should the radiography curriculum be adapted to prepare radiography students for the integration of AI technologies in the health care environment?"

For this review, radiography refers to the four different radiography categories, including diagnostic radiography, diagnostic ultrasound, nuclear medicine technology, and radiation therapy.

Step 2: Study Selection

Inclusion Criteria

Overview

The types of studies to be considered for this review include quantitative, qualitative, mixed methods studies, scoping, literature, systematic reviews, opinion papers, letters, and conference papers. The selection of study types included in this review is justified based on the need for a comprehensive and nuanced understanding of the topic. The review will consider articles from any country or region, provided that an English translation of the article can be sourced or a translation app is available [22]. The Participants, Concept, and Context (PCC) framework will be used to systematically organize the scope of the review, ensuring it aligns with the objective and the relevant studies are included [18,19].

Population

The population consists of radiography students and educators. In addition, articles that form part of multidisciplinary health

professions' groups of which radiography forms a portion will also be included.

Concept

The concept focuses on how AI technologies are reshaping the clinical environment and the corresponding adjustments required in the radiography curriculum to prepare radiography students for this evolving landscape.

Context

This review will consider articles from academic and clinical settings in all countries.

Exclusion Criteria

Studies specifically related to other health professions' disciplines will be excluded. Furthermore, technologies discussed in the literature that lack AI will be excluded from consideration. All studies that align with the inclusion criteria, including the PCC, will be included in the review. In addition, articles for which the full text is not available through institutional subscriptions, interlibrary loans, or after contacting the corresponding author will not be included in the review. The authors will attempt to maximize access through the available institutional resources, but limitations may still apply. A full list of the eligibility criteria is provided in Table 1.

Table 1. Eligibility criteria for the scoping review.

PCC[a] Framework	Include	Exclude
Population	• All 4 radiography categories • Radiography educators • Radiography students	All other health professions' disciplines
Concept	• Studies that discuss AI[b] or AI-based tools in the context of radiography	Studies using technology that does not incorporate AI-based tools
Context	• Academic and clinical radiography education • Undergraduate radiography education • Postgraduate radiography education • Continuing professional development	Other health professions' education programs
Study characteristics	• The review will consider all types of study designs. • Sources printed in all languages • Full-text articles	Full-text not available

[a]PCC: Population, Concept, Context.

[b]AI: artificial intelligence.

Step 3: Search Strategy

The search strategy aimed to include published and unpublished literature. A preliminary search was performed on Scopus to identify articles on the topic in collaboration with a library specialist. The Scopus database was chosen because it is the largest indexing and abstract database and hosts a number of widely acknowledged Radiography journals. The search strategy was developed by examining the text found in the titles and abstracts of the relevant literature and the index terms and keywords used to describe the articles. The process entailed screening the titles and abstracts of 50 articles. Thereafter, the search strategy was refined iteratively through consultations with the librarian and between the authors. The detailed final search strategy for all databases, EBSCOhost, PubMed, Scopus, and Web of Science can be found in Multimedia Appendix 2. Gray literature was retrieved from the databases, including book chapters, conference papers, and letters. The total number of sources found was 2224 (Table 2).

Table 2. Electronic databases and gray literature results.

Electronic resources	Sources, n
EBSCO (Academic Search Premier, CINAHL, ERIC)	362
PubMed	1214
Scopus	267
Web of Science	112
Gray literature	269
Results	2224

Step 4: Selection of Evidence

Following the search, all citations were imported and managed using the Covidence online software [23]. All the duplicates were removed after the studies were imported into the software program. The primary investigator (CK) and a research assistant screened the studies during the title and abstract phase based on the inclusion and exclusion criteria to ensure that they are

relevant to the review [24]. The inclusion and exclusion criteria will be piloted on the first 20 articles to ensure that the criteria are applied consistently and that the relevant studies are included.

After the initial screening, a full-text screening of the selected articles will be performed to determine the literature to be included in the review. The reference list of all selected articles will then be hand-searched for additional studies that may be eligible according to the inclusion criteria. Following the full search, all citations will be captured. Any disagreements that arise between the reviewers at each stage of the selection process will be resolved through discussions, or with an additional reviewer and the changes will be noted and shared in the final scoping review report. Furthermore, reasons for the exclusion of sources of evidence at full-text screening will be recorded and reported in the scoping review.

Step 5: Data Extraction

To meet the aim and research question, the data will be organized according to the Joanna Briggs Institute template source of evidence details, characteristics, and results extraction instrument [22], incorporating key study information such as authors, study population, year of publication, study location, study design, and the key findings (Multimedia Appendix 3). This data extraction instrument was created and will be piloted to minimize potential bias. Piloting of the data extraction instrument will include a selection of 3-5 articles from the scoping review dataset and the two reviewers will perform independent data extraction to ensure that all the necessary data will be captured [21]. The instrument will be used to determine if the inclusion and exclusion criteria have been met during evidence selection. Modifications to the instrument may be made during the course of the literature search and the findings will be detailed in the scoping review report.

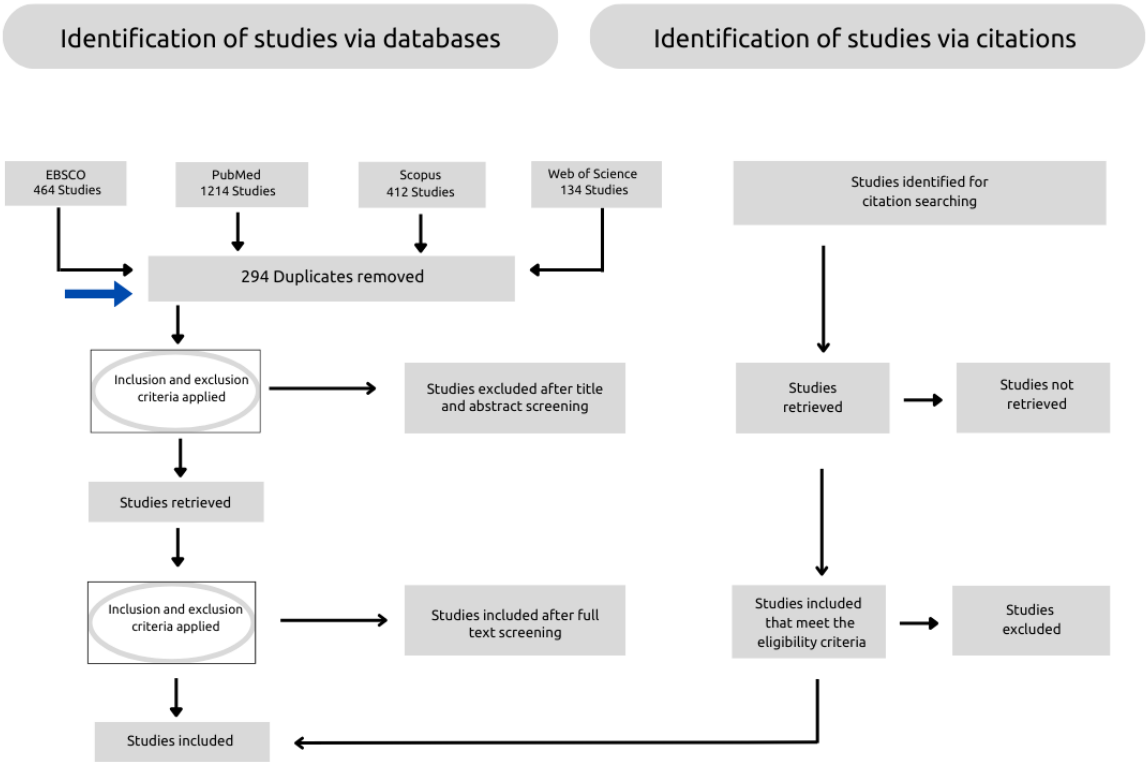
Step 6: Data Analysis

Scoping reviews should include a numerical summary outlining the types of literature that were retrieved and a thematic descriptive analysis [19]. The final themes of the scoping review will be developed using an iterative approach. A narrative description will then be used to synthesize the study findings using descriptive content analysis, and the identified themes will be reported.

Results

The final database searches were completed in October 2024 and in total produced 2224 items. Title and abstract screening of 1930 articles is underway after removing the 294 duplicates. The results will be presented in relation to the research question and the objective of the study. Furthermore, the results will be presented in 2 parts as proposed by Peters and colleagues [19]. The first part will consist of the results of the search and the inclusion of the studies will be presented with the PRISMA-ScR flow diagram (Figure 1). The blue arrow indicates the current status. The second part will consist of a narrative description that aligns with the objective of the scoping review. Data analysis and results may be further refined through the review process as the contents of the review are taken into consideration. Finalization of the scoping review is expected by March 2025. The results of the scoping review will be disseminated through publication in an accredited journal.

Figure 1. Flowchart of the PRISMA-ScR for the scoping review process. PRISMA-ScR: Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews.



Discussion

Addressing the call for an update to the radiography curriculum in response to new technological advancements such as AI is critical to prepare and equip current and future professionals for safe practice. This scoping review will map various studies and is anticipated to provide an overview of the adjustments needed in the radiography curriculum to prepare radiography students for the demands of AI-assisted health care environments. In return, the results will help to inform a variety of stakeholders, including radiography educators, radiography regulatory bodies, and radiography professional groups, to plan for needed changes in radiography education in response to the impact of AI-based technologies on clinical processes. To the best of our knowledge, this is the first scoping review to synthesize existing evidence of how the radiography curriculum might best prepare future practitioners for the demands of AI-assisted health care environments.

A strength of the scoping review is that all available studies of published data will be included. Current available literature focusing on how the radiography curriculum might need to change, considering the incorporation of AI technology in clinical practice, focuses on opinion and discussion pieces, and white papers [4,17,24]. In addition, some studies have highlighted the perceptions of educators and students on the incorporation of AI into radiography curricula; however specific methods of integration and a lack of implementation were noted [1]. Therefore, performing this review is warranted to help provide the necessary insights into changes to the curriculum that are aligned with the advances in technology.

A scoping review explores the breadth and not the depth of a topic, and the reviewers cannot comment on the quality of the studies included in the review. In addition, non-English articles may be excluded from this review, which can potentially lead to missing valuable work. However, for the search strategy, all languages are included and the number of studies for all languages will be documented. This process will show how many studies were identified but not included, promoting transparency in the selection process [22]. Furthermore, where possible translations will be sought to limit the omission of information.

This study will provide valuable insights into how the radiography curriculum should adapt to meet the educational needs of current and future practitioners to ensure competent and safe practice in response to AI technologies. Mapping the existing evidence is essential because the growing integration of AI-based technologies in clinical practice must be supported with appropriate education and training [1,4]. After collating and analyzing the findings of the scoping review, a manuscript containing the final analysis will be written and submitted for publication. In addition, this review will contribute toward a PhD in health professions education.

Acknowledgments

We would like to thank the librarian, Mr Yusuf Ras, for his contribution to the scoping review protocol.

Data Availability

All relevant data are available in the study or as multimedia appendices and will be made available upon request.

Authors' Contributions

CK conceptualized the scoping review, wrote the manuscript, and provided data. EA, PEH, and MV provided oversight for the scoping review protocol development.

Conflicts of Interest

None declared.

Abstract

Background: Indigenous people do not necessarily view disability in the same way as do other groups. Indigenous concepts of disability are connected to their ancestral history, cultural customs, and environmental context. Some Indigenous languages do not contain a word equivalent to disability. Western approaches to disability seldom reflect the voices of Indigenous people.

Objective: The objective of this scoping review is to collate the perspectives, concepts, and understandings of disability in Indigenous communities in Canada and to map the factors that influence social approaches to disability from an Indigenous perspective.

Methods: Following the methodological framework for scoping reviews of Arksey and O'Malley, we will search electronic databases, including PubMed, Scopus, Web of Science, EBSCOhost ProQuest, Autochtonia, and APA PsycINFO. We will search gray literature through the Google search engine, conference abstracts, dissertation databases, government documents, and Indigenous organization websites. We will include quantitative, qualitative, and mixed methods studies in English and French. The included studies will describe Indigenous approaches to disability, as they are understood based on personal, cultural, and historical contexts. Two reviewers will use Covidence software (Cochrane) to remove duplicates, screen articles, record the step-by-step selection process, and extract data from the included articles. We will follow the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analysis extension for Scoping Reviews) guidelines. We will present the findings in tables, charts, narrative summaries, and through fuzzy cognitive mapping. We will contextualize the literature's findings by comparing them with the stakeholders in Quebec and provide a discussion to explore potential solutions for the identified factors.

Results: An initial limited search was conducted in January 2024. The study will be conducted in 2025. Publication of the results is expected in late 2025.

Conclusions: We anticipate that the findings from the scoping review will be useful for professionals, researchers, policy makers, and Indigenous communities themselves interested in co-designing and implementing evidence-informed disability programs and services, which will prevent mismatches between the programs and the sociocultural context. We will disseminate

the results of this review through workshops with the participating communities, direct engagement with relevant local stakeholders, and through conference presentations and publications in scientific journals.

KEYWORDS

Indigenous health; intercultural dialog; cultural safety; traditional medicine; disability

Introduction

The way disability is defined affects the types of disability services offered, who uses the services, and the way they work. The traditional biomedical model, despite frequent criticism, continues to influence Western approaches to disability [1,2]. This model views disability as an individual issue, characterized by abnormalities of the body or mind that medical science treats and social services cater for. In this mindset, experts are seen as the professionals responsible for either treating disabled individuals or coordinating services for them. Also focused on individual abnormalities and perhaps more criticized than the biomedical model for treating differences as medical issues and creating population categories, the moral model depicts disability either as a source of stigma and shame or, alternatively, as a sign of strength [3,4].

Social and inclusion models of disability reflect interactions between people with disabilities and attitudinal or environmental barriers that prevent their full and effective participation in society [5]. These approaches go beyond disability as a personal attribute to frame disability in terms of the conditions created by the social environment that cause people to experience barriers to performance in life situations. In the same way, the International Classification of Functioning, Disability, and Health (ICF) reinforces this view by emphasizing that disability results from the interaction between health conditions and contextual factors both environmental and personal [6,7]. The ICF highlights the importance of addressing not only impairments but also the external barriers that limit activity and participation [3,7,8]. Another approach explores not only physical or mental impairments but also the societal norms that define certain characteristics as disabilities. It's important to examine how social conditions exacerbate these stigmatized characteristics within specific populations [9-11]. A constructive step might be to engage with Indigenous communities to discuss the language and concepts surrounding disability, particularly whether colonialism and its resulting social disadvantages have transformed the social meaning of disability for Indigenous people [12,13].

Literature over the last 2 decades describes Indigenous perspectives and beliefs about disability [12,14-16]. Many Indigenous languages have no word for "disability," suggesting it is a term produced by western constructs [17], rather than anything negative or based on difference [18,19]. Articles about the intersection of indigeneity and disability highlight the importance of family ties, community networks and spirituality [14,16,18,20-24]. Although clearly different from western views, Indigenous worldviews of disability are not monolithic. Views vary between Indigenous cultures and, within any 1 culture, may not be static but responsive to the recovery of traditions and to adaptations [24,25].

With no published systematic review about Indigenous perspectives of disability from Canada, a review from Australia provides a substantial advance in the field [23]. This examined the understanding of disability within Australian Indigenous communities, highlighting that some disability services are shaped by western norms and assumptions that do not reflect their values. The review also notes that scholarly literature on Indigenous conceptualizations, experiences, and practices of disability remains relatively underdeveloped. Our review explores similar themes within the Canadian context. Our aim is to describe the concepts of First Nations, Métis, and Inuit, the 3 constitutionally recognized Indigenous groups in Canada who comprise approximately 5% of the country's population [26] and reflect unique cultural, environmental, and historical influences. Our review will focus on Indigenous points of view, summarizing the diverse narratives and choosing not to reproduce damage-centered approaches that contributed to pain and oppression [27].

We describe here the protocol for a scoping review, a starting point of a larger research program. This will compare and combine different knowledge sources to inform partnerships that address knowledge, policy, and implementation gaps for disability support services in Indigenous communities. The broader research initiative will encompass the following knowledge resources: (1) the scoping review detailed in this protocol; (2) perspectives from personnel of community-based initiatives and Indigenous-led organizations; (3) perspectives of Indigenous elders and knowledge keepers; and (4) perspectives from disability service providers, researchers, policy makers and people encountering disabling situations from the communities and their peers. The Weight of Evidence approach [28] uses fuzzy cognitive mapping [29] and will integrate these diverse sources of knowledge.

Methods

Study Design

We used the PRISMA-P (Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols) [30] checklist (Multimedia Appendix 1) for drafting the protocol. We will conduct the scoping review according to the guidelines proposed by Arksey and O'Malley [31] and the modifications proposed by Levac et al [32]. The 6-stage process includes identifying the research question, identifying relevant studies, developing

a study selection and data extraction method, charting the data, collating, summarizing, and reporting results, and contextualization with stakeholders. We will adapt the final step to function as a contextualization exercise, guided by the weight of evidence approach [28] that contrasts literature findings with contributions from stakeholders. The final report will follow the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-analyses extension for Scoping Reviews) [33].

Our team consists of 2 Indigenous researchers with expertise in Indigenous perspectives, psychosocial interventions, and inclusion. Other authors bring significant experience working with Indigenous communities in Canada and Mexico, as well as extensive expertise in working with people with disabilities in Nigeria, Zambia, Canada, and Colombia. We will do the first contextualization in the province of Quebec, as we describe below. We will verbally share discussions with our Indigenous researcher partners in Nunavik and Indigenous community members in the Saguenay-Lac-Saint-Jean region (Mashteuiatsh community) and the team leading the Nisidotam Inclusion Initiative in the Greater Montreal area. This ensures that Indigenous worldviews inform the approach, analysis, and findings, including the discovery and description of key knowledge gaps. We may make changes to the protocol, and we will detail and justify any modifications in the final report.

Stage 1: Identifying the Research Question

Our research questions are as follows:

1. What does the literature reveal about Indigenous perspectives, concepts, and understandings of disability in Indigenous communities in Canada?
2. What are the key factors that influence disability among Indigenous communities in Canada?

Inclusion Criteria

The participants, concept, and context (PCC) framework will guide the inclusion of eligible studies in this scoping review [34].

Participants

This review will consider sources that include the First Nations, Inuit, and Métis in Canada as the population of interest. We will include the recognized names of Indigenous peoples as search terms in this review.

Concept

This review will consider studies on Indigenous perspectives, concepts, and understandings of disability in Canada, as well as the factors influencing disability among Indigenous people.

Context

This review will consider studies or reports conducted in any Canadian province or territory, as well as those with a substantial focus on the Canadian context.

Types of Sources

This scoping review will consider peer-reviewed and gray literature. Mixed methods, quantitative, and qualitative studies are eligible for inclusion. The publication date range will be unrestricted.

Stage 2: Identifying Relevant Studies

We will consider sources that describe or reflect Indigenous perspectives on disability, whether they are published in peer-reviewed journals or as gray literature. The study or report must be located within Canada or have a significant component of the Canadian context.

We will design a structured search strategy for the electronic databases PubMed, Scopus, Web of Science, EBSCOhost (Bibliography of Indigenous Peoples in North America), ProQuest (Canadian Business and Current Affairs Database), Autochtonia, and APA PsycINFO to identify relevant published studies. We will develop the strategy using Boolean operators, filters, and truncation for each database. We will search for relevant articles using a mixture of search terms and keywords. We will consider adapting the filter developed by the University of Alberta to retrieve studies related to Indigenous people [35]. The research team will draft and refine a search strategy with the support of a professional librarian. We will pilot the search strategy to check the appropriateness of the keywords and databases. As an example, Multimedia Appendix 2 presents the search strategy for Scopus database.

The search for potentially relevant documents in the gray literature will follow 4 different searching strategies [36]: (1) search gray literature databases such as the Canadian Research Index and the Indigenous Studies Portal at the University of Saskatchewan; (2) use customized Google search engines to examine the first ten pages of results. Combine keywords using simple Boolean operators or hand search relevant subsections of sites; (3) Target Indigenous associations and websites for relevant information; and (4) Consult with experts proficient in research synthesis and aware of relevant documents to gather additional insights. We will contact both Indigenous and non-Indigenous scholars to include multiple sources and ensure our search is as inclusive as possible.

We will hand-search the references for the included articles to identify any additional relevant articles. We will limit the search to articles published in English or French. We will not apply restrictions based on the year of publication or study design.

To stay updated of current work in the field, our scoping analysis methodology will allow us to continually circle back to take newer articles through the screening process and potentially include them in our analysis.

Stage 3: Study Selection

We will export the list of references into Covidence software (Veritas Health Innovation) [37] to conduct title or abstract and full-text screening, first using the software to remove duplicates. Two independent researchers will screen study titles and abstracts against the inclusion and exclusion criteria to identify potentially relevant articles for full-text review. Two reviewers will then conduct a full-text review to confirm the final selection of articles. We will resolve disagreements by consensus or by consulting a third reviewer. A PRISMA (Preferred Reporting

Items for Systematic Reviews and Meta-analyses) flow chart will show the study selection procedure.

Stage 4: Charting the Data

Two reviewers will use the Covidence data charting framework to extract the relevant data from the included articles. They will pilot the draft data extraction sheet on a random sample of 5 articles. They will use a free use application to chart the data. The first part of the data extracted will include the authors, study title, source or journal, publication type, year of publication, objectives of the study, study design, geographic location, Indigenous group, description of participants, language, findings on perspectives, concepts, understandings, and terminology used about disability. The second part will list all the factors that influence disability from the Indigenous perspective and their relationships. We will present a 3-column edge list, a tabular format to represent relationships in a fuzzy cognitive map. The columns will include causes (originating node), outcomes (landing node), and the sign of the relationship (–1 or +1) [29]. Additional columns will indicate supporting evidence for the relationship and corresponding reference. We will use 1 row for each relationship. If the evidence is quantitative, we will include relationships that are significant at the 95% confidence level. If the evidence is qualitative, we will include quotes, arguments or texts supporting the relationship. We will adjust and refine the data extraction form as needed throughout the data extraction process and document any modifications in the review report. Data extractors will resolve disagreements through discussion.

Stage 5: Collating, Summarizing, and Reporting Results

We will present the results of the review as a qualitative description, incorporating tables, figures, and maps where appropriate. We will present the findings of the scoping review in a fuzzy cognitive map to illustrate the perspectives, concepts and understandings of disability and the factors that influence disability from an Indigenous perspective.

Fuzzy cognitive mapping visually represents knowledge, helping clarify the complex factors that influence outcomes or decisions [38,39]. These maps show assumed causal relationships that can be based on data or unwritten knowledge [40] between concepts or factors (nodes) and the outcomes, connected by arrows or edges [38,39,41]. The source of knowledge assigns different values to the edges, indicating the direction of the causal relationships and quantifying the strength of their influence on the outcome [28,38,39,41,42].

We will create a map for each article included in the review. We will identify whether the influence of a reported factor is positive or negative (+1 or –1) and depict it in a 3-column edge table as described above. If the study shows that an increase in one factor leads to an increase in another factor, we will assign a positive relationship (+1). If it shows a decrease in the second factor, we will assign a negative relationship (–1) [42].

After creating an individual table for each included study, we will calculate the fuzzy transitive closure for each study using the open access software CIETmap (V.2.2) to determine the strength of influence one factor has on others through direct or indirect relationships [43].

We will use Harris' discourse analysis approach to weigh each relationship based on its relative frequency across all the transitive closure maps [44,45]. Factors appearing in multiple maps will be weighted as having a stronger causal influence than those appearing in only 1 or 2 studies [41,45]. By dividing each relationship's occurrence by the highest frequency, we will obtain values between 0 and 1, where values closer to 1 indicate more influence. We will create a composite map of all factors and relationships identified in the scoping review, with relationship weights based on their relative frequency [45]. Multimedia Appendix 3 illustrates an example of a fuzzy cognitive map.

We anticipate refining and expanding the data presentation approach as the nature of the available literature becomes known. We will highlight areas where evidence is lacking and make recommendations for decision-making, practice or further research.

We will report the review methods and findings according to the PRISMA-ScR guidelines. We will disseminate the results of the scoping review in a peer-reviewed publication and present and discuss them in relevant forums, workshops, conferences, and community spaces. Potential limitations of the review include that we may miss studies reported in Indigenous languages and that some local knowledge may not be accessible despite best efforts to search the gray literature.

Stage 6: Contextualization

We will contextualize with stakeholders in the final step of the scoping review [31,32], which is part of a broader participatory research project on disability among Indigenous peoples of Canada. We will adapt the "weight of evidence" approach [28] to contrast and combine the synthesized evidence from the literature with the experiential knowledge of stakeholders, including Indigenous scholars, elders, knowledge keepers, cultural advisors, individuals with disabilities from the communities and their peers, as well as members of community-based and regional organizations representing people with disabilities or First Nations and Inuit in Quebec. We will invite them to share their perspectives, concepts, and understandings of disability in Indigenous communities, and to create maps of the factors that influence disability from an Indigenous perspective.

We will adapt the fuzzy cognitive mapping protocol recommended by Andersson and Silver [39]. A facilitator and a notetaker will support each stakeholder mapping session.

After the stakeholders create their own maps, they will compare them with the composite map from the scoping review. We will combine the scoping review map with the users' maps to update the literature with stakeholder perspectives. The scoping review and the stakeholder maps will serve as the basis for engaging them to explore solutions for the identified issues.

Results

The preliminary database search was conducted in January 2024. The study is scheduled for 2025, and its results will be published in open-access, peer-reviewed journals by the end of 2025.

Discussion

Principal Findings

The proposed scoping review will identify and map evidence on Indigenous concepts, perspectives, and understandings of disability as well as the key factors that influence disability in Canada. This review offers space for perspectives outside Western paradigms, facilitating a subsequent intercultural dialogue. This dialogue allows stakeholders with different cultural backgrounds to engage in respectful, dynamic communication to address a concern [46], in this case, the conceptualization of disability in Indigenous communities. The review might encourage a more inclusive, comprehensive, and culturally safe understanding of disability. It will contextualize the existing literature in the rich heritage of Indigenous Peoples in Quebec, Canada, including their perspective of disability and the implications of this for disability policy in this province. It will serve as a prototype for contextualizing the literature in the specific belief systems of Indigenous groups in other provinces and beyond Canada.

To our knowledge, no previous literature review has covered this topic in Canada. However, a review published by Australian authors significantly advances the understanding of disability services and disability conceptualization within Indigenous communities.

Strengths and Limitations

This scoping review has several strengths. First, we will include gray literature. By doing so, we will add valuable insights and ensure we don't miss findings and diverse perspectives that may not be found in peer-reviewed academic sources. Second, by contrasting and integrating evidence from the literature with the knowledge of Indigenous communities and people with disabilities through fuzzy cognitive maps, the scoping review will provide a thorough overview. Third, the participatory nature of the exercise will engage all stakeholders in interrogation of the literature and the codevelopment of a uniquely provincial and inclusive perspective. In this important sense, participation in the review process can be a first step in the intercultural dialogue.

The scoping review will have certain limitations. Some studies in Indigenous languages might be missed, and certain local knowledge may remain inaccessible, despite diligent attempts to include gray literature. The review will not include a quality assessment of the studies, which may introduce a risk of bias. We will provide a description of the methodologies and different criteria used to facilitate the contextualization of the findings. Potential limitations could include challenges in language use during fuzzy cognitive mapping for stakeholders, operator bias (influence of facilitators), as well as issues with coding and weighting [29]. To address this, we will train facilitators in protocols to reduce these recognized weaknesses. We are aware that the inclusion of multiple interpretations, factors, and varying levels of methodological rigor across different groups could decrease the precision of results.

Future Directions

By mapping the literature and identifying knowledge gaps, this scoping review will be a first step toward identifying research priorities and developing effective policies and interventions for Indigenous groups with disabilities. Future directions include repetition of the contextualization exercise in other Canadian provinces, generating provincially specific reviews that take account of Indigenous views in that province and the provincial agencies concerned with Indigenous people living with disability.

In addition to scientific publication and conference presentations, we will share the findings through workshops with participating communities and civil society organizations working in disability in Quebec.

Acknowledgments

The authors would like to thank Genevieve Gore from the McGill University Library for assistance with the development of the search strategy and Julian Robbins from the Centre for Addiction and Mental Health (CAMH) for his feedback on this protocol.

Authors' Contributions

All authors contributed to drafting the initial protocol, critically reviewed it for intellectual content, and subsequently revised it for publication. All authors reviewed and approved the submission of the final manuscript.

Abstract

Background: Growing evidence shows various health and well-being benefits from nature contact in parks and other forms of protected areas. However, the methods to measure these outcomes lack systematic identification, critical appraisal, and synthesis. Researchers working in this area would benefit from a clear framework highlighting key considerations when selecting measurement tools, along with a summary of the measures used, and insights into the limitations of generalizing existing research findings.

Objective: The objectives of this scoping review are 2-fold. First, we aim to identify the instruments used to measure mental health and well-being outcomes of adults associated with direct nature contact in parks and other forms of protected areas. Second, we aim to evaluate the psychometric properties associated with the validity of these instruments to better understand the strengths and weaknesses of current measurement approaches.

Methods: Following PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines, 8 scholarly databases were searched (PubMed, Web of Science, PsycINFO [via ProQuest], ERIC [via EBSCOhost], CINAHL [via EBSCOhost], GreenFILE [via EBSCOhost], OVID, and GEOBASE) on January 4, 2023, for literature measuring the mental health and well-being outcomes associated with nature contact in protected areas. Sources were screened by reviewers based on clear inclusion or exclusion criteria relevant to the research questions: peer-reviewed English language studies measuring mental health and well-being focused on adults (aged 18+ years) with direct, in-person nature contact in parks and protected areas. Data will be extracted, analyzed, and represented according to 3 domains. This includes study details, characteristics of the measurement instruments, and their validity.

Results: The results of the study and submission of a manuscript for peer review are expected in April 2025. The results of the scoping review are expected to contribute to an understanding of the diverse methods used to measure mental health and well-being related to nature contact in protected areas. Expected findings will include an organized summary of existing quantitative and qualitative instruments for measuring mental health and well-being outcomes, including appraisal of the instrument's psychometric properties.

Conclusions: To the authors' knowledge, this will be the first scoping review undertaken on measures used to assess mental health and well-being outcomes related to nature contact in parks and protected areas context, offering a starting point from which to critically examine the validity and consistency of such methods. Findings will aid in identifying the strengths and weaknesses of current measurement approaches to mental health and well-being outcomes of nature contact and may be used to guide future research on this topic, helping researchers choose the best tool to assess outcomes.

Introduction

Overview

There is a growing body of research investigating the role of nature in human health and well-being, with numerous studies reporting improvements to physical, psychological, emotional, cognitive, social, and spiritual well-being from time spent in nature [1-4]. Within this context, parks and other forms of protected areas offer unique opportunities to connect with nature, and considerable research has highlighted the increasingly recognized health benefits afforded by these settings [5-8].

Globally, there are more than 295,000 protected areas covering 16.1% of the earth's terrestrial or freshwater area and 8.2% of its marine area [9]. There is also a highly ambitious global initiative to protect 30% of earth's land or freshwater and marine area by 2030, as per the United Nations Convention on Biological Diversity Kunming-Montreal Global Biodiversity Framework [10]. If this goal is achieved, the designation of parks and other forms of protected areas would represent the fastest and largest land or freshwater and ocean allocation in the history of the modern conservation movement. Protected areas differ from most urban green space and local-regional parks in that they have legislated management objectives to conserve nature and provide opportunities for human enjoyment. The International Union for Conservation of Nature (IUCN) defines a protected area as "a clearly defined geographical space, recognized, dedicated and managed, through legal or other effective means, to achieve the long-term conservation of nature with associated ecosystem services and cultural values" [11].

Protected areas can include national and subnational protected area designations, such as national parks, state or provincial parks, and a variety of other designations that fit within the IUCN definition. It is estimated that such areas receive more than 8 billion visits annually [12], underscoring their significance as an essential ecosystem service. It is also estimated that parks and protected areas provide health services valued at US $6 trillion annually worldwide (representing 8% of global gross national product) [13]. Evidence establishing the significance of protected areas to human health and well-being continues to grow at the same time that many nations are committing to significantly expand protected areas networks by 2030. Given these joint trends, this proposed review offers a timely stock take that will help direct the current state of knowledge toward a stronger evidence-informed practice related to the use of parks and protected areas as a nature-based mental health service.

In addition to being timely, the proposed review will provide an important new tool for researchers who face numerous challenges investigating the impact of nature on human health and well-being. Previous research has examined the impact of nature on human health, demonstrating that mental health and well-being outcomes are the most frequently studied [2]. Despite a growing wealth of research, steps to critically evaluate and provide decision support to researchers and practitioners at the level of instrumentation are lacking. The dearth of current decision support presents a critical gap as well-being is a wide-ranging concept, with still wider-ranging options related to measurement. Well-being can capture relatively transitory emotion and mood states, more stable aspects of positive identity such as self-acceptance and self-esteem, broad global evaluations such as subjective life satisfaction, and improvement in clinical conditions such as anxiety and depression.

The need for this review is underscored by a past systematic review conducted by Cooke et al [14]. While not specific to nature-based interventions, Cooke et al [14] identified more than 40 different instruments for measuring well-being that varied widely in length, psychometric properties (ie, validity), and use cases. Linton et al [15] argue that such variability may in part be due to a lack of agreed upon criteria of what an instrument should contain. As noted, despite the current variety, ongoing creation of new instruments, and proliferation of their use in nature-based contexts, there has been no systematic or critical examination of the methods used to measure health and well-being outcomes associated with nature contact in parks and other forms of protected areas. This is a critical knowledge gap that the proposed scoping review will address.

Researchers working in this area would benefit from a clear framework identifying the features to consider in measurement selection as well as a summary of the measures that have been used and their validity. A framework of this type would provide a clearer picture of aspects of well-being that have and have not been investigated or replicated and limits to the generalizability of the research to date. To support further research and decision-making related to outcome-based management in parks and other forms of protected areas, the proposed scoping review seeks to address two objectives: (1) to identify the instruments used to measure mental health and well-being outcomes of adults associated with direct nature contact in parks and other forms of protected areas and (2) to evaluate the psychometric properties associated with validity of the instruments used to measure mental health and well-being outcomes associated with direct nature contact.

Existing Reviews

The current protocol was informed by an initial review of existing peer-reviewed literature to identify potentially comparable knowledge syntheses. To capture the current state of research related to mental health and well-being outcomes from nature contact, we gathered and documented scoping reviews published within the past decade that focused on an adult population. A search was conducted in Google Scholar to locate relevant scoping reviews, using variations of keywords that included "nature contact," "mental health," "well-being," and "scoping reviews." Table 1 outlines details of 7 relevant knowledge syntheses. All identified studies focused on

constructs related to mental health and well-being. While 6 of the identified studies were specific to health and well-being outcomes related to nature contact, by contrast, none were specific to the unique context of parks and protected areas.

Table 1. Summary of comparable existing knowledge syntheses.

[a]Y: yes.

[b]N: no.

Cooke et al [14] reviewed 42 different instruments used to measure aspects of psychological well-being, psychosocial well-being, and psycho-physical well-being. The study categorizes these instruments according to 4 well-being categories (hedonic, eudaimonic, quality of life, and wellness) and a fifth category of composite measures. Evidence of reliability and validity of each instrument is tracked and reported, and authors report a substantial degree of variability in the reporting of evidence related to validity. Results do not report on patterns in the use of instruments according to intervention types or environmental contexts.

In 2 recent reviews, authors documented nature-based interventions and associated health and well-being outcomes. Wilkie and Davidson [18] examined 52 studies including a categorization of environmental settings, exposure times, and theoretical frameworks. They also report on targeted behaviors and outcomes, which includes mental health and well-being in 79% of studies reviewed and physiological health outcomes in 63% of studies. Results track specific outcomes (eg, self-esteem) that were measured but no details around measurement instruments. Nejade et al [2] similarly reviewed 39 papers that provided evidence of mental and physical health outcomes from nature-based health interventions. The forms of natural outdoor environments included green spaces, blue spaces, and mixed green-blue spaces, ranging from urban parks to wetlands, national parks, or reserves (n=2). The study provides a categorization of nature-based health interventions and activities, reports the mental and physical effects of engagement with natural outdoor environments, and discusses barriers and enablers of such engagement. Instruments used to assess health and well-being outcomes are not assessed.

Despite the proliferation of studies revealing the health and well-being benefits associated with nature contact, there is a clear need to identify and understand the specific instruments being used to assess these benefits. This is especially true in the context of nature contact in parks and other forms of protected areas, where rapid growth in visits to such areas is occurring alongside unprecedented national commitments to protect land or freshwater and marine area the world over. Research is needed to identify the most effective tools for assessing health and well-being outcomes vis-a-vis diverse research contexts (eg, types of environments, activities, and sociodemographic considerations) so that evidence-based policies and guidelines, as well as program outcomes, can be assessed consistently and effectively.

Methods

Research Design and Guiding Frameworks

This scoping review has been registered with the Open Science Framework [21] and developed in accordance with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews) guidelines [22]. The completed PRISMA-P checklist is available in Multimedia Appendix 1.

Scoping reviews are broader in nature than systematic reviews, allowing researchers to examine the extent, range, and nature of research activity in a chosen area as opposed to finding the best evidence possible to a tightly defined research question [23]. A scoping review was considered the most appropriate method to address the research objectives due to the capacity to answer broad questions and summarize findings to identify gaps in the literature [2,24]. The scoping review applies Arksey and O'Malley's [25] five-stage process by (1) identifying the research questions, (2) identifying relevant studies, (3) selecting for studies in the final review, (4) charting the data, and (5) collating, summarizing, and reporting the results. Levac et al [26] expands on this framework to include a sixth optional consulting stage, which the research team deemed unnecessary for the purpose of this study.

Each stage of the scoping review was guided by the Population, Concept, and Context (PCC) framework to establish cohesion between the research questions, search strategy, and inclusion criteria (Textbox 1). The PCC framework is recommended for scoping reviews as a less restrictive alternative to the Population, Intervention, Comparator, and Outcome framework typically applied to systematic reviews [27]. Throughout this process, the purpose of the scoping review will be referred to, and critically discussed by the research team, to ensure that all decisions align with the research objectives and, ultimately, inform both research and practice.

Textbox 1. Developing a scoping review protocol with Population, Concept, and Context.

- P (Population): adults (aged 18 years or older)
- C (Concept): mental health, subjective well-being, emotional health, psychological health, restoration, coping, attention, mood, and indigenous well-being (including spirituality)
- C (Context): direct contact with parks and protected areas (spatial scope)

Search Strategy

A comprehensive search strategy was developed by a multidisciplinary team of 6 researchers in collaboration with an experienced university librarian. Following the recommendations of the Joanna Briggs Institute [28] for developing a search strategy, a limited preliminary search was conducted in Google Scholar using keywords related to the research objectives that included "mental health," "mental well-being," and "protected areas." This preliminary search produced 22 peer-reviewed papers that were deemed relevant to the review topic. The titles and abstracts of each paper were screened, along with the key terms used to describe the papers. This preliminary review allowed the research team to identify a robust set of key terms for the search strategy. The full literature index used to develop the search terms for this scoping review can be found in Multimedia Appendix 2. The protected areas terminology used in the literature search reflects the internationally recognized IUCN definition of protected areas and protected area categories, including specialized applications (ie, marine-protected areas). In addition, to inform the development of the search strategy, a search in the APA (American Psychological Association) Dictionary of Psychology identified relevant terms related to mental health, well-being, and subjective well-being.

Searches were conducted in 8 scholarly databases (PubMed, Web of Science, PsycINFO [via ProQuest], ERIC [via EBSCOhost], CINAHL [via EBSCOhost], GreenFILE [via EBSCOhost], OVID, and GEOBASE) known to contain journals focusing on human health and the natural environment. The search hedge contained terms related to domains of protected areas, nature engagement or exposure, and human mental health and well-being (Table 2). The search targets the intersection of environmental settings (protected area), with actions or events (nature engagement or exposure), and associated outcomes (mental health and well-being). Protected areas are recognized not only as spaces designated for conservation but also as venues for nature engagement. There is substantial evidence linking nature engagement with improved mental health and well-being, including benefits associated with protected areas [8,29-32]. The search terms were grouped by the Boolean operator "OR" to enhance the accuracy and relevance of results by accounting for as many concepts as possible and then combined using the Boolean operator "AND" to ensure that only relevant literature that contains all listed search concepts would be generated. The proximity operator "NEAR/20" was used to identify terms within 20 words of each other, regardless of their order. To

promote transparency and replicability in future research, the full search strategy for each of the 8 databases is available in Multimedia Appendix 3.

All database searches were conducted on January 4, 2023. To limit the scope of the searches, the selected databases were filtered to include only peer-reviewed journal papers published in English. No date filters were used to limit results to ensure that all relevant studies were included. By excluding a date limiter, the search strategy is more likely to identify trends over time, for instance, when certain instruments were first used to measure mental health and well-being in a parks and protected areas context.

Table 2. Primary search hedge subsequently adapted by scholarly database.

Concept	Search terms
Protected area classification	"protected area*" OR "national park*" OR "conserv* area*" OR "provincial park*" OR "state park*" OR "wildlife area*" OR "wildlife sanctuar*" OR "tribal park*" OR "nature reserve*" OR "marine reserve*" OR "marine sanctuar*" OR "conserv* territor*" OR "protected landscape*" OR "protected seascape*" OR "habitat management area*" OR "species management area*" OR "natural area*" OR "wilderness" NEAR/20
Nature engagement	exposure OR access* OR time OR engag* OR visit* OR being OR activity OR exercis* OR experience* AND
Mental health and well-being	"well-being*" OR "psychological restoration" OR "psychological health" OR "restorative*" OR "life satisfaction" OR coping OR "stress hormone" OR cortisol OR "mental health" OR "subjective well*" OR cognit* OR stress* OR emotion* OR anxiety* OR anxious* OR depress* OR mood* OR "state of mind" OR "frame of mind" OR brain* OR mind* OR "self-esteem"

Study Selection Process

All studies identified by our search strategy were uploaded into the reference manager software Zotero (Corporation for Digital Scholarship) [33]. Study details were then imported into the scoping review software Covidence (Veritas Health Innovation Ltd) [34] where duplicates were removed. The screening (and data extraction process) was piloted by 2 independent reviewers (JB and RB). These reviewers screened a random sample of 20 sources to ensure relative consistency and understanding of the proposed inclusion or exclusion criteria.

All studies were screened by 2 independent reviewers (CER and RB) at 2 levels. At the first level, the title, keywords, and abstracts of each source were assessed against the following criteria listed in Textbox 2. Where both reviewers agreed based on explicit content that a criterion was not met, the study was removed. Where there was disagreement or a lack of explicit content to make a judgement, the study moved to level 2 for full text review using the same inclusion or exclusion criteria.

Textbox 2. Inclusion and exclusion criteria.

Inclusion criteria

- Relevant to the research questions.
- Measures mental health and well-being.
- Protected area context.
- Focuses on direct contact (being physically present) with protected areas.
- Peer-reviewed papers (accessible for retrieval).
- Focuses on adults (aged 18 years or older).
- Available in English.

Exclusion criteria

- Not relevant to the research questions.
- Measures only other forms of health and well-being (physical, social, etc).
- Nonprotected area context.
- Focuses on nondirect forms of contact with protected areas (virtual reality, photograph viewing, etc).
- Books, book chapters, or reviews: conference proceedings, dissertations, theses, systematic or scoping reviews, gray literature, news articles, social media content, opinion papers, and inaccessible peer-reviewed papers.
- Includes children (younger than 18 years).
- Not available in English.

At the level of full-text screening, the research team attempted to retrieve the full-text files of all potentially relevant studies through available university library services. If unable to retrieve the full text through the library services, a member of the

research team contacted the corresponding authors to obtain a full-text file. Sources that remained unavailable were removed from the review. Once again, 2 independent reviewers (JB and RB) screened the full-text files applying the same inclusion or exclusion criteria that were used at level 1. Disagreements between reviewers at each stage of the selection process were addressed through discussion, involving a third reviewer to resolve conflicts as necessary.

Data Extraction and Analysis

Data will be extracted using Covidence by 2 independent reviewers (JB and RB) and compared for quality assurance to reduce bias. Any discrepancies that arise will be discussed and conflicts will be resolved by a third reviewer (CER). The proposed data extraction form (Table 3) will be used to identify and extract relevant variables that best address the research objectives. Extracted data from each paper will include descriptive information (eg, author names, title, and year of publication) and study methodology (eg, location, study design, sample, measurement instrument, and timing). Data pertaining to any quantitative or qualitative instruments used to measure mental health and well-being outcomes will also be extracted (eg, dimensions of well-being measured, instrument name, number of items, response scale, and end user engagement). Where a study includes more than 1 instrument of interest, each instrument will be recorded separately.

Table 3. Proposed data extraction template, indicating fields for which researchers will extract data with sample outputs.

Domains	Data extraction fields	Sample outputs
Characteristics of the study	• Reference • Study location • Protected area designation • Study design • Measurement form • Timing of measurement • Time spent in nature	• Full citation of listed study • Canada • National Park • Mixed methods, etc • Questionnaire, interview, etc • While in protected area • Two days, 1 week, etc
Details provided about the quantitative instruments in each study	• Dimensions of well-being • Instrument name • Source • Number of items • Scale size • Substantive validity • Structural validity • External validity	• Affect (eg, feeling, emotion, attachment, or mood) • Positive and Negative Affect Schedule (PANAS) • Author (year) • 20 items • 5-point scale • n=1 (100%) • n=1 (100%) • n=0 (0%)
Details provided about the qualitative instruments in each study	• Dimensions of well-being • Instrument name • Source • “End user” engagement • Multiple researchers involved in theming process • Member checks	• Affect (eg, feeling, emotion, attachment, or mood) • Semistructured interview • Author (year) • n=1 (100%) • n=0 (0%) • n=0 (0%)

Drawing on validity criteria from Simms [35], information that the researchers provide about the quantitative measurement instruments in the “Methods” section of each study will be assessed for 3 aspects of construct validity: substantive validity, structural validity, and external validity. Substantive validity is information about whether a measure is theoretically linked to the construct being studied. Structural validity is information about the degree to which the scores of a scale are an adequate indication of what the items measure, while external validity is information about whether the study findings can be generalized to other contexts [35,36]. Each study will be scored as either yes (1), the validity information was provided, or no (0), the validity information was not provided.

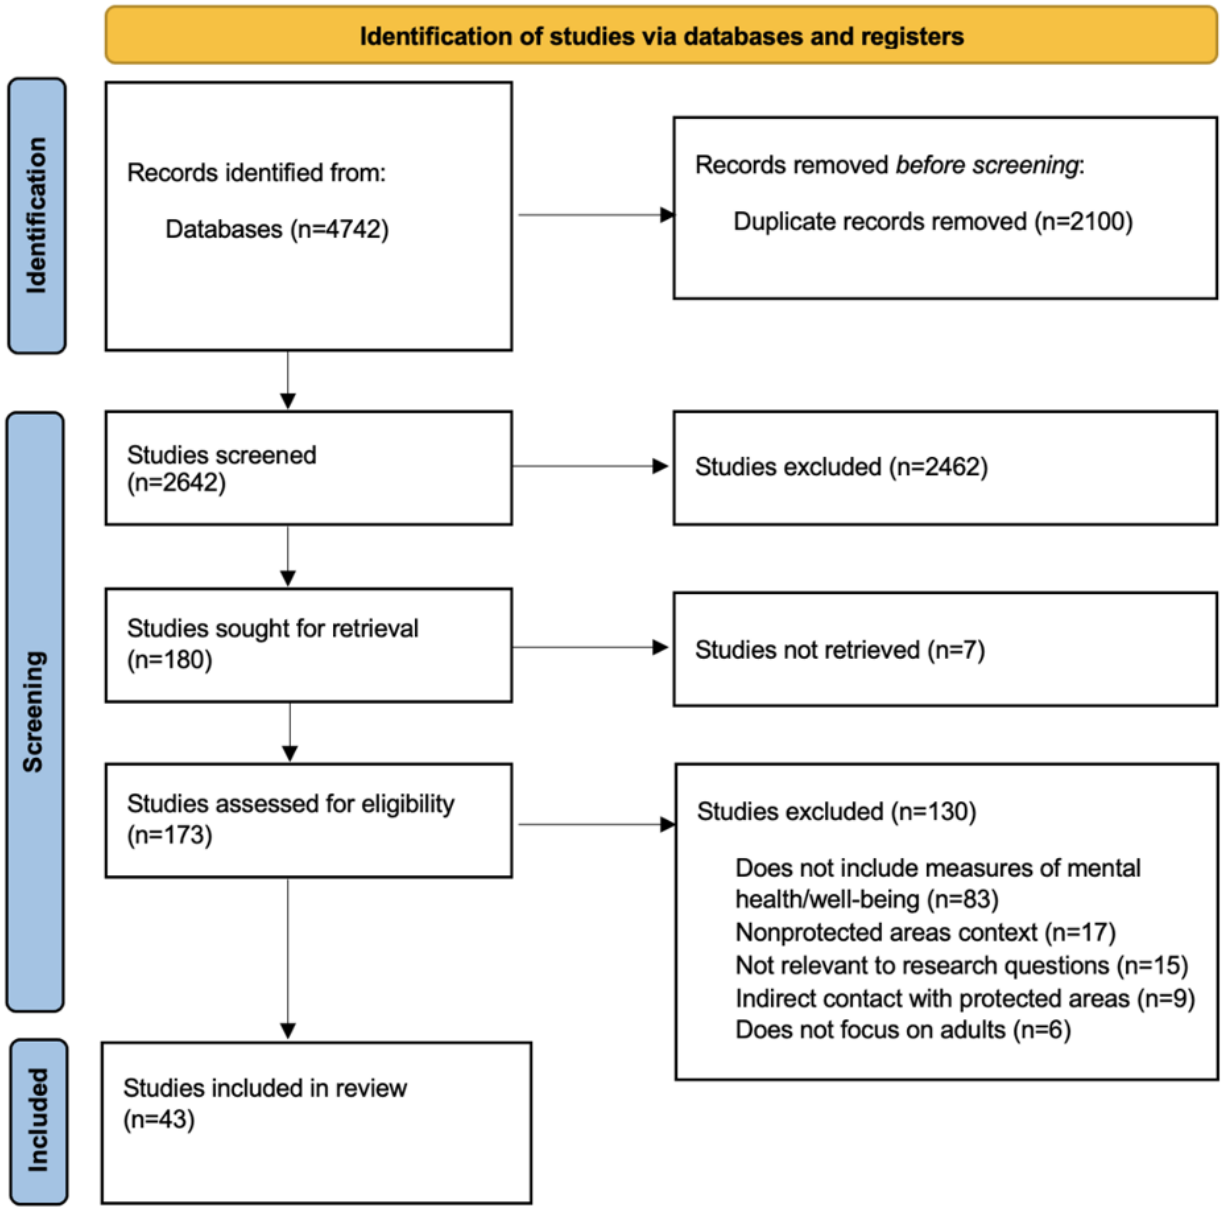
A quality appraisal will also be conducted on qualitative measurement instruments used in reviewed studies. This appraisal indicates whether multiple reviewers were involved in the theming process and checks were performed. Similar to the quantitative instruments, each criterion will be scored as yes (1) or no (0) based on whether studies provide evidence that these activities were incorporated into the methodology.

Results

Preliminary results of the study selection process are reported here using a PRISMA diagram (Figure 1) in accordance with PRISMA-ScR guidelines [28]. Searches in the 8 scholarly databases on January 4, 2023, yielded an initial 4742 studies (1 merged). From these initial studies, 2642 unique studies were identified for title and abstract screening, after the removal of 2100 duplicates. Through title and abstract screening, 180 studies were selected for full-text review, eliminating 2462 studies as they did not meet the previously outlined inclusion criteria. The full-text papers were sought for retrieval (7 were unavailable), resulting in 173 studies assessed for eligibility through the full-text review process. A total of 43 papers were selected for the final analysis. This pool is larger than those in other scoping reviews on adjacent topics [1], which affects the scope and time frame of the analysis. An updated search was conducted on December 11, 2024, yielding an additional 8 papers to be included in the analysis, for a total of 51 papers.

The results of the final scoping review and submission of a manuscript for peer review are expected in April 2025.

Figure 1. PRISMA flow diagram of the study selection process showing results and exclusions.



Discussion

Overview

This protocol details the methodology for a scoping review of the instruments that measure health and well-being linked to nature contact in protected areas, including their psychometric properties. Existing reviews have focused primarily on constructs related to mental health and well-being of adult populations associated with nature contact, although none specifically identify parks or protected areas. The volume of studies retrieved through the selection process suggests a robust evidence base regarding the health and well-being benefits of nature contact, with a likely diversity of measurement tools used. The review will identify, evaluate, and compare measures to provide a comprehensive overview of the quantitative and qualitative methodological instruments and tools used in research to date.

Strengths and Limitations

The scoping review is subject to limitations, in that it does not include gray and white literature, as well as studies that are not available in English. Given this, some relevant sources may be missed. Peer-reviewed papers not indexed in the searched databases may also be missed, but this limitation was deemed acceptable, given the need to manage the scope of the project. In addition, the extent to which the psychometric properties of an instrument can be evaluated is limited to the information provided within the included studies, which may be lacking descriptions of scale development. A deeper investigation would require looking elsewhere for additional resources, which is

beyond the scope of this review. Nevertheless, this review will provide a strong evidence base on which to build future research.

Conclusions

To the authors' knowledge, this will be the first scoping review undertaken on measures used to assess mental health and well-being outcomes related to nature contact in a parks and protected areas context. Findings will aid in identifying the strengths and weaknesses of current measurement approaches to mental health and well-being outcomes of nature contact and may be used to guide future research on this topic. For example, nature prescriptions—a health care program comprising written directives by health professionals for visits to natural settings (either individually or in groups) relying heavily on parks and other forms of protected areas—now exist in at least 6 countries [37]. Canada has more than 12,000 health care professionals prescribing nature in parks, and China's national health strategy includes a commitment to build more than 1000 forest therapy facilities nationwide [38].

Given the unprecedented interest and growth in nature-based health care commitments, it will be necessary to identify and use methods that effectively consider contextual factors. Relevant factors can include demographics (age, gender, and ethnicity) and activities, durations, and environments prescribed. All of these factors must be documented to best ensure reliability and validity when evaluating the outcomes (or benefits) and efficacy of nature prescription programs. This proposed review is also very timely, given the projected growth in the global estate of protected areas as per the United Nations Convention on Biological Diversity Kunming-Montreal Global Biodiversity Framework (detailed in the "Introduction" section).

Adherence to the PRISMA-ScR guidelines will ensure that the findings of this scoping review are of high quality and replicable. Furthermore, by providing insights into the validity of the measurement instruments used, we provide an opportunity to strengthen the methodological quality of future studies. The outlined scoping review will have significant implications for researchers, policy makers, and practitioners working at the nature conservation and human health interface. This review will provide a means to both understand previous research and undertake innovative research initiatives related to mental health and well-being outcomes associated with nature contact in parks and protected areas.

Acknowledgments

Funding to support this work was provided by the Parks Canada Agency (GC1727) and the John McMurry Research Chair in Environmental Geography at Wilfrid Laurier University.

Data Availability

The datasets generated and/or analyzed during this study are available from the corresponding author on reasonable request. The datasets will be reported in the final scoping review manuscript.

Authors' Contributions

JB and RB drafted the first manuscript and contributed to data curation and analysis. CER, LL, MWG, and CJL revised the manuscript. CJL and CER also contributed to study conceptualization, funding acquisition, and supervision of the process. All authors contributed to study design and reviewed and edited the final manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Every day, approximately 800 women die from pregnancy-related causes, alongside 2.6 million stillbirths and 2.8 million neonatal deaths annually. Inadequate referral by skilled birth attendants hinders timely access to necessary emergency obstetric care, challenging progress toward the maternal health Sustainable Development Goal (SDG) 3. The COVID-19 pandemic further disrupted care in low- and middle-income countries, forcing women to rely on traditional birth attendants, thereby affecting the referral system. It is crucial to understand the experiences of both skilled and traditional birth attendants regarding upward referrals in emergency obstetric care to identify barriers and facilitators within these systems in low- and middle-income countries.

Objective: This study aims to map existing evidence on the experiences of skilled and traditional birth attendants regarding upward referral systems in emergency obstetric care within low- and middle-income countries.

Methods: We will conduct a scoping review guided by the Joanna Briggs Institute's methodological framework. Studies will be included if they report on experiences with upward referral in obstetrical emergencies. We will consider studies published in English and French from 2016 to July 2024. The literature search will be conducted in databases including PubMed, EBSCOhost (Academic Search Complete and CINAHL with full text), Scopus, Web of Science, and Google Scholar. Identified citations will be managed using EndNote version 21 (Clarivate Analytics) and Rayyan. Two independent reviewers will screen eligible studies and resolve disagreements through discussion with a third reviewer. Data will be extracted using a validated form and analyzed through content analysis, with findings presented narratively. This protocol aligns with the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines. The review will offer a comprehensive narrative of upward referral systems in obstetrical emergencies, focusing on transitions from traditional birth attendants to health care facilities and from lower to higher levels of health care.

Results: The preliminary search was completed in August 2024, and the database search will be conducted within the next 6 months. Findings will be disseminated through medical education conferences and publications.

Conclusions: This review contributes a comprehensive narrative of upward referral systems in obstetrical emergencies, aiming to enhance understanding and improve transitions from traditional birth attendants to health care facilities and between different health care levels. It could significantly impact maternal and neonatal care by identifying the referral experiences of both skilled and traditional birth attendants. The insights may inform interventions that integrate traditional birth attendants into health care

systems, potentially reducing maternal and neonatal mortality. The results will guide future research aimed at developing a model to improve upward referrals for obstetric emergencies in sub-Saharan Africa.

KEYWORDS

referral systems; upward referral; obstetric emergencies; traditional birth attendants; skilled birth attendants; low- and middle-income countries; birth attendants; obstetric; middle-income countries; scoping review protocol; pregnancy; neonatal deaths; deaths; obstetric care; health care; medical education; mortality; Africa; pregnant; women's health

Introduction

Pregnancy and childbirth can pose risks to both the mother and fetus [1], sometimes leading to life-threatening situations known as obstetric emergencies [2]. In such cases, specialized care is necessary and provided through a well-established referral system [3], typically an upward referral, which refers to the process by which health care providers at lower levels of the system seek assistance from specialized or better-equipped providers [4]. This system ensures a smooth transfer of patients between different levels of health care facilities, optimizes service delivery, and reduces the risk of complications [5] that can lead to mortality. Skilled birth attendants (SBAs) and traditional birth attendants (TBAs) are crucial in this process [6,7]. Alongside pregnant women, these frontline caregivers navigate the complexities of pregnancy and childbirth, often requiring swift intervention to ensure positive maternal and neonatal outcomes. However, the varying experiences of different stakeholders can negatively impact the obstetric referral process [8].

Every day, approximately 800 maternal deaths occur due to pregnancy-related causes [8], alongside 2.6 million stillbirths and 2.8 million neonatal deaths annually [9]. The global community is committed to improving health care quality to address these alarming statistics [8]. In line with Sustainable Development Goal (SDG) 3, which aims to ensure healthy lives and well-being for all, specific targets highlight the urgency of action. SDG 3, Target 1, aims to reduce the global maternal mortality ratio (MMR) to below 70 maternal deaths per 100,000 live births by 2030. Target 2 seeks to prevent the deaths of newborns and children younger than 5 years to fewer than 25 deaths per 1000 live births and reduce neonatal mortality to 12 deaths per 1000 live births [9]. However, challenges remain, especially in low- and middle-income countries (LMICs) [8], which are defined as countries with a gross national income per capita ranging from US $1086 to US $4255 [10]. Despite the United Nations' recognition of the right to access the highest attainable standard of physical health, including the integration of referral systems [11], obstetric emergencies continue to pose significant threats to the health and lives of mothers and newborns worldwide [8]. TBAs historically played a pivotal role in maternal health care before the formalization of midwifery, but interest in their role has diminished over time [6,12]. Since the 2000s, the focus has shifted toward skilled birth attendance, sidelining TBAs in routine deliveries due to their ineffectiveness in reducing maternal mortality [7]. Nevertheless, a significant proportion of women in LMICs continue to seek TBA services, highlighting their enduring importance [13].

In contrast, SBAs are recognized as a key strategy for reducing high maternal mortality rates and are pivotal indicators of progress in maternal mortality reduction efforts [7]. Addressing high maternal mortality rates through referral systems requires a comprehensive understanding of the experiences of pregnant women, SBAs, and TBAs [7]. However, the current health care system operates in fragmented silos, hindering collaboration between different systems. This lack of integration undermines efforts to combat maternal mortality, despite some pregnant women preferring TBA practices over Western medicine [12].

Research based on the Three Delays Model by Thaddeus and Maine highlights challenges affecting the timeliness of obstetric referrals within health care facilities. These challenges occur at both patient and institutional levels, impacting the referral process [7]. They include difficulties in identifying and reaching health care facilities, often involving TBAs in the referral process, and obstacles in receiving adequate care, often linked to SBAs who are responsible for essential obstetric care during pregnancy [14].

To improve maternal health outcomes, it is crucial to explore and understand the experiences of women, TBAs, and SBAs. Understanding stakeholders' perceptions and navigation of the referral process can help identify gaps in service delivery, such as limited access to emergency obstetric care facilities or communication challenges between health care providers and pregnant women. Addressing these challenges can enhance the efficiency and effectiveness of obstetric referral systems, ensuring timely access to needed care for women.

Although previous studies and reviews have examined referrals in obstetric emergencies [1-3,5,8,14] since the adoption of the SDGs, none have focused on the experiences of upward obstetric emergency referrals in LMICs for both SBAs and TBAs, advocating for integrated referral systems that can save the lives of mothers and babies. Therefore, this review aims to provide a comprehensive overview of the current state of birth attendants' experiences with referral systems in obstetric emergencies in low-income countries.

Methods

Study Design

Using the steps of the Joanna Briggs Institute (JBI) Scoping Review Methods [14], the researchers will examine and map the available literature related to the experiences of birth attendants with upward obstetric emergency referrals in LMICs. This scoping review protocol has been developed and registered with the Open Science Framework. The protocol will be implemented, and the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews) guidelines will be used to guide the reporting.

Main Objective and Review Questions

The main objective of this review is to examine available evidence regarding birth attendants' experiences with upward referral systems in emergency obstetric care in sub-Saharan Africa (SSA) since the inception of the SDGs. Based on the objective of this review, the following research questions have been developed:

1. What are the publication characteristics of evidence on upward obstetric referrals?
2. What are the experiences of birth attendants regarding upward obstetric emergency referrals in LMICs?

The objective of this scoping review is part of the PhD study titled "Developing a Model to Enhance Effective Upward Referral of Obstetric Emergencies from Community Health Centres in Oliver Tambo District, Eastern Cape, South Africa: A Grounded Theory Inquiry."

Eligibility Criteria

The eligibility criteria for this review will be based on the JBI mnemonic for formulating systematic review questions, which describe the population, concept, and context of the study [14]. Textbox 1 summarizes the criteria.

Textbox 1. Eligibility criteria.

Inclusion criterion:

- Population:
  - Skilled birth attendant: a professional health care worker who attends to pregnant women
  - Traditional birth attendant: an unskilled person who attends to pregnant women
- Concept:
  - Upward referral of women during labor and childbirth
  - Referral of women during pregnancy
  - Referral from traditional birth attendants to a health care facility
- Context:
  - Low- and middle-income countries
- Study designs:
  - Qualitative designs
  - Quantitative designs
  - Mixed methods designs
  - Conference proceedings abstracts
  - Gray literature
- Time period:
  - From January 2016 to July 2024

Exclusion criterion:

- Population:
  - Professional health care workers who do not attend to pregnant women
  - Unskilled individuals who do not attend to pregnant women
- Concept:
  - Referral of women outside the pregnancy and childbirth experience
  - Neonatal emergencies
- Context:
  - High-income countries
- Study designs:
  - Letters to the editor
  - Reviews
- Time period:
  - After July 2024

Population

The scoping review will include all relevant peer-reviewed and gray literature focused on upward referral systems in emergency obstetric care in LMICs. The population sample for the review will consist of birth attendants including SBAs and TBAs.

Concept

The concept will be guided by the following: Experiences, perceptions, and upward obstetric emergency referrals**.** According to the World Health Organization (WHO) [15], “referral can be defined as a process in which a health worker at one level of the health care system, having insufficient resources (eg, drugs, equipment, and skills) to manage a clinical

condition, seeks the assistance of a better or differently resourced facility at the same or higher level to assist in or take over the management of the client's case." Furthermore, an obstetric emergency is defined as a complication or situation of a serious and often dangerous nature, developing suddenly and unexpectedly, and demanding immediate attention in order to save lives [8].

Context

The context of this review will focus on LMICs within emergency obstetric care settings.

Types of Sources

This scoping review will include both experimental and quasi-experimental study designs such as before-and-after studies and interrupted time-series studies. In addition, analytical observational studies, including prospective and retrospective cohort studies, case-control studies, and analytical cross-sectional studies, will be considered for inclusion. Descriptive observational study designs, including case series, individual case reports, and descriptive cross-sectional studies will also be included. Qualitative studies focusing on qualitative data, including, but not limited to, designs such as phenomenology, grounded theory, ethnography, qualitative description, action research, and feminist research, will be considered for inclusion. Furthermore, text and opinion papers will also be considered in this scoping review.

Search Strategy

An initial limited search in PubMed and ScienceDirect was undertaken to identify papers on the topic. The text words from the titles and abstracts of relevant papers, along with the index terms used to describe them, were used to develop a full search strategy (Table 1).

Table 1. Preliminary search strategy.

Date	Database	Search query	Results, n
January 29, 2024	PubMed	((“obstetric labor complications”[MeSH Terms] OR (“obstetric”[All Fields] AND “labor”[All Fields] AND “complications”[All Fields]) OR “obstetric labor complications”[All Fields]) AND (“referral and consultation”[MeSH Terms] OR (“referral”[All Fields] AND “consultation”[All Fields]) OR “referral and consultation”[All Fields] OR (“hospital”[All Fields] AND “referrals”[All Fields]) OR “hospital referrals”[All Fields]) AND (“developing countries”[MeSH Terms] OR (“developing”[All Fields] AND “countries”[All Fields]) OR “developing countries”[All Fields])) AND (2016/1/1:2024/1/31[pdat])	11
July 3, 2024	Science Direct	referral OR referral process OR referral pathway OR care pathway) AND obstetric labour complications AND Developing countries	712

Second, a systematic search will be conducted across 4 remaining electronic databases, namely EBSCOhost (including Academic Search Complete and CINAHL with full text), Scopus, Web of Science, and Google Scholar.

The search strategy, including all identified keywords and index terms, will be adapted for each included database or information source or both. Peer-reviewed journals will be reviewed for primary studies with a clear empirical base, using qualitative, quantitative, and mixed methods addressing the research question. Studies will be identified by searching literature from January 2016 to July 2024. In addition, papers will be searched through the “cited by” search feature as well as through citations included in the reference lists of included papers. The search terms will include referral system, LMICs, obstetric emergency, SBAs, and TBAs. Boolean operators (AND, OR) will be used to separate keywords, and Medical Subject Headings (MeSH) terms will be included during the search. The search syntax will be modified as needed. Reference lists of selected papers will also be searched for additional papers of interest. The services of an experienced subject librarian will be used to ensure that a robust search strategy is followed. The search strategy will be piloted to check the appropriateness of selected electronic databases and keywords. To compile all relevant evidence sources, identify, and remove duplicate records, the EndNote X21 reference manager will be used to import and manage eligible studies.

Source of Evidence Selection

Following the search, all identified citations will be collated and uploaded into EndNote version 21, and then imported into the Ryann systematic review app, where duplicates will be removed. Following a pilot test, titles and abstracts will be screened independently by FZJ and ELMK for assessment against the inclusion criteria for the review. Potentially relevant sources will then be retrieved in full. The full text of selected citations will be assessed independently by FZJ and ELMK to determine whether they meet the inclusion criteria. Reasons for the exclusion of sources of evidence in the full text that do not meet the inclusion criteria will be recorded and reported in the scoping review. Any disagreements between the reviewers at each stage of the selection process will be resolved by OBB. The results of the search and study inclusion process will be fully reported in the final scoping review and presented in a PRISMA-ScR flow diagram [16].

Data Extraction

Data will be extracted from the papers included in the scoping review by FZJ and ELMK independently, using a data extraction tool developed by the reviewers. The data extracted will be informed by the formulated review questions and will include—in addition to paper details such as authors, year of publication, design, and setting—specific details about the participants or population, reasons for referral, challenges experienced, support identified related to the referral, and further recommendations for upward obstetric emergency referrals.

Before data extraction, the tool will be pilot-tested independently by FZJ and ELMK. The draft data extraction tool will be modified and revised as necessary during the process of extracting data from each included evidence source. Any modifications will be documented in the scoping review. OBB will afterwards check that no relevant information has been omitted. The information to be extracted using this tool is detailed below (Textbox 2).

Textbox 2. Initial data extraction tool.

Criteria:

- Authors or year of publication or both
- Research design
- Study setting
- Nature of population or sample
- Reasons for referral
- Challenges experienced related to the referral
- Support experience related to the referral
- Recommendations related to the referral

Data Analysis

Knowledge and experiences of skilled and traditional BAs regarding referral in obstetric emergencies to combat maternal and child mortality rates will be extracted from this review. The data will be analyzed to develop a comprehensive model for effective referral in resource-constrained settings.

Data summarization and reporting will adopt a fundamental descriptive approach, using content analysis [17]. A narrative approach will present the findings from the included studies, using thematic content analysis to describe the themes that are relevant to experiences with referral systems in obstetric emergencies in low- and middle-income countries. In addition, any other emerging themes will be reported.

Ethical Considerations

This study was approved by the university's ethics committee for BioMedical Research (ethics approval BREC/00006633/2024).

Results

As of August 2024, the preliminary search was completed, and the database search will be conducted within the next 6 months. Findings will be disseminated through medical education conferences and publications.

Discussion

Principal Findings

It is anticipated that this review will map out the different experiences of birth attendants regarding upward referral in obstetric emergencies. It is also anticipated that the experiences of SBAs are different from those of TBAs. These insights will enrich the body of knowledge related to referrals in LMICs. The findings have the potential to aid in improving care for mothers and newborns in several ways. First, the study will synthesize information on referral systems in obstetric emergencies within resource-constrained health care settings. Second, it will identify referrals from both SBAs and TBAs to health care facilities. This information could support the development of interventions that advocate for including TBAs in health care systems to reduce maternal and neonatal deaths. Third, the review's findings will inform a future study aimed at developing a model to enhance effective upward referral of women with obstetric emergencies during labor in an SSA country.

Comparatively, researchers [1,2] have highlighted logistical challenges in emergency referrals, concentrating on gaps in primary care systems and delays in reaching tertiary facilities. This study, on the other hand, provides a more comprehensive understanding of the systemic and interpersonal dynamics influencing emergency referrals in LMICs. The dual focus on both TBAs and SBAs is unique, as it addresses an unexplored area in studies such as [7], which observed that traditional and formal care providers act as fragmented health structures, preventing collaboration. However, in LMICs, a significant proportion of women continue to seek TBA services, highlighting their enduring importance [13]. Therefore, the insights generated could serve as a foundation and guidance for future research aimed at developing a model to improve upward referrals for obstetric emergencies in SSA.

Policy and Practical Implications

The scoping review aims to provide insights into the experiences of both SBAs and TBAs regarding upward referral systems in emergency obstetric care. It will be instrumental in identifying key gaps and challenges in the referral process.

By linking the anticipated results to the SDGs, particularly SDG 3 on good health and well-being, the review highlights the critical role of improving referral systems to reduce maternal and neonatal mortality. The review will inform policy makers about effective strategies to enhance referral processes, ensure timely access to emergency obstetric care, and better integrate TBAs into the health care system.

Health care providers are expected to benefit from the insights this scoping review will provide regarding training needs for

effective referrals and collaboration between SBAs and TBAs. This will improve referral practices and ensure smoother transitions of care.

Furthermore, the review will emphasize the importance of community involvement in supporting and understanding the referral process. Recommendations for engaging communities through educational campaigns and support systems may strengthen the overall referral network.

Potential Challenges and Limitations

The review includes only studies published in English and French, which may exclude relevant research in other languages and limit the comprehensiveness of the findings. Furthermore, it focuses on studies published and indexed in selected databases, potentially overlooking unpublished research.

Conclusion

This review contributes a comprehensive narrative on upward referral systems in obstetrical emergencies, aiming to enhance understanding and improve transitions from TBAs to health care facilities and between different health care levels. It could significantly impact maternal and neonatal care by describing the referral experiences of skilled TBAs in obstetric emergencies. The insights may inform interventions that integrate TBAs into health care systems, potentially reducing maternal and neonatal mortality. The results will guide future research aimed at developing a model to improve upward referrals for obstetric emergencies in an SSA country.

Acknowledgments

The authors would like to thank Dr Cedric Mbobnda Kapche for critically reviewing this manuscript.

Data Availability

All data generated and analyzed will be included in the published scoping review article and will be available upon request.

Conflicts of Interest

None declared.

Abstract

Background: Social robots (SR), sensorimotor machines designed to interact with humans, can help to respond to the increasing demands in the health care sector. To ensure the successful use of this technology, acceptance is paramount. Generative artificial intelligence (AI) is an emerging technology with the potential to enhance the functionality of SR and promote user acceptance by further improving human-robot interaction.

Objective: We present a protocol for a scoping review of the literature on the implementation of generative AI in SR in the health care sector. The aim of this scoping review is to map out the intersection of SR and generative AI in the health care sector; to explore if generative AI is applied in SR in the health care sector; to outline which models of generative AI and SR are used for these implementations; and to explore whether user acceptance is reported as an outcome following these implementations. This scoping review supports future research by providing an overview of the state of connectedness of 2 emerging technologies and by mapping out research gaps.

Methods: We follow the methodological framework developed by Arksey and O'Malley and the recommendations by the Joanna Briggs Institute. Our protocol was drafted using the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-analyses extension for Scoping Reviews). We will conduct a systematic literature search of the online databases MEDLINE, Embase, CINAHL (Cumulative Index to Nursing and Allied Health Literature), Web of Science, and IEEE Xplore, aiming to retrieve relevant data items via tabular data charting from references meeting specific inclusion criteria which are studies published from 2010 onwards, set in the health care sector, focusing on SR with physical bodies and implemented generative AI. There are no restrictions on study types. Results will be categorized, clustered, and summarized using tables, graphs, visual representations, and narratives.

Results: After conducting a preliminary search and deduplication in the second quarter of 2024, we retrieved 3176 preliminary results. This scoping review will be supplemented with the next methodological steps, including retrieving the results in a reference management tool as well as screening titles, abstracts, and full text regarding specific inclusion criteria. The completion of these steps is scheduled for the second quarter of 2025. Limitations based on the heterogeneity of the included studies and the general breadth of a scoping review compared to a systematic review are to be expected. To reduce bias, we adopted a system of dual reviews and thorough documentation of the study selection.

Conclusions: The conducted preliminary search implies that there are a sufficient number of heterogeneous references to complete this scoping review. To our knowledge, this is the first scoping review on generative AI in health care SR.

Introduction

Background

Social robots (SR) are interactive robots designed to engage with humans in a social or collaborative manner, often mimicking human behaviors, communication, and social cues [1-3]. SR are already being used in geriatric care, rehabilitation, and the care of people with cognitive disabilities [4]. Since much progress has been made regarding the development of SR in recent years [5], it is to be expected that they will find widespread use in the health care sector in the next few years [6]. Between 2005 and 2010, 1300 units of "Paro," an artificial seal for therapy of patients with dementia [7], were sold in Japan [8]; as of 2013, "Paro" was adopted in 80% of local care institutes in Denmark [9]. These examples illustrate that SR could be a way of responding to the needs of people in need of care and of filling the gap between the supply and demand of health care professionals. Other examples for SR that can be applied in the health care sector are "Cruzr" [10], a service robot [7,10]; "NAO" [11], a household robot [7,11]; or "Lio" for older adult care [7,12].

For SR to be effectively integrated and successful, their acceptance is paramount. Simply introducing these innovative robots is not sufficient if individuals are hesitant or unwilling to interact with them [13]. Lum [14] emphasizes that the fundamental challenge for the practical application of SR is the willingness of people to accept them in their everyday lives. In democratically constituted, liberal societies, acceptance is deemed a factor for a successful take-up of a technology by the population [15]. While positive effects such as assistance with everyday tasks [16,17], maintaining of individual autonomy [17-19], or increase of happiness [18] are associated with the use of SR in older adult care, their acceptance is noted to vary [6], with acceptance toward the SR depending on the area of their application [15]. With the ongoing development and practical use of SR, the question of their acceptance as a possible component of people's everyday routines moves further into focus [6,14].

Dialog management is positioned as one of the main goals of human-robot interaction (HRI) [20], increasing user satisfaction and task efficiency [20,21]. In this context, generative artificial intelligence (AI) like OpenAI's ChatGPT [22], being extensively trained on conversational dialog [23,24], could be used to translate instructions given in natural language into actions executable by a SR [25,26], improving multiparty interactions [21]. Since late 2022, there has been a significant growth in the field of generative AI [27], a technology which will have an impact on all industry sectors with the potential to change how people work and to increase productivity [28]. We believe that by implementing generative AI in SR, usability and user acceptance, key elements of HRI, could be vastly increased. Speech, gesture, mimic recognition, robot customizability, intuitive operation, and interaction among others, are aspects we believe to highly benefit from the potential of generative AI. We expect this emerging technology to largely influence the use and functionality of SR, facilitating their widespread use in the health care sector. Health care professionals, patients, and other persons in need of care could benefit from such advanced robots fulfilling a wide array of valuable tasks. With this scoping review, the authors intend to map out if and how these emerging technologies are interconnected.

Definitions and Terms

Social Robots

Sarrica et al [29] point out that there is a wide array of various definitions for SR, which are partially built on existing definitions or introduce new concepts. For example, Bendel [7] refers to SR as sensorimotor machines explicitly designed to be used in the immediate vicinity of and for direct interaction with humans. A machine is defined as an assemblage of parts that transmit forces, motion, and energy to one another in a predetermined manner [30], consequently implying the necessity of a physical body as well as the presence of sensors and motors for interaction with and perception of the environment by a robot in a narrow sense. While Bendel [7] presents the option to broaden the concept of robots and include software robots like chatbots within SR by relativizing the sensorimotor and physical components, scientific definitions overall tend to describe SR as semiautonomous or autonomous physical bodies, with "machines" and "physical" being some of the main dimensions underlying different definitions [29]. As Kuipers et al [31] point out, the creation of robots with a human-like competence of real-world manipulation is a major challenge of research, since the ability to physically change the surrounding world is of utmost relevance to humans [32]. In the context of care, the burden of physical work is high and further increasing [33,34]. Against this background, we consider only SR with a physical body for this review to ensure a high level of comparability of the results.

Generative AI

Generative AI is a type of AI able to generate content [28]. It is based on different kinds of underlying models, for example, generative adversarial networks, encoder-decoder networks, neural networks, or transformers [27]. Subtypes of generative AI are large language models, deep neural networks which are pretrained with millions of parameters on large amounts of unlabeled text [35]. This training enables them to learn the relationship between words or portions of words [28]. Unlike decision tree models, which use algorithms to create predictions or rules based on incoming data, generative AI uses specific algorithms trained on large amounts of data to generate new, previously unseen content [27]. This generated content can be manifold, for example, human-like texts, images, and music [27]. Compared to a conversational AI, which can provide users with human-like responses in a conversation, generative AI can not only generate such responses but generate the content of

these responses as well [36]. These responses can even surpass the original programming of the generative AI [36]. Since late 2022, the field of generative AI has grown significantly [27,37]; pretrained and then task-specifically modified large language models became the dominant pattern in the field of natural language processing [38-44], with examples being Google's BERT (Bidirectional Encoder Representations from Transformers) [38] and OpenAI's GPT-3 [39]. Generative AI gained increasing public focus since the release of ChatGPT in late 2022, while the concept of generative models of AI began to be recognized since the 2010s [27]. One of the goals in the development of ChatGPT was to facilitate a better reciprocal understanding of the communication between human users and robots [45].

Acceptance

Acceptance, acceptability, adoption as well as other related terms in the context of technology acceptance are often used interchangeably [46], describing the same overall concept. Acceptability is described as the user's willingness toward the use of a system [47]. User acceptance can be defined as "the demonstrable willingness within a user group to employ (information technology) for the tasks it is designed to support" [48]. The aforementioned terms are occasionally used exchangeable with other concepts of human-computer interaction like user satisfaction [49]. User acceptance can be specified as the users' intention to use a future technology, their willingness to integrate it into their daily life [50], and the prospective judgment of this new technology [51]. Beetz et al [15], specify acceptance of assistive robotics as being based on trust. Human-related aspects such as cultural background, living conditions, or expectations toward the functionality of a robot as well as criteria of the robot itself such as design [6,32], language capability, or range of functions are relevant for the acceptance of an SR [6]; specifically, an anthropomorphic approach on the design of SR is deemed to be of high relevance [14]. In the literature, the terms facilitators and barriers are commonly used to describe factors of technology uptake in general, for example, facilitators of the implementation of SR can be mobility aspects [52], being physically accessible [52,53], or offering an economic advantage [54]. Davis [55] developed the Technology Acceptance Model to describe why a person does or does not use a technology. A person's attitude toward using a technology depends on the technology's perceived usefulness and its perceived ease of use, the behavioral intention to use a technology depends on the aforementioned attitude toward using and the perceived usefulness directly [55]. Thus, this model implicates a complex relationship between the user's subjective ability to accept, and the quality of a technology of being acceptable. Based on a revision of this model [56], Heerink et al [57], proposed the Almere Model for technology acceptance of SR by older adult users, examining 12 areas related to HRI: anxiety, attitude toward technology, facilitating conditions, intention to use, perceived adaptiveness, perceived enjoyment, perceived ease of use, perceived sociability, perceived usefulness, social influence, social presence, and trust [57]. The Almere Model integrates the multi-dimensionality of acceptance formation by relating robot-specific factors to their subjective perception by humans.

Literature Gap

To address the intersection of SR and generative AI, we conducted a preliminary search for systematic reviews, scoping reviews, or protocols for reviews in the online databases MEDLINE, Embase, CINAHL, Web of Science, and IEEE Xplore based on our search strategy presented in stage 2. For example, some of these reviews focus on AI in the health care sector in general [58-101]; other reviews focus on social or surgical robots in the health care sector in general [102-118]; a few highlight the use of AI in surgical robots [119,120] or the use of chatbots [80,88,121] in the health care sector; Clabaugh and Matarić [122] conducted a systematic review on enablers of autonomy of SR; Huang et al [123], conducted a systematic review on antecedents and consequences of the application of intelligent SR; Hung et al [124], published a protocol for a systematic review on the facilitators and barriers to the use of robots equipped with AI in older adult care; Lee et al [125] conducted a systematic review and meta-analysis on the effect of AI-equipped SR on cognitive function.

However, none of these reviews focus specifically on the implementation of generative AI in SR in the health care sector and the interconnectedness of these 2 emerging technologies.

Aim

The aim of this scoping review is to map out if and how 2 emerging technologies: generative AI and SR are interconnected. This scoping review is based on an overview of relevant publications that have considered the implementation of generative AI in physical health care SR. We intend to explore whether generative AI is applied in SR in the health care sector, what models of generative AI and SR are used for this implementation, in which setting these implementations take place, and if user acceptance is among the reported outcomes following these implementations.

Methods

Study Design

In this review, we follow the methodological framework developed by Arksey and O'Malley [126] and the recommendations by the Joanna Briggs Institute [127]. We apply the following stages here: (1) identifying the research question, (2) identifying relevant studies, (3) selection of studies, (4) data charting, and (5) collating, summarizing, and reporting the results. To report our results, we use the PRISMA-ScR (Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews), attached in (Multimedia Appendix 1), and, where applicable, PRISMA-P (Preferred Rpeorting Items for Systematic Reviews and Meta-Analyses Protocols; Multimedia Appendix 2).

Research Team

The research team conducting this review consists of a medical student researcher interested in the fields of medical sociology and medical data science, PL; a researcher with a background in health economics, CG; a professor for digitalization working in the field of digital transformation and applications, DF; the head of information literacy education and systematic review,

medical library, CD; a professor for medical data science and an expert on human-computer interaction, FB; and a senior researcher working in the field of medical informatics and health care organization and innovation, TS.

Stage 1: Identifying the Research Question

The main research questions of this protocol are as follows: (1) Are generative AI models implemented in SR in the health care sector? The following subquestions are posed: (2) Which models of generative AI and SR are used for these implementations? (3) What are the settings of these implementations? (4) Has the acceptance of SR been reported as an outcome following these implementations?

Answering these questions can support future research by mapping out potential research gaps and providing an overview of the state of connectedness of 2 emerging technologies, SR, and generative AI.

Stage 2: Identifying Relevant Studies

To identify relevant studies, a systematic literature search of the electronic databases MEDLINE (via Ovid; 2010 onwards), Embase (via Ovid; 2010 onwards), CINAHL (via EBSCOhost; 2010 onwards), Web of Science (2010 onwards), and IEEE Xplore (2010 onwards) will be conducted. The selection of these databases follows the recommendation of a member of the research team (CD), an information specialist of the medical library of Charité, covering a broad and interdisciplinary field including computer science, social and behavioral sciences, and medicine. To construct our search queries, we followed the guidelines of the Peer Review of Electronic Search Strategies (PRESS) [128]. Textbox 1 presents the main search terms underlying these search queries. An initial search query was built with Ovid for MEDLINE. The online tool Polyglot Search Translator [129] is used to adapt this search query for the databases Embase, CINAHL, and Web of Science. For IEEE Xplore, the initial search query is adapted manually to account for the different syntax and limit of search terms per search clause. Duplicates will be deleted by using the online tool Systematic Review Accelerator [130] after the corresponding results have been documented and managed using the reference managing software EndNote (Clarivate).

The search terms are based on the expertise of the research team, an internal focus group, and an additional use of the AI chatbot, ChatGPT (OpenAI) to detect further relevant synonyms and terms. These terms are combined using the appropriate Boolean operators AND Specialty OR to generate the search queries. The exact search queries for MEDLINE, Embase, CINAHL, Web of Science, and IEEE Xplore are referenced in (Multimedia Appendix 3).

Textbox 1. Overview of the main search terms.

Social robot

- Social robot
- Interactive robot
- Companion robot
- Humanoid robot
- Personal robot
- Emotional robot
- Assistive robot
- Service robot
- Communicative robot
- Socially assistive robot
- Socially interactive robot
- Care robot
- Household robot
- Pleasure robot
- Sex robot
- Anthropomorphic robot
- Autonomous robot
- Therapy robot
- Entertainment robot
- Robotics

Generative AI

- Generative AI
- Generative artificial intelligence
- Artificial intelligence
- AI
- Large Language Model
- LLM
- Foundation Model
- Deep Neural Network
- Machine Learning
- ChatGPT
- OpenAI
- YouChat
- Stable Diffusion
- DALL-E
- Runway
- Midjourney
- MusicLM
- VALL-E
- ElevenLabs
- Codex

- AlphaCode
- GitHub Copilot
- Emotion recognition
- Speech recognition
- Gesture recognition
- Facial expression analysis

Health care sector

- Health care
- Health care Sector
- Health service
- HCS
- Medical Sector
- Hospital
- Clinic
- Nursing home
- Rehabilitation
- Primary care
- Speciality care
- Mental health
- Public health
- Long-term care facility
- Physician
- Nursing
- Allied health professions
- Medical practitioner
- Care
- Medical device
- Health informatics
- Patient
- Person in need of care
- Invalid
- Convalescent
- Sick person
- Elderly
- Elderly person
- Elderly care
- Nursing home
- Nursing personnel
- Aged

Stage 3: Study Selection

The PCC (Population, Concept, and Context) Framework was used as a basis for the inclusion criteria. The population is SR with physical bodies; the concept is the implementation of generative AI in SR; and the context is the health care sector or SR intended for the health care sector. The framework underlying this scoping review is presented in Textbox 2,

inclusion and exclusion criteria to be used in this scoping review are highlighted in Textboxes 3 and 4.

The screening process is divided into 2 subsequent steps: an initial title and abstract screening, and a secondary full-text screening. At least 2 reviewers (PL and TS) will conduct the primary title and abstract screening independently, using the eligibility criteria. Then, the secondary full-text screening of all references included in the title and abstract screening will be conducted by at least 2 members of the research team (PL and TS) independently, using the same eligibility criteria. In the secondary screening, disagreements will be resolved by discussion and consensus of 3 members of the research team (PL, TS, and CG). Any restrictions regarding study design, time frame, or language are not intended. A PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) flow diagram will be used to show a graphic representation of the process of study selection.

Textbox 2. Overview of the Population, Concept, and Context framework of this review.

- Population: social robots (SR) with physical bodies.
- Concept: implementation of generative artificial intelligence in SR.
- Context: in the health care sector or SR intended for the health care sector.

Textbox 3. Overview of inclusion criteria.

- Studies focusing on social robots (SR) with physical bodies are considered.
- Generative artificial intelligence must be implemented in these SR.
- Studies set in the health care sector are considered, or studies focusing on SR intended to be used in the health care sector.
- Studies published since 2010 are considered, as the concept of generative models of artificial intelligence began to be recognized in the 2010s [27].
- No restrictions concerning study design (ie, reviews or case studies are included), time frame, or language

Textbox 4. Overview of exclusion criteria.

- Social robots without physical bodies are excluded (ie, chatbots or artificial intelligence avatars).
- Surgical robots are excluded.
- Studies published before 2010 are not considered.
- Studies focusing on social robots outside of or not intended for the health care sector are not considered.

Stage 4: Data Charting

The variables that are to be extracted are based on recommendations by 2 members of the research team (DF and FB). We extract data describing the specifications of the applied SR and model of the implemented generative AI, the characteristics of this Implementation and HRI, as well as general information regarding for example, but not limited to, studies' populations, reported outcomes, or country of origin. Textbox 5 conceptualizes the items we aim to extract from the included studies.

The authors will create preliminary data charting forms in Microsoft Excel, which will undergo independent pilot testing using a sample of publications (for example 10 articles). After achieving consistent results and obtaining approval from at least 2 researchers of the team (DF, FB), data charting will be conducted by one team member (PL) for all included full-text articles. A total of 2 other team members (CG and TS) will verify the charted data to ensure the inclusion of all relevant information. A draft of a data charting form is attached in (Multimedia Appendix 4). A team member (CD) will provide support for this process.

Textbox 5. Overview of data extraction items.

Items and description

- Author and year: name of first author, year of publication.
- Study type: What type of study was conducted (eg, randomized controlled trial, cohort study, case-control study, qualitative study, etc)?
- Study design: framework, methods, and procedures applied to answer the research question.
- Origin: where the study was conducted.
- Population and sample size: which and how many participants were in the study.
- Aim: purpose of the study.
- Make of social robot (SR): model and developer of SR.
- Shape of SR: traits of the physical body of SR (eg, number of appendices, anthropomorphic or animal-like shape).
- Mobility of SR: ability of SR to move.
- Autonomy of SR: whether the SR is autonomous or controlled remotely.
- Interface of SR: means of communication or interaction with SR (eg, speech, display, touchscreen, gestures, facial expressions, emotion recognition, remote control, haptic, etc).
- Human-robot interaction: specific traits of interaction with SR (eg, duration, tasks, and intention).
- Model of generative artificial intelligence (AI): specific model of implemented generative AI.
- Use of generative AI: what the implemented generative AI is used for.
- Element of health care sector: sub-sector of the health care sector in which SR was applied (eg, inpatient or outpatient sector, nursing home, day care, home care, etc).
- Outcome acceptance: if user acceptance has been reported as a study outcome.
- Acceptance measurement: tools or models used to measure user acceptance.

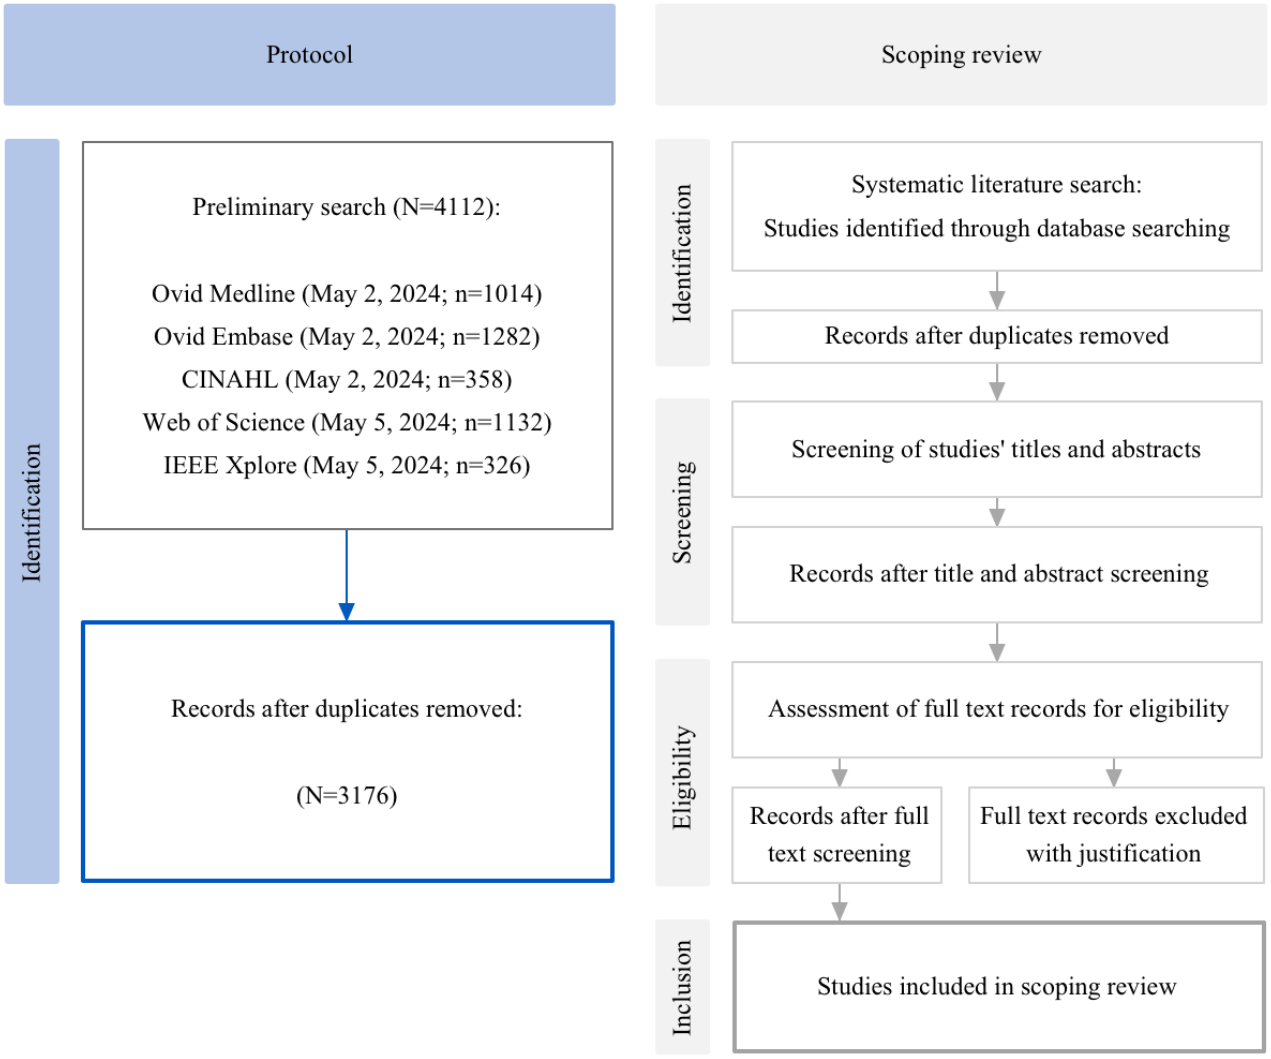
Stage 5: Collating, Summarizing, and Reporting the Results

The studies will be collated, categorized, summarized, and reported based on the data items extracted in the former step, for example, the type of SR, the context of HRI, the use of generative AI, the country of origin, derived acceptance-promoting aspects, etc. To synthesize the results, we will cluster similar publications by classifying the collected data items. The findings of this synthesis will be presented through a series of adequate tables, graphs, and visual representations, as well as corresponding narrative summaries. While we intend to use the main categories of data items from the former steps, we anticipate and remain open to discovering further categories, as well as expanding or modifying existing ones, as this review progresses. A team member (CD) will provide guidance for this stage.

Results

A preliminary literature search was conducted in the second quarter of 2024 to screen relevant existing literature as well as to verify no other scoping reviews of the same focus have been published. This preliminary search of the electronic databases MEDLINE, Embase, CINAHL, Web of Science, and IEEE Xplore was based on the search strategy presented in Stage 2 of this protocol. In this preliminary search, we retrieved a total of 4112 references, of which 3176 remained after deduplication. Figure 1 presents a flow diagram of our preliminary search for this protocol, and of the subsequent scoping review. Following these preliminary results, we deem the literature sufficient to conduct this scoping review. To our knowledge, this is the first scoping review on the implementation of generative AI in Health care SR. We intend to complete the following methodological steps of the scoping review by the second quarter of 2025.

Figure 1. Flow diagram of this protocol's preliminary search and subsequent scoping review.



Discussion

Principal Findings

The authors anticipated to retrieve relevant studies, gaining an overview of scientific literature to decide if it is feasible to conduct a scoping review on this topic. We anticipated the results to be sufficient in number, since generative AI and SR are emerging technologies of high relevance. The preliminary search provided 3176 results after deduplication. Based on these preliminary results, we anticipate that there is sufficient literature to conduct this scoping review. To our knowledge, no other reviews of the same scope have been published.

Limitations

Based on the methodology of this protocol, some limitations can be derived. The authors aim to synthesize results from publications that are expected to have widely heterogeneous populations, origins, outcomes, and overall methodologies. For example, different age groups or cultural backgrounds of participants limit our ability to generalize the findings of this review. In general, scoping reviews tend to be inherently limited by focusing on breadth rather than depth [131]. Also, the selection of databases, search terms, inclusion criteria, and studies based on the research team's experience might pose a source of possible bias. To reduce overall bias, we adopted a system of dual reviews, discussing conflicting results with senior researchers of the team, and thoroughly documenting the process of study selection.

Conclusions

This scoping review on the interconnectedness of 2 emerging technologies will outline the implementation of generative AI in health care SR, and to map out and categorize which models of generative AI and SR are used in these implementations. Based on relevant literature and the expertise of the research team, it is the authors' intention to answer the primary and secondary research questions: (1) Are generative AI models implemented in SR in the health care sector? (2) Which models of generative AI and SR are used for these implementations? (3) What are the settings of these implementations? (4) Has the acceptance of SR been reported as an outcome following these implementations? While there are previous reviews on either AI or SR in general in the health care sector, there is merely a scant number of reviews on AI-equipped social or surgical robots, and there are, to our knowledge, no other reviews of the same scope as our review. Conducting this scoping review supports future research by mapping out further research gaps

and by providing an overview of the state of the connectedness of SR and generative AI, a relatively new technology with vast potential.

Acknowledgments

The authors would like to thank Meghan Forrest, and the Medical Library of Charité – Universitätsmedizin Berlin for providing methodological guidance and support.

We used the generative AI tool ChatGPT by OpenAI as stated in Stage 2 to detect further search terms, which then have been revised by the research team.

Abstract

Background: Maternal obesity is associated with significant racial disparities. People who identify as non-Hispanic Black and Latinx are at the highest risk related adverse short- and long-term health outcomes (eg, hypertension in pregnancy and postpartum weight retention). Remote lifestyle interventions delivered during and after pregnancy hold promise for supporting healthy weight outcomes; however, few are tested in groups of people who self-identify as non-Hispanic Black and Latinx or address the neighborhood-level and psychosocial factors driving maternal health disparities. Implementing remote lifestyle interventions within community-based programs that serve birthing people may optimize trust and engagement, promote scalability and sustainability, and have the broadest public health impact.

Objective: The goal of this trial is to test the effectiveness of a culturally adapted remote lifestyle intervention (Healthy for Two–Home Visiting) implemented within home visiting compared to usual home visiting services on postpartum weight retention among pregnant or postpartum individuals, in particular those who identify as non-Hispanic Black and Latinx. Facilitators and barriers to implementation of the intervention within home visiting will be examined.

Methods: We describe the rationale and protocol for this hybrid type I effectiveness-implementation randomized controlled trial. In this paper, we highlight the community-engaged approach and trial design features that enable the implementation of the intervention within home visiting and demonstrate its applicability to the target population. Participants will be 360 pregnant individuals with overweight or obesity enrolled between 20 and 33 weeks of gestation and randomized 1:1 to Healthy for Two–Home Visiting or usual home visiting services. The primary outcome is weight retention at 6 months post partum, calculated as 6-month postpartum weight minus earliest pregnancy weight (≤18 wk of gestation). The measures of implementation include intervention feasibility, acceptability, reach, adoption, and fidelity. Throughout the paper, we highlight the community input used to improve intervention effectiveness and study implementation and as a strategy to promote maternal health equity.

Results: This study was funded in June 2021, and recruitment began in April 2023. As of November 2024, we enrolled 90 participants. Data collection to assess the intervention's effectiveness is expected to end in June 2026. Implementation evaluation is expected to conclude in December 2026.

Conclusions: This hybrid type I effectiveness-implementation randomized controlled trial integrates a culturally adapted remote lifestyle intervention into early home visiting services to examine its effectiveness on postpartum weight retention compared to usual home visiting. We anticipate that the study results will enable an understanding of the drivers of successful implementation

within a community-based setting to maximize the future sustainability and dissemination of a strategy for reducing long-term obesity and other maternal health disparities.

Introduction

Background

Maternal obesity is a persistent public health concern, with widening racial and ethnic inequities [1-3]. In the United States, 57% of women who self-identify as non-Hispanic Black and 47% of women who self-identify as Latinx, Hispanic, or of Spanish origin (hereinafter referred to as Latinx) have obese status compared to 38% of people who identify as non-Hispanic White [4]. Nearly 50% of pregnant people who identify as non-Hispanic Black or Latinx exceed the recommended guidelines for gestational weight gain (GWG), contributing to adverse maternal and infant health outcomes (eg, hypertension in pregnancy, preterm birth, and maternal mortality) [5-8], as well as an estimated economic impact of up to US $32 billion from conception through the offspring's first 5 years of life [9]. It is imperative to focus public health prevention efforts on non-Hispanic Black and Latinx pregnant individuals who are most susceptible to worsening obesity (ie, postpartum weight retention [PPWR]) [10-13] and other long-term health problems, including cardiovascular disease [14-17]. Pregnancy offers an opportunity to initiate healthy behaviors that limit GWG and its associated health risks because individuals are motivated to have a healthy baby [18]. This ideal window for health promotion extends to the period after birth when it is critical to sustain healthy changes and improve care transitions, especially among individuals with known barriers to health care access and quality [19]. These individuals have increased exposure to negative social determinants of health (eg, environmental, financial, cultural, and linguistic barriers; racism; limited health literacy; and inadequate insurance coverage), which impacts postpartum visit attendance [20,21] and further exacerbates health risk [22-24].

Counseling and lifestyle interventions during and after pregnancy are a recommended and well-established strategy for limiting GWG [25-28] and reducing PPWR [29-32], and their implementation is being tested in real-world settings; for example, our team is testing a remote health coaching intervention to limit GWG integrated into prenatal care clinics [33,34]. However, there are several evidence gaps. First, few interventions have been tested in racial and ethnic minority groups [32,35], with especially low representation of Latinx individuals [36]. Second, few interventions have been implemented and tested in community-based settings where pregnant and postpartum individuals considered high risk access safety net services. Finally, interventions that address health-constraining social factors that contribute to disparities in maternal health outcomes are limited [31,37,38].

Importantly, implementing effective remote lifestyle interventions within community-based programs that pregnant individuals access and trust may optimize their benefits, promote scalability and sustainability, and have the broadest public health impact. Home visiting is an evidence-based public health strategy targeting pregnant individuals considered high risk and families with children aged up to 5 years. Home visitors provide health education, promote positive parenting and early learning, and link families with needed community resources and social support [39]. Early home visiting has been shown to prevent child abuse and neglect, improve maternal and child health, enhance family socioeconomic status, and promote child development and school readiness [40]. Early home visiting is an ideal setting for delivering lifestyle interventions for pregnant and postpartum individuals because home visitors are uniquely positioned to address social and environmental factors impacting health behavior (eg, neighborhood food availability and walkability) [39]. A recent randomized trial testing a lifestyle intervention embedded in early home visiting services showed lower GWG and PPWR up to 12 months, greater achievement of 5% weight loss, smaller waist circumference, and reduced sugar intake at 12 and 24 months [41], as well as greater success in reducing access to sugar-sweetened beverages in the home up to 24 months [41,42].

Objectives

The goals of this paper are to (1) describe the design of this hybrid type I effectiveness-implementation randomized controlled trial testing the effectiveness of the Healthy for Two–Home Visiting (H42-HV) remote lifestyle intervention integrated into home visiting compared to usual home visiting services on PPWR among pregnant and postpartum individuals; (2) highlight the design features of this trial that enable its implementation within home visiting and the applicability of the intervention to the target population, in particular those who identify as Latinx and non-Hispanic Black; and (3) highlight our application of a community-engaged approach to the conceptualization and design of the study to improve intervention effectiveness and study implementation and as a strategy to promote maternal health equity.

Methods

Study Design, Aims, and Hypothesis

We designed this hybrid type I effectiveness-implementation randomized controlled trial to test the effect of the H42-HV lifestyle intervention integrated into home visiting from mid- to late pregnancy (20-33 wk) through 6 months post partum, compared to usual home visiting services, among pregnant and postpartum individuals with overweight or obesity. The primary outcome is PPWR calculated as 6-month postpartum weight minus prepregnancy (≤18 wk of gestation) weight. Additional measures of effectiveness include GWG and maternal health behaviors, wellness, and health care use. Our main hypothesis is that participants in the H42-HV arm will have lower PPWR than those in the usual home visiting services arm.

Hybrid type I effectiveness-implementation trials assess the primary outcome of clinical effectiveness and evaluate implementation strategies of the intervention as secondary outcomes to better understand facilitators and barriers to real-world dissemination. This hybrid approach could efficiently and in a timely fashion inform the pathways from translation of evidence into practice upon establishing the effectiveness of the intervention, guide future sustainability efforts, and facilitate greater subsequent public health impact [43,44]. To this end, the study will also examine home visiting organizational factors that could impact the implementation of the intervention. We will use the practical, robust implementation and sustainability model (PRISM) framework [45] and domains from the Consolidated Framework for Implementation Research (CFIR) [46] to assess intervention feasibility, acceptability, reach, adoption, and fidelity.

The protocol has been registered with ClinicalTrials.gov (NCT05619705).

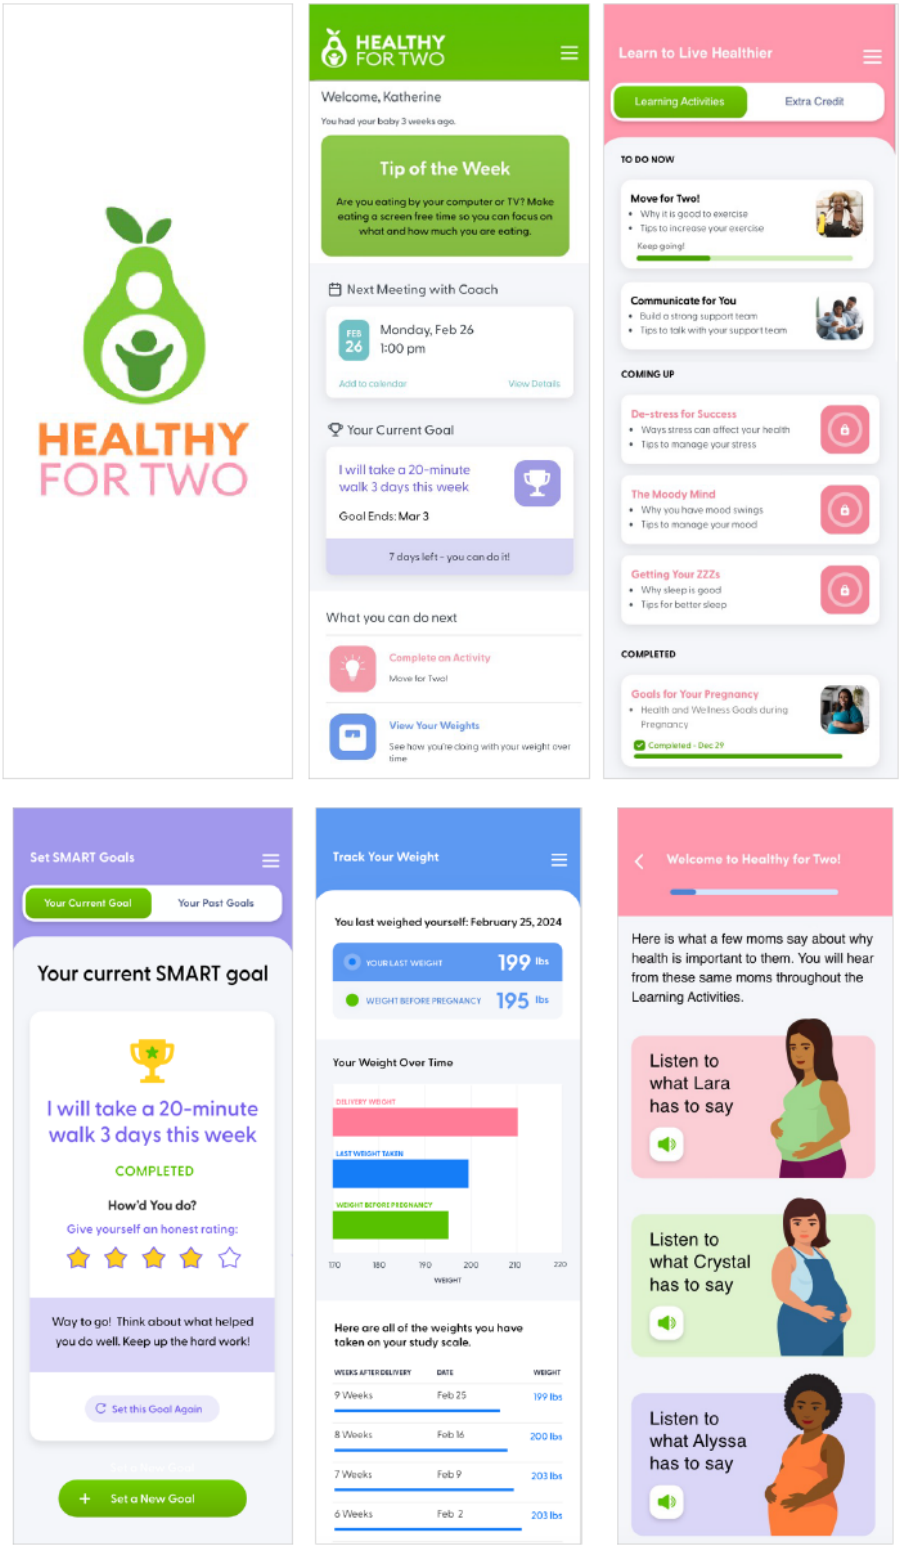
Application of a Community-Engaged Approach

We used a community-engaged research approach to inform the conceptualization and design of the study, including the adaptation of the H42-HV intervention and its integration into early home visiting services. On the basis of the continuum of community engagement in research [47], our level of engagement is best characterized as community participation because the community was actively engaged with a defined role in all stages of the research process. Prior studies clearly demonstrate the importance of early and sustained stakeholder involvement to develop and implement remote health interventions for underserved populations [48-50]. The study principal investigators (WLB and KMB) engaged home visiting stakeholders while developing the proposal and, once funded, used a variety of strategies to establish and sustain 2-way engagement, communication, and information sharing. All aspects of the study were enhanced by feedback from a diverse group of stakeholders who serve individuals identifying as Latinx or non-Hispanic Black, including regional and state leaders in home visiting and participating home visiting program managers and home visitors. Stakeholders also included current or recently pregnant individuals who identify as Latinx or non-Hispanic Black and participate in home visiting services.

During the conceptualization phase, we met with state and program leaders to gather information about the relevance of the intervention and its alignment with state and program public health priorities. We also explored the feasibility and acceptability of implementing the intervention within the home visiting setting. In the planning phase of the study, we established a translation and cultural adaptation team of primarily native Spanish-speaking maternal and child health professionals (ie, dietitian, midwife, and nurse) and health professional students (ie, those studying nursing and medicine) to translate and adapt the H42-HV intervention for Spanish-speaking individuals (the adapted version is called Sanos los Dos).

Once funded, we established a coordinating council with home visitors, leaders from participating programs, and Spanish- and English-speaking community members. Regular meetings with the coordinating council informed all aspects of the study protocol as well as implementation measures, recruitment processes, intervention adaptation, and safety protocols. We asked for specific feedback about the referral process, recruitment materials (flyers and videos), intervention approach and messaging, cultural adaptability, and community resource needs through semistructured one-on-one interviews (6 with home visiting program leaders and 7 with coordinating council members). We performed end-user testing of the H42 mobile health (mHealth) app (Figure 1). We conducted 6 interviews with parents and 2 with home visitors, applying a process known to impact the usability and engagement of culturally adapted digital health tools [49,51].

Figure 1. Healthy for Two mobile health app.



Overall, the feedback highlighted facilitators and barriers to the integration of the H42-HV intervention into home visiting programs and identified strategies for recruitment, adaptations to meet the language and cultural needs of individuals who identify as Latinx and non-Hispanic Black, and effective coordination between the home visitor and health coach. We describe how we addressed feedback from the coordinating council and the additional stakeholders in each of the following subsections.

Home Visiting Programs and Setting

In the formative phase of the trial, we engaged with 7 home visiting programs from across 5 counties in Maryland, United States, that serve predominantly pregnant and postpartum individuals who identify as Latinx or non-Hispanic Black, speak English and Spanish, and have low incomes and literacy levels. Once we launched recruitment, we invited additional early home visiting programs to refer participants to be screened and enrolled in the study. We did not limit ourselves to a particular

model of home visiting and included evidence-based and non–evidence-based models [39]; for example, the partnering home visiting models include but are not limited to Healthy Families America, Healthy Start, Nurse Family Partnership, and Babies Born Healthy. Depending on the model, home visitors are either nurses or paraprofessionals. Participating home visiting models enroll families in early pregnancy and follow them 6 months to 5 years post partum, but the frequency and intensity of home visits vary by model.

Participant Eligibility

As this is an effectiveness trial, we apply the broadest eligibility criteria to enhance generalizability [43,44,52]: age ≥18 years, singleton pregnancy between 20 and 33 weeks of gestation, and planning to enroll in home visiting services at 1 of the study's participating sites. We are focusing this study on individuals who are overweight or obese (BMI ≥25 kg/m^2) before pregnancy as they are at the highest risk for future cardiometabolic disease [53], and we are excluding conditions that may impact an individual's ability to medically or physically participate in the intervention if randomized to that arm (eg, advised not to exercise by provider or diagnosed with type 1 diabetes). Textbox 1 presents additional eligibility criteria.

Textbox 1. Eligibility criteria.

Inclusion criteria

- Age ≥18 y
- 20-33 wk of gestation
- Prepregnancy BMI ≥25 kg/m^2 (calculated based on self-reported prepregnancy height and weight)
- Able to provide informed consent
- English or Spanish speaking
- Intention to enroll in early home visiting services at a participating site
- Ability to complete telephone-assisted screening and electronic consent

Exclusion criteria

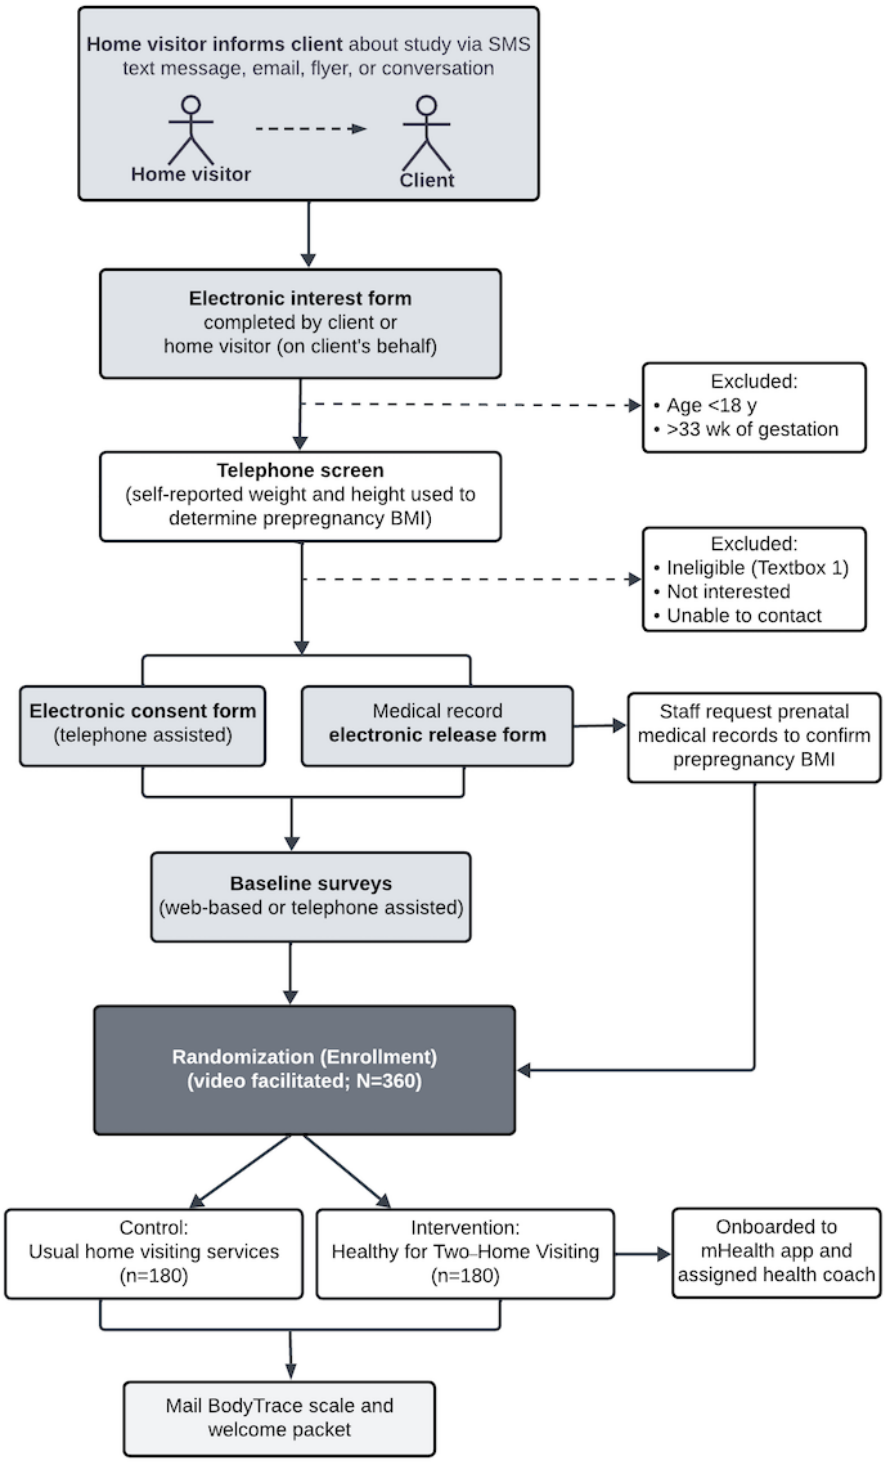
- Diagnosed with type 1 diabetes
- Pregnant with multiple fetuses
- Advised not to engage in exercise by medical provider
- Not cleared by the study's clinicians or home visiting program staff
- Planning to relocate outside of Maryland in the next year
- Active substance abuse (except marijuana)
- Psychiatric or substance use–related hospitalization in the past year
- Active eating disorder

Evidence shows that starting an intervention early in pregnancy has the greatest impact on pregnancy outcomes and GWG [54,55]. However, many home visiting programs rely on several steps to occur before services can begin, that is, entry in prenatal care, referrals from clinic, screening by outside agency for eligibility, and outreach by home visiting program. In response to input from participating home visiting programs, we selected a broad enrollment window during pregnancy (20-33 wk of gestation) and will continue intervention delivery through 6 months post partum. Given state and program leader feedback about the potential for home visiting enrollment in late pregnancy, we selected the primary outcome as return to prepregnancy weight or below because PPWR is a risk factor for future obesity.

Screening and Recruitment

With feedback from home visiting program partners (refer to the Application of a Community-Engaged Approach subsection), we designed the role of home visitors to be low touch and aligned with the procedures they already use in their program and visits. Figure 2 outlines the study design and recruitment procedures. Home visiting staff inform potentially eligible clients about the study via conversation, email, or SMS text message using a "toolkit" of different materials available in English and Spanish to accommodate program, staff, and client needs and preferences (eg, suggested dialogue, paper flyers or postcards, and an informational video lasting 2-3 min). All recruitment materials include a link and QR code to an "electronic interest form" (to be completed by clients or home visitors on their behalf) that requests basic eligibility information to preemptively exclude clients aged <18 years and >33 weeks of gestation, as well as additional details to facilitate the next steps of the screening process.

Figure 2. Study design and recruitment procedures. mHealth: mobile health.



Upon receiving a completed "electronic interest form," research staff reach out to the potential participant via telephone to further assess interest and screen for eligibility. After confirming eligibility, research staff complete a telephone-assisted electronic consent process that includes obtaining a signed authorization for the release of medical records, including prenatal and infant records as well as claims data. After consent is obtained, study staff immediately request prenatal clinic records for height and prepregnancy weight measurements to confirm BMI criteria, and participants complete web-based or telephone-assisted baseline data collection surveys. Once these steps are complete, consented participants meet virtually with staff for a video-facilitated randomization (enrollment) visit. At randomization, participants receive instructions for taking home weight measurements using a study-provided smart scale shipped to their home; intervention participants are oriented to the H42 mHealth app and provided the name of their health coach. In response to home visitors' interest in the result of each client they refer (ie, ineligible, unable to contact, or enrolled), we provide them with the option to "opt in" to live email updates on referral outcomes.

Randomization and Blinding

A total of 360 participants will be randomized 1:1 to the H42-HV arm or comparison arm. Randomization is stratified by home visiting program region+primary language served (ie, central Spanish or English, capital Spanish or English, eastern Spanish or English, southern Spanish or English, or western Spanish or English) and BMI (≥30 kg/m^2 vs 25-29.9 kg/m^2) and within each stratum using randomly varying block sizes of 2, 4, and 6. The randomization scheme was generated using Stata (version 17.0; StataCorp LLC) and imported into REDCap (Research Electronic Data Capture; version 14.0.31; Vanderbilt University) [56,57]. Assignment remains masked until a participant is randomized. Due to the nature of this lifestyle intervention, participants, home visitors, the intervention team, and the safety monitor will not be blinded to randomization assignment after randomization. Until the end of the trial, all nonintervention study staff and coinvestigators, including the principal investigators and data collectors, will remain blinded, with the exception of the lead biostatistician.

H42-HV: Intervention Design and Approach

Overview

The intervention was adapted from our previously designed and pilot-tested remotely delivered lifestyle intervention (called Healthy for Two/Healthy for You) to limit GWG and PPWR in a racially diverse population with low literacy [33,34]. The person-centered intervention uses a standard behavioral approach to weight management [58], teaching strategies aligned with social cognitive theory, such as self-monitoring, goal setting, and problem-solving [59]. The overarching goal of the H42-HV intervention is for participants to have lower PPWR 6 months after delivery.

Intervention Components and Adaptations

Overview

We used an iterative approach for translating and adapting intervention content and technologies using feedback from our key stakeholders (refer to the Application of a Community-Engaged Approach subsection). In addition to shifting intervention timing and focus to the postpartum period, we reframed messaging about program goals to achieving "overall health and wellness" versus a "healthy weight." Consistent early feedback from home visitors suggested that strong internalized weight biases among their clients may impact intervention engagement and acceptability. Weight stigma is pervasive in health care settings, has detrimental impacts on overall health and the use of health care services [60,61], and has more recently been regarded as a social determinant of poor birth outcomes [62]. Textbox 2 summarizes the adapted components of H42-HV.

Textbox 2. Healthy for Two–Home Visiting intervention components.

Person-centered health coaching (English or Spanish)

- 10 total telephone or video meetings (4 pregnancy, 6 postpartum) lasting approximately 30 min using a person-centered approach, plus 2 as-needed "boosters"
- Starts between 20 and 33 wk of gestation and continues through 6 mo post partum
- Coaches have access to a mobile health (mHealth) coaching interface to view participant app engagement and health progress (refer to the H42 mHealth App subsection)

Self-weighing via a home smart scale

- Participants self-weigh at least once weekly on a cellular-enabled home smart scale
- Paper and electronic "wellness journal" available to self-monitor diet and exercise

H42 mHealth app (hosts web-based learning and goal-setting activities, smart scale weight displays, and 2-way participant-coach messaging; promotes engagement via dynamic in-app messages and email reminders)

- Learning activities: 10 educational modules focused on diet, exercise, social support, stress, mood, and sleep. Learning methods include the following: simple, brief education on core topic; audio quotes from 3 ethnically diverse mothers describing personal challenges or successes and behavioral strategies that help them meet health and wellness goals; 5 simple multiple-choice quiz questions to reinforce key concepts; open-ended free-text questions, ranging from 4-9 total per learning activity, to promote goal-oriented thinking, problem-solving, and identification of barriers and successes.
- Add-on learning: videos and external links covering topics such as breastfeeding, gestational diabetes, and smoking cessation
- Goal setting activity: tool that aids participants in setting their own specific, measurable, achievable, relevant, and time-bound (SMART) goals and rating their progress
- Weight display: real-time view of home smart scale weights with feedback to support goal of returning to prepregnancy weight
- Coach-participant messaging: synchronous communication stream primarily used for scheduling and delivery of individualized intervention content (ie, PDF files, images, etc)
- Home page: personalized summary to facilitate intervention adherence (ie, date and time of upcoming coach meetings, most recent coach message, reminders to weigh) and engagement (ie, seasonal health or wellness "Tip of the week")
- Coach and coach manager interface: coach interface with dynamic access to participant weight data and engagement with app (ie, SMART goals, free-text entries); coach manager interface with real-time access to participant and group-level data for individualized case management and ongoing support and management of all coaches

Person-Centered Health Coaching

The cornerstone of the H42-HV intervention is *health coaching* using an evidence-based person-centered approach [63] aimed at enhancing participants' intrinsic drive to make health-related behavior changes (diet, exercise, and stress management). Participants complete up to 12 coach meetings (10 planned plus 2 as-needed "boosters") via video or telephone when they join the study (between 20 and 33 weeks of gestation) through 6 months post partum. Coaches aim to complete 4 meetings during pregnancy and 6 meetings post partum, with flexible cadence to account for varying enrollment dates. The frequency of coach meetings is consistent with similar interventions showing an effect on PPWR [29,33,64] and based on evidence that moderate- (ie, ≥6 contacts) to high-intensity (ie, ≥12 contacts) lifestyle interventions have the greatest effect on GWG [26,65]. Coaches receive enhanced training on weight bias and cultural sensitivity as well as supporting behavioral changes in the context of common social and environmental barriers such as food insecurity and neighborhood safety.

Health Behavior Tracking (Self-Weighing via Home Smart Scale)

Participants are instructed to weigh themselves weekly on a *cellular-enabled home smart scale* (Body Trace; BodyTrace, Inc) [66] that transmits live data to the H42 mHealth app and coach interface described in detail in the next subsection. Coaches emphasize that self-weighing is a core tool to assess progress, similar to monitoring one's exercise minutes and the type and amount of food and drinks consumed. Participants have the option to track and share diet and exercise behaviors with their coach as well as daily ratings of their mood and sleep using a simple paper "wellness journal" or "electronic wellness journal" delivered daily or weekly via SMS text message or email.

H42 mHealth App

Our team designed the *web-based mHealth app* (Figure 1) *and coach interface* based on intervention content tested in past trials [33,34]. The H42 mHealth app is accessible via mobile phone and delivers education tailored to a <6th-grade reading level [67-69] via interactive learning activities that provide guidance on making healthy lifestyle changes in the context of common environmental barriers (eg, eating healthy on a budget and low-cost ways to manage stress). Supplemental health topics (eg, breastfeeding, infant health, and depression) are also available because our formative research and work by others suggested that pregnant and postpartum people across races are more likely to use digital health tools that offer credible, perinatal-specific health information beyond nutrition and exercise [70,71]. The mHealth app contains a goal-setting activity, facilitates 2-way participant-coach communication, displays smart scale data, and promotes adherence and engagement via dynamic in-app messages and email reminders (Figure 1). End-user testing of the English and Spanish versions of the app completed in preparation for the trial (the testing involved 3 English-speaking and 3-Spanish speaking parents and 2 bilingual home visitors) generated reactions to app design and images, usability, interactive functionality, cultural appropriateness, and effectiveness. Consistent feedback gathered (and addressed) included preferences for a brighter color palette, more images, less text and fewer numbers, more traditional Latinx food options, larger-sized body types, simpler graphics (ie, bar graph vs line graph), and a stronger representation of family (ie, households with multiple children). If cost is a barrier, the study subsidizes web-based access (eg, by providing data cards).

The *coach/coach manager interface* provides dynamic access to participant smart scale weights and app activity (ie, goals and free-text responses) as well as food and exercise data for those who choose to track these behaviors using the "electronic wellness journal" that syncs data to the interface. The interface additionally serves as a documentation and scheduling tool. A coach manager interface provides individual and aggregate summary data to facilitate regular participant oversight, ongoing support, and the management of coaches and intervention adherence monitoring throughout the study.

Usual Home Visiting Services Comparison

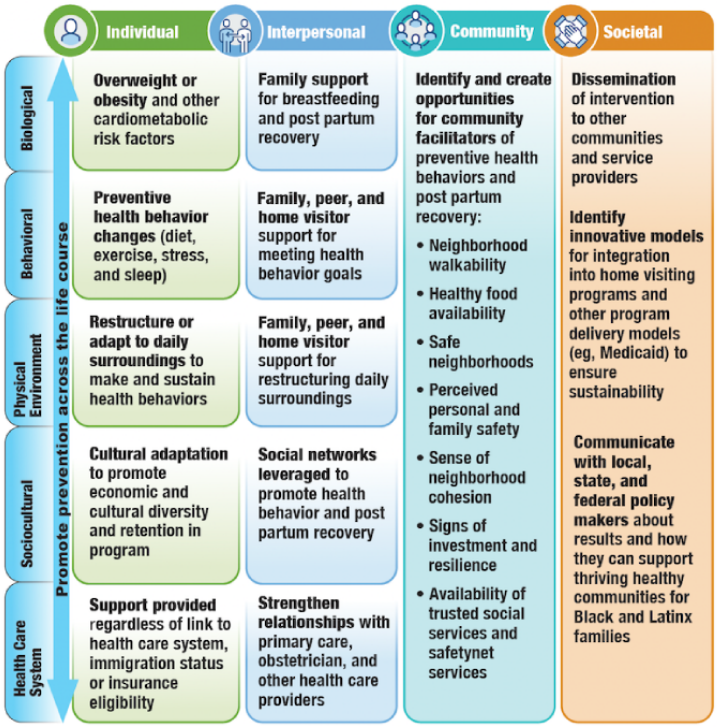
Participants randomly assigned to the comparison arm receive usual home visiting services per agency guidelines and requirements. In addition, we provide a brief, publicly available educational video on urgent maternal warning signs [72,73]. Private, staff-monitored Facebook groups are offered to disseminate information on healthy pregnancy and allow for community building and retention for both groups (usual home visiting services and H42-HV). Both groups are also provided county-specific resource lists with information on green spaces, food banks, mental health resources, medical centers, and intimate partner violence support. This resource list is available as an electronic map (using Google Maps) and a paper version.

National Institute on Minority Health and Health Disparities Research Framework Adaptation for the H42-HV Intervention

We adapted the National Institute on Minority Health and Health Disparities research framework [74] to depict the multilevel influences (individual, interpersonal, community, and societal levels) that embedding the remote intervention into early home visiting services has on health outcomes and disparities, including the social determinants of health (Figure 3). The H42-HV intervention impacts *individual-level* factors by promoting a healthy lifestyle in women with cardiovascular risk factors, regardless of insurance coverage or health literacy. While coaches provide education and strategies for making healthy changes (ie, adding fruits and vegetables to participants' diet), home visitors address context-specific barriers (eg, healthy food availability) and leverage context-specific assets (eg, local food banks) to increase success at achieving behavioral goals. At the *interpersonal level*, home visitors provide social support and connect participants with social support networks that promote a healthy lifestyle and provide tools to navigate family or peer norms, while health coaches teach participants effective communication skills to strengthen the support they receive from their existing network (eg, home visitors, health care providers, family members, and peers) and tailor this support toward making healthy changes. The H42-HV intervention addresses *community-* and *societal-level* influences by connecting participants with local resources and promoting

parent and infant use of health care services (eg, postpartum care and primary care). Ultimately, the study is designed to promote a holistic approach to reducing cardiometabolic health inequities among birthing people.

Figure 3. National Institute on Minority Health and Health Disparities research framework adaptation for the Healthy for Two–Home Visiting intervention.



Data Collection and Data Sources

Effectiveness Measures and Methods

Tables 1 and 2 summarize the methods of measurement and timing aimed at improving access and retention as well as minimizing participant burden (also refer to Figure 4). Early conversations with home visiting program leaders indicated that home visitors would not have time to collect study data; therefore, data collection procedures were designed to not involve home visitors. Data are collected through 4 methods: a cellular-enabled home smart scale, medical record review, web-based surveys via REDCap, and Medicaid claims data.

Table 1. Schedule of intervention effectiveness measures: electronic medical record review, smart scale, and Medicaid claims.

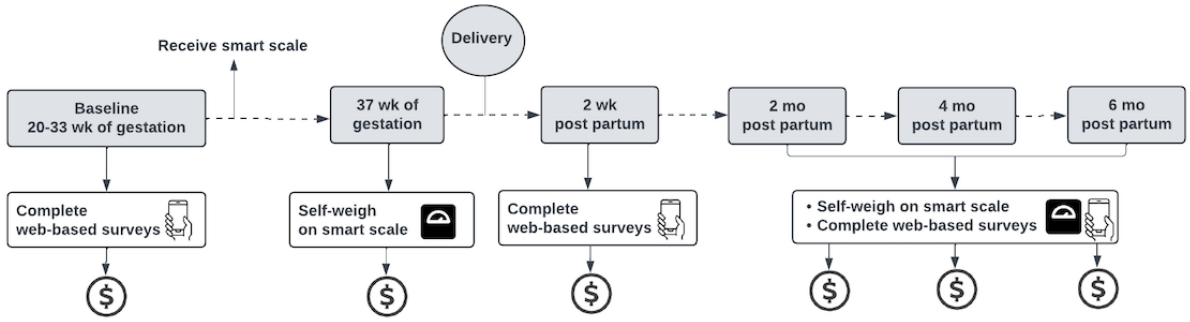
Figure 4. Data collection and retention.



Assessment and Verification of Maternal Weight Using a Smart Scale

Smart scale weights are collected at 4 time points: 37 weeks of gestation; and 2, 4, and 6 months post partum (Table 1). Participants are instructed to weigh themselves in light indoor clothes without shoes on their home smart scale (BodyTrace [66]). The smart scale transmits data to the study team via cellular connectivity (no Wi-Fi or cellular plan is required), which is ideal for rural client communities with intermittent Wi-Fi or those with reduced access to cellular data or inconsistent data plans. The BodyTrace smart scale was selected

because it demonstrates good concordance with in-person assessments [88,89] and has been used in several large weight management trials [90,91], including those with racially diverse populations with low incomes and literacy levels [92-94]. The scale is mailed to participants' homes after randomization, and brief SMS text reminders to weigh are sent at each study assessment time point (ie, "Time to step on your scale"). Staff monitor weight data transmitted to the study's REDCap server in real time and reach out to participants with no weight by the middle of each designated assessment "window," which ranges from –10 days to +10 days at designated study outcome assessment time points. Staff also monitor battery power and the strength of the cellular connection to assist participants with related issues, as needed. To mitigate the disruption that environmental factors (eg, potential for multiple users or scale displacement) can have on data quality, we programmed a dynamic weight cleaning procedure that requires participants to confirm questionable weights by responding to a 1-question survey sent via SMS text message. For intervention participants, this cleaning procedure ensures real-time accuracy of the weight graphs in the H42 mHealth app, as well as automated reminders, including in-app messages that prompt participants to weigh if a confirmed weight is not available after 7 days. After 14 days, coaches are notified to conduct personalized outreach to remind participants to weigh themselves.

Obtaining Medical Records and Abstracting Information on Prepregnancy Weight

Participants consent to pre- and postnatal medical record release for themselves and their infant from before pregnancy through 1 year post partum (Table 1). We use a secure electronic fax system (OpenText Fax; Open Text Corporation) to request medical records from prenatal clinics, offices, and hospitals. "Prepregnancy" weight is defined as the earliest measured weight obtained from medical records up to 18 weeks of gestation; when not available, we use self-reported weight. We also abstract height, parity, and comorbid conditions from medical records.

Web-Based Surveys

We used REDCap to build and design web-based surveys using standard instruments selected to minimize participant burden and enable completion at home (Table 2). Collectively, surveys take 10 to 20 minutes to complete, depending on the total number and length of those designated at each time point; staff-led telephone-assisted surveys are available, when preferred.

Demographics and Social Determinants of Health

Maternal and infant demographics and social determinants of health are collected using standard questions from the PhenX toolkit [78], the 2020 US Census Informational Questionnaire [75], and the Accountable Health Communities Health-Related Social Needs screening tool [77]. Additional common data elements, using standard and commonly used measures related to participant characteristics and social determinants of health, were incorporated, as required by the National Institutes of Health–Health Equity and Action Network for data harmonization at the National Institutes of Health Multiple Chronic Diseases Disparities Research Consortium [76]. Experiences with chronic, routine discrimination [95] are assessed using the 9-item Everyday Discrimination measure [85], which demonstrates good reliability (Cronbach α=0.88) and is shown to be a strong and consistent predictor of health and well-being [85].

Maternal Health Behaviors, Attitudes, and Experiences

Dietary intake is assessed as estimates of servings of fruits and vegetables, added sugars, whole grains, fiber, and calcium using the 26-item Dietary Screener Questionnaire [79], which demonstrates agreement with 24-hour dietary recalls [96]. Exercise frequency and intensity are measured using the 7-item International Physical Activity Questionnaire–Short Form, which has acceptable reliability (pooled ρ=0.76) and some agreement with the accelerometer standard (pooled ρ=0.30) in a diverse sample [80].

Mood is assessed using the 10-item Edinburgh Postpartum Depression Scale for postnatal depression, which illustrates moderately high validity (sensitivity=85%, specificity=77%) and split-half reliability (r=0.88) in the original sample of 60 mothers [81]; these results have been confirmed in other validation studies [97]. We measure stress using the 4-item Brief Perceived Stress Scale [98], which is a shortened version of the original 14-item scale [82] and has acceptable psychometric properties [99]. We assess sleep using the 6-item Brief Pittsburgh Sleep Quality Index [83], which shows good internal consistency (Cronbach α=0.79, McDonald ω=0.91) and adequate validity (sensitivity=76%, specificity=77%) in a large population-based sample [83]. Perceived social support is quantified using the 8-item Duke-UNC Functional Social Support Questionnaire [84], which has favorable test-retest reliability (r=0.50-0.85) and is significantly correlated with other social support measures [84].

Several questions from the standard and core measures of the Pregnancy Risk Assessment and Monitoring System (PRAMS) [86] assess pregnancy and breastfeeding intentions and practices, contraception, substance use (tobacco, marijuana, and alcohol), and experiences with or use of health care before and after birth.

Infant Health, Sources of Care, and Feeding Practices

Infant overall health, feeding, and sources of care are assessed using the PRAMS [86] and Infant Feeding Practices Survey [87]. The use of community and safety net programs (ie, Supplemental Nutrition Program for Women, Infants, and Children) is also measured using the PRAMS [86].

Engagement With Home Visiting Services

Engagement with home visiting services and the frequency of contacts with home visitors will be collected at all postpartum time points to assess the "dose" of home visiting during the study.

Intervention Satisfaction

Intervention participants complete a satisfaction survey at the end of the study using an adapted survey tool administered and reported on in previous trials [33,34].

Medicaid Claims Data

We will request Maryland Medicaid claims data for all consented participants with Medicaid to assess maternal and infant health care use outcomes (ie, attendance at prenatal care visits, postpartum visit, primary care visits, infant visits, and receipt of infant vaccines) via a data use agreement with the Maryland Department of Health (Table 2).

Implementation Process Measures and Methods

Overview

Measures to evaluate the implementation are based on the PRISM framework [45] and domains from the CFIR [46]. Table 3 outlines all implementation outcomes and measures.

Table 3. Implementation process measures and methods.

PRISM[a]+CFIR[b] domains	Implementation process measure	Data collection method (before, during, and after the trial)
Organizational perspectives	Home visiting program perceived usability, adaptability, and relative priority of the intervention	Surveys before and after program orientation; focus groups after the trial
Organizational characteristics (inner setting from the CFIR)	Home visiting program culture, management support and cooperation, systems, training, staffing, and incentives	Home visiting leader surveys before the trial
External environment (outer setting from the CFIR)	Home visiting program regulatory environment (policies and incentives); patient needs and resources	Home visiting leader surveys before the trial; county reports; census and county rankings database
Reach	Total number of clients enrolled out of those screened and eligible; total number of clients enrolled out of new pregnant clients enrolled in the home visiting program	Study recruitment and enrollment data; home visiting program leader surveys after the trial
Implementation (engaging, reflecting, and evaluating process from the CFIR)	Engagement of program leaders in implementation process; qualitative feedback on the progress and quality of the implementation	Coordinating council, formative interviews with home visiting program leaders, focus groups, and research team discussion and reflection throughout the trial
Adoption	Proportion of sites across the state that opt to participate in the study; adoption of training and recruitment procedures; level of involvement supporting intervention participants	Home visiting staff focus groups after the trial; review of study recruitment and enrollment data
Fidelity of the intervention (coach and participant)	Coach adherence to meeting guides and patient-centered approach; participant adherence to intervention components and perceived acceptability	Review of audio-recorded coach meetings during the trial; reports from data management systems; participant acceptability survey after completing the study

[a]PRISM: practical, robust implementation and sustainability model.

[b]CFIR: Consolidated Framework for Implementation Research.

Organizational Perspectives

To support state and program leader feedback gathered during the conceptualization phase of the study (refer to the Application of a Community-Engaged Approach subsection), home visitors' perspectives of the intervention were assessed via survey before and after a 1-hour study staff–led orientation (an overview of study goals, design, and referral procedures) that they received before the trial. They rated the importance of, and the need for, resources to address various health-related topics (eg, nutrition and exercise) with their clients before the training and after they rated intervention acceptability, appropriateness, and feasibility [100]. At the end of the study, we will conduct 2 focus groups with home visitors from participating programs to further explore the perceived usability, acceptability, and adoption of the intervention. Interview guides will be developed using the PRISM framework [45] and include questions assessing facilitators and barriers to implementation.

Organizational Characteristics (Inner Setting From the CFIR)

Features of home visiting programs through which the implementation process will proceed and features that may support or impede the programs' ability to successfully implement the intervention (eg, structure, enrollment, staffing, service modality, and curriculum) were assessed before the trial using a survey completed by home visiting program leaders.

External Environment (Outer Setting From the CFIR)

The county-level economic, political, and social contexts within which the home visiting programs reside and which may affect their ability to successfully implement the intervention (eg, social determinants of health, obesity rates, demographics, reimbursements, and health and wellness resources) will be assessed before the trial using a survey completed by home visiting program leaders and publicly available data from county reports, US Census Bureau data [75], and a county rankings database [101].

Study Reach

We will quantify study reach as (1) the total number of clients enrolled in the study out of new pregnant clients enrolled in home visiting during the enrollment period and (2) the total number of clients enrolled in the study out of those screened and eligible for the study.

Implementation (Engaging, Reflecting, and Evaluating)

We will measure implementation through a combined strategy of gathering feedback from home visiting programs about the progress and quality of the implementation and holding regular debriefings with personnel and team about progress and experience.

Adoption of Intervention

We will track the proportion of home visiting sites across the state that opt to participate in the study and assess the level of involvement in study procedures and the intervention via survey and home visitor focus groups after the trial.

Fidelity of the Intervention: Coach and Participant Adherence (During and After the Intervention)

We will examine intervention fidelity and its impact on the primary outcome using common procedures applied in multicomponent remote lifestyle intervention trials [102,103]. Health coach fidelity to a participant-centered approach and standard meeting components (eg, reviewing successes and progress as well as setting goals) will be measured using an iterative quality assurance process of sampling and reviewing audio-recorded coach meetings. We will track participant adherence to each component of the intervention (coach meetings, mHealth app, and smart scale use) and intervention acceptability using an end-of-study survey.

Retention Strategies for Participants

On the basis of our experience with recruiting and retaining pregnant women, we will use several methods to achieve high retention, including rapport building, sending birthday and birth cards, and using email and SMS text message reminders based on each participant's preferred method of contact. Participants will be provided gift cards after each data collection visit: US $10 at enrollment; US $10 at 37 weeks of gestation; US $15 at 2 weeks post partum; and US $20, US $25, and US $30 at 2, 4, and 6 months post partum, respectively (Figure 4). As participants will be engaged in home visiting and consider the program part of their care, we anticipate low risk for loss to follow-up.

Methods for Ongoing Home Visitor and Community Engagement

Home visitor engagement will involve monthly recruitment updates shared with sites and site supervisors, raffle incentives, ongoing training opportunities on topics of interest, and brief one-on-one "check-ins" between a study team member and home visitor "site champion" aimed at quickly mitigating concerns or struggles pertaining to study procedures. Community engagement throughout the trial will involve quarterly newsletters to all stakeholders (ie, coordinating council members and state-level leaders), including home visitor and community member "spotlights" and participant success stories. In addition, each home visiting site will receive an annual financial incentive.

Analytic Approach

Sample Size and Power Estimates

With 360 participants, our objective is to determine the minimum detectable difference (MDD) for the primary outcome of PPWR between the 2 study groups. Our assumptions are as follows: a 2-tailed type I error rate of 0.05, a type II error rate of 0.10, and ≥70% follow-up for the main outcome of PPWR at 6 months. On the basis of the past experience [33] and published literature, we anticipate <30% loss to follow-up for 6-month weight measurements, consequential to various forms of dropout (eg, lost to follow-up). With this dropout rate and the assumption that the dropout is consistent with missing at random, we expect to randomize 360 participants (n=180, 50% per arm) to retain an effective sample size of 252 participants (n=126, 50%/arm) for our primary outcome. SDs for the MDD evaluation were informed by previous studies of similar combined diet-exercise lifestyle interventions to limit weight gain in pregnancy and promote postpartum weight loss [26,41,104,105]. Under these considerations, the resulting MDDs range from 2.3 to 3.6 kg with corresponding SDs for PPWR of between 5.5 and 8.8 kg.

Main Analytic Model for the Primary Outcome of PPWR

Analysis will follow the intention-to-treat principle. The main analysis will assess the between-group difference in PPWR (the difference between earliest pregnancy weight and weight at 6 mo post partum) using a mixed effects model characterized by a mean model relating the outcome to the predictors and a variance-covariance model addressing variance of all available longitudinal weight outcomes and correlation between outcomes measured over time within individual. The predictors in the mean model will include a group indicator (0 for the comparison arm and 1 for H42-HV) as well as 3 binary indicators for 2-, 4-, and 6-month postpartum visits, respectively, with baseline visit as the reference, and the corresponding group-by-visit interaction terms, adjusting for study sites (region and primary language served) and baseline BMI category used for randomization stratification, as fixed effects. The regression coefficient of the group by 6-month postpartum weight interaction term will estimate the intervention effect on the primary outcome, that is, mean difference in PPWR at 6 months between the intervention and control groups. We will use an unstructured variance-covariance model to allow full flexibility on outcome variances and longitudinal correlations for the repeatedly measured weight data. A model-based 2-tailed *t* test will be used to evaluate the intervention effect and derive the associated 95% CI. The Kenward-Roger approximation will be used to calculate the *df* for the *t* test, with $P<.05$ considered statistically significant [106].

Data from all randomized participants will be used in this analysis, with missing data included using a software-specified missing indicator. The main analysis will assume that outcome data are missing at random and use an observed data likelihood approach implemented through the mixed effects regression model, where baseline characteristics associated with the probability of missing outcome data will be further adjusted for in the mean model. Sensitivity analysis through multiple

imputation of missing outcome data under plausible missing-not-at-random scenarios will be conducted to evaluate the robustness of the findings from the main analysis conducted under the missing-at-random assumption.

Secondary Outcomes and Additional Analyses

Secondary outcomes include maternal, infant, and organizational process outcomes. For secondary maternal outcomes, available data from all randomized individuals will be included. Between-group differences in GWG (defined as the difference between the weight at 37 weeks of gestation and prepregnancy weight) and infant weights will be assessed using the same mixed effects modeling approach as described for the primary outcome, with separate models for each outcome. Between-group differences in the binary outcomes of diet, exercise, breastfeeding, and women's wellness measures (depression, sleep, stress, and social support) will be described between the H42-HV and comparison arms using standard cut points for the scales and modeled using logistic regression model–based longitudinal models implemented through a generalized estimating equations approach [107]. The mean models will similarly use the group indicator, visit indicators, and the corresponding group-by-visit interaction terms, adjusting for the variable used to stratify the randomization. Robust variance estimates will be used for statistical inferences to derive 95% CIs for the population-average estimates and corresponding *P* values. Conforming to recommended maternal postpartum care use and well-baby care use over time will separately be modeled using a similar generalized estimating equations approach as described for the longitudinal binary outcomes.

Exploratory Analyses for the Heterogeneity of the Intervention Effect

We will explore for potential moderators of intervention effects by conducting subgroup analyses based on baseline survey data (race, ethnicity, home visiting program characteristics, baseline BMI category [overweight or obese], language spoken at home, low English proficiency, income, and education level) and examining effect modification by adding appropriate interaction terms to the primary mixed effects model. We do not expect the intervention effects to vary across subgroups, and we will interpret carefully any observed heterogeneity, or lack thereof, given the exploratory nature of these analyses.

Safety Surveillance and Monitoring

For active surveillance, a safety medical officer will oversee the postdelivery review of medical records, including labor and delivery notes and infant discharge summaries. We will administer safety surveys after delivery and at 2, 4, and 6 months post partum to enable tracking of all maternal and infant hospitalizations, emergency department visits, and labor and delivery triage evaluations (Table 2). We have developed protocols to alert the team and manage high levels of depressive symptoms or interpersonal violence (Table 2). The Johns Hopkins Institutional Review Board is required to review all serious safety events. In addition, the study has a sponsor-approved data safety and monitoring plan, and oversight from the Mid-Atlantic Center for Cardiometabolic Health Equity Data and Safety Monitoring Board that meets twice a year to review study progress, intervention adherence, and adverse events (mild, moderate, and severe).

Ethical Considerations

The protocol received initial approval from the Johns Hopkins Institutional Review Board in June 2022 (IRB00307430) and was determined to be minimal risk. Standard continuing reviews occur yearly; protocol amendments are also reviewed and subsequently updated in the ClinicalTrials.gov registry. During the informed consent process (refer to the Screening and Recruitment subsection), participants are made aware of their right to privacy and confidentiality and are informed that all health information is deidentified or stored on secure servers. They are also advised that they can withdraw from the study at any time without consequence from the research team and medical or home visiting services, and if this occurs, Johns Hopkins may use any data collected before withdrawal. Participants will be provided gift cards after each data collection visit (for details, refer to the Retention Strategies for Participants subsection). In addition, each home visiting site will receive an annual financial incentive.

Results

This study was funded in June 2021, and recruitment began in April 2023. As of November 2024, we enrolled 90 participants. Data collection to assess the intervention's effectiveness is expected to end in June 2026. Implementation evaluation is expected to conclude in December 2026.

Discussion

Anticipated Findings

We designed this hybrid type I effectiveness-implementation randomized controlled trial to test a remote lifestyle intervention for weight management during pregnancy and post partum in a community-based setting that serves individuals who identify as Latinx and non-Hispanic Black. The goal of this hybrid trial is to evaluate the effectiveness of a newly adapted remote lifestyle intervention (H42-HV) and effectively integrate the intervention into early home visiting services to reduce PPWR. We hypothesize that participants who receive the H42-HV intervention will have a lower mean difference in PPWR at 6 months than control group participants. This would add to the limited evidence supporting the effectiveness of counseling and lifestyle interventions during and after pregnancy in minimizing GWG [25-28] and reducing PPWR [29-32] among racial and ethnic minority groups [32,35]. Furthermore, because few counseling and lifestyle interventions for pregnant and postpartum people have been tested in community-based settings, the use of implementation science methods will enable the gathering of important data about the facilitators and barriers to implementing the intervention in the early home visiting setting and among this population considered vulnerable. Early home visiting programs hold promise to be an ideal setting to integrate lifestyle interventions because of their unique ability to address relevant social and environmental conditions impeding healthy behaviors (eg, access to healthy foods and transportation), as well as support and improve transitions to

postpartum care. We anticipate that our study findings will demonstrate feasibility comparable to that reported in another trial of a lifestyle intervention embedded into early home visiting [41,42]. Through the implementation science approach, we will also provide evidence to support policy translation, including the expansion of H42-HV delivery into other US states' home visiting programs, and into Medicaid Managed Care coaching and case management programs as Medicaid coverage expands into the postpartum period in more states [108].

Strengths and Limitations

A major strength of the trial's design is the community-engaged approach, which began during the grant conceptualization and preimplementation phases to inform project design. Community-engaged research approaches have increased dramatically in the last few decades and are linked with statistically positive outcomes and success in recruiting and retaining racially and ethnically diverse populations experiencing marginalization [109-111]. Community-engaged research has many benefits, including ensuring intervention appropriateness, acceptability, and applicability [112-115]; ensuring that study methods and intervention are properly adapted to the population of interest [114,116,117]; and promoting trust, transparency, and bidirectional learning between research teams and stakeholders [112,118,119]. Adopting this approach has already guided key research design decisions, including (1) limiting the primary role of home visitors to the recruitment of study participants to minimize impact on workflow, (2) enrolling participants during mid- to late pregnancy (20-33 wk) to align with client enrollment in home visiting programs, (3) defining the primary outcome as weight retention at 6 months post partum to allow time for increased support during the postpartum period, and (4) focusing study goals and messaging on achieving "overall health and wellness" versus a "healthy weight" to minimize the effects that weight bias internalization may have on recruitment and intervention acceptability. Using remote data collection procedures was another important design consideration (ie, smart scale and access to prenatal medical records), given the transportation barriers of home visiting clients living in rural locations and anticipated challenges they might have in reporting their height and weight to confirm eligibility—an issue that was confirmed soon after study launch. We anticipate that the continued involvement of our coordinating council as well as other methods of community engagement will drive future decisions about the interpretation of data and dissemination of findings.

The iterative process of end-user interviews that informed the design, features, and functionality of the H42 mHealth app was especially valuable for adapting and improving it, including methods for incorporating weight goals and progress (ie, simple, colorful graph versus weight change statistics) and translating the interactive goal-setting activity for Spanish-speaking participants. Comprehensive measures of adherence to coaching, the H42 mHealth app, and the smart scale are a major strength of the study, given the growing complexity of remote lifestyle intervention packages and the critical need to differentiate the effects of unique components [27]. Similarly, access to robust engagement metrics for distinct mHealth app features (ie, interactive goal setting, coach messaging, access to weight data, comprehension quizzes, and educational videos) may build upon the patterns of website engagement characterized by Power et al [120] in a sample of individuals with low-income status who identified as Latinx; of note, in this particular study, website engagement was a strong predictor of weight retention at 6 months post partum.

The design of our study has limitations that could impact the interpretation of the results. First, control participants will have access to a scale for data collection, and regular self-weighing is a key component of behavioral weight management [58]. From a health equity and ethical perspective, we decided that we would refrain from instructing control participants not to weigh themselves outside of data collection and, instead, statistically control for the number of measured weights across the groups. Nonetheless, given the enhanced level of engagement with self-weighing in the intervention group (ie, reminders, ability to view progress on the app, and feedback from the coach), we expect the frequency of weighing in the control group to be significantly lower, and frequency is the strongest known predictor of overall weight change [121]. Another limitation is our limited ability to formally measure and control for the varying levels of support that the home visitors offer clients throughout the trial, which may differentially impact behavior change (eg, addressing access to healthy food and discussing a healthy lifestyle). This lack of control precludes our ability to measure intervention effectiveness for a Latinx and non-Hispanic Black, English- and Spanish-speaking sample considered high risk outside of the context of home visiting. Although home visitors were intentionally removed from intervention delivery, early feedback conveyed a preference among some home visitors to be actively involved, specifically with the ability to access SMART goals (assuming clients' permission). The differences in home visitor training (ie, nurse vs paraprofessional), curriculum, and the intensity of home visiting models in the trial (ie, frequency of visits ranging from weekly to 2 visits total during the first 6 mo post partum) may also differentially impact client success. We expect qualitative data on intervention adoption captured in focus groups after the trial to enhance our understanding of the potential role home visitors play in moderating intervention effects and will leverage these insights for future trial designs and intervention adaptions.

Conclusions

There is a critical need to develop effective lifestyle interventions for pregnant and postpartum individuals who identify as Latinx and non-Hispanic Black and experience the greatest risk for adverse pregnancy outcomes. This study has the potential to provide a high-quality assessment of the effectiveness of a remote lifestyle intervention for a Latinx and non-Hispanic Black population considered high risk and highlight facilitators and barriers to its implementation in a grounded service strategy specifically geared toward improving maternal and infant health. We expect the study to yield important findings that aid in refining future lifestyle intervention approaches for pregnant and postpartum people, particularly those who identify as non-Hispanic Black and Latinx, and facilitate scalability in community-based settings,

ultimately improving maternal and infant long-term health and promoting health equity.

Acknowledgments

This trial was funded as 1 of 3 studies at the Mid-Atlantic Center for Cardiometabolic Health Equity funded through the National Institute on Minority Health and Health Disparities Centers for Multiple Chronic Diseases Associated with Health Disparities: Prevention, Treatment, and Management (RFA-MD-21-007) under the P50 mechanism.

Abstract

Background: Personalized approaches to behavior change to improve mental and physical health outcomes are needed. Reducing the intensity, duration, and frequency of stress responses is a mechanism for interventions to improve health behaviors. We developed an ambulatory, dynamic stress measurement approach that can identify personalized stress responses in the moments and contexts in which they occur; we propose that intervening in these stress responses as they arise (ie, just in time; JIT) will result in positive impacts on health behaviors.

Objective: This study aims to (1) use an experimental medicine approach to evaluate the impact of a smartphone-delivered JIT stress management intervention on the frequency and intensity of person-specific stress responses (ie, stress reactivity, nonrecovery, and pileup); (2) evaluate the impact of the JIT intervention on the enactment of health behaviors in everyday life (physical activity and sleep); and (3) explore whether changes in stress responses mediate the interventions' effects on health behaviors.

Methods: In a 2-arm phase 2 clinical trial, we will enroll 210 adults in either a JIT stress management intervention or an active control condition. For 4 weeks, participants will complete 8 brief smartphone surveys each day and wear devices to assess sleep and physical activity. After a 1-week run-in period, participants will be randomized into the JIT intervention or an active control condition for 2 weeks. Participants in the JIT intervention will receive very brief stress management activities when reporting greater than typical stress responses, whereas control participants will receive no personalized stress management activities. Participants enrolled in both conditions will engage in self-monitoring for the entire study period and have access to a general

stress management education module. Self-report outcomes will be assessed again 1 month after the intervention. We will use mixed-effects models to evaluate differences in person-specific stress responses between the intervention and control groups. We will conduct parallel analyses to evaluate whether the intervention is associated with improvement in health behavior enactment (ie, sleep and physical activity). The Pennsylvania State University Institutional Review Board approved all study procedures (STUDY00012740).

Results: Initial participant recruitment for the trial was initiated on August 15, 2022, and enrollment was completed on June 9, 2023. A total of 213 participants were enrolled in this period. Data are currently being processed; analyses have not yet begun.

Conclusions: We anticipate that this research will contribute to advancing stress measurement, thereby enhancing understanding of health behavior change mechanisms and, more broadly, providing a conceptual roadmap to advance JIT interventions aimed at improving stress management and health behaviors.

Introduction

Background

Broadly defined stress processes (eg, chronic stress and allostatic load) are associated with an increased risk for poor mental and physical health outcomes [1]. Traditional research on this topic tends to focus on between-person assessment examining, for example, whether those with more major life events or more chronic stressors for relatively long periods have worse health. However, chronic stress is characterized by a series of repeated acute events, each including exposure to stressors and slow and delayed recovery from stressful events [2]. Thus, to effectively characterize and intervene in stress processes, a granular measurement of acute stress is needed that uses a personalized, within-person approach. In this case, the goal is to understand an individual's stress experience at a given moment compared to another moment (eg, their normal resting state). Such an approach captures the dynamic and temporal nature of the stress experience that occurs within an individual as they navigate their natural environment. Furthermore, this within-person approach to capturing stress experiences affords the opportunity to identify and intervene in such processes before, or at the onset of, their occurrence to attenuate the association between stress and poor health outcomes [3-5].

To help advance stress measurement approaches, we developed and refined methods for the self-report assessment needed to measure and characterize how individuals experience stress in their everyday lives in a way where each stress event can be adequately captured and studied [4,5]. We proposed that a stress event can be broken down into distinct components. Specifically, our approach focuses on assessing events that elicit immediate emotional and cognitive responses (ie, reactivity), the degree to which we adapt and recover (ie, recovery), and the temporal patterns of responding to and recovering from multiple stressors over time (ie, pileup). This assessment strategy took a within-person approach that permitted the repeated assessment of stress experiences close to their occurrence. It estimated how these stress response components (ie, reactivity, recovery, and pileup; RRP) unfold with time and in natural contexts. We demonstrated the utility of assessing these specific components of the stress responses (ie, RRPs) across 3 indicators (ie, negative affect, perseverative cognition, and subjective stress) to index "moments of risk," where such moments are specific to a person and context [6-8]. Furthermore, we were able to link specific stress response targets to health behaviors (ie, sleep and physical activity) both within and between individuals [9,10]. Given that these stress response components and indicators are related to the enactment of health behaviors in everyday life, we contend that they may be potent targets for intervention, and we aim to test this using the experimental medicine approach [11-13].

There is growing awareness and need for better personalized and precision medicine approaches in the behavioral sciences [14]. Advances in smartphone technology (ie, apps, location, and activity) and the widespread use of mobile and sensing devices have led to the development of ecological momentary interventions that use contextual information and self-report data to match intervention content to contextual needs and deliver that content in real time [3,15]. A just-in-time (JIT) intervention framework advances this approach using rule-based algorithms to deliver the right intervention at the right time based on prespecified triggers (eg, specific variable, context, or combination of variables and context).

We suggest that our stress response assay is well suited to inform the JIT and related interventions. First, our approach is highly personalized in deriving person-specific estimates of momentary or daily risk. We have chosen to not implement static threshold–based general rules applied across all individuals; for example, with the intervention content delivered when some predetermined threshold value is exceeded (eg, a score of ≥6 on a 7-point scale) or when individuals report being in a specific location deemed risky. Although intervention delivery using this method may still benefit the recipient, it does not fully allow for adaptation to the individual with time or across changing contexts. The approach proposed in this protocol, and in some of our previous work [4,5], goes beyond using group or

sample-level fixed-risk estimators, providing an adaptive and individualized framework to identify moments of maladaptive stress responses across several key indicators specific to the person. Second, we have developed, tested, and refined an intervention algorithm that uses our stress assay to process real-time information to identify and provide personalized intervention content as stress targets arise. This approach includes providing intervention content matched to general availability and the intensity and frequency of the individual's experience. We propose that the implementation of this stress assay and the JIT intervention framework has the potential to inform approaches to individualized stress management, intervention design, and implementation science more broadly.

Aims

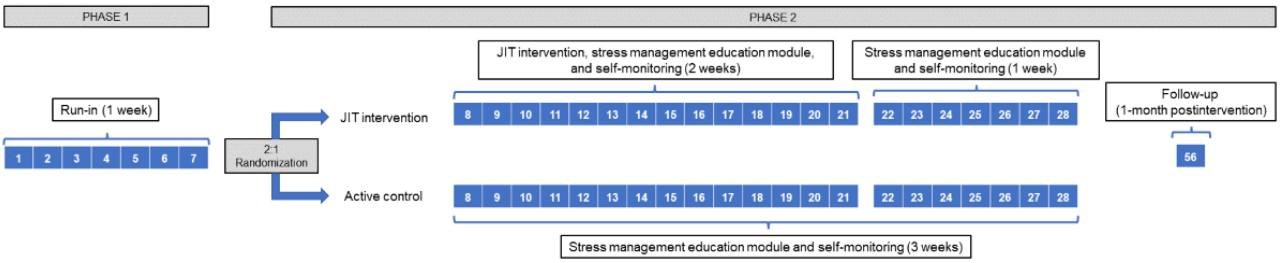
This study aims to determine the effectiveness of a JIT stress management intervention, delivered via a study smartphone, on the outcomes of stress responses, sleep, and physical activity. This study will leverage our optimized stress assay to identify moments of risk and deliver empirically derived multimodal JIT intervention content in everyday life, with the aim of modifying stress response components (ie, RRPs) across multiple indicators (ie, negative affect, preservative cognition, and subjective stress) to subsequently produce positive change in daily physical activity and night sleep. Using the experimental medicine approach within the context of a phase 2 clinical trial, our primary aim is to evaluate the impact of a 2-week smartphone-delivered JIT intervention (relative to an active control consisting of self-monitoring and stress management education) on the frequency and intensity of stress responses (RRPs), as measured by (person-specific) negative affect, perseverative cognition, and subjective stress. Our secondary aim is to evaluate the impact of the JIT intervention on the enactment of health behaviors in everyday life (ie, daily physical activity and night sleep). Our third aim is to explore whether the interventions' effects on health behaviors are mediated by changes in our target mechanism (RRPs).

Methods

Project Overview and Trial Design

This study is a 2-arm phase 2 clinical trial (ClinicalTrials.gov NCT05502575). The study has 2 phases (Figure 1), including a 1-week baseline eligibility "run-in" period (phase 1), followed by a 2-week randomized controlled trial (phase 2) for those eligible after phase 1, with a 1-week observational interval following the intervention.

Figure 1. Study design. JIT: just in time.



Ethical Considerations

The Pennsylvania State University Institutional Review Board approved all study procedures (STUDY00012740). All participants provided informed consent. All study data are deidentified and encrypted. Participants were compensated equitably for participation according to what study phases and components they completed, as detailed in the Procedures section.

Phase 1

Phase 1 of this study serves 3 primary purposes. First, it is a data-capture period that enables us to collect individual baseline data on each participant to be used to inform the JIT intervention algorithm in phase 2. Second, it allows us to screen for participant compliance with the protocol and ensure that those enrolled in phase 2 meet minimum standards for data completeness (ie, >70%). Third, this period allows us to exclude participants who do not regularly report stress during everyday life and thus may not be impacted by our intervention.

Phase 2

Phase 2 is the clinical trial portion of the study and will serve as the between-group test of our JIT intervention on night sleep and physical activity. This study phase will be initiated immediately following phase 1 and is 3 weeks long. Participants who are eligible for phase 2 will be randomized into one of two conditions as follows: (1) JIT intervention (ie, JIT stress management, self-monitoring, and web-based stress education module) or (2) active control (ie, self-monitoring and web-based stress education module). The first 2 weeks of phase 2 are the active intervention period, while the final week is a self-monitoring period.

Participants

To examine the impact of our intervention on our primary outcomes without the influence of age-related stressors or increased probability of health comorbidities that could impact our measures of sleep and physical activity, our target population will be generally healthy middle-aged adults. Specifically, we will recruit English-speaking men and women aged 35 to 65 years who report good general health and are free of physical limitations from the mid-Atlantic region of the United States.

We will exclude people who report (1) residing in the same household as current or former participants (to prevent any contamination of the intervention or unblinding of condition allocation); (2) an inability to answer smartphone survey SMS text messages due to restrictions or policies in the workplace; (3) a diagnosis of a mental health condition that required a

medication adjustment or hospitalization within the last 3 months; (4) being a primary caretaker for a parent, child, and family member who is severely disabled; (5) employment that requires shift work as this will result in abnormal sleep patterns; (6) a diagnosis of sleep apnea, use of a continuous positive airway pressure machine, or score above threshold on STOP-BANG; (7) the use of physician-prescribed pharmaceutical sleep aids or over-the-counter sleep aids for ≥3 days per week; (8) an inability to be physically active or who have medical contradictions for physical activity; or (9) physical exercise of ≥200 minutes per week at a moderate or vigorous intensity or ≥10 hours of walking per week as this raises the possibility of ceiling effects on activity.

Recruitment and Screening

Participants will be recruited through advertisements posted in the local communities (eg, community centers, grocery stores, libraries, and cafés), online channels (eg, social media and study recruitment websites), and mailed flyers. Interested participants can contact the study team via phone or email and will be given a brief study overview. Participants can also access study information and preliminary web-based screening forms using a link on the recruitment materials. Individuals interested in participating will be screened to determine eligibility and scheduled for an introductory training session if eligible. All screening and scheduling will be conducted via phone using a script.

Randomization

Randomization for this study will occur upon enrollment into phase 2 using discrete codes entered into the smartphone app by a research assistant blind to study goals. Participants will be allocated on a 2:1 ratio that favors the JIT intervention condition to provide a sample size large enough to support our planned analyses. To balance participant characteristics within the study conditions, participants will be equally randomized across 3 age categories (including those aged 35 to 44, 45 to 54, and 55 to 65 years) and by sex (male and female). Masking of the participant group identities from the training personnel, data collectors, and analysts will be used. Group assignments will be unmasked for analysis when the trial is complete and after all data have been entered.

Sample Size

Our initial power calculations suggest that our study target for participants enrolled in phase 2 should be 210 (n=140, 66.7% assigned to the JIT intervention condition and n=70, 33.3% assigned to the active control condition). In our previous work with a similar assessment schedule, we observed compliance rates of >70% on the momentary surveys and >80% on the device wear time across 2 weeks in 95.2% (120/126) of the participants (unpublished data). Of those participants, the lowest quartile reported approximately 3 stressor events across 2 weeks. Thus, we estimate that approximately 15% of participants enrolled in phase 1 will not qualify for phase 2 due to no reported stressors or low compliance rates with study procedures. It is also likely that some participants may choose not to continue participation in phase 2 even if they are eligible due to the intensive assessment schedule. We estimate that refusal will account for 25%, and an additional 10% of those participants may either drop out during phase 1 or become ineligible. Thus, we estimate that up to 50% of the participants enrolled in phase 1 may not continue to phase 2. Therefore, we expect to recruit and enroll approximately 450 participants in phase 1 to reach our target of 210 participants in phase 2.

Equipment

Study Smartphone

All study participants will be provided with an Android LG Rebel 3 smartphone. The smartphones will be preloaded with the MovisensXS app (Moviesens GmbH [16]), a secure assessment app that delivers, collects, and uploads the study smartphone surveys to a secure server. Devices will also be preloaded with the stress management intervention content. Each phone will have an active data plan and Wi-Fi capability to allow instantaneous survey uploads, intervention delivery, and access to the web-based stress education modules. Participants will only have access to the smartphone functions relevant to the study procedures, and all other smartphone capabilities will be locked.

Device-Assessed Sleep

Objective sleep outcomes will be collected using the Actiwatch Spectrum Plus (Philips Respironics [17]). Participants will be asked to wear the water-resistant Actiwatch on their nondominant wrist for the study's duration, only removing the device when bathing or swimming. This device measures wrist movement time series using the digital integration method and will be configured to collect activity data at 32 Hz. At study completion, data from the Actiwatch will be processed to detect off-wrist periods and downloaded in 15-second epoch files using the Respironics Actiware software (version 6.0.9; Philips Respironics).

Device-Assessed Physical Activity

Participants will be asked to continuously wear a water-resistant ActivPAL4 activity monitor (PAL Technologies [18]) for the duration of the study. The ActivPAL4 monitor will be adhered to the midline of either thigh, halfway between the knee and hip, with adhesive tape. Participants will be instructed to remove the device only if bathing or swimming and will not be required to charge the device. This device uses an inclinometer and accelerometer to measure posture and activity intensity to quantify the time spent sitting, lying, standing, or stepping. Activity data will be collected at 20 Hz, with device data downloaded and processed using the PALbatch software (version 8.10.11.54; PAL Technologies).

Procedures

Phase 1 (Run-In Period)

Phase 1 of this study is 1 week in duration. Participants will attend a 90-minute introductory training session with a research assistant. During this visit, participants will take part in an informed consent procedure. They will be notified that they may be invited to another longer study after they have completed the 1-week study. However, no further information about the study or eligibility criteria for participation will be provided.

After informed consent is obtained, participants will participate in a study protocol training session to learn how to use the study smartphone to answer surveys. Each participant will be able to practice the surveys with a research assistant to ensure that they understand the survey items and how to operate the smartphone. Participants will also receive instruction on properly adhering and caring for the wrist-worn actigraphy device and the physical activity monitor. Finally, they will be asked to complete a demographics survey and baseline questionnaires. Each participant will receive a quick reference participant booklet that reviews relevant survey and device information.

During the 1-week study period, participants will be asked to complete 8 brief smartphone surveys per day that are delivered to the study smartphone, including 1 survey upon waking in the morning, 6 surveys delivered randomly throughout the day between 8 AM and 9 PM, and 1 survey at the end of the day before going to sleep. Participants will continuously wear the actigraphy and physical activity devices for the entire week. At the end of the 1-week study period, participants will attend a second session to return their devices and receive compensation (up to US $100). At this time, research assistants will assess survey and device data for compliance and completeness to determine whether the participant meets the criteria for eligibility into phase 2.

Eligibility for Phase 2

Survey data from phase 1 of the study will be used to inform the delivery of the JIT intervention in phase 2. Therefore, it is essential for participants who enter phase 2 to meet the minimum criteria for complete data on which to apply our intervention rules. For this reason, we will assess participant compliance with the study procedures and data completeness before inviting participants into phase 2. Specifically, participants who complete phase 1 will be eligible for phase 2 if they (1) return all study devices, (2) report at least 1 stressor in their surveys during the 1-week run-in period, (3) meet an acceptable rating threshold for survey compliance (ie, >70%), and (4) have valid accelerometry data for at least 5 nights during the 1-week study period. Given that these compliance checks will be conducted during a brief session, the physical activity data will not be assessed for completeness as it requires considerable time to download and review.

Once all devices are obtained and compliance checks are done, participants will be compensated according to completed study procedures. At the time of compensation, each participant will either be dismissed or invited to participate in phase 2 of the study. Those deemed eligible to participate in phase 2 will receive a brief overview of study procedures. They will participate in the consent procedure for phase 2 and a refresher training session if interested. If they are not interested, they will be dismissed.

Phase 2 (Clinical Trial)

Phase 2 will be initiated immediately following phase 1. The study procedures for phase 2 are similar to phase 1 (ie, 8 smartphone surveys per day and wearing study devices) but also involve randomization into either the JIT intervention condition or the active control condition. Participants will undergo another informed consent procedure and a brief review on using the study smartphones and how to wear and care for the study devices. All participants will be notified during the session that they will have access to web-based stress management education modules on the home screen of their smartphone (refer to Active Control Condition section); they may also receive additional prompts delivered to their smartphone and will be asked to follow all instructions provided to them to the best of their ability.

Given that both the participants and researchers will be blind to condition allocation, no training specific to interacting with the JIT intervention materials will be provided to participants. Importantly, no specialized training or instruction is required to participate in the intervention condition as all necessary instructions will be provided on the device when the intervention content is delivered. We adopt this approach as it may facilitate the scaling up of intervention delivery in the future (eg, by not requiring in-person or online training). After the phase 2 training session, participants will attach their study devices and continue to answer surveys delivered across the 3-week study period.

For the first 2 weeks of the 3-week study period, participants randomized into the JIT intervention condition will complete the 8 smartphone surveys per day, wear the 2 study devices continuously, and receive multimedia JIT intervention content to their smartphone during moments and days identified as appropriate for intervention (Figures 2 and 3). Participants randomized into the active control condition will continue to complete 8 smartphone surveys daily and continuously wear the 2 study devices. However, they will not receive any personalized stress management content. Participants in both conditions will have access to web-based stress management education information regarding the causes, consequences, and remediation of stress. This information was developed and curated by stress experts on our team (JMS, MJZ, and JAJ; ie, representing an informational standard of care) and will be available on study smartphones for the entire 3-week study period.

Figure 2. Just-in-time intervention algorithm. EOD: end of day. NA: negative affect; PC: perseverative cognition; RRP: reactivity, recovery, and pileup; SS: subjective stress.

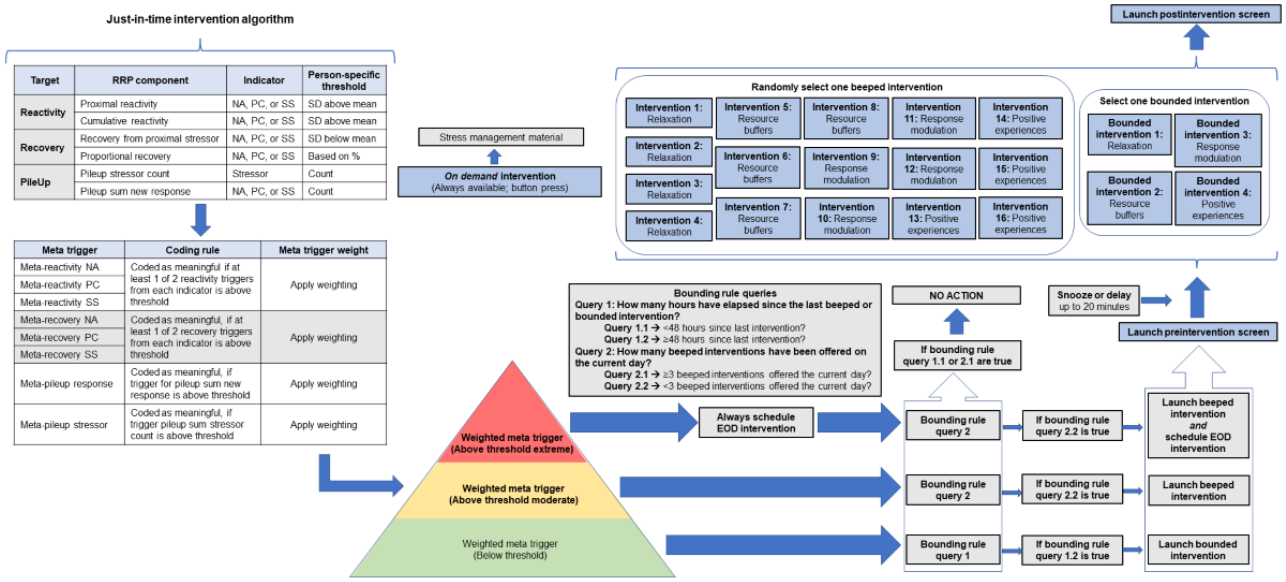


Figure 3. End-of-day (EOD) intervention algorithm. EMA: ecological momentary assessment; NA: negative affect; PC: perseverative cognition; RRP: reactivity, recovery, pileup; SS: subjective stress.

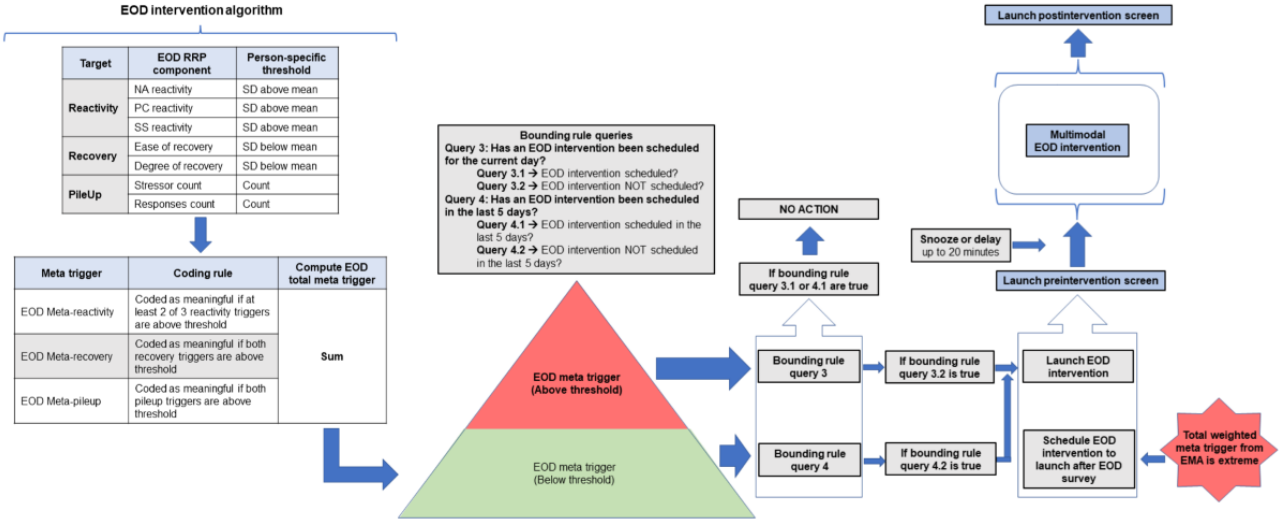

During the final week of the 3-week study period, the delivery of the JIT intervention content will cease (access to the web-based stress management education module will continue), and participants in both conditions will continue to engage in self-monitoring only. This final week of self-monitoring will provide information about the short-term impact of the JIT intervention and the immediate effects of tapering JIT intervention content. It will also evaluate whether any effects persist in whole or in part once the JIT intervention ceases. At the end of the 3-week study period, participants will attend a final session to return their devices and debrief about the study. A research assistant will assess participant compliance with the study procedures, and participants will receive their earned compensation of up to US $300 for phase 2.

Follow-Up

One month after the completion of phase 2, participants will be invited via email to complete a web-based follow-up self-report survey to assess changes in stress, sleep, and physical activity with measures capturing key study constructs. Participants will have 1 week to complete this survey to receive US $15 compensation.

Measures

Demographics

At baseline, participants will provide information on the following demographic characteristics: sex, age, race, ethnicity, education level, current work status, household income, subjective social status, marital status, number of adults and children in the home, and height and weight (ie, BMI). We will also inquire about active gymnasium memberships and the use of wearables and smartphone apps for sleep and physical activity.

Baseline and Follow-Up Measures

The measures selected for this study are intended to capture a broad range of constructs that may impact stress and stress

responses in everyday life, including personality, mood and affect, tendencies for ruminative and perseverative thinking styles, social support, and current stress. These person-level factors will help characterize our sample and may serve as potential explanatory variables for treatment response heterogeneity. We are also capturing information on current health status and preintervention and follow-up measures of self-reported sleep behaviors and sleep disturbance, physical activity behaviors, and physical activity intention or automaticity. The measures being assessed in this study and their assessment schedule are summarized in Table 1.

Smartphone Surveys

Overview

The smartphone surveys in this study capture momentary and global ratings of stressful events, subjective stress, positive and negative affect, perseverative cognitions, and health behaviors as participants go about their daily lives. There are 2 types of smartphone surveys in this study, including those that are self-launched by the participant by button press within the smartphone app (ie, morning and evening surveys) and those that are automatically delivered to the participant at semirandom intervals throughout the day (ie, beeped surveys). The self-launched surveys serve as broader retrospective assessments of these outcomes across the day. In contrast, the beeped surveys are meant to capture more proximal assessments of these outcomes in the contexts in which they occur (at the moment). The information collected in the smartphone surveys will be used to derive our indicators of stress in real time and inform the delivery of JIT intervention content (Figures 2 and 3).

Morning Survey

Participants will be asked to launch and complete the morning survey each day within 30 minutes of waking. This survey will assess the duration and quality of the previous night's sleep, current stress, affect, perseverative cognitions, plans for physical activity, and expectations for the day ahead.

Beeped Surveys

The beeped surveys will be automatically delivered to participants at 6 random times each day between 8 AM and 9 PM during the study period and are scheduled at semirandom intervals (1 to 4 hours apart; typically 2.5 hours apart) to capture most waking hours. These brief surveys assess the participant's current location, activities, social interactions, recent stressors, affect, perseverative cognitions, and physical activity (duration and intensity). Participants can delay (up to 15 minutes) or dismiss any survey if they cannot complete it at the indicated time.

Evening Survey

Participants will be asked to complete the evening survey each night before going to bed and instructed to think about their entire day (ie, from waking up) when completing the survey. This survey assesses stressful experiences and reactions to them; overall day-level affect and perseverative cognitions; physical activity (duration and intensity); consumption of caffeine, nicotine, and alcohol; use of backlit devices before going to bed; and daytime nap duration.

Objective Sleep

Two research staff (who have been satisfactorily trained on scoring sleep data by a sleep expert on our team) will independently score downloaded data from the sleep watch. Sleep intervals and relevant sleep outcomes will be derived using a previously validated algorithm [36]. Outcomes will include total sleep time, wake after sleep onset, sleep efficiency, and nap count or frequency and duration. Total sleep time will be calculated by the number of minutes between sleep onset and awakening. Wake after sleep onset is the total time spent being awake between sleep onset and awakening. Finally, sleep efficiency will be calculated as the proportion of actual sleep from sleep onset to awakening relative to the total sleep duration interval (%). Naps will be delineated as other sleep periods >30 minutes in length that occur outside of the main nighttime sleep period.

Objective Physical Activity

The physical activity data will be aggregated into 1-minute epochs. Using the sleep and wake times from the sleep data, all sleep periods will be excluded in the subsequent data aggregation process. Furthermore, any continuous sitting or standing events that are >5 consecutive hours will be classified as nonwear and will also be excluded. The remaining valid wake period will be classified into either time spent sedentary, standing, or stepping. Time spent stepping will further be classified into time spent in light physical activity or moderate to vigorous physical activity using the 100 steps per minute cut point [37]. Other relevant objective physical activity outcome variables will include step count and number of sit-to-stand transitions. The physical activity data will be further aggregated depending on the level of analysis as necessary (eg, hourly, daily, and person-level summary).

JIT Intervention

General Approach

In line with the principles of the JIT intervention approach, our goal was to develop empirically supported stress management content that is delivered during particularly stressful moments. It uses a nudge framework [38] to help a person reorient to a nonstress state via improved affect and reduced perseverative and maladaptive cognitions. More broadly, each nudge aims to help build a diverse toolkit of stress management skills that can be implemented in everyday life. Furthermore, this allows us to implement a personalized approach to intervention delivery using real-time information specific to the individual at a given moment to deliver content at moments of presumptive risk or need [39].

Intervention Content

The development and testing of our intervention content have been described previously [40]. Briefly, we developed our intervention content within 4 broad categories: relaxation, response modulation, positive experiences, and resource buffers.

Relaxation

These techniques aim to shift the body from a state of elevated or negative arousal to a relaxed or neutral state. Participants could do controlled breathing, deep breathing, progressive muscle relaxation, or an object-focused meditation.

Response Modulation

These techniques aim to promote self-regulatory behavior, in particular, to manage emotions, promote efforts to change thoughts and associated emotions to a more positive meaning, reduce impulsive behavior, and focus attention away from emotion-eliciting situations or thoughts. Participants could perform a reappraisal task to learn how to rethink negative situations, an attentional deployment task to train them to focus on positive stimuli, a third-party observer task that asks them to imagine how an outsider would view their stress, or an affect labeling task to encourage the ability to use words to self-describe negative emotional events.

Positive Experiences

This category aims to facilitate engagement in activities that can induce positive mental states. Participants could imagine saying positive statements to themselves, reacting to positive imagery, engaging in a gratitude exercise, or a reminiscing task that engages them to relive a positive event in their lives.

Resource Buffers

This category aims to increase the quality of life at the moment to enhance function and resilience. Participants could engage in a self-affirmation task to embrace those facets of their life that are most positive, a self-efficacy task to encourage them to find moments they have successfully dealt with life events, a social comparison task that allows them to learn from others who have successfully dealt with stress in their lives, or a best

possible self activity (imagining an idealized version of themselves and how they might achieve that self).

Intervention Types

Overview

The intervention content was developed to be appropriate for everyday life, including the consideration of general availability to engage with the intervention content. Therefore, we developed 2 intervention types of differing lengths and time of day availability, and all content was intended to be displayed to the participant on a smartphone. Each activity is intended for the participant to do independently, not requiring interaction with others.

Microinterventions

These very brief interventions (ie, microinterventions) are no more than 1 to 2 minutes in duration. This suite of microintervention content includes 16 brief videos, including 4 microinterventions across each of the 4 categories described above. For any given participant randomized into the JIT condition, when an intervention moment is identified (refer to Intervention Delivery section), 1 of the 16 microinterventions will be randomly selected from the suite of videos and presented to them on the smartphone. To maximize engagement and increase the potential for exposure to the different skills and activities, each time an intervention is delivered, it will not be placed back in the pool of available videos for potential delivery until all 16 videos have been used.

Once a microintervention is initiated, participants will receive an audible alert from the phone, and once activated, they will be notified that their stress levels appear elevated and that a recommended intervention is available to help reduce their stress. Next, they will receive a description of the activity they will engage in and how to be prepared to do it most effectively. They will then initiate the intervention video on the smartphone and follow the guided instructions. Each activity is designed so that previous training is unnecessary, but continued engagement may increase one's enjoyment and ease in doing the activity. At the end of each intervention, we will ask the participant to consider what worked with the intervention and plan how to use it in a future moment of stress. To this end, participants must consider when they are stressed and thus engage in some self-monitoring of their behaviors. Furthermore, by encouraging participants to use the activity on their own, they may be more likely to practice and improve their skills.

End-of-Day Intervention

We also wanted to provide a longer, more comprehensive intervention that covered the various domains of our broader intervention approach while providing an opportunity for more focused skill-building. This 20-minute singular intervention will be delivered in the evening when people may have more time to engage in the focused activity. It comprises multimodal components that cover several broad domains and represents a progression of many of the techniques and categories noted above. The goal is to guide an individual through more extensive training to reduce stress via improved affect and reduced perseverative cognitions. It is intended to be repeated to build general skills in the broad domains it covers. Similar to what was outlined previously, participants will receive stressor-focused framing before and after the intervention.

Intervention Delivery

As described earlier, in our previous work, we developed a stress assay that used self-reported survey data on different stress response indicators (ie, negative affect, perseverative cognitions, and subjective stress) and several stress targets (ie, RRPs) to be able to derive person-specific means and SDs [4,5]. Using this information, we were able to establish person-specific thresholds that would indicate meaningful derivations from an individual's norm (ie, identifying when they are stressed), as well as moments or days that were associated with poor health behavior enactment (eg, sleep and physical activity [9,10]). In this study, we aim to use this assay to identify "moments of risk" and intervene "just in time" to prevent downstream impacts on our health behaviors of interest (ie, sleep and physical activity). To provide intervention content at these moments of elevated stress while also maximizing the probability of participant engagement with the intervention content, we developed several pragmatic principles and boundaries to guide our intervention delivery. We refer to these general principles and rules as our intervention algorithms. These algorithms, when paired with the smartphone survey data in real time (ie, uploaded from the smartphone to the study server via mobile data plan), allow us to process the participant's survey data, aggregate the information across moments and days, provide a solution (ie, trigger) for whether or not intervention content should be delivered to the participant at that moment, and subsequently deliver the content to the participant, all in near real time.

To provide us with the greatest opportunity to interfere with current or ongoing stress responses and to maximize the probability of availability, we decided that interventions would only be delivered immediately following the completion of a survey (beeped or evening). This ensures that the participant is near their study smartphone should an intervention be delivered. It also allows us to intervene in active or ongoing stress responses in the contexts in which they occur. Although this approach has some limitations, such as requiring the individual to have the mental resources to engage with the intervention during periods of elevated stress, it was chosen in an attempt to optimize intervention impact and participant engagement. This approach also provides a natural connection between this study's intervention and survey types.

We have created 2 overlapping intervention algorithms to match intervention types (ie, microinterventions and end-of-day intervention) to survey data (ie, beeped and evening) while accounting for participant availability and burden. We developed the JIT intervention algorithm (Figure 2) to process information from the beeped surveys and trigger brief microinterventions during the day. Then, we developed the end-of-day intervention algorithm (Figure 3) to process information from the evening survey and trigger the longer end-of-day intervention. These algorithms, when combined, allow us to leverage our stress assay to detect moments of elevated stress responses in individuals at both the moment and day level, providing brief interventions in the moment or longer and more focused

interventions at the end of the day, when there are generally fewer daily demands on an individual.

In broad terms, the intervention algorithms use survey data from phase 1 to derive person-specific thresholds for each participant to inform intervention delivery in phase 2. This approach highlights the importance of selecting highly adherent participants to continue to phase 2 of the study. Once enrolled in phase 2, person-specific thresholds will be continuously updated as surveys are completed and intervention content is delivered. When survey data are collected from participants throughout the day and in the evening, it will be automatically uploaded and processed in the algorithm in real time to determine whether a participant's state indicates elevated stress levels. The algorithm will access all previous responses preceding that specific moment and the person-specific thresholds to do this. This information will then be combined with the current survey data to determine whether there is a meaningful deviation from an individual's norm. Each meaningful score will be weighted and combined with other meaningful scores for that specific moment to derive a weighted summary risk score. Each moment's risk level will then be evaluated based on the weighted summary risk score. Depending on this score, an intervention may be delivered to a participant at that moment, and, in some cases, a longer intervention may also be scheduled for delivery at the end of the day. This process will be repeated continuously for each participant as survey data are uploaded.

As an initial attempt to manage participant expectations and burden in this study, we incorporated a set of rules that will govern the upper and lower limits of intervention delivery (ie, ensure both a minimum and maximum frequency) and serve 2 purposes. First, our lower bound rules ensure that at least some intervention material is pushed out to each participant who is randomized into the JIT intervention condition, even in the absence of person-specific elevated stress. This includes providing a microintervention at least every 48 hours, regardless of whether elevated stress levels triggered an intervention, and an end-of-day intervention at least once every 5 days. We think this approach will keep participants engaged while providing a minimum "dose" of intervention content. We are also aware that participants in this study may experience stress below our intervention threshold (especially as their time and exposure to intervention content progresses) or that we may miss some stress responses or events with our survey schedule. Therefore, providing some minimum level of intervention content could provide the skills or resources to maintain the treatment effect, prevent future stress responses, or buffer any ongoing subthreshold stress. Second, the upper bounds of our intervention delivery will prevent us from overwhelming participants should they experience a bout of frequent or intense stress. To prevent undue participation burden related to engaging in microintervention content, we will limit microinterventions to a maximum of 3 on any given day (between 8 AM and 9 PM). We will provide the option to dismiss or delay any intervention for up to 20 minutes. We will have access to the uptake of all intervention content, including the date and time it was delivered and initiated by the participant, its duration, and the completion time.

Active Control Condition (Self-Monitoring and Stress Management Education)

In this study, participants enrolled in the active control condition will engage in self-monitoring for the duration of phase 2. Although there is some evidence that self-monitoring on its own might be a strategy for reducing negative affect and perseverative cognition [41], we wanted to provide a more stringent test of the "just in time" aspect of our stress management intervention. Therefore, we decided to bolster our comparison condition by providing access to a stress management education module comparable to any usual care stress management resource that an individual could access if needed. With this in mind, we developed 8 brief readings and tips that focused on stress education and the impact of stress in everyday life and adapted these materials into a web-based reading or reference module [40]. All participants enrolled in phase 2 of the study will have access to this module on the home screen of their study smartphone. If the module link is activated, they will be provided with a summary of the purpose of the module, followed by a list of 8 topics they can choose. Each module will take about 2 minutes to read and is followed by a brief, generic stress management tip that can be incorporated into everyday life. The stress management tips were derived from the same 4 categories outlined earlier, with 2 activities from each of the 4 categories included in the module. Participants will have access to this module 24 hours per day for the entirety of phase 2 and can access the readings as often as they want. User statistics will be collected each time a participant accesses the module, including the topics accessed, the number of times the module is accessed per day across the study, and a singular item about acceptability.

Proposed Analyses and Analytical Approach

All collected data will be subjected to a rigorous data-cleaning procedure to identify invalid data points (eg, out-of-range, implausible, and outlier variables will be scrutinized). General descriptive statistics (ie, mean, median, percentages, and SD) will be used to characterize the study sample. To evaluate the effect of the smartphone-delivered JIT intervention on RRP (specific aim 1), we will use mixed-effects models to evaluate any significant differences in RRP scores between the 2 study groups (ie, intervention group vs control group). In addition to the main effect differences between the 2 groups, we are interested in the potential cumulative effect of receiving multiple interventions across the 2-week study duration (testing a "dose" effect of the microinterventions) or whether potential benefits do not occur immediately but rather develop during the intervention period (eg, if it takes some time for the JIT intervention to lower stress responses). To evaluate this latter effect, we will test the group-by-time interaction effect in a multilevel (eg, momentary RRP nested within days, days nested within person, and person nested in group) mixed effect model. Analyses will be conducted using the SAS statistical program (version 9.4; SAS Institute Inc).

For our second aim, evaluating whether the intervention is associated with improved health behavior levels (ie, sleep and physical activity), we will use the same approach described for our first aim. That is, we will evaluate the overall treatment

effect and how this effect changes with time. Unique in this evaluation, we will test these relationships using continuous outcome (ie, the amount of time spent on these health behaviors) as well as the likelihood of meeting the threshold for recommended levels of physical activity (≥150 minutes of moderate to vigorous physical activity/week) and sleep (>7 hours/night). That is, we are interested in finding out whether participants who receive the innovative JIT intervention were more likely to meet recommended levels of physical activity or sleep.

Finally, we will test whether changes in RRPs mediate the group-level effects of the intervention on health behaviors. In other words, we want to evaluate whether any benefits observed in health behaviors are due to the changes in stress responses (RRPs). All evaluations will be conducted using an intent-to-treat analysis, with imputation conducted for missing data as appropriate, and a per-protocol (completers) analysis. Given the large number of analyses planned, we will evaluate and implement appropriate methods to reduce the likelihood of false positives (eg, false discovery corrections). Theoretically informed but more exploratory analyses will be conducted to examine if there are individual difference moderators of observed effects.

Results

Participant recruitment for the trial was initiated on August 15, 2022. Initial enrollment was completed by June 9, 2023, with 213 participants enrolled. Each of the multiple data sources (eg, ecological momentary assessment survey reports, physical activity, and sleep) is being cleaned and processed for use. Study analyses have not yet begun.

Discussion

Principal Findings

In this trial, we will evaluate the effectiveness of a JIT stress management intervention, delivered via a study smartphone, on the outcomes of stress responses, sleep, and physical activity. We hypothesize that those receiving the JIT intervention and standard stress management material will show better stress response processes, greater engagement in physical activity, and better sleep than those receiving only standard stress management material.

This study will provide valuable insight into the potential utility of characterizing, in a personalized manner, components of everyday stress responses and using individualized moment and day-level risk indicators to deliver JIT stress management microinterventions (relative to generic stress management educational materials coupled with intensive self-monitoring). The JIT stress management microintervention condition is predicted to enhance stress response (ie, reduced reactivity, better recovery, and less pileup) across multiple indicators (subjective stress, affect, and cognitions) relative to the control condition. In turn, it is thought that enhanced stress response processes will allow individuals to successfully engage in more positive health behaviors; namely, the group receiving the JIT intervention will exhibit more physical activity, less sedentary time, and improved sleep.

Our stress response components (RRPs) have been developed based on preliminary work and theoretical considerations; however, it is important to note that both their specific implementation (eg, the level at which momentary risk is presumed) and how they are used to trigger JIT microintervention can be readily adapted. Thus, this study is not intended to serve to finalize or concretize the specific implementation of this approach or the intervention itself (eg, the triggering algorithm and microintervention content); rather, it is meant to serve as a foundational proof-of-concept demonstration of this approach that can (and should) be adapted, refined, and tailored by others to specific samples, contexts, and research or clinical questions. It may also be fruitful to consider matching microintervention content to the nature or type of stressor experienced and the context (eg, location and social features) in which it was experienced.

This trial requires a high level of engagement by participants. Although there is the presumptive benefit of receiving stress management to enhance motivation and no side effects as might be experienced in a pharmaceutical trial, there is the requirement of actively responding to multiple brief surveys each day for a lengthy period. Clearly, this raises the possibility of self-selection, biasing the type of person who ultimately enrolls in the study. If the results of this trial indicate positive benefits for our primary outcomes, participant burden will have to be carefully considered moving forward to address issues related to generalizability and potential for dissemination.

Several other domains represent exciting future directions for this line of work to continue to refine, extend, and enhance the JIT microintervention approach we have developed. For example, developing and implementing additional stress target measurement indicators (eg, physiology and positive affect) for inclusion in the stress assay should be possible. Similarly, this work can be extended to encompass various health behaviors at different temporal scales. This stress assay can be used for intervention in "intensive" ways and integrated into more standard intervention formats (eg, face-to-face). For example, it can generate a highly reliable between-person risk indicator for risk stratification; moreover, our assay will provide risk components to allow personalized (precision) approaches to (standard) intervention. The time-varying nature of the stress assay would also allow for the development and implementation of not only JIT but also adaptive interventions, ones that "learn" what is effective for each individual and deliver what is most helpful for that individual at that moment (or stressful moments anticipated to occur in the near future).

Conclusions

This trial evaluates the effects of a novel, personalized JIT stress management intervention on everyday stress responses and the enactment of physical activity and sleep behaviors. Overall, we hypothesize that we will see the benefits of intervention over our active control condition and hope that this stress assay and adaptive JIT intervention approach will prove a valuable assessment and intervention tool for measuring and treating stress and stress-related disorders.

Acknowledgments

This study is supported by the National Institutes of Health Science of Behavior Change Common Fund Program through awards given by the National Institutes of Aging (grants UH2-AG052167 and UH3-AG052167).

Data Availability

The datasets generated during and analyzed during this study are not yet publicly available while data analysis is ongoing but are available from the corresponding author on reasonable request.

Authors' Contributions

The study was conceptualized by MJZ, MJS, DMA, OMB, DEC, RSS, SBS, CNS, PAG, and JMS. The stress assay was developed by MJZ, MJS, DMA, OMB, DEC, DM-C, JK, RSS, SBS, MJLT, and JMS, and the intervention content was developed by JAJ, MJZ, DEC, CNS, EMR, PAG, and JMS. The intervention algorithm was developed by JAJ, MJZ, MJS, DMA, DM-C, JK, RSS, SBS, MJLT, and JMS. The trial implementation was performed by JAJ, EMR, NLS, and JMS. All authors reviewed and approved the manuscript before submission.

Conflicts of Interest

Outside of this work, OMB received subcontract grants to The Pennsylvania State University from Proactive Life LLC (formerly Mobile Sleep Technologies) doing business as SleepSpace (NSF/STTR #1622766, NIH/NIA SBIR R43-AG056250, R44-AG056250).

Abstract

Background: Many transgender women with HIV achieve suboptimal advancement through the HIV Care Continuum, including poor HIV health care usage, retention in HIV medical care, and rates of viral suppression. These issues are exacerbated by comorbid conditions, such as substance use disorder, which is also associated with reduced quality of life, increased overdose deaths, usage of high-cost health care services, engagement in a street economy, and cycles of incarceration. Thus, it is critical that efforts to End the HIV Epidemic include effective interventions to link and retain transgender women in HIV care through full viral suppression.

Objective: This study builds on the promising findings from our two Health Resources and Services Administration-funded demonstration projects, The Alexis Project and Text Me, Girl!, which used peer health navigation (PHN) and SMS text messaging, respectively, for advancing transgender women with HIV to full viral suppression. Though the effectiveness of both interventions has been established, their comparative effectiveness, required resources or costs, cost-effectiveness, and heterogeneous effects on subgroups, including those with substance use disorder, have not been evaluated. Given the many negative personal and public health consequences of untreated or undertreated HIV, and that HIV services for transgender women are frequently delivered in resource-limited, community-based settings, a comprehensive economic evaluation is critical to inform decisions of stakeholders, such as providers, insurers, and policy makers.

Methods: Text Me, Alexis! is a 3-arm randomized controlled trial. Participants (N=195) will be randomized (1:1:1) into: PHN alone (n=65), SMS text messaging alone (n=65), or PHN+SMS text messaging (n=65). Using the same time points as the Health Resources and Services Administration demonstration projects, the repeated-measures design will assess participants at baseline, 3, 6, 12, and 18 months post randomization. Over the course of the 90 days, participants in the PHN arm will receive unlimited navigation sessions; participants in the SMS text messaging arm will receive 270 theory-based SMS text messages (3 messages daily) that are targeted, tailored, and personalized specifically for transgender women with HIV; and participants in the PHN+SMS text messaging arm will receive a combined PHN and SMS text message intervention. The desired outcome of Text Me, Alexis! is viral suppression and cost-effectiveness.

Results: Recruitment began on April 10, 2024, and the first participant was enrolled on April 11, 2024. Data collection is expected to be completed in July 2027. Primary outcome analyses will begin immediately following the conclusion of the follow-up evaluations.

Conclusions: Transgender women are a high-priority population for reaching End the HIV Epidemic goals. Findings have the potential to improve individual and population health outcomes by generating significant improvements in viral suppression among transgender women and guiding service provision and public policy.

HIV/AIDS; transgender women; SMS text messaging; peer health navigation; HIV Care Continuum

Introduction

Background

Current national data suggests that over 14% of transgender women in the United States are currently living with HIV [1], a rate at least 30 times higher than that observed in the general population aged 13 years and older (0.44%) [2]. National data on transgender women with HIV demonstrate lower rates of linkage to HIV care, retention in care, antiretroviral therapy (ART) uptake, ART adherence, and viral suppression than cisgender men and women [3,4]. Thus, any concerted effort to End the HIV Epidemic must include effective interventions to link and retain transgender women in HIV care through durable viral suppression [5,6]. The HIV prevalence rate of transgender women in Los Angeles County (LAC) exceeds national prevalence estimates, with an estimated 33% of transgender women with HIV, of whom only 58% achieved sustained viral suppression in 2022 [7]. As such, transgender women have been identified as a high-priority population, and LAC as a priority county for Ending the HIV Epidemic [6-8].

Transgender women in the United States experience numerous barriers to retention in HIV care, ART adherence, and viral suppression, including structural determinants of health, such as poverty and housing instability [9,10]; lack of access to health insurance [11]; transphobic stigma and discrimination from providers, including HIV specialists [11-13]; and disproportionate rates of individual-level health disparities including lack of perceived support [14], experiences of violence [15], cycles of incarceration [10,16], and untreated or undertreated substance use disorders (SUD) and mental health disorders, which are highly comorbid [17,18]. A 17-year comparison study in LAC demonstrated that these conditions have worsened among transgender women, with decreased levels of income and housing stability, increased incidents of physical harassment and abuse, and increased rates of HIV and sexually transmitted infections [19].

Evidence demonstrates that transgender women who are successfully linked and retained in HIV care go on to achieve rates of viral suppression similar to that of cisgender men and women, confirming linkage and retention to HIV care as critical intervention outcomes [20,21]. Among transgender women, access to gender-affirming resources and care [6,13], greater medication self-efficacy [22], and tailored HIV messaging (eg, addressing fears of ART or hormone drug-drug interactions) [23-25] are all associated with higher odds of ART uptake and adherence.

As an intervention modality, peer health navigation (PHN) is considered generally well-suited for application among transgender women, as it can be tailored to each participant's needs, and is premised on increasing participants' self-efficacy [20,26,27]. Interventions including PHN have been shown to be efficacious in improving rates of HIV care engagement, ART adherence, and viral suppression among transgender women [28-30]. However, due to the intensity of PHN, some transgender women may prefer a lower-intensity intervention such as SMS text messaging to deliver gender-affirming, transspecific SMS text messages, which are based on theories to improve self-efficacy and avoid or reduce health risks. SMS text messaging is a viable option since telehealth and technology-based interventions have demonstrated both acceptability and effectiveness among transgender women [23,28,29,31,32].

The promising findings gleaned from our team's two Health Resources and Services Administration-funded Special Projects of National Significance demonstration projects guided the Text Me, Alexis! randomized controlled trial design. Reback et al [33] demonstrated that increased attendance to PHN sessions was associated with significant and sustained (ie, through 18 months) achievement of both behavioral (coefficient range 0.12-0.38) and biomedical (coefficient=0.10) HIV milestones (all $P \leq .01$); 85% were linked to HIV care, and 83% of the participants that enrolled detectable and achieved a 1 log viral load reduction went on to achieve viral suppression [28]. Additionally, Reback et al [24] produced significant and sustained (ie, through 18 months) overall increases in ART uptake, self-reported ART adherence as "excellent," and achievement of an undetectable viral load defined as 200 copies/mL (49% vs 77%, 5% vs 38%, 35% vs 52%, all $P \leq .001$) [25]. The Alexis Project has been included in the Substance Abuse and Mental Health Services Administration's intervention guide for persons with substance use and mental health disorders, and Text Me, Girl! has been included in the Ryan White HIV/AIDS Best Practices Compilation. Thus, the appropriate next step was Text Me, Alexis!, the randomized controlled trial to simultaneously assess the relative efficacy of these interventions, and their respective costs and benefits to determine their efficiency and inform widescale implementation.

An economic evaluation was included to inform "real-world" resource allocation decisions faced by relevant stakeholders. Economic value (ie, the extent to which a stakeholder's resources are efficiently allocated) is a fundamental concern for any intervention targeting transgender women with HIV, given the number of persons in need and the fact that services for transgender women are frequently delivered in resource-limited, community-based settings [3,19,20].

Primary and Secondary Aims

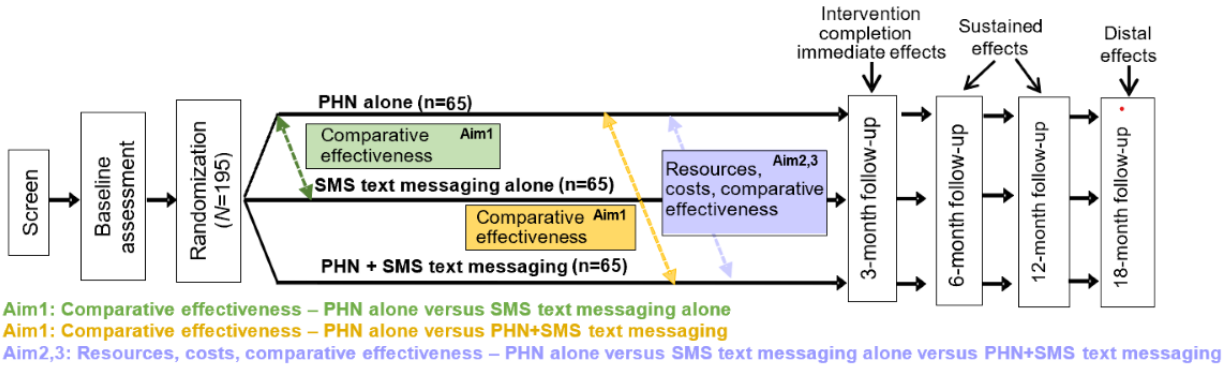
The primary aim of the Text Me, Alexis! study is to determine the comparative effectiveness of PHN alone, SMS text messages alone, and PHN+SMS text messaging combined with the goal of viral suppression and cost-effectiveness, and to identify the resources (eg, time and materials) required to prepare for, implement, and sustain each intervention, and estimate the associated costs. Further, the study will conduct a comprehensive cost-effectiveness analysis to determine the relative value of each intervention from the health care–sector, state policy makers, and societal perspectives. The secondary aim of the study is to determine heterogeneous intervention effects of PHN alone, SMS text messaging alone, and PHN+SMS text messaging due to social and structural determinants of health (eg, poverty, housing insecurity, food scarcity, educational attainment, and lack of insurance) and differing individual-level characteristics (eg, racial or ethnic identity, age, SUD—by type, and time since HIV diagnosis) among transgender women with HIV.

Methods

Study Design

Following screening, informed consent, and baseline assessment, participants (N=195) are randomized (1:1:1) into: PHN alone (n=65), SMS text messaging alone (n=65), or combined PHN+SMS text messaging (n=65). The 3-arm repeated-measures design will assess participants at baseline, 3 (immediate effects), 6, 12 (sustained effects), and 18 (distal effects) months post randomization to determine the relative effectiveness of the interventions, including heterogeneous treatment effects across subgroups and over time, the implementation and sustainment costs of each intervention, and their cost-effectiveness relative to one another. The study uses an "intent-to-treat" design whereby all assessments are administered to all participants regardless of their level of participation or retention in the study (Figure 1).

Figure 1. Comparative-effectiveness and cost-effectiveness design. PHN: peer health navigation.

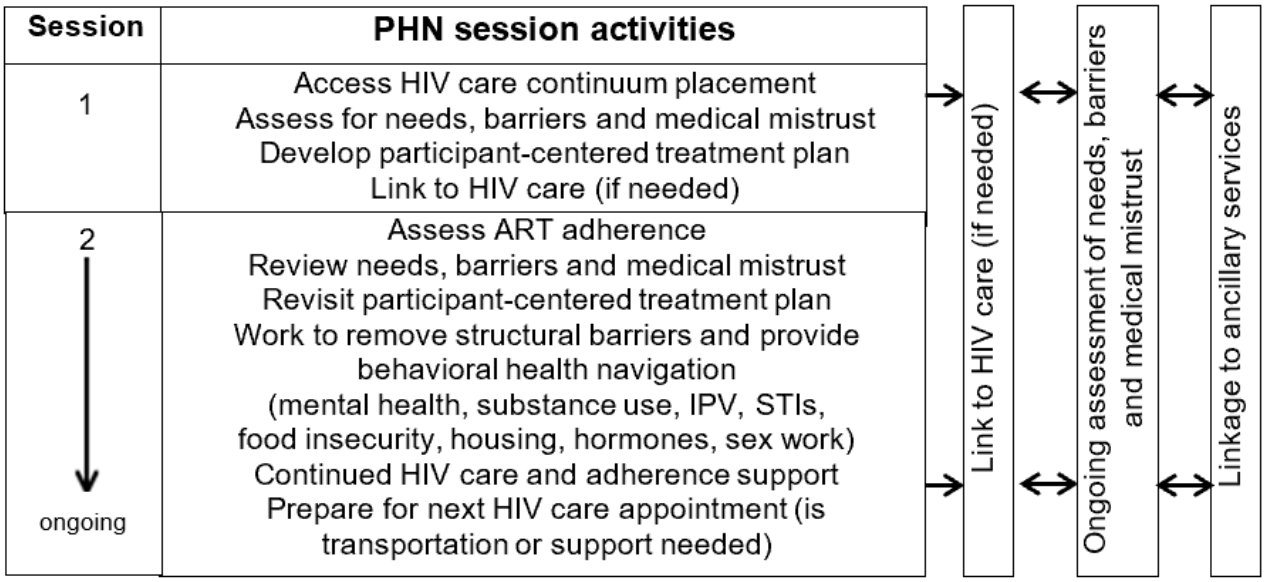


Study Arms

PHN

PHN is based on the theoretical foundation of social cognitive theory (SCT). Participant-centered PHN helps to (1) identify barriers to HIV care, (2) identify and link participants to needed auxiliary services, and (3) increase participants' self-efficacy in working with HIV care providers and other social service and treatment facilities. PHNs do not provide counseling or psychotherapy; they work with each participant to successfully navigate complicated health care and social service systems. The PHN intervention uses an individualized, participant-centered treatment plan with the goals of removing multiple and complex barriers that can impede linkage to and retention in HIV care and medication adherence to achieve virological suppression. Each participant works with a PHN to develop a participant-centered treatment plan and get linked to HIV care or other needed auxiliary physical, mental health, and psychosocial services (eg, hormone therapy, dental care, hepatitis testing or care, SUD treatment, mental health treatment, legal services, and job training or development; Figure 2). A priority of the first session is to schedule an HIV care appointment for the participant if needed. The PHN also works with each participant to establish HIV self-efficacy regarding her treatment plan. To establish an immediate connection, participants are introduced to a PHN immediately following randomization. PHN sessions are unlimited for 90 days.

Figure 2. PHN intervention delivery system. ART: antiretroviral therapy; IPV: intimate partner violence; PHN: peer health navigation; STI: sexually transmitted infection.



SMS Text Messaging

The SMS text messages are based on, and equally distributed across, three theories: social support theory (SST) [34-36], social cognitive theory [37,38], and health belief model (HBM) [39]. Table 1 illustrates how the SMS text message library was developed to have a theoretical foundation and be transculturally responsive. Participants receive three daily, theory-based SMS text messages for 90 days (270 unique scripted messages); participants do not receive the same scripted SMS text message twice. SMS text messages are evenly arrayed across: (1) HIV Care Continuum (HIV positivity/physical and emotional health, linkage/retention in HIV Care, and ART adherence/viral load suppression); and (2) theoretical foundation (SST, HBM, or SCT; Table 2).

SMS text messages are transmitted through gradual automation administration daily, including weekends, in real time, within a 10-hour period, and every 5 hours. Optimum hours were determined to be noon, 5 PM, and 10 PM, though participants may personalize the schedule to any 10-hour period and can choose to have the messages delivered through their cell phone or email. Both dosing (ie, three messages per day) and timeframe (ie, 10 hours) were determined during our prior SMS text messaging studies [23,25]. The intervention was designed to be cost-efficient, sustainable, and easily scaled by health clinics or community agencies. The automated SMS text message delivery system was developed by Dimagi [40]. Participants are asked to notify a research assistant immediately if they lose their cell phone or change their phone number or email address.

Table 1. Sample Text Me, Girl! SMS text messages: displays theoretical foundation, HIV Care Continuum placement, and adaptation from a general message to a transspecific message.

Theoretical foundation	HIV Care Continuum	General message	Transspecific message
Social support theory	HIV positivity/physical and emotional health	Take care of yourself	Trans pride is taking care of yourself
Health belief model	Linkage/retention in HIV care	See your doctor	Protect your trans beautiful body, see your doctor
Social cognitive theory	ART[a] medication adherence	Take your meds	Take your meds, girl! You can do it!

[a]ART: antiretroviral therapy.

Table 2. SMS text message content by theoretical foundation.

	HIV Care Continuum			Total
	HIV positivity/physical and emotional health	Linkage/retention in HIV care	ART[a] adherence/viral load suppression	
Theoretical foundation				
Social support theory	30	30	30	90
Health belief model	30	30	30	90
Social cognitive theory	30	30	30	90
Total	90	90	90	270

[a]ART: antiretroviral therapy.

PHN+SMS Text Messaging (Combined)

Participants in the PHN+SMS text messaging arm receive the same PHN and SMS text messaging interventions described above, but in concert to determine the effectiveness of the combined intervention when compared to PHN or SMS text messaging alone.

Theoretical Mechanisms of Behavioral Change

The theoretical foundations of the interventions serve as mechanisms of behavior change, increasing advancement through the HIV Care Continuum and maximizing potential public health impacts.

SST

According to SST, social support encompasses instrumental, emotional, and informational assistance. These forms of social support have been shown to mediate the relationship between stressful events and health outcomes [34-36].

HBM

HBM asserts that believing specific health behaviors can reduce threats to health predicts one's likelihood of engaging in protective health behaviors. The HBM is most effective when informative messages are culturally appropriate to the target population [39].

SCT

SCT posits interactive causal relationships among personal determinants, behavior, and environmental influences [37,38], and is designed to improve participant self-efficacy. Effective HIV care interventions must increase individuals' self-efficacy and guide them in developing self-regulation skills, offer practice and feedback opportunities, and engage resources to maintain health-promoting behavior change.

Participants

Inclusion criteria are (1) identifying as a transgender woman; (2) being 18 years or older; (3) having a verified HIV-positive serostatus; (3) not currently in HIV care, or had not had an HIV care visit in the previous 6 months, or had a viral load of ≥200 copies/mL on her last laboratory test result, or not currently prescribed ART, or prescribed ART but does not rate her ability to take all her medications as "excellent"; and (4) ability to receive daily SMS text messages on either a personal cell phone or via an email account. Potential participants must be able and willing to provide informed consent and comply with study requirements. Individuals are excluded if they do not meet all eligibility criteria.

Recruitment and Enrollment

Six recruitment strategies are used to ensure a diversity of participants are enrolled. (1) Web-based: banner ads and digital flyers will be placed through geo-mapping on appropriate websites and social media platforms and are optimized for mobile platforms at 300×250 pixels. (2) Print media: local ads will be placed in print media for transgender women. (3) Outreach: 2 research assistants conduct outreach in identified areas where transgender women congregate. Optimal sites, days, and times have been identified, including bars or clubs, motels, parks, boulevards, street corners, mini markets, boutiques, wig shops, electrolysis offices, salons, and lingerie stores. Outreach locations are continually modified through ongoing community mapping and input from the Community Advisory Board. (4) Poster advertisement and club cards: posters are placed throughout the research site and community collaborating sites to inform potential participants how to receive further information. Club cards will be distributed at dance clubs, bars, and transspecific events. (5) In-reach: potential participants often drop into the research site to inquire about services or to receive a daily hot meal. (6) Long-chain referral: current study participants are asked to recruit a maximum of three potential new participants. All recruitment and promotional activities are discussed at Community Advisory Board meetings.

Potential participants who inquire about the study are scheduled for intake within 48 hours. At intake, potential participants are screened for eligibility, complete the informed consent process, and take an informed consent quiz to verify their understanding of study procedures. At baseline, potential participants complete the baseline assessment, collect biospecimens, and are randomized to an intervention arm. Potential participants are considered enrolled and given a study ID number following randomization.

Randomization

Stratified block randomization with random block sizes is used to assign participants to each of the 3 study arms. To ensure balance with respect to certain covariates, participants are grouped by three stratification factors: (1) age (<35 and ≥35

years), (2) race or ethnicities (Latinx, all other race or ethnicities), and (3) HIV Care Continuum placement (linked, not linked to HIV care). Block randomization helps ensure balance in the number of participants assigned to each arm, while random block sizes make the sequence of assignments less predictable to research staff.

Measures

All data will be collected on an audio computer-assisted self-interview administered via the Qualtrics system. The following describes the measures used to address the study's specific aims.

Diagnostic and Statistical Manual of Mental Disorders (Fifth Edition)

The *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders* [Fifth Edition]) diagnostic items are necessary to make a determination of mild, moderate, or severe SUD. These findings are used to describe the sample characteristics and to determine the extent and effects of these individual-level health disparities as barriers to advancement along the HIV Care Continuum.

HIV Health Assessment

The assessment records demographics (eg, sexual identity, age, and race or ethnicity), educational attainment, housing status, access to insurance, HIV treatment status (including the position in the HIV Care Continuum), HIV medication status (including medication type and dose), and self-reported ART adherence.

The Los Angeles Transgender Health Survey

The instrument consists of seven modules: screening, sociodemographic characteristics, health care access and medical history, sexual behaviors (at all stages of gender transition), drug and alcohol use, legal and psychosocial issues, and HIV prevention.

Substance Use Frequency

This brief assessment assesses substance use, injection drug use, and injection protocols in the past 30 days.

HIV Treatment Adherence Self-Efficacy Scale

The HIV Treatment Adherence Self-Efficacy Scale (HIV-ASES) consists of 12 items assessing participants' self-efficacy to adhere to their HIV medication regimen, to measure behavior change associated with SCT [41].

HIV Treatment Optimism Scale

The HIV Treatment Optimism Scale is a 19-item scale associated with components of the HBM (perceived susceptibility to disease, perceived severity of the disease, perceived benefits of preventive behavior, and barriers to preventive behavior) [42].

Inventory of Socially Supportive Behaviors

The Inventory of Socially Supportive Behaviors (ISSB) is a 40-item scale measuring instrumental, emotional, and informational dimensions of SST [36,43].

Rapid HIV Antibody Test

Potential participants are administered a rapid HIV antibody test (INSTI HIV 1/HIV 2) during the screening process to verify HIV-positive status. Participants who show documentation of HIV-positive serostatus (eg, laboratory results, ART prescription) are not given an HIV antibody test.

Urine Drug Screen

Urine samples are tested using a 5-panel urine dip card [44], with drug detection cut-off values at: amphetamines (1000 ng/mL), cocaine (300 ng/mL), opiates (300 ng/mL), methamphetamines (500 ng/mL), and tetrahydrocannabinol (50 ng/mL). Valid samples are indicated by the temperature of the sample (33 °C to 36 °C) [44].

Viral Load Test

Participants receive a viral load test at each time point to assess virologic suppression or control as indicated by an undetectable HIV-1 level on the Aptima HIV-1 Quant Dx assay, which is the lower limit of quantification of ≤30 copies/mL [45]. Participants who access their electronic health records and provide viral load results within 14 days of the assessment are not reassessed with viral load testing performed as part of the study.

Drug Abuse Treatment Cost Analysis Program

The Drug Abuse Treatment Cost Analysis Program is a standardized, customizable tool designed to help identify intervention resources across diverse settings for the purposes of estimating the implementation and sustainment costs associated with the intervention [46].

Nonstudy Medical and Other Services

The usage of health care services by participants is self-reported using a time-anchoring methodology via the Nonstudy Medical and Other Services form [47-49]. Health care services will include nonstudy: HIV care, inpatient, outpatient, and emergency department services; SUD treatment medications; residential and outpatient SUD treatment days; hospital SUD detoxification days; and mental health treatment visits. This information is measured for the 90 days prior to baseline, then "since the last assessment." The use of nonmedical and other resources required for the economic evaluation from state policy maker and societal perspectives (eg, criminal-legal, labor productivity, and travel time to medical care) is also self-reported and collected via the Nonstudy Medical and Other Services form.

Patient-Reported Outcomes Measurement Information System-Preference

The PROMIS (Patient-Reported Outcomes Measurement Information System)-Preference (PROPr) measures a participant's health-related quality-of-life across the following PROMIS domains: cognitive function abilities, depression, anxiety, fatigue, pain interference, pain intensity, physical function, sleep disturbance, and ability to participate in social roles and activities [50-52]. The PROPr is also capable of generating a health utility index value, based on the participant's scores for each domain, that represents the general US

population's preference for the respondent's current health state. PROPr has 5 levels for each domain, ranging from "no problems" to "extreme problems." The health-utility value produced by PROPr can range from –0.022 to 1, where 0 represents death, 1 represents perfect health, and values below 0 represent states perceived to be worse than death. The health-utility value is used to calculate quality-adjusted life-years (QALYs) [50,53].

Statistical Analyses

Aim 1

The primary outcome of HIV care will be viral suppression (defined as less than 200 copies/mL). Secondary outcomes include the HIV-ASES, the HIV Treatment Optimism Scale, the ISSB, and urine drug screen results (test results for each of the 5 substances identified in the urine drug screen will be treated as different indicators). These outcome variables will be assessed at baseline and 3, 6, 12, and 18 months post enrollment. The resulting dependent variables will fall into one of two categories: (1) dichotomous variables (primary outcome: virologic suppression, and secondary outcome: urine drug screen results), assumed to follow a binomial distribution; or (2) continuous random variables (secondary outcomes: HIV-ASES, HIV Treatment Optimism Scale, ISSB scores), assumed to follow a normal distribution. All distributional assumptions will be evaluated prior to the conduct of analyses, and statistical methods chosen accordingly. Each of these dependent variables will be separately regressed on treatment condition (PHN alone vs SMS text messaging alone vs PHN+SMS text messaging), a set of baseline covariates (individual-level demographic characteristics), and time-varying covariates (social and structural determinants of health), using hierarchical linear regression where responses at each time point are nested within individuals. All analyses will be conducted on available study-related data from all participants, regardless of whether or when they drop out of treatment. The effect of interest will be a time × treatment condition interaction effect which will estimate the differential course and impact of the three intervention modalities over the follow-up period.

A generalized linear mixed model (GLMM) [54-56] will be used to conduct analyses of all outcomes following an intent-to-treat approach. The GLMM is an ideal statistical procedure for analyzing a broad class of longitudinal outcomes, including costs. As described above, key indicators of HIV care will be regressed on treatment conditions and a series of baseline and time-varying covariates. Treatment condition will be used to predict the slope of time, creating a time × treatment interaction term that is the effect of interest in the proposed study. We will also report on the relationships between time-varying covariates and the outcome measures, including time-shifted analyses where the value of the covariate at a previous timepoint is used to predict the outcome measure at a subsequent timepoint. Hypothesis testing for any given outcome will involve fitting the statistical model of interest and testing the effect of interest, as well as all other estimable effects in the model. We will use an iterative model-building approach where the simplest model is fit to the data first, and additional explanatory factors are added iteratively, in order of theoretical importance. Likelihood ratio tests are used to determine if the more complicated of the 2 models is a significant improvement over the simpler model. Variables of interest such as those specified in Aim 1 will always be included in the final model as the statistical tests of those parameter estimates (be they significant or nonsignificant) are of primary interest to this study.

Aims 2 and 3

The economic analyses will follow well-established guidelines [57-59]. The study will incorporate all resources or costs associated with the PHN, SMS text messaging, and PHN+SMS text messaging interventions from the health care sector, state policy maker, and societal perspectives [58-60]. The health care sector perspective includes all formal medical costs incurred by the system on behalf of participants, including the cost of the intervention, and participant out-of-pocket costs. The state policy maker perspective is crucial to informing resource allocation decisions on behalf of the public, who is primarily responsible for funding health care among this underserved population, given data indicating that most transgender women are either public health care insurance beneficiaries or uninsured [11,19]; moreover, the direct costs associated with criminal-legal resources, social safety-net programs, etc are paid for using public funds. In addition to the resources or costs included in the state policy maker perspective, the societal perspective accounts for those associated with untreated or undertreated HIV and comorbid conditions, such as premature mortality, reduced labor productivity, and those incurred by victims of crime [61,62].

The resources required to implement and sustain each intervention in a "real-world" setting (Aim 2) will be estimated using a detailed microcosting analysis, guided by a tailored version of the Drug Abuse Treatment Cost Analysis Program. The microcosting analysis will consist of gathering relevant administrative data and conducting semistructured interviews with site personnel in order to capture quantitative data regarding the resources (time and materials) used to deliver the interventions. The intervention implementation phase is considered to be the time period from conception (including planning activities) until the "steady state." Resources will be categorized as "fixed start-up" (incurred once), "time-dependent" (recurring, but does not vary with the number of participants), and "variable" (used every time a participant is served). The site visits and initial interviews will be conducted early in the study (~6 months following the first randomization). Follow-up interviews will be conducted virtually upon the study reaching a "steady state" (~12 months following the initial interview), to identify the time-dependent and variable resources required to sustain the intervention. "Steady state" will be determined with the assistance of site personnel. Implementation and sustainment costs will be estimated by assigning nationally representative price weights to the identified resources [58]. Research-specific costs will be excluded.

After estimating the implementation and sustainment costs associated with each intervention (PHN, SMS text messaging, and PHN+SMS text messaging), the relative value of each will be estimated according to the stakeholder perspective. This

process entails capturing all relevant resources used by participants in each arm, assigning nationally representative price weights to them, estimating the predicted mean costs, and testing for differences between resource categories. Estimating the incremental costs between arms according to resource category allows for a careful evaluation of the downstream savings resulting from improvements in HIV care and reductions in related risk behaviors. These include savings resulting from reduced usage of high-cost health care (eg, emergency department visits and inpatient stays) and criminal-legal resources, as well as increased labor and other forms of productivity. Price weights will be derived from sources reflecting national "real-world" costs faced by state policy makers and society.

The primary outcome of the cost-effectiveness analysis (Aim 3) will be the incremental cost-effectiveness ratio (ICER), which will be calculated as the incremental, predicted-mean cost of a given intervention relative to an alternative, divided by the incremental predicted-mean effectiveness of the 2 interventions. The primary measure of effectiveness for the economic evaluation will be QALYs. The secondary measure of effectiveness will be advancement along the HIV Care Continuum. The QALY is a measure that combines the health-related quality-of-life associated with an individual's health state and the time spent in that state and is recommended as the primary effectiveness measure in economic evaluation studies due to its ability to be compared across interventions and disorders [58,63]. In addition, generally accepted thresholds for defining value have been established for QALYs, unlike clinical measures [64,65]. The HIV Care Continuum is an important and widely accepted model or tool for assessing HIV care outcomes at both an individual and a public health level; thus, the additional cost required to achieve a one-step increase along the HIV Care Continuum for the average transgender woman with HIV will be a critically important clinical and policy-relevant measure. Two ICERs (one for each effectiveness measure) will be calculated for each stakeholder perspective at both 3 months (intervention completion; immediate effects) and 18 months (distal effects).

To help address censored data, we will model the person period and estimate all regressions using a multivariable GLMM. Separate regressions will be estimated to predict the mean value for each resource category, at each time period, by study arm. The statistical method of recycled predictions will be used to obtain the final predicted mean values [58]. Similarly, individual regressions will be used to predict the health utility index value and HIV Care Continuum steps gained for each participant, at each time point. QALYs gained will be estimated using the predicted health utility values and the area under the curve methodology [58]. The most appropriate distributional and link functions for each GLMM regression will be chosen according to the fit of the observed data [58].

To account for sampling uncertainty in point estimates, the *P* values and SEs will be estimated using nonparametric bootstrapping techniques within the multivariable framework combined with methods to address missing data based on recommended approaches [66]. All monetary values will be adjusted for inflation, and all measurements obtained beyond 12 months of baseline will be discounted for time preference using the recommended rate of 3% [58,65].

The most cost-effective strategy for each outcome measure (QALYs; HIV Care Continuum placement) will be determined using the rules of strong and extended dominance. Parametric methods based on parameters obtained from bootstrapping will be used to estimate cost-effectiveness acceptability curves for each ICER, which illustrate the probability that an intervention is cost-effective for different value thresholds [57].

Power Analysis

A simulation approach was used to conduct the power analysis and determine that N=195 (65 per arm) was an appropriate sample size to detect the effect of each intervention on our primary outcome, and the likelihood of virologic suppression over time [67]. Power by simulation is more flexible than traditional approaches because it can estimate power under a wide variety of circumstances, including when these assumptions are not met.

Ethical Considerations

All study procedures are approved by the Western Institutional Review Board (Study #1352118; Institutional Review Board Tracking #20231531). This trial has been registered at ClinicalTrials.gov under the number NCT06408350. All procedures performed in studies involving human participants were in accordance with the ethical standards of the institutional or national research committee and with the 1964 Helsinki Declaration and its later amendments or comparable ethical standards. Informed consent was obtained from all individual participants included in the study.

Results

Recruitment began on April 10, 2024, and the first participant was enrolled on April 11, 2024. Recruitment spans approximately 33 months; enrollment goals are approximately 6 enrolled participants per month. Data collection, including all follow-up assessments, is expected to be completed in July 2027.

Discussion

Principal Findings

Many transgender women have suboptimal advancement through the HIV Care Continuum, including poor HIV health care usage, retention in HIV medical care, and rates of viral suppression; moreover, these issues are exacerbated by comorbid conditions such as SUDs. The Text Me, Alexis! study is a comparative-effectiveness research trial with a comprehensive economic evaluation that builds upon the promising findings of two Health Resources and Services Administration-funded demonstration projects in order to identify the optimal intervention for advancing transgender women with HIV to full viral suppression. Though the effectiveness of the demonstration projects has been established, their comparative effectiveness, required resources or costs, cost-effectiveness, and heterogeneous effects on subgroups, including those with SUDs, have not been evaluated.

Challenges

There are several challenges to the Text Me, Alexis! study. First, housing instability, substance use, engagement in sex work, and other individual-level, social, and structural disparities may interfere with study participation. The PHN alone and PHN+SMS text messaging arms were designed to address these issues and work with each participant to assess and minimize or remove barriers and link participants to an array of ancillary social services. Additionally, in the demonstration project, despite experiencing several health disparities including low educational attainment, low income, and housing instability, SMS text messaging alone demonstrated significant improvements in ART uptake, ART adherence, and achievement of an undetectable viral load, which were durable through 18-month follow-up. Second, episodes of short-term incarceration may interrupt study progress and follow-up assessment rates, due to factors such as actual or perceived participation in the street economy, or minor homeless infractions. Study staff monitor the public records database for participants who miss appointments. When an incarcerated participant is found, we begin a correspondence with the participant immediately upon release. Third, loss of ART or selling ART due to lifestyle needs ("diversion")—ART adherence will be stressed through the participant-centered treatment plan and via adherence-specific SMS text messages, including strategies for keeping medication safe, and a discussion on how ART adherence outweighs selling the drug. Finally, fear of drug-drug interaction—some participants may be concerned about ART and gender-affirming hormone therapy interactions and prioritize gender-affirming hormone therapy over ART uptake or adherence. These concerns will be acknowledged and corrected in PHN sessions and SMS text messages.

Conclusions

The public health significance of Text Me, Alexis! has the potential to be quite profound, as comparative- and cost-effectiveness research trials are critical steps in the development and adoption of scalable and effective HIV care intervention, especially among key populations that rely on service provision in resource-limited, community-based settings.

Acknowledgments

Funding for this study is provided by the National Institute on Drug Abuse (NIDA; #RO1DA056287; Multiple Principal Investigators: CJR and SMM). CJR and RJL acknowledge additional support from the National Institute of Mental Health (P30MH58107), SMM acknowledges additional support from NIDA (P30DA040500), and MJL acknowledges additional support from NIDA (K01DA051329).

Data Availability

The datasets generated during or analyzed during this study are available from the corresponding author upon reasonable request.

Conflicts of Interest

None declared.

Authors' Contributions

CJR and SMM conceived of the study design and wrote the original draft of the manuscript. TB wrote the statistical analysis sections for Aim 1 and the secondary aim; SMM and AJ wrote the statistical analysis sections for Aims 2 and 3. RJL provided oversight on all sections related to medication adherence and viral suppression. MJL, RPM, DR, and PJJ reviewed and edited the manuscript.

Abstract

Background: Low back pain (LBP) is highly prevalent and disabling, especially in agriculture sectors. However, there is a gap in LBP prevention and intervention studies in these physically demanding occupations, and to date, no studies have focused on horticulture workers. Given the challenges of implementing interventions for those working in small businesses, self-management offers an attractive and feasible option to address work-related risk factors and manage LBP.

Objective: This study will (1) investigate the effectiveness of self-management strategies for nursery and landscape workers by comparing within-subject control and intervention periods and (2) determine if adoption and effectiveness differs between participants randomly assigned to review self-management videos only and those who also receive multimodal implementation support. We will also identify contextual factors impacting effectiveness and implementation.

Methods: A pragmatic, mixed methods, hybrid effectiveness and implementation design will be used to compare back pain with work tasks, disability, medication and substance use, and psychological factors between a baseline control and intervention periods. We aim to recruit 122 English- and Spanish-speaking horticulture workers with back pain, 30 supervisors, and 12 focus group participants. Participants will review short video modules designed to increase awareness of opioid risk and introduce self-management and ergonomic choices and use 1 self-management and 1 ergonomic strategy for 10 weeks. They will be randomly assigned to 2 implementation groups: video modules only or video + multimodal personalized support (checklist guidance, review of video feedback for ergonomic problem-solving, and text message reminders). Questionnaires will be administered at 3-month time points: baseline, pre- and postintervention, and at 3 and 6 months. Qualitative analysis of field notes, open-ended comments, and focus groups will expand understanding of results with comprehensive documentation of the context, barriers and facilitators, and reasons for adoption.

Results: The project was funded on September 29, 2023 (Centers for Disease Control and Prevention National Institute of Occupational Health and Safety, CDC NIOSH; U54OH011230-07S1), as a core research grant for the Southeast Coastal Center for Agricultural Health and Safety. The design, creation, and editing of English and Spanish videos was completed in June 2024 after comprehensive formative evaluation. Enrollment began in June 2024 with anticipated completion in 2027.

Conclusions: We hypothesize that both self-management interventions will result in reductions in work task pain and disability and that the video enhanced with multimodal personalized support will result in greater reductions than the video alone. If self-management is effective, mitigating pain positively impacts quality of life, productivity, and retention, while increasing the use of nonpharmacological alternatives to opioids addresses an important public health issue. Implementation aims will help inform reasons for results, barriers and facilitators, and potential for similar interventions in these and similar industries with physically challenging outdoor work.

Introduction

Background

Low back pain (LBP) is the most common musculoskeletal disorder among agricultural and horticultural workers [1-5], negatively impacting worker's physical and mental health, increasing absenteeism, and shortening work longevity [6-11]. Further, LBP contributes to lower productivity, loss of experienced workers, and increased workman's compensation costs. The financial impact of high out-of-pocket costs and lack of paid leave often drive agricultural and horticulture workers to seek pain relief from prescription medications and illicit substances [12-14]. In one study of farmers with LBP, 71% relied on pain medication without consulting a physician compared to only 35% of white-collar workers [15].

Viable alternatives to pharmacological management of LBP have never been more important [16,17]. Despite guidelines recommending nonpharmacologic management, opioids are commonly prescribed for work-related injury and pain more frequently than for nonoccupational musculoskeletal disorders [18-22]. Although opioid prescribing has declined gradually since 2010, opioid fatalities from prescription and illicit synthetic opioids have continued to rise [20,23]. The precipitous increase in opioid overdose associated with fentanyl manufactured in clandestine laboratories [23,24] has elevated the importance of highlighting and promoting uptake of nonpharmacological alternatives for management of LBP [20]. In rural areas, opioid prescription rates are particularly high [25], and access to nonpharmacologic treatment options is limited [16]. A preliminary study supporting this protocol found that over half of agricultural workers (n=129) reported using opioids at some point [14]. Of those who had used opioids, most (77%) reported they received a prescription for a work-related injury. Participants explicitly linked work hazards and chronic pain with increased risk of opioid dependence, citing the need to continue working and "live with pain" as a cultural norm contributing to the problem [14]. While progression to opioid use disorder is complex, opioid misuse has devastating effects on health and work. A systematic review of the impact of prescription medications for occupational musculoskeletal injuries found that opioid use was associated with slower return to work, longer duration of disability, poorer self-reported work function, and poorer functional improvements [26]. Opioid prescriptions within the first 2 weeks of a work-related injury, opioid use for longer than 7 days, and higher dose supplies are associated with subsequent work disability or delayed recovery and greater work loss [26]. Owners of nursery and landscaping businesses in Florida reported problems with turnover, frequent absences, and low productivity among workers who used opioids, resulting in decreased labor availability [14]. Landscape and nursery work characteristics including low skill discretion, job strain (low control and high demand), high physical effort, and heavy lifting are risk factors for opioid use disorder [27]. Few opioid prevention efforts have been focused on underlying work-related factors such as musculoskeletal pain [18,28]. The substantial worker and employer burden of LBP in the horticulture industry and the devastating effects of opioid dependency highlight the need for efforts to manage and limit LBP and reduce unwarranted opioid use for musculoskeletal injury. Strategies to (1) increase workers' awareness of the risks and consequences of opioid use, (2) encourage workers to discuss options with health care providers after more acute injuries, and (3) provide alternatives for nonpharmacological strategies to manage pain or limit ergonomic stress [28] may increase knowledge and self-efficacy while reducing stigma [20,28].

Self-management is defined as the ability to manage pain, treatment, psychosocial, and lifestyle implications of a chronic condition [29,30], with the overall goal for individuals to safely manage symptoms and lifestyle without seeking unnecessary medical intervention [30-33]. Encouraging active involvement and empowering individuals to select options to manage work-related pain tailored to each worker's circumstances and preferences encompasses the principles of self-management for chronic conditions [6]. Effective self-management strategies should optimize pain coping strategies to manage and reduce symptom exacerbation through problem-solving [30]. Self-management is recommended for the management of chronic LBP in a number of guidelines and strategic initiatives [16,34,35], with moderate effectiveness for pain, and small to moderate effectiveness for pain-related disability reported in a systematic review and meta-analysis [36]. Increasing self-management of chronic pain that frequently limits work activities is one of the Health People 2030's targets [35]. However, most studies investigating effectiveness of self-management approaches have involved patients receiving

clinical care rather than groups who continue to work in physically demanding occupations. Self-management skills such as problem-solving, action planning, self-tailoring, and self-monitoring may provide a worker-centered approach for horticulture workers to promote self-efficacy and coping skills for adjusting work activities and managing pain [29,30,37].

There are limited training initiatives to address musculoskeletal pain for horticulture workers and most workers rely on supervisor's advice or learning by experience. Many studies have concluded that education can positively influence work-related musculoskeletal pain by promoting behavioral change, modifying health beliefs, and improving attitudes, although gaps in optimal implementation persist [38]. Although some studies reported additive effects of improving physical activity or ergonomic adjustments [38], none focused on agriculture, nursery, or landscape workers. Collectively, there is a crucial need to determine optimal implementation of effective self-management programs for workers, especially for those who do not have resources to receive treatment in typical health care settings [39,40]. Therefore, examining the effectiveness of training to assist workers with learning self-management and ergonomic strategies will provide valuable information, while studying implementation outcomes will help determine engagement, adoption, and feasibility.

Prior Work

This protocol builds from a preliminary study of streamlined individualized participatory ergonomic (PE) methods in clam aquaculture workers with similar physically challenging work [39,41]. Workers with chronic LBP were introduced to ergonomic concepts to reduce risk, selected 3 pertinent and acceptable strategies from a list, reviewed videos, and received text reminders. Significant improvements in disability, work-task pain, pain anxiety, and coping compared to baseline were observed ($P<.05$; n=19), with pain improvements greater than published minimal detectable change for 74% of the participants. The methods were both feasible and acceptable. These promising results led to recommendations to establish whether these approaches are effective in a larger cohort over longer timeframes, in different contexts, and with follow up [39].

We will investigate the effectiveness of self-management and ergonomic individual choices along with behavior change support for nursery and landscape workers. The first aim is to determine if self-management videos combined with multimodal personalized support is more effective than self-management videos alone for improving LBP management among horticulture workers. We hypothesize that compared to the video modules alone, the combined multimodal personalized support will result in (1) greater reductions in work task pain and disability, (2) lower prevalence of high-impact chronic pain, (3) greater reduction in substance use to manage pain, (4) greater reeducation in pain anxiety and depression, and (5) improved coping and self-efficacy. The second aim is to identify contextual factors that impact engagement, adoption, effectiveness, and implementation of nonopioid alternatives for LBP self-management. Understanding the external context and individual and team characteristics will help explain the results, provide important implementation perspectives, and inform translation.

Methods

Study Design

The exploration and preparation phases of the study were started in 2023, with the video training module creation, evaluation, modifications, and production completed in June 2024. A 2-arm pragmatic randomized controlled hybrid type II effectiveness and implementation study [42-44] will be conducted using mixed methods and a within-subject control period. The Standards for Reporting Implementation Studies (StaRI) standards checklist is included in Multimedia Appendix 1.

Ethical Considerations

The study was approved by the University of Florida Institutional Review Board (IRB202300756) and registered as a clinical trial through ClinicalTrials.gov (NCT06153199). Participants will be compensated for their time. Workers will receive US $25 for the baseline data collection and US $50 for subsequent steps for a possible total of US $225, while supervisors or owners will receive US $50 for the 2 data collection sessions for a possible total of US $100.

Employers will provide permission to discuss the study with workers and to conduct the study in the workplace. After determining eligibility, research staff will describe the purpose of the study, study-related procedures, risks, and benefits, and participants will sign an informed consent if they agree to participate. We will ensure that participants understand that participation is voluntary and that they can withdraw from the study at any time without consequences. A Certificate of Confidentiality (42 USC §241(d)) will protect participant privacy related to potentially sensitive information about the use of pain medication and other substances. If individual workers are not eligible or do not want to participate, they will be able to view the educational videos with their teams. If participants who are randomly assigned to the intervention enhanced with multimodal support are not comfortable being videotaped, we will provide deidentified video clips of other workers with blurred faces performing tasks similar to the tasks they have identified as difficult due to pain.

Recruitment

Recruitment Methods

We will recruit nursery and landscape workers in Florida through community partners and contacts from the Southeastern Coastal Center for Agricultural Health and Safety. We will use direct communication, email lists, websites, word-of-mouth referrals, and community meeting announcements to identify employers who are interested, followed by presenting the study to workers. We will recruit workers with a range of disability, pain impact, and persistence, anticipating that participants will be primarily male, with higher numbers of female participants in the nursery teams, and that approximately 50% will identify Spanish as their first language. Initial contact and permission will be through owners and supervisors to enroll nursery and landscape businesses and their employees.

Inclusion and Exclusion Criteria

Criteria for inclusion are (1) working full time (30 hours or more per week) in nursery or landscape businesses, (2) 18 years of age or older, (3) English or Spanish speaking, and (4) experiencing continuous or intermittent LBP over the past 3 months. We will exclude individuals who (1) report history of trauma, major spine surgery, or spinal nerve blocks in the past year; (2) are seeking disability or workmen's compensation, or (3) self-disclose pregnancy.

Sample Size Projections

A priori sample size was calculated using data from the pilot study comparing pain and disability measures pre and post–self-management PE interventions for 19 seafood workers [39]. For each participant and pain or disability outcome, averages of 4 baseline measurements and 2 postintervention measurements were used to calculate the difference in pre- to postintervention outcomes. Mean changes over a control period are assumed to have a mean 0 difference but share the same SD as the intervention period. Changes over the 2 periods for the same person are assumed to be independent. Data were simulated from a simple linear mixed model (LMM):

$$Y_{ijk} = \alpha_i + \beta_1 X_{ijk} Z_{ijk} + \beta_2 (1 - X_{ijk}) Z_{ijk} + \varepsilon_{ijk}$$

In this model equation, Y_{ijk} is the outcome of observation period k of individual j in cluster i, X_{ijk} indicates the intervention group (1: video + support, 0: video), Z_{ijk} indicates the intervention period (1: intervention period, 0: baseline period), α_i is the random intercept of cluster i, and ε_{ijk} is the error term. The variance of α_i was set as 5% of ε_{ijk}, such that the intraclass correlation is close to 0.05. For each set of simulated data, a generalized estimation equation model was used to test the null hypothesis β_1=0. We ran 1000 simulations to calculate the power for each of the different settings of the number of clusters and cluster sizes. Table 1 shows the power based on individual randomization. Fitting a LMM yielded comparable results. The planned enrollment of 102 participants (24 clusters) will provide adequate power for the primary outcomes, pain with most difficult work activities and total disability. An additional 20% enrollment for attrition results in a total anticipated sample of 30 clusters and 122 participants (teams of 3-5 participants) for the comparative effectiveness goals.

Table 1. Statistical power (%) based on individual randomization for differentiating between the 2 implementation groups using preliminary data.

Number of clusters	Cluster size	Projected Sample size	Power (%) calculated using results from Dunleavy et al. [39].			
			Pain with most difficult work activities (mean –16.1, SD 18.8)[a]	Average pain (mean –5.2, SD 17.3)[a]	Total disability (mean –2.5, SD 3.5)[a]	Difficulty level with most problematic work activity (mean 9.0, SD 28.5)[a]
20						
	3	60	96.9	28.4	88.7	33.8
	5	100	99.8	43.9	98.3	49.5
	10	200	100	73.5	100	73.5
25						
	3	75	98.9	32.3	93.3	40.7
	5	125	100	48.6	99.4	57.5
	10	250	100	80	100	84
30

	10	300	100	87.3	100	88.8

[a]Mean difference, SD from Dunleavy et al [39].

Target Enrollment and Randomization

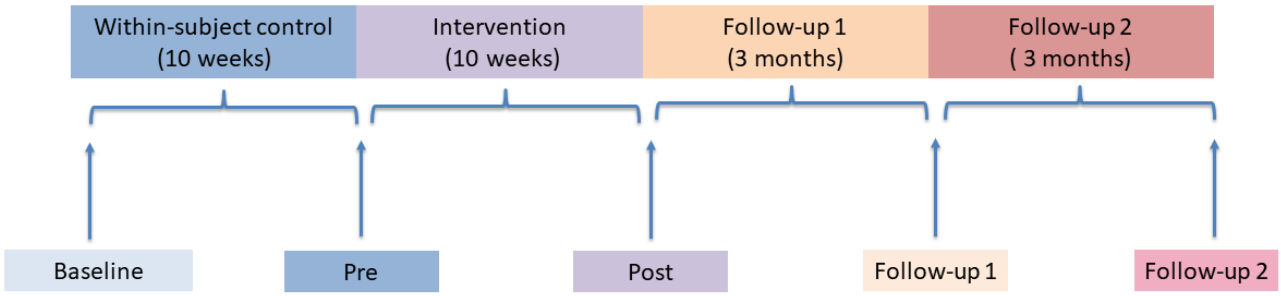
Our target enrollment of 122 workers will be recruited over 3 years starting in June 2024 with anticipated completion in 2027. For each team, we will enroll at least 1 supervisor or owner to provide support and comments on the overall feasibility and results, for 30 supervisors. In year 4, we will also invite 12 stakeholders to participate in focus groups (see aim 2) for a total expected enrollment of 164. Participants will be randomized to one the intervention groups after the baseline control period using stratified block randomization by type of work (nursery, landscape), and within each employer group to ensure a 1:1 distribution. The random assignment table was created prospectively by the statistician and participant numbers are generated in the REDCap (Research Electronic Data Capture) software (version 9.1.1; Vanderbilt University) [45] when baseline data are downloaded to reduce the risk of bias. Participants will receive incentives after completion of the surveys, training, and interviews.

Data Collection

Timelines

Five measurement periods will allow longitudinal comparison of change from the within-subject control period (10 weeks), across the pre- and postintervention period (10 weeks), and follow-up (3 and 6 months; Figure 1).

Figure 1. Timelines.



Questionnaires

Questionnaires in English or Spanish will be administered in the workplace on tablets using the REDCap platform [45]. The REDCap is a secure, web-based software platform with questionnaire support and data management functions [45]. Primary dependent variables will be collected at all timepoints—pain (severity, interference, and persistence); pain with specific work tasks; disability; work ability; and pain medication use [46-51]. Affective or cognitive characteristics impacting adoption and effectiveness (secondary dependent variables or potential confounders) such as coping, fear, anxiety, and depression will also be collected [52-55]. Branching logic will be used to pipe answers for the most difficult work activities and choices of strategies into subsequent questionnaires. In addition to demographics, medical and work characteristics will be collected. Disability will be assessed using Roland-Morris Disability Index [49], Patient Specific Functional Index (PSFS) for work tasks considered most difficult due to back pain [39,50,56-58], and Work Ability Index instruments [48]. Pain constructs from the National Pain Strategy recommendations (severity, interference, persistence, and impact) [46,47], along with pain with the specific work tasks identified in the PSFS, will be measured using Likert scales [39]. Substance use will be recorded using the National Institute on Drug Abuse quick screen [23] with additional questions on over-the-counter pain medication and other substances. Affective and cognitive measures include the Pain Anxiety Symptom Scale [53], Center for Epidemiological Studies Depression Scale short form [52], Coping Strategy Questionnaire [55,59,60], and Self-Efficacy for Chronic Condition management short form [54]. Instruments were translated by a certified translation agency if validated Spanish versions were not available.

Qualitative Methods

Understanding the context (circumstances and unique factors surrounding the study) will help explain results and provide implementation outcomes [43,61,62]. We will use relevant components of the Exploration, Preparation, Implementation, Sustainment conceptual framework, including inner (individual and team) and outer (industry, regulations, and environment) contextual factors (Figure 2) [63]. Qualitative data will be compiled from (1) researcher observations and field notes; (2) anchor-based and open-ended questions reflecting engagement (opinions of intervention delivery and support, recommendations to others), adoption (use of strategies in past 7 days), and feasibility (ease of use, barriers and facilitators); (3) perceived effectiveness (including global rating of change); (4) supervisor and worker comments; and (5) data collected during final stakeholder focus groups (Figure 3). Spanish-speaking research team members will contribute to observations and if needed, will translate comments. We will record comments, expansions, and clarifications and will ask workers specifically about the acceptability of introducing information about opioid risk and self-management at home and in the workplace. Supervisors and owners will be asked to provide their opinions from an organizational perspective. Recommendations will be confirmed, prioritized, and expanded ensuring robust and iterative analysis.

In addition, 2-3 focus groups will be conducted during the last quarter of the study. Industry representatives, employers, supervisors, and select participants will be invited to contribute their opinions. We will invite industry leaders committed to support wide-spread dissemination and translation of interventions, and workers able to comment on their real-world perspectives with 1 focus group conducted in Spanish. Focus group questions will help explain findings and patterns identified throughout the study and generate recommendations for future interventions. Question prompts will reflect any similarities or differences generated from earlier data analysis to confirm themes and conclusions, further ensuring triangulation and rigor. Interview and focus group recordings will be recorded using participant numbers only, transcribed, and translated if appropriate [64]. Comprehensive data analysis will be conducted progressively throughout the study, contributing to triangulation and trustworthiness of the qualitative analysis [64,65].

Figure 2. Contextual framework: selected components from the EPIS (Exploration, Preparation, Implementation, Sustainment) Model.

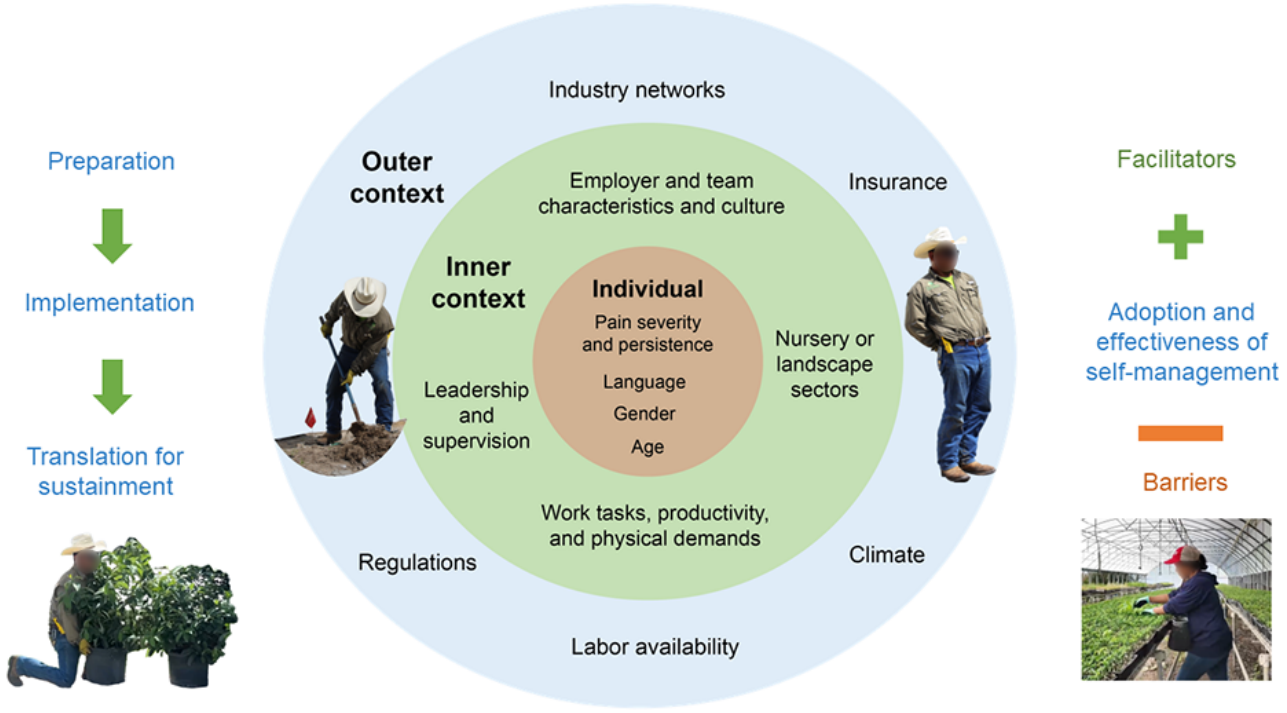


Figure 3. Qualitative methods.

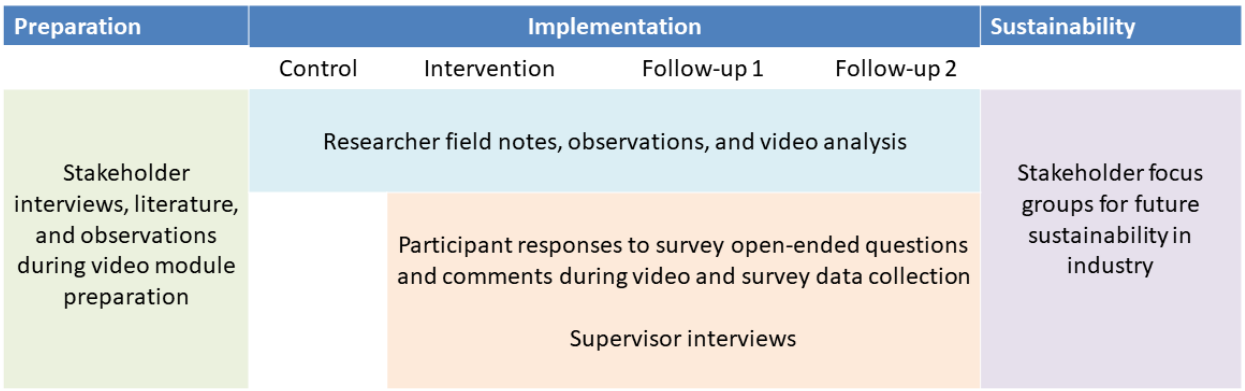

Risk Exposure for Tasks

Participants will be videotaped while performing their self-identified most difficult work tasks at baseline and after the intervention. After categorizing video clips by tasks, subtasks, and variations using hierarchical task analysis, the risk for each task will be categorized using the Rapid Entire Body Assessment (REBA) checklist [59,60]. The REBA is a commonly used measure to reflect ergonomic risk in the workplace and reflects extreme postures in tree nursery workers better than other observational instruments [66]. We will use a software system (Tumeke) [67], which identifies and reports the REBA for the postures and movements in the cycle with the highest risk to help with consistency of analysis. The risk assessment measures will be documented for specific tasks rather than used to compare individual change due to the variability of tasks and potential difficulty capturing the exact same tasks for all participants. Tasks will be recorded as changed or unchanged.

To further understand the impact of work adjustments and variations, simulations of various ergonomic scenarios will be conducted in laboratory settings with 3D analysis. Tasks with multiple variations and those which are changed will be selected and replicated. These simulations will involve creating different work environments and task setups to replicate the typical conditions encountered by the participants. By analyzing these simulated scenarios, we aim to identify potential ergonomic improvements and assess relative risk for variations of the tasks rather than evaluating individual change.

Intervention

Video Training Module Design and Preparation

Three short video modules were created specifically for nursery and landscape workers, tasks, and environments. The instructional design was informed by stakeholder discussions, review of current evidence, targeted in-depth interviews with industry experts (insurance safety consultants, association leadership, owners, supervisors, and workers; n=15), and work

observation conducted during the preparation phase. Stakeholders also completed surveys which helped prioritize a preliminary list of work tasks considered most problematic for back pain.

Nursery and landscape worker characteristics informed design of multimedia visual representation of work activities and content with representation of genders and ethnicities in the videos and resource materials. Scripts were designed and evaluated for language consistent with lower than eighth grade literacy level to meet the lowest anticipated educational level, while structure and organization to reduce cognitive load, and design accounting for multiple language versions was built in from the first draft (Textbox 1).

The videos emphasize the importance of managing and limiting pain using active nonpharmacological self-management and conserving work longevity to facilitate ongoing support of family. The modules cover (1) the need to manage pain without relying on medication and substances, as well as the risk of opioid use; (2) self-management strategies for pain at home and at work (general exercise, specific back exercise, nutrition and hydration, deep breathing and positive thinking, rest, relaxation, and sleep); and (3) work-specific ergonomic strategies to address physical risk factors during nursery and landscape tasks. The videos encourage selection of relevant strategies for pain management of exacerbations, emphasize prevention through lifestyle and behaviors such as exercise, nutrition, and sleep, and proactively planning work tasks and adjusting movement to minimize risk (Figures 4 and 5). Sector-specific video clips of relevant work activities were filmed in nursery and landscape work settings and represent workers with a mix of genders and ethnicities, along with key stakeholder commentary to provide relevance.

Textbox 1. Design choices matched to characteristics.

Multimedia visual representation

- Videos and narration; minimal use of text with simple language, short sentences, images to represent key concepts, and advance organizers [68,69].
- Check list support materials (print) [68,69].
- Infographics and resource materials.
- Text messages include graphics and gifs for movement.

Health literacy and cognitive load considerations

- Literacy levels lower than eighth grade [68,70].
- Organization to maximize working memory and reduce cognitive load using advance organizers, smaller “chunks” and grouping of concepts [71].
- Graphics to represent choices as advance organizers.
- Short modules to minimize overload.
- Encouragement to choose relevant options for self-efficacy.
- Message design and visual representation, for example, focus on positive options for movement and work adjustments rather than what not to do or representation using symbols with negative connotations such as red crosses.
- Contrasting recommended movement in color with those that should be adjusted in black and white video.
- Music and screen transitions to divide concepts.

Multiple languages

- English version design and initial formative evaluation to identify and adjust vocabulary and grammar difficult to translate into Spanish.
- Length of clips adjusted to time needed for Spanish narration using transitions.

Feasibility for workplace

- Video delivered on iPads in 5-minute modules to maintain attention to use in the field for “toolbox” talks, team discussions, or as part of general safety meetings.
- Options based on the work and team location rather than requiring classroom settings to promote feasibility.

Figure 4. Self-management strategy options.

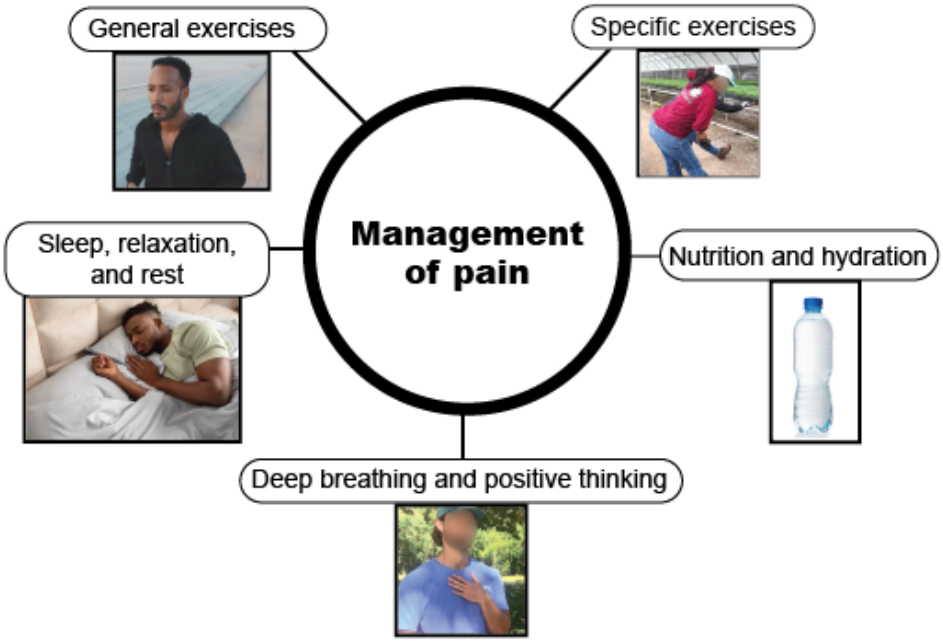

Figure 5. Ergonomic strategy options.

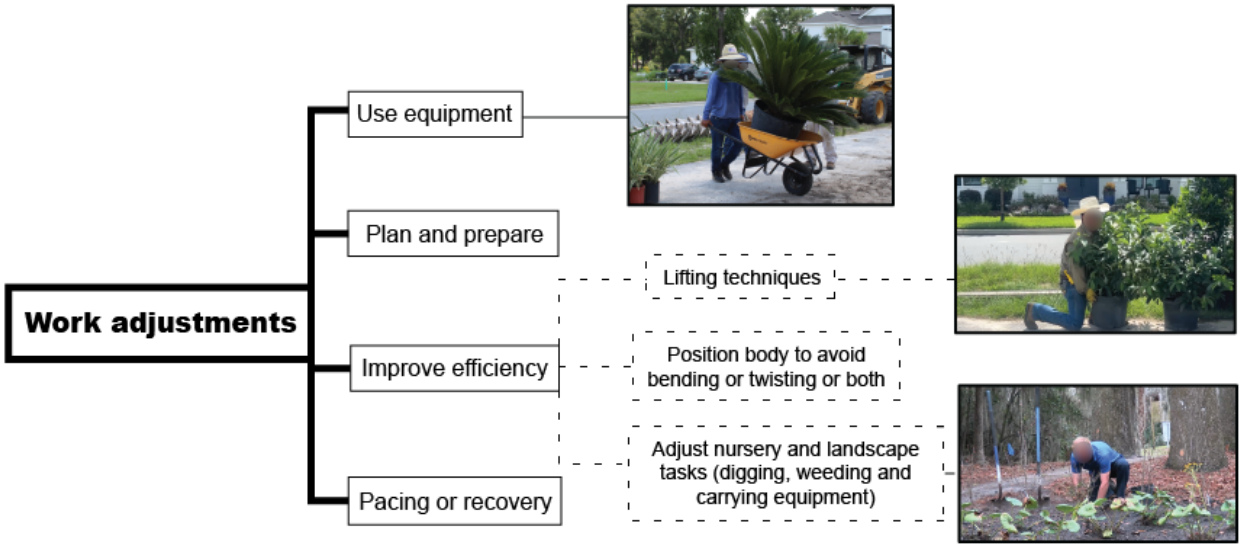

Video Formative Evaluation

The design incorporated iterative feedback from instructional design and health literacy experts and input from the research team who have expertise in pain management, rehabilitation, psychology, opioid misuse, and ergonomics. The scripts were evaluated for health literacy and inclusivity, followed by formative review by the experts in our multidisciplinary team. The adjusted English script was evaluated by owners, supervisors, workers, communication and industry experts, as well as bilingual stakeholders for words and concepts that are difficult to translate.

Supervisors, workers, and outside stakeholders (n=27) reviewed the video for content, format, representation, understanding, and provided comments. Additional video clips were added, and some content reorganized for flow and organization to reduce cognitive load. Final narration was completed after the second revision. The script was translated into Spanish by a certified agency and reviewed again for consistency, language, messaging, and cultural acceptability, prior to adding the Spanish narration and titles. Spanish speaking supervisors, workers, and stakeholders (n=12) also evaluated the Spanish videos with minor changes.

Self-Management and Ergonomic Options and Implementation Strategies

The self-management and ergonomic options (Figures 4 and 5) and implementation strategies (Table 2) were selected using evidence, stakeholder interviews, and established theoretical frameworks (health beliefs [72,73], self-determination [74-76], social cognitive [77,78], and Bronfenbrenner's Ecological Systems Theories [79]). The theoretical frameworks will help to interpret effectiveness outcomes for the group and for

different subgroup characteristics and determine if interventions are modifiable to fit with internal and external contexts [80].

After the within-subject control period, participants will be randomly assigned to 1 of the 2 implementation arms. Workers in both groups will view the tailored educational video modules in the workplace and select 1 self-management (Figure 4), and 1 ergonomic strategy (Figure 5), to use during the 10-week intervention period. Workers assigned to the arm enhanced with additional support (video + support) group will be provided checklists to use while reviewing the videos and asked to consider strategies they do not use or could use more frequently [81]. To assist workers with problem-solving, participants in this group will be shown video recordings of their own work and encouraged to problem-solve ergonomic alternatives [39,41,81]. Finally, the workers in the video + support group will receive weekly SMS text message reminders to support their specific choices. These automated messages will be delivered using the Mosio text platform [82] at the beginning (ergonomics) and at the end (self-management) of the week. The messages are preprogrammed and will include graphics and gifs to represent concepts from the videos. Supervisors will also be asked to support workers for ergonomic choices and provide their opinions of engagement, adoption, and feasibility.

Table 2. Implementation outcome measures.

Implementation strategy	Engagement	Adoption	Feasibility
Tailored short educational video modules delivered in the workplace using iPads	• Acceptability, relevance—questions during or after training • Opinions of the videos and delivery	• Number of ergonomic and self-management strategies used • Frequency of strategy use • Intent to use strategies in the future	• Ease of use of strategy • Facilitators or barriers • Time for delivery • Feasibility in the workplace environment
Worker choice of preferred strategies matched to self-identified most difficult work tasks	• Acceptability	• Number of ergonomic and self-management strategies used • Frequency of strategy use • Intent to use strategies in the future	• Ease of use • Barriers and facilitators
Supervisor involvement	• Supervisor engagement (observation)	• Uptake and involvement of workers from supervisor's perspectives	• Supervisor interviews—feasibility, reasons for adoption, fit with organization, and environment • Barriers and facilitators
Visual feedback for positions and movements	• Qualitative comments and questions during review of video	• Use of strategies	• Time • Recognition of positions and postures • Opinions of relevance and acceptability
Ergonomic problem-solving	• Involvement in problem-solving • Supervisor comment discussion among workers	• Use of strategies	• Opinions of ergonomic strategies and problem-solving • Supervisor observations of suggestions for work tasks, changes in work practices
Text message reminders including images and gifs	• Questions and return texts		• Feasibility for workers • Opinions of text messages

Data Analysis

Aim 1

LMMs or generalized linear mixed models (GLMM) will be used to compare within-subject changes in the primary and secondary outcomes (1) over time (baseline, pre, and post) between the intervention periods and the control period and (2) between video and video + support interventions, depending on the distributional feature of the outcome. A general regression structure will be used:

$$g(EY_{ijk}) = \alpha_i + \gamma_j + \beta' X_{ijk}$$

In this equation, Y_{ijk} is the change of the outcome over observation period k of individual j in cluster i; $g(EY_{ijk})$ is the link function for the mean of Y_{ijk}; α_i and γ_j are random intercepts specific to cluster i and individual j, respectively; and X_{ijk} and β are vectors of covariates and associated coefficients. X_{ijk} indicates intervention (1: intervention video+support, 0: control video only), and baseline characteristics (demographics, occupation, and baseline pain or disability levels). For continuous outcomes that are symmetrically distributed (after transformation), the following traditional LMM will be used:

$$Y_{ijk} = \alpha_i + \gamma_j + \beta' X_{ijk} + \varepsilon_{ijk}$$

where ε_{ijk} are normal random errors. For skewed continuous outcomes, a GLMM with a gamma distribution will be used. Intervention effects will be represented by mean differences in the continuous outcome between the comparison groups. For

categorical outcomes such as prevalence of chronic high impact pain, we will either dichotomize the outcome and fit a logistic mixed model or directly fit a Bayesian multinomial logit model that is available in the R package. Intervention effects will be represented by odds ratios. We will also reparameterize the model to obtain relative risks for measuring intervention effectiveness. These models will account for correlations within each team, as well as within each subject. Results will be verified by general estimating equation models in case within-team or within-subject correlation structures are mis-specified. Missing values for either outcome or covariates will be managed by multiple imputation or the Expectation-Maximization algorithm.

Aim 2

Qualitative analysis will help explain effectiveness and implementation outcomes concurrently [43,61]. Contextual factors that support or hinder engagement, adoption (use of interventions), feasibility, and effectiveness will be described. We will examine general barriers and facilitators and specific patterns for workers in the nursery and landscape sectors. The qualitative analysis will be used to develop a comprehensive matrix of team context, organization, and individual characteristics to explain effectiveness of interventions and implementation results. Using directed deductive content analysis, initial codes will be developed from analysis of preparatory interviews for (1) contextual factors; 2) barriers and facilitators contributing to the degree of impact of the interventions; and (3) opinions of ease of use, overall satisfaction, and reasons for engagement, adoption, and feasibility results. We will use NVivo qualitative analysis software (version 14; Lumivero) to code content and identify categories and subcategories to describe patterns and relationships that emerge. We anticipate comparing themes for (1) intervention groups, (2) participants with different degrees of pain severity and persistence, (3) individuals and teams who adopt and implement the strategies consistently compared to those who do not, (4) individuals who respond positively to the interventions compared to those who do not improve, and (5) subsectors of the industry. Once themes are identified, interconnections, interactions, and relationships will be described and explained. Recommendations for future implementation and sustainability will be confirmed and prioritized.

Results

Preparatory literature searches, stakeholder interviews, and observations were started in January 2023 and completed in August 2023. The stakeholder interviews confirmed the limited formal training for prevention of musculoskeletal repetitive strain injury and overall need for addressing LBP in the industry. The project was funded on September 29, 2023 (CDC NIOSH U54OH011230-07S1), as a core research project for the Southeast Coastal Center for Agricultural Health and Safety. The video recording and creation started in April 2023 and was completed in June 2024. Formative evaluation of drafts 1 and 2 of the videos, revisions, translation into Spanish, and narration were completed in April 2024, and final video edits were completed in June 2024. The first group was enrolled in June 2024. As of December 6, 2024, we have enrolled 14 participants and 4 supervisors from 3 employers. Data collection is anticipated to be completed in late 2027 or early 2028 with plans for final analysis and dissemination of findings shortly thereafter. Qualitative data for Aim 2 will be coded and analyzed progressively for team characteristics and trends.

Discussion

Importance of Study Findings

In this paper, we present the protocol for a randomized within-subject controlled hybrid intervention study with coprimary aims to examine the effectiveness of self-management videos combined with multimodal personalized support compared to self-management videos alone for improving LBP and disability in nursery and landscape workers, as well as to identify contextual factors that impact implementation including engagement, adoption, effectiveness, and feasibility. Improving self-management strategies to reduce transition from intermittent to high-impact chronic LBP will contribute to important Healthy People 2030 objectives [35] while addressing research and practice gaps to mitigate musculoskeletal pain.

In nursery and landscape businesses, prevention of musculoskeletal injuries has not typically received high priority. Despite the size and growth of the industry, horticulture has rarely been included with other agriculture sectors in studies addressing musculoskeletal injury prevalence [5] or risk factors [5,6]. There is a death of intervention studies to prevent or mitigate LBP in agriculture [2,10,66], with few intervention studies specifically targeting nursery and landscape populations [5]. Feasible, easily implemented interventions to manage pain and reduce risk factors are essential for small businesses in the horticulture industry who face major challenges with labor availability. Variability in work environments, seasonal fluctuation in workloads, weather constraints, and productivity requirements make the adaptability, efficiency, and ease of adoption paramount for any training intervention. Current “training on the-job” from more experienced workers and supervisors is challenging with turnover and difficulty retaining experience workers who can pass on best practices. Efficient delivery methods providing structured evidence-based information and strategies would provide consistency. Short videos tailored for both sectors are a pragmatic option to address the needs while remaining flexible for work priorities and productivity. This study will contribute to knowledge about the effectiveness of interventions specifically tailored to the characteristics, work tasks, and work settings for these workers.

Awareness of the risks and consequences will highlight the importance of nonopioid alternatives [14]. Opioid education is not effectively integrated into workplace safety training but embedding discussion of opioid risk within a more holistic approach to prevention and mitigation of LBP may promote help-seeking behavior and reduce stigma and communication barriers [20]. Introducing the risk of opioids along with options to manage pain using self-management and ergonomic alternatives is likely to be received more positively than opioid education alone.

Awkward postures, repetitive actions, and intermittent lifting, digging, or shoveling have been identified as inherent ergonomic risk factors for landscape workers [5]. Similar risks are present in nursery work with awkward stooped trunk postures, repetitive low load lifting, and intermittent heavy lifting [10,11]. Larger companies often have more access to mechanical equipment, while small work units seldom have sufficient resources for major engineering redesign recommended in the NIOSH hierarchy of controls [6]. Modifying the way people work or reinforcing the use of available equipment in small businesses is, therefore, more realistic than major equipment modifications. Typically, smaller companies do not have access to ergonomic and safety experts, and may not provide health care benefits. Feasible, easily implemented interventions to manage pain and reduce risk factors are, therefore, needed for businesses in the nursery and landscape industry.

PE approaches involve workers in identifying possible solutions to reduce work-related stress and have been used in a variety of ways in large manufacturing, construction, and health care settings [83-86]. The evidence for effectiveness of PE in large corporations is mixed for group changes for time off work, return to work, self-assessed productivity, and prevalence of LBP [85,87-94]. In contrast, PE has been found to improve overall perceived health, decrease back pain intensity, and reduce absences due to back pain [94]. Comprehensive PE interventions are often time-consuming and challenging to implement across large corporations. Solutions suggested by workers may be feasible, but changing organizational processes can be difficult. Thus, PE has been suggested to be especially beneficial for small teams, enterprises with restricted finances, and rural or less developed areas [86,95,96]. Although PE has not been studied extensively in agricultural settings [39,41,86,95,96], there is some evidence of lowered ergonomic risk and improved management of symptoms among farmers [86]. In another study, construction workers reported significantly less general fatigue after a typical workday, and increased influence on their work compared to controls [81]. A modified approach to encourage workers to choose relevant options for changing their work activities to minimize ergonomic stresses may be feasible to empower nursery and landscape workers to manage back pain [40].

In this study, changes in the primary (pain, disability, and medication use) and secondary (pain-related anxiety, coping, self-efficacy) measures from the preintervention to postintervention timepoints will be compared to a within-subject baseline within-subject period. We will also compare 2 forms of training implementation—video modules alone and video enhanced with multimodal personalized support. We hypothesize that the video + support will facilitate greater engagement, and increased adoption, thereby contributing to greater reductions in work task pain and disability compared to a baseline control period than the video alone. If either intervention is effective, mitigating pain and enhancing knowledge, skills, and attitudes to manage pain successfully is likely to impact quality of life, productivity, and retention. Improvements in pain and disability could result in decreased use of pain medication and other substances, important outcome public health priorities. Even if observed differences are not significant, identifying characteristics of those who respond will contribute evidence for preventing the transition from low to high-impact chronic pain. The mixed methods will help explain results and surrounding inner and outer contextual factors, facilitators and barriers contributing to implementation success for individuals, teams, and specific strategy choices [44]. Qualitative analysis will also inform recommendations and provide ideas for sustainability of effective interventions. Analysis from multiple perspectives will also help explain emerging or complex factors inherent with the dynamic workplace environment and business models, to guide decisions for others considering these approaches. If self-management is effective for horticulture workers (or specific subgroups), simultaneously studying implementation outcomes (engagement, adoption, and feasibility) will facilitate translation of the intervention from research to practice and scaling to the workforce. Potential limitations that may impact the success of this study are consistent with other hybrid effectiveness implementation studies. First, although we anticipate that our recruitment goals are achievable, external factors such as productivity requirements may impact owner and supervisor willingness to allow workers to participate. As attrition is expected, we plan to enroll additional participants to achieve adequate power. We will emphasize benefits for employers such as limiting absenteeism, improving retention, and reducing potential risks of medication or substance use to manage pain while working. Second, we also anticipate that owners and supervisors who agree to participate are already committed to supporting workers. This may result in a sample of workers associated with positive contextual factors that may not be generalizable to all employers. However, these factors will be documented to help interpret results from an implementation perspective. Third, weather and seasonal variations are likely to impact productivity and, therefore, willingness to participate, particularly for landscape companies. These factors will also impact scheduling for data collection, for example, hurricane or weather delays. We have built in a 2-week window for data collection to accommodate the scheduling but there may be a need for additional flexibility. Finally, cultural, language, and educational literacy variations are expected. All instruments and materials have been translated and checked thoroughly while research assistants who speak Spanish fluently are essential.

Conclusions

Interventions to reduce the burden of LBP that consider the unique characteristics and business models within the nursery and landscape sectors are lacking. Given the high incidence of LBP, the risk of opioid use, impact on labor availability and productivity, and the limited attention to musculoskeletal disorders in these sectors, this study will provide valuable information to address both employer and worker needs. The hybrid type II effectiveness and implementation study will investigate the effectiveness of self-management interventions for pain and disability, along with the engagement, adoption, and feasibility, for 2 forms of implementation while also documenting the context, facilitators, and barriers for nursery and landscape businesses [44]. Increased awareness of opioid risk and options for alternate nonpharmacological strategies to manage pain will also provide an important contribution to a

high priority public health challenge. We anticipate self-management will result in reduced pain and disability. Further, targeting self-management can empower workers and improve pain coping, reducing pain anxiety, depression, and associated use of pain medications. Short video training modules presenting realistic strategies to manage pain and limit work stress are likely to be feasible in the workplace while multimodal personalized support is likely to facilitate engagement and adoption of context-specific solutions. The qualitative methods used will help elucidate whether these options are feasible for small- to medium-sized horticulture businesses, document barriers and facilitators, and describe the inner and outer contextual factors influencing adoption and effectiveness. If the video and multimodal personalized support intervention is more effective than viewing training modules alone, this knowledge will inform best practices and may be easily adapted for other physically challenging agricultural sectors.

Acknowledgments

This study was funded by the Centers for Disease Control National Institute of Occupational Safety and Health (CDC NIOSH) of the US Department of Health and Human Services (U54OH011230-07-00) as core research project for the Southeastern Coastal Center for Agricultural Health and Safety, awarded to the University of Florida on September 30, 2023. The content is solely the responsibility of the authors and does not represent the official views of, nor an endorsement by, the CDC/NIOSH of the Department of Health and Human Services. The Southeastern Coastal Center for Agricultural Health and Safety provided support for the funding application, organization, contacts for recruitment, opportunities to discuss the study with community partners, and the stakeholder advisory board. The authors would like to thank the community partners including Ed Bravo, and the Florida Nursery Growers Landscape Association for assistance with exploration prior to grant submission, preparation, and support for stakeholder recruitment, as well as Big Trees Landscaping, Tropic Traditions, University of Florida Grounds and Maintenance, and Anthony Zaleski for assistance with video recording of work tasks in preparation and for the video modules. Shena Hays and Hillary Carter from the University of Florida College of Public Health and Health Professions Instructional Design and Media team provided video capture and editing for the training modules while Truly Hardemon and Lior Flum assisted with input and review of the instructional design and video content. The authors would also like to thank Cyrus Saleem for assistance with the survey design, Jane Morgan-Daniels and Margaret Ansell for review of the materials for health literacy recommendations, and Maria Vanegas for Graphic contributions. The University of Florida Redcap survey platform support is funded by a National Center for Advancing Translational Sciences grant (UL1TR001427).

Data Availability

Deidentified data will be made available to researchers upon written request. A data-sharing agreement will be developed and signed that provides commitments to (1) use the data only for research purposes and not to identify any individual; (2) securing the data using appropriate computer technology and security protocols; and (3) destroying or returning the data after analyses have been completed. This data sharing plan may be modified as recommended by the funding agency or university policies at the time of study completion.

Authors' Contributions

Study conceptualization, funding acquisition, and methodology was performed by KD, JMB, BH, KKG, and HLR. The data analysis plan was developed by KD, JMB, BH, KKG, HLR, and YY. with project administration contributions from KD and JMcB. The original draft was created by KD, with full writing, review and editing completed by KD, JMB, JMcB, KKG, HLR, and YY. All authors reviewed and approved the submission.

Conflicts of Interest

None declared.

Abstract

Background: Although evidence-based treatments have been developed for childhood behavior problems, many families encounter barriers to treatment access and completion (eg, local availability of services, transportation, cost, and perceived stigma). Smartphone apps offer a cost-efficient method to deliver content to families.

Objective: The aim of this study is to evaluate the effectiveness of the UseIt! mobile health system as both stand-alone and coach-assisted interventions via a randomized controlled trial. The UseIt! System is designed to reduce disruptive behaviors in young children.

Methods: A nationwide sample of parents of children aged 5 years to 8 years with disruptive behaviors (N=324 dyads) are randomly assigned to the stand-alone app (UseIt!; n=108), the coach-assisted app (UseIt! plus supportive accountability; n=108), or the control app (mindfulness app; n=108). The UseIt! App provides parents with tools and troubleshooting to address disruptive behaviors, along with a behavior diary to track behaviors and strategies over time. The coach-assisted condition includes a bachelor's level paraprofessional who provides weekly phone calls to promote engagement with the app. The control condition is composed of a mindfulness app. The web-based, self-assessed outcome measures (post treatment and 6-month follow-up) include measures of app usage, parenting knowledge (eg, knowledge of parent management training and cognitive behavioral therapy skills), and strategies (use of evidence-based parenting strategies), symptom reduction (eg, behavior problems), and parent mental health (eg, anxiety, stress, and depression). We hypothesize that both intervention conditions will show greater parent knowledge and use of skills along with greater symptom reduction relative to the control condition. Further, we hypothesize that those assigned to the coach assisted condition will report greater knowledge, skill use, and symptom reduction than the stand-alone app. We will use intent-to-treat analyses to regress outcomes on study conditions to evaluate for differences across conditions.

Results: Recruitment of study participants began in December of 2022 and is ongoing. We have recruited over half of our intended sample of 324 parent-child dyads (n=214) as of December 2024. These dyads have been randomly allocated to each of the intervention conditions, with 71 assigned to the coach-assisted condition, 72 assigned to the stand-alone app, and 71 assigned to the control app condition. Data collection is projected to be completed by late 2026.

Conclusions: The current study aims to address a gap in the literature regarding the feasibility, effectiveness, and utility of a smartphone app that includes a coach-assisted arm. Digital therapeutics have the potential to enhance the reach and scalability of skills-based psychosocial interventions. Findings from this study will advance scientific knowledge and have implications for clinical practice.

mobile health; disruptive behaviors; parent management training; randomized controlled trial; externalizing behavior

Introduction

Background and Rationale

In the United States, approximately 1.5 million school-age children meet *DSM-5* (*Diagnostic and Statistical Manual of Mental Disorders* [Fifth Edition]) diagnostic criteria for a disruptive behavior disorder (DBD) [1]. DBDs, a category of disorders that broadly involves problems concerning the self-control of behaviors (eg, conduct disorder [CD] and oppositional defiant disorder [ODD]), account for more than half of all mental health referrals for children [2,3]. Longitudinal studies reveal that these problems in early childhood can be risk factors for persistent problems later in life, including substance use disorders and internalizing disorders, if left untreated [4]. DBDs are typically treated with psychosocial evidence-based therapies [5] that include parent management training (PMT) skills (eg, praise, rewards, consequences, and time-outs) and cognitive behavioral therapy (CBT) skills (eg, problem-solving and emotion labeling) [6]. Meta-analyses point to the substantial effectiveness of these interventions at reducing symptoms and maintaining treatment gains over time [7,8]. Despite the effectiveness of evidence-based treatments, many families do not have access to these services, and often stop attending or fail to practice new skills between sessions. Barriers to access include local availability of services, transportation, cost, and perceived stigma. Barriers to noncompletion include poor motivation and low engagement, along with competing demands for time, transportation problems, and copayment costs [9].

The Promise of Digital Therapeutics

Recent advances in technology, in particular mobile health (mHealth) systems, have the potential to overcome these barriers and promote better data collection for researchers [10]. mHealth technologies, including smartphones, create an opportunity to develop personalized interventions that are delivered to families in their day-to-day settings [11]. A smartphone-based mHealth system has numerous potential advantages for improving access to, and engagement in, evidence-based treatments for childhood behavior problems. Such applications can deliver content to improve understanding of skills, provide opportunities for learning through skills practice, and give feedback to families regarding areas for improvement [12,13]. In a recent meta-analysis, of 25 clinical trials, mobile technology use was associated with superior treatment outcome across all study designs and types of control conditions (effect size=.34) [14]. mHealth technologies can also be used to collect data on between-session treatment adherence and skills practice. Evaluating the extent to which patients and families are using the skills they are learning outside of treatment sessions is especially important for psychosocial treatments for disruptive behavior problems which are overwhelmingly skills-based. Remote digital assessments have many advantages over traditional retrospective self-reports including reduced recall bias, the ability to obtain a more representative sample of behavior across situations and contexts, and the ability to track changes in behavior [15-17].

Rigorous evaluations of mHealth interventions targeting child behavioral concerns are in their nascent stage. A 2024 systematic review of mHealth interventions targeting behavioral problems in youth indicated a wide range of effect sizes, from small to large, across the 11 studies reviewed. Most sample sizes were small (ie, less than 100), and the few larger studies did not focus on clinical outcomes (eg, satisfaction, acceptability, and app usage, without behavioral outcomes) [18]. Other recent studies reflect similar findings (ie, improvements in child and parental symptoms, with a wide range of effect sizes), but have similar limitations (ie, small sample sizes, outcome measures focused on satisfaction or acceptability of apps rather than empirically based measures of symptom improvement) [19-22].

The Role of the Coach in mHealth

There is growing evidence in the field of digital therapeutics that some degree of human interaction is important to sustain app usage and achieve meaningful outcomes [23-25]. Although various models have been proposed, the “Coaching” model affords many of the benefits of human interaction (eg, support and accountability) at a level of service that remains highly scalable [23]. Mohr’s Supportive Accountability (SA) Model, which is flexible and can be tailored to clinical conditions and service users, details that the intervention is supported by a coach who provides a social presence and accountability to boost motivation and engagement. Effectiveness studies have shown that various paraprofessionals can successfully be trained as coaches for a wide range of interventions and clinical populations [23].

Previous Pilot Trials of the UseIt! mHealth System

The UseIt! app combines aspects of PMT and CBT to provide parents with evidence-based skills to decrease disruptive behaviors in their children. To date, we have completed 2 pilot randomized controlled trials (RCTs) to test preliminary target engagement and effectiveness of the UseIt! mHealth system. The first trial tested the UseIt! mHealth system as a stand-alone intervention (N=34). Parent-child dyads enrolled in the study and were randomly assigned to either the UseIt! mHealth app condition (n=17) or to a waitlist condition (n=17). Overall, results supported the feasibility of the intervention, but attrition was high in the waitlist control group. This informed our decision to have an active control group rather than a waitlist control group in the current study. The second pilot trial tested the UseIt! mHealth system as an adjunct to therapy in community settings (N=39 parent-child dyads). Though treatment targets moved in the expected direction, high clinician turnover in community settings limited the sustainability and scalability of this approach. This informed our decision to include a bachelor’s level paraprofessional “coach” rather than a clinician in this study.

Study Aims and Hypotheses

Primary Aim

We aim to evaluate the effectiveness of the UseIt! mHealth system as both a stand-alone (n=108) and coach-assisted (n=108) intervention compared with a control app condition (n=108). We expect that (1) the 2 UseIt! intervention conditions will score higher on parenting knowledge (primary outcome) and show greater posttreatment reductions in disruptive behavior symptoms (secondary outcome) compared with the control condition, and (2) the coach-assisted UseIt! condition will score higher on parenting knowledge and show greater posttreatment reductions compared to the stand-alone UseIt! condition.

Secondary Aims

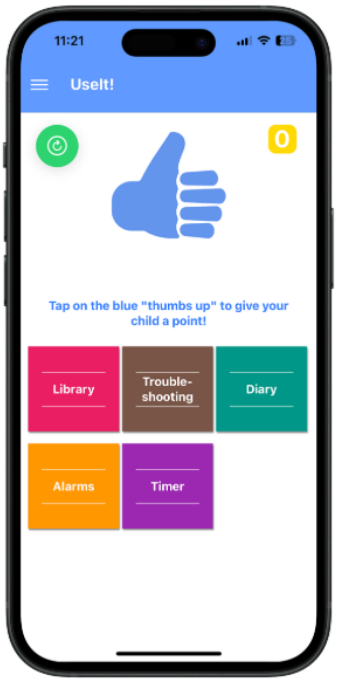
We will also test mechanisms of therapeutic change. In particular, we will test whether gains in knowledge of parenting skills are associated with reductions in disruptive behavior symptoms. Finally, we aim to evaluate the effectiveness of the components of UseIt! mHealth system. We will compare app usage across the stand-alone and coach-assisted conditions and test whether the app usage indices are associated with target engagement, knowledge of parenting skills, and symptom reduction at post-treatment. We expect that families who use the app more often will have higher skill acquisition and usage scores at post treatment ("dose" effects) though we do not have specific hypotheses regarding individual app features.

Methods

The UseIt! Smartphone App

The UseIt! system includes a free cross-platform mHealth app that runs on both iOS and Android devices. The app is securely connected to a portal where app feature usage is stored. The portal was designed for the research team to track and monitor the usage of the app by parents. The app contains six features: (1) a troubleshooting guide that provides detailed skill recommendations for problem situations, (2) a behavior diary for tracking behaviors and skills used each day, (3) a digital library that provides definitions and instructions for each skill, (4) a point counter for parents to award points to their children, (5) a skills-alarm for reminding parents to practice the various skills, and (6) a timer for use with parenting skills (eg, time-outs, managing screen time, routines). Users can examine diary entries, viewpoints awarded, and set the skills alarm through the app. See Figure 1 for a screenshot of the app's home page.

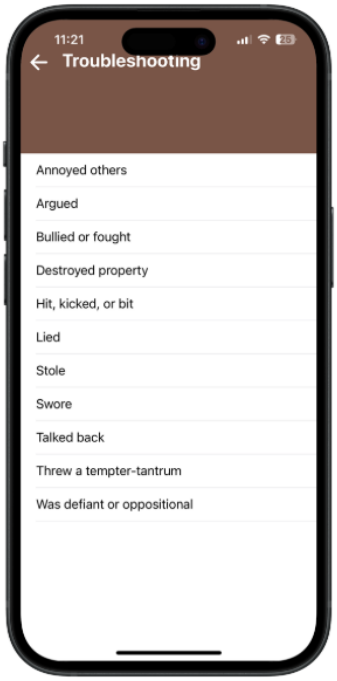
Figure 1. Home page of the UseIt! smartphone app.



Troubleshooting Guide

The UseIt! troubleshooting guide contains information to help parents effectively respond to problem behaviors. Parents are presented with a list of potential negative behaviors (eg, bullied or fought). After selecting a behavior, appropriate skill options (eg, time-out) are displayed with tips to effectively apply each skill. Once a skill has been used and the behavior has stopped, parents are reminded to praise their child for positive behaviors (Figure 2).

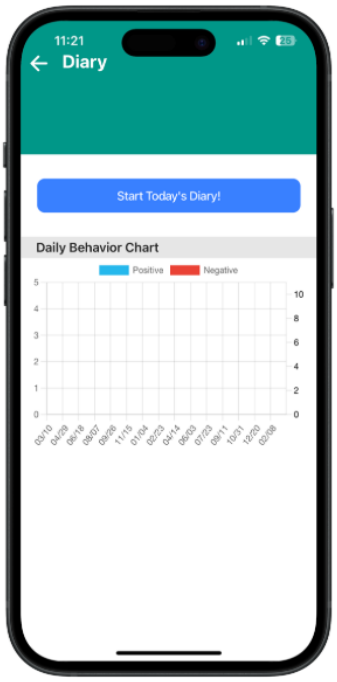
Figure 2. Troubleshooting guide.



Behavior Diary

The behavior diary cues participants (via a notification) to complete a series of questions about behaviors and PMT and CBT skills used each day. The results are displayed graphically and can be reviewed by the user to track progress over time. This allows the user to keep track of what skills the family has tried for different behaviors (both positive and negative child behaviors) and which ones have been helpful in various contexts (Figure 3).

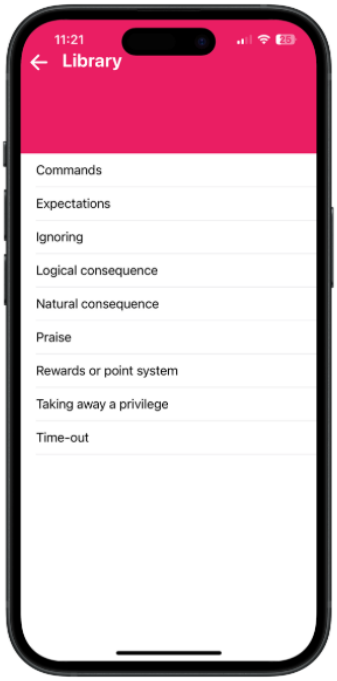
Figure 3. Daily behavior diary.



Digital Library

The UseIt! digital library provides detailed information about using strategies for positive and negative child behavior. Each skill is defined and presented with tips for how and when to effectively use each skill. The digital library contains more information than the troubleshooting guide and is designed as an information source for reviewing PMT and CBT topics (Figure 4).

Figure 4. Digital library.



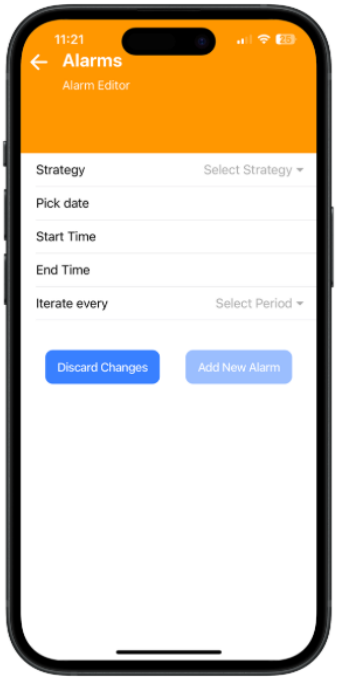
Point Counter

Treatment for disruptive behavior disorders typically includes prizes for treatment adherence, positive behaviors, and skill use. Parents can award points to children for target behaviors (eg, cleaning dishes) and skill usage. The UseIt! point counter features an on-screen button ("Give your child a point") which parents press to reward their child with a point. The feature functions as a digital rewards program that parents can use to keep track of points and reward their children. See Figure 1 for a view of the point counter window.

Skills Alarm

Skills alarms can be set at any time via the app. Users can set dates and times for notifications to activate. These notifications remind parents and children to practice specific skills throughout the week (eg, "remember to praise your child"). Parents are able to view a list of active and inactive alarms (Figure 5).

Figure 5. Skills alarm.



Timer

Timers can be set for use with a variety of skills (eg, time-outs, screen time management, and routines) to promote use of the skills.

Recruitment

We use a 2-pronged recruitment strategy to maximize enrollment. The two recruitment avenues are (1) the Clinical and Translational Science Institute patient registry (Pitt+Me) at the University of Pittsburgh and (2) BuildClinical. The Clinical and Translational Science Institute patient registry (Pitt+Me) is an institutional research participant registry that uses enhanced study descriptions and social media to engage the community in research. BuildClinical is a clinical trial recruiting system that helps investigators recruit participants for clinical trials more efficiently. Using study-specific digital advertisements displayed on search engines, health websites, and social media platforms, BuildClinical generates participant referrals. BuildClinical also provides tools to streamline the recruitment and prescreening process. The platform stores information in a HIPAA (Health Insurance Portability and Accountability Act)-compliant manner and allows for remote enrollment.

Participant Eligibility

Inclusion criteria for this study are that (1) parents or guardians must have a child between the ages of 5 and 8 years, (2) the child must be above the 90th percentile for either or both ODD and CD on the Vanderbilt Assessment Scale, (3) the child must be in residence with the parent or guardian for at least 80% of the time, (4) the parent or guardian must consent to study participation, and (5) the parent or guardian must have a smartphone device with daily internet access. Exclusion criteria are the child (1) having a known preexisting behavioral or mental health diagnosis requiring alternative treatment (eg, bipolar disorder, major depression, and pervasive developmental disorder) or (2) currently receiving treatment for childhood disruptive behavior.

Sample Size Determination

Power analyses were conducted in PASS (version 13.0.8; NCSS) to ensure that the sample size is adequate to test the primary hypotheses with adequate statistical power. All analyses assumed 0.80 power and 2-sided tests. Estimated sample sizes are determined based on an assumed 5% attrition and missing data post treatment (102 per group) and 10% total attrition at 6-months (97 per group). Using an analysis of covariance approach to test for differences across 3 groups post treatment (n=108 each) and assuming R^2=0.20 from 5 covariates, we expect 0.80 power (α=.05) to detect an effect size difference of Cohen *f*=0.16 among the 3 groups, *f*=0.14 (*d*=0.28) between both UseIt! treatment groups versus the control group, and *f*=0.18 (*d*=0.36) between any 2 groups.

Design

The study is a RCT with 3 conditions. Parents of children aged 5 to 8 years (n=324) are randomly assigned to one of 3 conditions: a stand-alone UseIt! app condition, a UseIt! app and Coach condition, and a control app condition (Smiling Mind app). Data are collected via web-based surveys at baseline, post treatment (4 months after baseline), and at 6-month follow-up. Randomization takes place after the baseline is completed.

Study Conditions

Stand-Alone UseIt! App Condition

Participants are assigned to the UseIt! App as a stand-alone intervention for 4 months.

UseIt! App + Coaching Condition

Participants are assigned to the UseIt! App and are provided with an mHealth “Coach” for 4 months. The primary objective of the coaching condition is to promote engagement with the UseIt! mHealth platform. The mHealth coach is a bachelor’s-level paraprofessional with a degree in psychology or an allied discipline (eg, social work) who provides support to parents in the coach-assisted condition. We selected a bachelor’s-level coach over a master’s-level coach to enhance the scalability of this intervention condition. The coach uses the SA coaching model using the training guidelines outlined by Dopke and colleagues [26]. During the intervention phase of the study, parents are contacted by the coach once per week by phone and also allowed to contact the coach during regular business hours. The coach provides motivation and accountability but does not provide therapeutic or clinical support. The primary goal of the coach is to increase participant engagement with the UseIt! mHealth system. Specific coaching content and tasks include (1) social support, (2) promoting engagement with the app, (3) goal setting (4) monitoring progress, and (5) encouragement and motivation. Parents are provided with appropriate referrals for any crises. The coach is instructed to respond to questions that lie outside the domains of motivation and accountability (ie, content-specific therapeutic support) by redirecting the parent to the content-specific app features (ie, Troubleshooting and Library). Only the parents interact with the coach. To maintain the scalability of the condition, the target time spent with each family is 15-30 minutes per week. The coach maintains a “coach-log” to track the frequency, duration, and content of contact with each participant.

Control Condition (Smiling Mind App)

Parents in the control app condition are assigned to use a mindfulness app called Smiling Mind [27] for 4 months. We selected a mindfulness app because it is an active control condition, but one that we do not expect to engage the same treatment targets as the UseIt! mHealth system. Meta-analytic findings indicate that mindfulness-based interventions for school-age children are associated with medium to large effect sizes for disruptive behaviors [28]. For parents, dispositional mindfulness has been found to be associated with lower rates of children’s externalizing and internalizing problems [29], and a mindfulness-based program was associated with decreased parent reports of child attention-deficit/hyperactivity disorder symptoms and decreased parental stress [30]. Other studies with youth found that a combined approach (parent and youth mindfulness training) improved externalizing problems and attention [31]. As an active control condition, we expect that a mindfulness app will likely have some influence on parenting

and child behavior. This provides us with a rigorous control condition while also allowing us to test the specificity of target engagement. We expect the Smiling Mind app will only enhance mindfulness, but not PMT and CBT skills (other than mindfulness). We selected the Smiling Mind app [27] in particular because (1) it can be downloaded at no cost, (2) it is available for both Android and Apple (iPhone) devices, and (3) app-use can be tracked.

Study Procedures and Randomization

Participants provide their contact information to the Pitt + Me or BuildClinical systems after accessing the study advertisement. Trained research assistants then contact families and conduct the initial screening to determine study eligibility. If determined eligible, a future call is scheduled to obtain consent from the parent, and assent from the child to participate. After consent, parents are provided a Qualtrics link to complete the initial baseline assessment. After completion of the assessment, families are randomly assigned to group 1 (standalone UseIt! app; n=108), group 2 (UseIt! app + coach; n=108), or group 3 (control app condition; n=108). We use stratified randomization to ensure that the groups are equivalent on key clinical features (screening severity and referral source (ie, Pitt + Me or BuildClinical). Parents assigned to the Coach condition are walked through the initial setup and login process, along with a brief training on how to use the applications over the phone. Families can be set up and trained in approximately 30 minutes. If parents cannot be reached after 3 weeks, instructions are sent via email. Parents assigned to the stand-alone UseIt! app condition are sent a tutorial video with the same information. Parents use the app condition assigned for 4 months before the administration of the posttreatment assessment, via Qualtrics. Six months following the posttreatment assessment, parents again are prompted to complete the 6-month follow-up assessment via Qualtrics.

Measures

Table 1 for a summary of study constructs, measures, and assessment time points.

Table 1. Measures.

Construct	Measure or instrument	Time point
PMT[a] and CBT[b] skill knowledge	Knowledge of Effective Parenting Test	Baseline, post treatment, 6-month follow-up
Symptom severity	Vanderbilt Assessment Scale	Baseline, post treatment, 6-month follow-up
Parenting practices	Alabama Parenting Questionnaire	Baseline, post treatment, 6-month follow-up
Parent depression	7-item Generalized Anxiety Disorder Scale	Baseline, post treatment, 6-month follow-up
Parent anxiety	9-item Patient Health Questionnaire	Baseline, post treatment, 6-month follow-up
Parenting stress	Parental Stress Scale	Baseline, post treatment, 6-month follow-up
Social support	Social Provisions Scale	Baseline, post treatment, 6-month follow-up
PMT and CBT skill use	Parenting Skill Use Diary	Baseline, post treatment, 6-month follow-up
App use	Automatically recorded	Active app phase
Mindfulness	Mindful Attention Awareness Scale	Baseline, post treatment, 6-month follow-up
Service use	Service Assessment for Children and Adolescents	6-month follow-up
Supportive accountability	Supportive Accountability Inventory	Post treatment (coach condition only)
Usability	Post-Study Usability Questionnaire	Post treatment

[a]PMT: parent management training.

[b]CBT: cognitive behavioral therapy.

Primary Outcome: PMT and CBT Skill Knowledge

The knowledge of effective parenting test [32] is a 21-item measure of parental knowledge of effective parenting skills. The measure was developed as a potential treatment target for evidence-based psychosocial treatments of disruptive behaviors in children. The knowledge of effective parenting test assesses parental knowledge of domains including praise, rewards and point systems, attending and ignoring, commands and expectations, consequences, and time-outs. Parents are presented with a series of video and text-based parenting scenarios and questions with 4 multiple-choice response options. Scores range from 0 to 21. The measure has good reliability (Cronbach α=0.84). The measure has also demonstrated convergent validity with other measures of parenting knowledge and parenting-related constructs (eg, child behavior and parental psychopathology).

Secondary Outcomes

Symptom Severity

The Vanderbilt Assessment Scale-Parent Report (VASPR [33]) is a 55-item parent-report screen for attention-deficit hyperactivity disorder (ADHD), ODD, and CD. It also includes 7 items on internalizing symptoms and 8 items on school performance and social functioning. Symptom items are rated using a 4-point scale and the performance items are rated on a

5-point scale. The measure has Cronbach alphas ranging from 0.79 to 0.95 and strong evidence of construct validity.

Parenting Practices

The Alabama Parenting Questionnaire (APQ [34]) is a 42-item measure that assesses five dimensions of parenting: (1) positive involvement, (2) monitoring, (3) positive discipline, (4) consistency, and (5) corporal punishment, using a 5-point scale ranging from 1 to 5. The internal consistency of the scale is acceptable with α values for the 5 domains ranging up to .80. The measure has well-established construct validity.

Parent Depression

The Patient Health Questionnaire-8 (PHQ-8 [35]) measures symptoms of depression using a 4-point scale from "not at all" to "nearly every day." Total scores range from 0 to 24. The measure has a reported Cronbach α of .82 and strong construct validity.

Parent Anxiety

The General Anxiety Disorder-7 Scale (GAD-7 [36]) is a 7-item measure of anxiety. Items are rated on a 4-point scale from "not at all" to "nearly every day." The measure includes an item to assess the duration of anxiety symptoms. The measure has excellent internal consistency (Cronbach α=0.92), good test-retest reliability (intraclass correlation [ICC]=0.83), and strong convergent validity with other measures of anxiety.

Parenting Stress

The Parental Stress Scale (PSS [37]) is an 18-item measure of stress related to parental experiences. Items are rated on a 5-point scale from "strongly disagree" to "strongly agree." Scores range from 18 to 90. The internal consistency of the scale is acceptable with a Cronbach α of 0.83, a test-retest reliability of 0.81 (ICC), and strong convergent validity of both other parental stress measures (ie, Parental Stress Index), and other measures related to parenting stress (eg, loneliness, marital satisfaction, and social support).

Social Support

The Social Provisions Scale [38] is a 24-item measure that assesses 6 dimensions of support, including attachment, social integration, opportunity for nurturance, reassurance of worth, reliable alliance, and guidance. The measure uses a 5-point scale ranging from 1 to 4, strongly disagree to strongly agree. The measure has been validated across samples, with Cronbach α ranging from 0.65 to 0.76 for the 4 subscales, and a total reliability estimate of 0.91. The measure also demonstrated convergent validity with related measures of social support.

PMT and CBT Skill Use

The Parenting Skill Use Diary [39] assesses daily use of parenting skills in everyday parenting contexts (eg, child sharing and helping, hitting, and fighting). Respondents are presented with a checklist of behaviors to report on for the past week. For each behavior they select, they are next asked to identify which skills (eg, praise, reward, time-out, and loss-of-privilege) they used in responding to the behaviors. The instrument has demonstrated the ability to capture significant between-person variability in appropriate PMT skills. A weekly summary score discriminated between parents or guardians whose children screened positive versus negative for CD (area under the receiver operating characteristic curve [AUC]=0.72) and ODD (AUC=0.70).

App Use

Parents assigned to both UseIt! conditions (ie, stand-alone app and coach conditions) have their data stored on the secure portal, accessible to the research team. We collect the behavior diary tracked by parents, which displays data on child behavior (both positive and negative) along with CBT and PMT skills. We are also collecting data on time spent on the app along with modules accessed. App usage (eg, modules used and time spent) is also tracked for the Smiling Mind app (control condition).

Mindfulness

The Mindful Attention Awareness Scale [40] is a 15-item scale designed to assess core characteristics of mindfulness. Parents are asked how often they are engaging in a variety of mindfulness-related behaviors, such as finding it difficult to stay focused on what is happening in the present moment, finding themselves preoccupied with the future or past, and not noticing feelings of physical tension or discomfort until the really grab their attention. The measure's response scale ranges from 1 (almost always) to 6 (almost never). The measure is scored as an average of all 15 items. The measure has adequate validity (Cronbach α=0.87 and convergent validity with other measures of mindfulness (eg, mood disturbances and stress).

Service Use

An abbreviated version of the Service Assessment for Children and Adolescents (SACA [41]; 25 items) was used to measure mental health service usage. The SACA asks about various inpatient and outpatient treatment services for mental or behavioral health problems that have been used by the child in the past 6 months [41]. Most items are yes or no questions. The measure is a widely used research tool with strong evidence of reliability and validity.

Supportive Accountability

The Supportive Accountability Index (SAI [42]) is an 8-item measure of how well a given platform functioned to help keep parents accountable to accomplish a given goal. The measure was included to assess the effectiveness of the Coach in the coach condition of the app in helping to keep parents accountable with skill learning and use. Items are rated on a 1-7 scale, from 1=strongly disagree to 7=strongly agree. Total scores are summed, ranging from 8-56. The measure has acceptable validity (Cronbach α=0.68) and good convergent and divergent validity.

Usability

The 19-item Post-Study System Usability Questionnaire (PSSUQ [43]) is used to assess overall user satisfaction with the UseIt! apps. Internal consistency of the PSSUQ is excellent (α=.91 to .96).

Technological Literacy

The Technological Self-Assessment Scale (TSAT [44]) is a 13-item parent report screen for technological ability. The

measure was created for this study by the research team to provide an indicator of parent knowledge and experience with their computers and phones. For example, items ask parents if they know how to search for information on the internet if they have ever downloaded an app, and if they have social media accounts. Items are scored Yes or No, and scores range from 0 to 13.

Data Analyses

Primary Analyses

Our primary analytic strategy will use intent-to-treat analyses. We will examine reasons for any missing data and perform multiple imputation (eg, Multiple Imputation for Chained Equations [45]) for data missing at random. To evaluate the effectiveness of the UseIt! mHealth system as both a stand-alone (n=108) and coach-assisted (n=108) intervention compared to a control app condition (n=108), we will regress the primary and secondary outcomes on the study condition. We will also perform a priori tests to compare both UseIt! groups to the control and to compare the coach-assisted and stand-alone UseIt! groups. Cohen *d* effect sizes will be estimated for between-group differences as well as pre-post changes within each group.

Secondary Analyses

We will also test whether gains in knowledge of parenting skills are associated with symptom reduction. We will regress the posttreatment knowledge of parenting skills on study condition, pretreatment knowledge, and their interaction. We will also compare app usage across stand-alone and coach-assisted conditions and test whether the app usage indices are associated with target engagement and symptom reduction at post-treatment. App usage outcomes will include the number of each of the app features that are used, along with frequency and duration (in minutes). We will use generalized linear models with the appropriate link (eg, log link for count data and identity link for continuous outcomes) to regress each usage outcome on study condition (stand-alone versus coach).

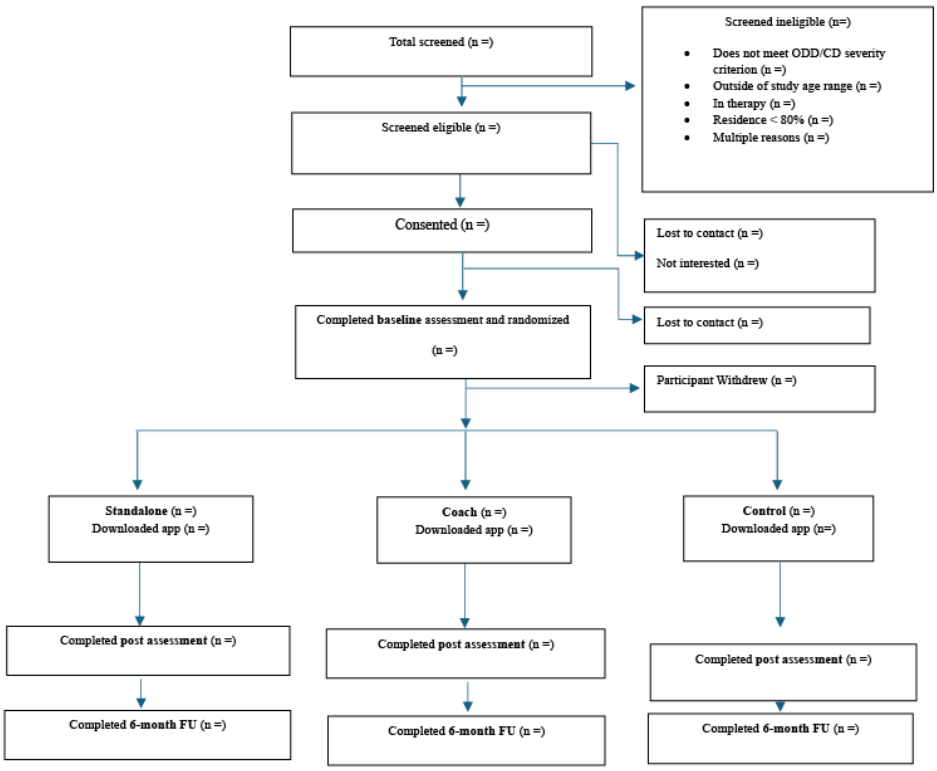
Ethical Considerations

Ethical approval has been obtained from the institutional review board at the University of Pittsburgh (protocol # STUDY22030138). Informed consent from parents is obtained by trained research staff. So as not to artificially inflate the rates of app usage, participants are not compensated for using the app but only for assessments completed. Participants in each condition are compensated US $20 for baseline assessment completion, US $40 for the postassessment, and US $60 for the 6-month follow-up assessment. All study data are deidentified and stored securely.

Results

The study was funded in September 2022. Study recruitment began in December 2022. As of December 2024, we have recruited over half (n=214) of our target sample of 324 parent-child dyads. Of these, 72 parents have been assigned to the stand-alone condition, 71 to the coach condition, and 71 to the control condition. Recruitment is ongoing and completion is expected in another 12 to 14 months. Follow-up data collection is expected to be completed by the end of 2026. Figure 6 displays the trial flowchart for this study.

Figure 6. Trial flowchart. FU: follow-up.



Discussion

mHealth parenting programs have the potential to improve outcomes for parents and children [14]. Further, supportive accountability, defined as a degree of human interaction throughout the program, has the potential to enhance outcomes for mHealth interventions by increasing motivation and engagement [23]. The current study aims to add to the literature base on effective mHealth interventions to treat disruptive behaviors in children. The study will allow us to test the degree to which the UseIt! app can modify parenting (ie, skill acquisition and usage) and whether such target engagement is associated with symptom reduction. The UseIt! mHealth system also allows researchers unique access to data on child behaviors and parent skills tracked on a daily basis. This data will not only allow parents to track behaviors and skills for themselves (allowing parents to visualize progress) but will also allow researchers a system to track change over time. The coaching model used in the study is highly scalable, providing a flexible model of coaching that can be tailored to a variety of clinical conditions and service settings. We expect that those assigned to the coach condition will have the largest increases in parent knowledge and skill use, along with the largest decreases in child behavior problems. We also expect that those assigned to the UseIt! stand-alone app condition will report greater improvements in parent knowledge, skill use, and child behavioral concerns, compared with the control app condition.

Strengths and Limitations

This study has several strengths and adds to the existing literature. To our knowledge, it is the largest RCT of an mHealth smartphone-based app targeting child behavioral concerns to date. The trial adds to the literature base of the SA model [23] and aims to provide preliminary evidence to the effectiveness of the model in the context of a smartphone-based app targeting parents. We selected clinically relevant outcome measures for the trial, including validated measures of parenting knowledge, parent skill use, parent mental health, and child behavior problems. We also collect app usage data, both for use as a moderator of intervention effects, and to inform future work to promote increased usage in other studies. A few limitations are also worth noting. First, we expect up to 10% attrition over the course of the study. We have taken several steps to minimize attrition, including increasing participant compensation at each time point. We also factored 10% attrition into our power analysis to determine sample size, ensuring that the trial will still be fully powered. Another limitation is that outcome measures are based primarily on parent report. This limitation is mitigated by substantial evidence that parents are accurate reporters of child behavior problems.

Conclusions and Future Directions

In summary, the current study aims to address a gap in the literature regarding the feasibility, effectiveness, and utility of a smartphone app that includes a coach-assisted arm for treating disruptive behaviors in young children. Digital therapeutics have the potential to enhance the reach and scalability of skills-based psychosocial interventions, as even small effects can be meaningful on a population level if the intervention can be delivered efficiently on a large scale at a low cost. The UseIt! mHealth system is able to deliver therapeutic content to parents across a variety of settings and has the potential for meaningful impact. Findings from the current trial will advance scientific knowledge and have the potential to enhance clinical practice.

Acknowledgments

This study was supported by grants to the first author from the National Institutes of Health (R01HD106930; R34MH106619; R21HD090145; K01MH093508) and the Klingenstein Third Generation Foundation (Fellowship in Access to Care). The authors would like to thank Abby R Angus and Emma K Toevs for assistance with the study.

Abstract

Background: Regulating gestational weight gain (GWG) in pregnant women with overweight or obesity is difficult, particularly because of the narrow range of recommended GWG for optimal health outcomes. Given that many pregnant women show excessive GWG and considering the lack of a “gold standard” intervention to manage GWG, there is a timely need for effective and efficient approaches to regulate GWG. We have enhanced the Healthy Mom Zone (HMZ) 2.0 intervention with a novel digital platform, automated dosage changes, and personalized strategies to regulate GWG, and our pilot study demonstrated successful recruitment, compliance, and utility of our new control system and digital platform.

Objective: The goal of this paper is to describe the study protocol for a randomized controlled optimization trial to examine the efficacy of the enhanced HMZ 2.0 intervention with the new automated control system and digital platform to regulate GWG and influence secondary maternal and infant outcomes while collecting implementation data to inform future scalability.

Methods: This is an efficacy study using a randomized controlled trial design. HMZ 2.0 is a multidosage, theoretically based, and individually tailored adaptive intervention that is delivered through a novel digital platform with an automated link of participant data to a new model-based predictive control algorithm to predict GWG. Our new control system computes individual dosage changes and produces personalized physical activity (PA) and energy intake (EI) strategies to deliver just-in-time dosage change recommendations to regulate GWG. Participants are 144 pregnant women with overweight or obesity randomized to an intervention (n=72) or attention control (n=72) group, stratified by prepregnancy BMI (<29.9 vs ≥30 kg/m^2), and they will participate from approximately 8 to 36 weeks of gestation. The sample size is based on GWG (primary outcome) and informed

by our feasibility trial showing a 21% reduction in GWG in the intervention group compared to the control group, with 3% dropout. Secondary outcomes include PA, EI, sedentary and sleep behaviors, social cognitive determinants, adverse pregnancy and delivery outcomes, infant birth weight, and implementation outcomes. Analyses will include descriptive statistics, time series and fixed effects meta-analytic approaches, and mixed effects models.

Results: Recruitment started in April 2024, and enrollment will continue through May 2027. The primary (GWG) and secondary (eg, maternal and infant health) outcome results will be analyzed, posted on ClinicalTrials.gov, and published after January 2028.

Conclusions: Examining the efficacy of the novel HMZ 2.0 intervention in terms of GWG and secondary outcomes expands the boundaries of current GWG interventions and has high clinical and public health impact. There is excellent potential to further refine HMZ 2.0 to scale-up use of the novel digital platform by clinicians as an adjunct treatment in prenatal care to regulate GWG in all pregnant women.

Introduction

Background

High maternal prepregnancy BMI and high gestational weight gain (GWG) elevate the risks for poor pregnancy outcomes (eg, gestational diabetes and hypertension) and fetal outcomes (eg, large for gestational age birth weight) [1-6]. High BMI and GWG may also "program" the child's metabolism for life [7,8] and increase the future risks for obesity and type 2 diabetes in both mothers and their offspring [1-6]. As such, managing GWG has high clinical and public health significance, and it can improve maternal health and impact the etiology of obesity or diabetes in offspring at a crucial time in the life cycle [1-6,8].

Guidelines from the Institutes of Medicine (IOM) [1] and National Academy of Medicine [2] recommend that the optimal total GWG should be based on a woman's prepregnancy BMI category (ie, overweight: 6.8-11.3 kg; obese: 5.0-9.1 kg). However, evidence from a meta-analytic review including over 1 million pregnant women found that nearly 50% of women exceeded their recommended goals [9], and this was prevalent among those with normal weight as well as those with overweight or obesity. Furthermore, data from a meta-analysis of almost 200,000 women from 25 international cohort studies in the LifeCycle Project [6] showed the highest risk for adverse outcomes among women with both high BMI and high GWG. Given these concerns as well as the rapidly changing landscape of health care delivery since the COVID-19 pandemic, there is a critical and timely need for scalable approaches to effectively regulate GWG. One such strategy that may reach more pregnant women and reduce the burden on prenatal clinicians who monitor GWG is an automated approach that relies on a digital platform with remote delivery and passive remote data collection to monitor and effectively and efficiently regulate GWG.

Prior Work

Our team's prior work successfully constructed energy balance models to predict maternal GWG [10] and infant birth weight [11]. Expanding the work of Thomas et al [12], we built a novel dynamic mathematical model of energy balance and behavior to predict GWG [13,14]. It describes how physical activity (PA) and energy intake (EI) behaviors are influenced by social cognitive determinants (attitude, subjective norm, perceived control, intention, and self-regulation) [15-17] and depicts how components (ie, education, behavior coaching, goal setting, nutrition counseling, and engaging in PA and healthy eating activities) impact PA and EI social cognitive determinants and behaviors to regulate GWG. We also explored how the energy balance model could be extended to explain infant birth weight [11,18].

Prior research has shown that behavioral interventions can impact GWG [19-27] and more specifically that participants who received behavioral intervention components (eg, counseling, guided PA, and prescribed diet) had a lower mean GWG, decreased likelihood of exceeding GWG guidelines, and lower risk for adverse maternal and infant outcomes [20]. There was also evidence for a dose-response relationship whereby intensive interventions with more subject contact were associated with a stronger impact on GWG [20]. Moreover, the findings from qualitative and prospective cohort studies support an intensive approach to managing GWG in pregnant women with overweight or obesity because they may be more likely than women with underweight or normal weight to overestimate the amount of weight they should gain, underreport EI, and have low motivation to engage in PA on their own [28-41]. Taken together, there is ample evidence from the literature for an approach that considers the unique needs of pregnant women with overweight or obesity and personalizes intervention dosages to regulate GWG.

Many GWG interventions use a "one size fits all" approach and are not designed to consider individual variability in how women gain weight over the course of gestation. Our approach adapts personalized dosages for each woman in a way that gives more intensive treatment only to the women who need more assistance to regulate GWG. We piloted a proof-of-concept study [42] and feasibility-initial impact randomized trial [8,10,19,43-45] to examine the impact of the Healthy Mom Zone (HMZ) intervention on GWG. The social cognitive theory–based components [15-17] noted above were designed with the Multiphase Optimization Strategy [46] translational science framework [47-50], and control systems methodology [51-55],

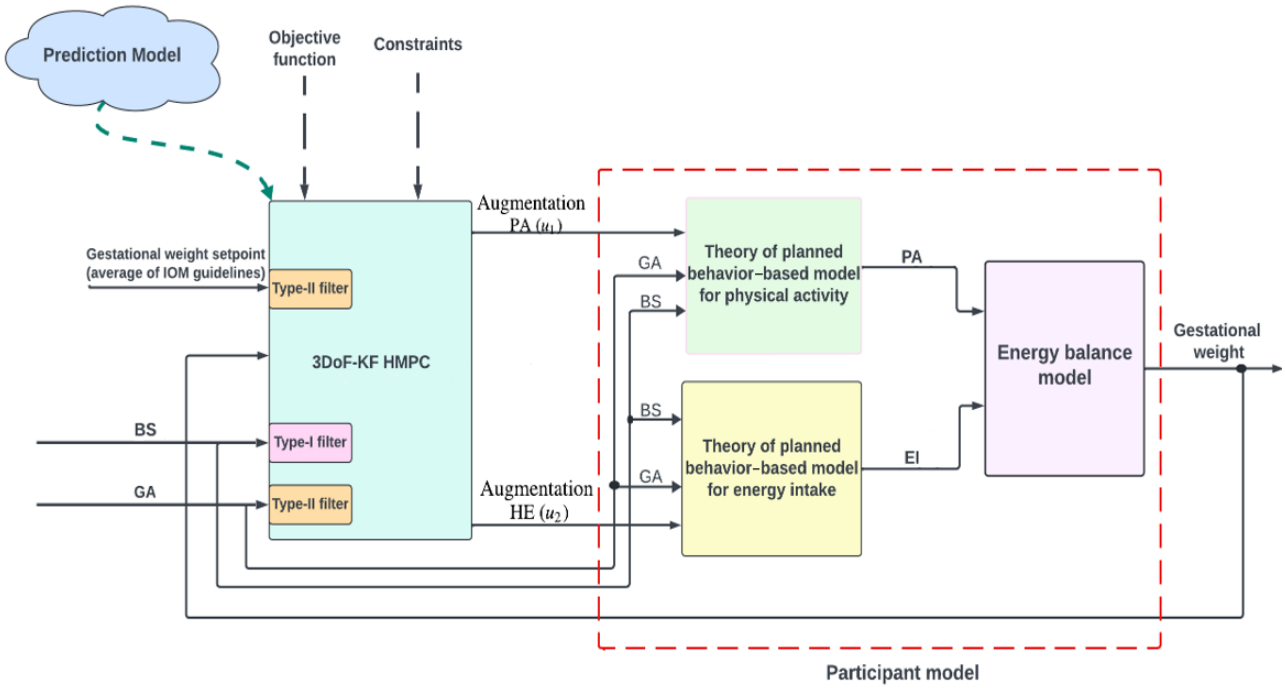
with the long-term goal to scale-up use by clinicians as an adjunct treatment to prenatal care in order to regulate GWG. This multiphase approach [46] builds an intervention in a principled manner whereby key constraints expected to impact scalability (eg, implementation feasibility and subject or staff burden) are considered from the start so that the end goal is an optimized (effective and efficient) and scalable intervention that delivers the best possible outcome [46]. Our translational science framework [47-50] guided by the Quality Implementation Framework [49] and Quality Implementation Tool [50] aligns with the paradigm shift in the literature to prospectively examine implementation markers (eg, subject acceptability, dosage exposure, and staff burden) from the start of an intervention to identify and resolve challenges during delivery that impact efficacy and scalability [49,50].

Our feasibility trial that randomized 31 pregnant women with overweight or obesity to the adaptive GWG intervention (delivered in person or remotely) or a control group over the course of pregnancy and used mobile health tools and online surveys to measure study outcomes showed high measurement compliance (85%), low burden (eg, average 1 min per day to complete measures), and low attrition (3%) [19]. The control system driven by decision rules and a woman's observed GWG informed when to adapt dosages (GWG within goals [1,2], maintain dosage; GWG greater than goals, adapt dosage) [19]. Participants in the intervention group had a 21% lower mean GWG and were more likely to have GWG within goals than controls. Exploratory analyses showed promise for the HMZ intervention to impact secondary outcomes, including PA minutes, active kcal, EI kcal, and PA and EI social cognitive determinants. Furthermore, maternal nighttime awakenings were related to higher GWG [45], and maternal eating behaviors (uncontrolled eating or restraint) were related to GWG and infant birth weight [44].

Because our long-term goal is to deliver the best possible impact on GWG and maternal or infant outcomes and develop an approach that is scalable for future use in the real world, we used these feasibility findings to make refinements to the intervention content (eg, promoting healthy sleep or eating behaviors), delivery (all content available for remote delivery to ensure scalability), and decision process for evaluating and predicting GWG. More specifically, our initial control system was manually operated (ie, plotted each woman's weight in individual participant files) and not particularly scalable. We thus improved this system by designing a new model-based control system with a hybrid model predictive control algorithm and our dynamic model of energy balance and behavior (Figure 1) [10,13,56]. This enables projections of within-person GWG over time (even when data are missing at the current time point) and has been found in past studies to yield robust personalized suggestions and accurate inferential results even with missingness [56-68]. We also built an architecture for a novel digital platform that makes it possible to deliver just-in-time recommendations directly to a subject in ways that target a broader array of outcomes and can reach more women. The platform provides a web-based interface equipped with secure user access control that automates the linkage of subject data collected with mHealth tools to the new model-based predictive control system that implements a Control Optimization Trial approach [10,51] consisting of semiphysical system identification and Hybrid Model Predictive Control. The platform displays graphical or numeric summaries of a woman's past weight, behaviors (eg, PA, EI, and sleep), social cognitive determinants, and other factors; computes optimized dosage changes across multiple maternal variables; and produces a host of personalized PA or EI strategies to regulate GWG. This refined version of the intervention is denoted HMZ 2.0.

In order to activate recruitment, examine participant compliance with the measurement protocol, pilot test the HMZ 2.0 data transfer pipeline, examine intervention session delivery and user acceptability of the digital platform, and conduct simulations for controller-recommended dosage changes, we conducted a 28-day pilot study.

Figure 1. Dynamic model of energy balance and behavior to predict gestational weight gain (GWG). The intervention components are education, counseling, goal-setting, self-monitoring, and physical activity (PA)/healthy eating (HE) active behavior strategies (eg, guided activity sessions and cooking demonstrations). The figure depicts the block diagram of the closed-loop control system framework for managing GWG in pregnant women with overweight or obesity and describes the influence of intervention components, baseline intervention dosage, and gestational age (GA) on GWG. The participant model consists of 2 behavioral models targeting PA and energy intake (EI) behaviors, respectively, and an energy balance model. Outputs from the behavioral models serve as inputs to the energy balance model, which calculates changes in GWG by assessing the difference between EI and energy expenditure. The hybrid model predictive controller (HMPC) uses filtered signals of set point and measured disturbances (baseline intervention dosage and GA). A Type-I filter is used to filter the baseline, represented by a binary signal that indicates the preintervention phase (0) or the intervention phase (1). In contrast, a Type-II filter is used to filter the set point and GA. The HMPC-based optimizer determines a sequence of control actions, referred to as PA and HE dosage augmentations. BS: baseline; IOM: Institutes of Medicine.



HMZ 2.0 Pilot Study Results

We recruited and enrolled 10 pregnant women (mean age: 32.1 years; mean gestational age at enrollment: 14 weeks). Participants completed the HMZ 2.0 preintervention measurement protocol lasting 7 to 9 days (depending on the day of enrollment), completed daily and weekly study measures over a 3-week period while also participating in three 60-minute weekly intervention sessions (content from the first 3 weeks of the HMZ 2.0 baseline intervention) delivered by a trained staff member through the HMZ 2.0 digital platform, and completed the postintervention measurement protocol (7-9 days) and a poststudy brief interview to understand user acceptability. The results of this pilot study are presented below.

We had 59 participant contacts, of which 31 (53%) were assessed for eligibility and 10 (32% of eligible participants) were enrolled in the pilot study. Successful recruitment of participants involved social media (30%), community-based flyers and handouts (eg, campus locations and local events such as farmer's markets; 30%), word of mouth (20%), and clinic referrals (20%).

Participant compliance with the HMZ 2.0 measurement protocol was excellent, with compliance rates of 88% for the daily or weekly online surveys and MyFitnessPal app, 92% for using the Fitbit Aria Wi-Fi scale each day to assess weight, and 98% for wearing the Fitbit Charge 6 monitor each day to assess PA, sedentary behavior, and sleep behaviors. Moreover, the flow of data through the HMZ 2.0 pipeline was exceptional. Data transfer from devices and Research Electronic Data Capture (REDCap) to the digital platform was smooth, with <2% evidence of technical problems or glitches, and 100% of problems were resolved without issue.

A total of 30 intervention sessions (3 per participant) were delivered, of which 80% (24/30) were delivered with a hybrid approach (in person with the platform) and 20% (6/30) were delivered with a fully remote approach using Zoom and the platform. Attendance and compliance with the sessions were 100%. All the women (10/10, 100%) liked the utility of the HMZ 2.0 digital platform, and 90% (9/10) liked to see their real-time data and set weekly goals with trained study staff. In the poststudy brief interview, 1 woman commented that it was "nice to use [the platform] prior to sessions so I was able to come prepared and ask questions." Another woman said, "The platform was easy to move from page to page." A third woman noted, "We covered different topics during the sessions, so I liked being able to go back to the platform and look at the content again." The participants also provided constructive feedback on the platform and suggested the following refinements: soften the color scheme on the website pages, include a page with session schedule and location information, and include a link to directly email the study staff to reduce the burden of looking through study materials for contact information. The platform was refined to address these concerns.

Simulations to illustrate the estimated model are presented in Figure 2, which shows the Control Optimization Trial framework for the recommended dosages within the system identification phase, adhering to the 2-week and 3-week delay. The first panel displays the participant's weight in pounds (black solid line) and the setpoint (solid magenta line), which indicates the mean of the IOM guidelines (dashed red line) [1]. Different colors are used to represent the various intervention phases. The preintervention phase lasts for 7 to 9 days (9 days in this case), followed by a 2-week baseline period. During both the preintervention and baseline phases, no augmentations or dosages are administered. The first dosage is recommended after 2 weeks in the dosage 1 phase, starting on gestational day 126. The second dosage follows 2 weeks after dosage 1 in the dosage 2 phase. The second panel contains 2 subpanels: one for the manipulated variable augmentation PA and another for PA kcal. The last panel similarly includes subpanels for augmentation healthy eating and EI kcal. The simulation results show that the hybrid model predictive controller effectively manages the participant's weight within the IOM bounds once the controller is activated. As illustrated, both in the system identification and controller phases, recommendations for PA or healthy eating dosages lead to reduced EI (healthy eating dosage recommended) or increased PA (PA dosage recommended), ultimately facilitating weight reduction through decreased EI and increased PA.

After the dosage 2 phase, the controller phase begins, during which the controller recommends further dosages based on predicted participant weight and the logic outlined in Figure 3, which illustrates the conceptual framework for the controller's augmentation or dosage recommendations, operating similarly to a finite state machine. Each state is represented by 2 digits: the first digit denotes augmentation PA (PA dosage) and the second digit indicates augmentation EI (healthy eating dosage), and either the PA dosage or EI dosage is updated at any given time. The controller recommends dosages with a minimum user-specified delay of 2 weeks between all dosages, except between dosage 2 and dosage 3, where a 3-week delay is specified. Transitions between dosages are governed by an auxiliary signal a_k. If a_k equals 1, the controller can transition from the current dosage state to the next; otherwise, it remains in the current dosage state.

Figure 2. Simulation illustrating the various stages of the control optimization trial implemented in the Healthy Mom Zone (HMZ) 2.0 intervention using an estimated model of an HMZ 1.0 representative participant. EI: energy intake; HE: healthy eating; HMPC: hybrid model predictive controller; IOM: Institutes of Medicine; PA: physical activity; RMSE: root mean square error.

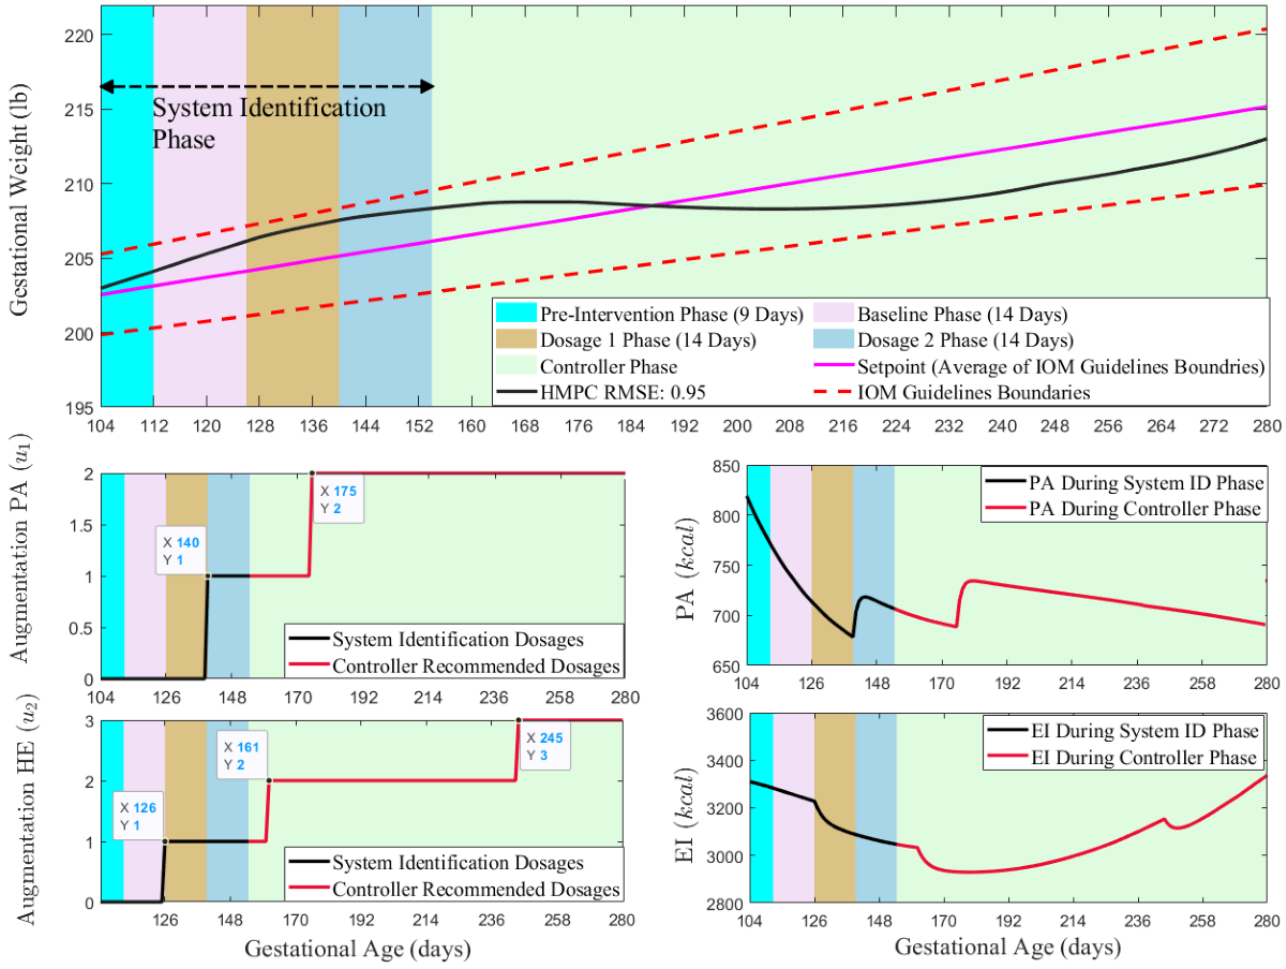


Figure 3. Dosage sequence pattern for the hybrid model predictive controller within the Healthy Mom Zone (HMZ) 2.0 intervention.

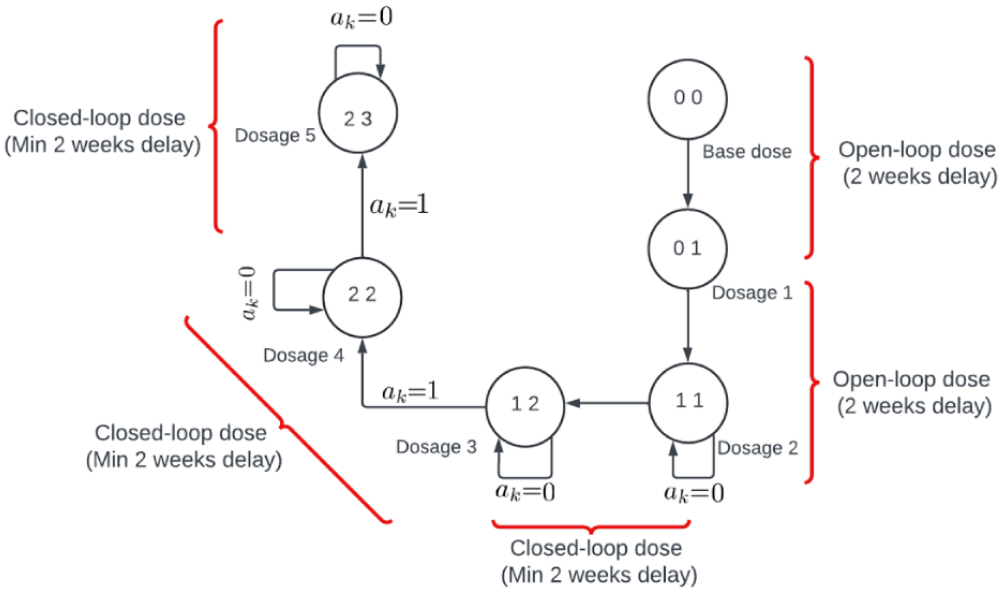


Goal of This Study

The goal of this study is to describe the protocol for a randomized controlled optimization trial to examine the efficacy of the enhanced HMZ 2.0 intervention with the new automated control system and digital platform to regulate GWG and influence secondary maternal and infant outcomes while collecting implementation data to inform future scalability. Aim 1 is to examine the efficacy of the intervention in terms of GWG (primary outcome) and maternal PA and EI behaviors and social cognitive determinants on comparing intervention and control groups. It is hypothesized that the intervention group will (1) have lower pre- to postintervention GWG and be more likely than controls to achieve GWG within the guidelines [1,2], and (2) have higher PA kcal (and total kcal) and PA or EI determinants and lower EI kcal than controls. Aim 2a is to measure pre- to postintervention differences in secondary maternal sleep and eating behaviors. It is hypothesized that the intervention group will have fewer nighttime awakenings and less uncontrolled eating than controls. Aim 2b is to examine the impact of the intervention on birth weight and adverse pregnancy, labor, and delivery outcomes. It is hypothesized that the intervention group will show lower birth weight adjusted for gestational age and will have lower occurrences of adverse pregnancy, labor, and delivery outcomes than controls. Aim 3 is to examine the impact of implementation markers on intervention efficacy in terms of GWG and secondary outcomes. It is hypothesized that subject engagement, acceptability, dosage exposure, and staff burden or acceptability will moderate the effect of the intervention on study outcomes. This information will inform how to scale-up the HMZ 2.0 intervention for future use by prenatal clinicians.

Methods

HMZ 2.0 Intervention Description

HMZ 2.0 is a multidosage, individually-tailored, adaptive intervention with social cognitive theory and behavior components [15-17]. The “baseline dosage” is delivered to all intervention participants, and it consists of up to 24 weekly modules (depending on gestational age at study enrollment) including the following:

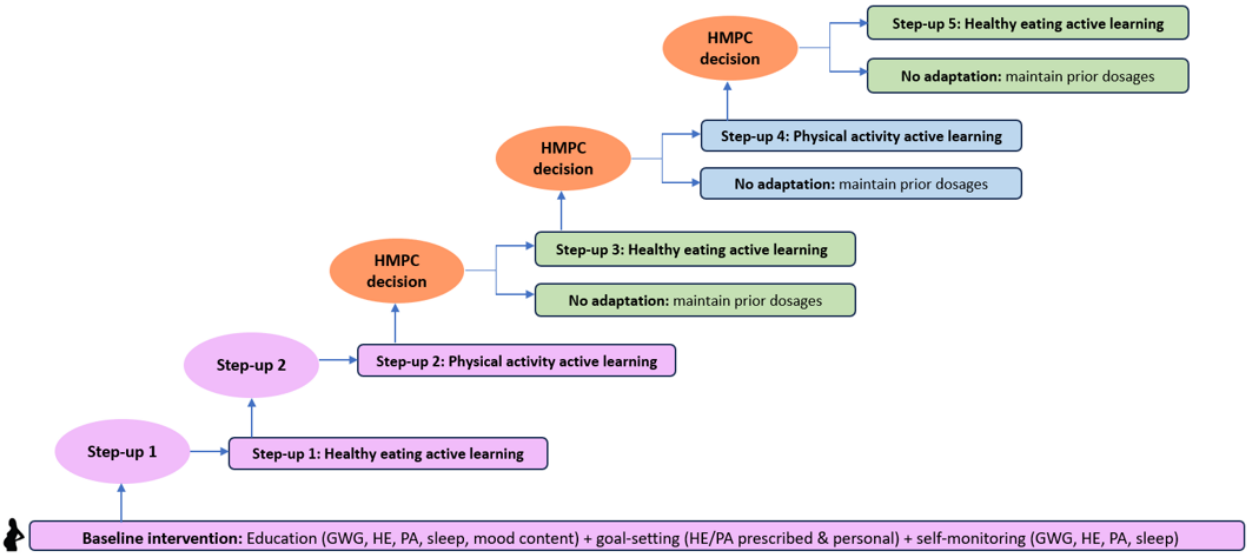
- Education: Knowledge-based content on meeting guidelines (GWG, PA, EI, sleep behaviors, and good sleep hygiene) [1,2,69-75]; mood (eg, depressive symptoms, stress, and anxiety); safely engaging in prenatal exercise; and awareness of stressful situations that prompt uncontrolled and emotional eating, hunger cues, cravings, and mindful eating choices [76,77]. We also provide knowledge about recently published evidence-based studies on how a mother’s health impacts her baby (eg, sleep, brain development, and food preferences) and developmental milestones (eg, when eyebrows develop), which is shared over the course of the intervention. Our pilot work [42] demonstrated that women specifically asked for education materials that provided this information.
- Personalized behavior coaching or counseling: Individually tailored behavior coaching from a prenatal fitness instructor and registered dietitian on GWG, PA, and EI that uses information and feedback from a woman’s prior week to inform the future week’s motivational cues and strategies to increase PA, improve diet quality, and overcome barriers (this can be delivered in person or through a remote synchronous or asynchronous approach for future scalability).
- Goal setting and action planning: Guided and self-selected PA and EI goals [69-71,78] using implementation intentions to target when, where, and how each woman will work toward goals and how these PA or EI goals relate to GWG. Example goals include targets for daily steps (eg, 10,000 steps) and activity time (eg, 30 minutes), as well as fruit or vegetable intake for lower energy density [79] and increasing water intake to maintain good hydration [80,81]. HMZ trimester-specific prenatal PA and recipe booklets (developed by our team) provide detailed examples for PA (eg, 150 min/week of moderate-intensity activities; 10,000 steps/day) and EI kcal goals [78].

- Self-monitoring: Women use mHealth tools (eg, Wi-Fi weight scale, activity monitor, and dietary intake app) to self-monitor GWG, PA, or EI [82]. The HMZ digital platform visually displays their daily or weekly data. Feedback is given to each woman on how to use the devices and self-monitor their behaviors in relation to their GWG and PA or EI goals [19,43,78,83].

Adaptive Intervention Dosage Changes

The model-based predictive control algorithm in the HMZ 2.0 digital platform continually and automatically evaluates GWG. It relies on a dynamic model and solving a receding horizon online optimization problem that identifies when a woman's forecasted GWG is anticipated to exceed the GWG guidelines [1,2,84-86], and based on a structured sequence of decisions that form part of the model, a dosage change is recommended (Figure 4). Only women who have a forecasted need for added support to regulate GWG will receive adaptive dosages in addition to the baseline intervention. Dosages are additive such that a woman receives more intensive support for eating healthy and engaging in PA with each adaptation up to a maximum of 5 adaptive dosages. The web-based user interface provides an easy and intuitive way to integrate expert-supervised dosage change recommendations to regulate GWG. The HMZ 2.0 prenatal fitness instructor and registered dietitian review the participant's data and recommend individually tailored behavioral strategies that are delivered through the HMZ 2.0 digital platform. Each woman's unique preferences and past successes with PA or EI strategies are considered when customizing the dosage adaptation to promote engagement, enjoyment, and compliance, which can in turn influence GWG. These active learning strategies include, for example, multiple PA-guided workouts with a variety of prenatal cardiovascular and resistance training exercises (preapproved for safety and with physician consent for participation) [69,70], as well as healthy eating cooking demonstrations, portion size control strategies to substitute high energy density foods with low energy density options such as water-rich fruits or vegetables [43,71], using food scales and portion size containers, customized grocery planning, and meal replacements. There are a host of easy-to-adopt and practical recommendations for integrating PA or EI strategies into daily life (eg, walking in 5- to 10-minute increments throughout the day to increase PA kcal by 200 kcal/day, reduce sitting by 5 min/hour from 9 AM to 5 PM, and replace 8 ounces of whole milk with skim milk to reduce EI kcal by 100 kcal/day) to facilitate behavior change while adhering to safety standards [69,70]. All dosages can be delivered in person or through a remote approach (synchronous and asynchronous for selected sessions), depending on the participant's preference.

Figure 4. Healthy Mom Zone (HMZ) 2.0 adaptive intervention design. Participant weight is measured daily and continuously evaluated against the Institutes of Medicine (IOM) gestational weight gain (GWG) ranges. All intervention women will receive the baseline intervention plus step-up 1 plus step-up 2 during the system identification open-loop experiment. Dosages 3 to 5 are delivered to selected intervention participants based on hybrid model predictive controller (HMPC) decisions in the closed-loop experiment. HE: healthy eating; PA: physical activity.

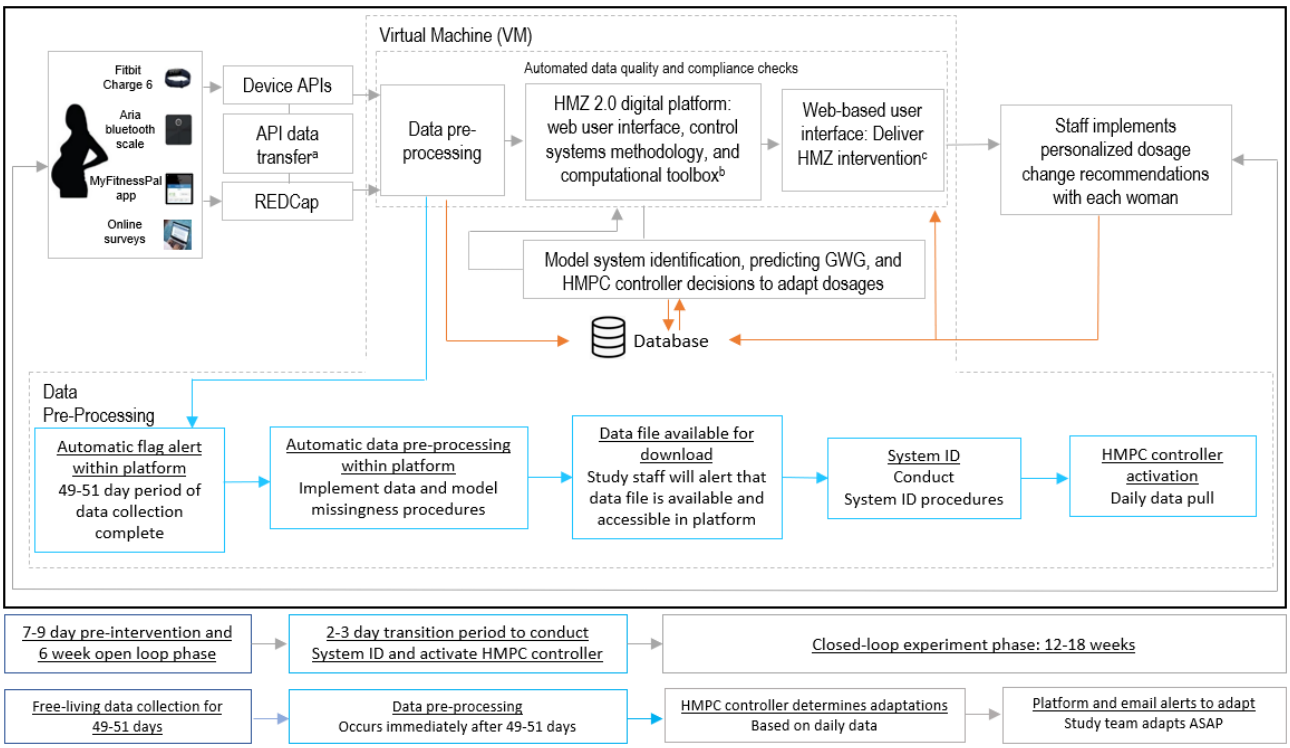


HMZ 2.0 Automated Data Pipeline and Digital Platform

The data pipeline for HMZ 2.0, illustrated in Figure 5, is orchestrated by Apache Airflow [87], a workflow management platform, where daily jobs are scheduled, including (1) retrieving deidentified data from various sources, such as the application programming interface (API) of the REDCap [88] database; (2) preprocessing survey data, including aggregating subscales and back-calculating EI [89,90]; (3) imputing missing data via multiple imputation [91,92] and machine learning–facilitated [93-95] techniques programmed into the platform; (4) feeding the imputed data into the advanced hybrid model predictive control system to generate the adaptive decision-making process; and (5) continuously monitoring errors and warnings in the Airflow monitoring dashboard during steps 1-4, scanning data quality, and initiating automated alerts that notify different pillars of the study team based on the issue type. As the participants in the study cohort change with time, tasks for each new participant are dynamically created. The scripts are version controlled, and data generated throughout the pipeline are saved in a PostgreSQL relational database to ensure data reproducibility. The HMZ 2.0 web-based platform has been

built with Django, an advanced Python web framework to scale-up future production and access (see Figure 6 for the digital platform architecture and website examples). Heterogeneous user interfaces have been built for study staff (and future clinicians), participants in the intervention group, and participants in the control group. The web-based platform provides an access-controlled admin dashboard where authorized users can manually update settings, curate data, or export deidentified datasets for further analyses. For example, during intervention sessions, study staff can access participants' general information, data, educational content, goals, and intervention dosages, and participants will have access to selected resources that are tailored to their specific needs.

Figure 5. Healthy Mom Zone (HMZ) 2.0 data transfer pipeline. API: application programming interface; GWG: gestational weight gain; HMPC: hybrid model predictive controller. *Real-time deidentified 24-hour data stream into REDCap, **Access control (user ID) by authorized study staff, ***Access control (user ID) by intervention study staff (and in the future, dissemination to clinicians).



Recruitment

Recruitment began in April 2024 and will continue through May 2027. Pregnant women with overweight or obesity (N=144) are being recruited for this study. Our team has extensive expertise with recruiting pregnant women. Our past studies have yielded over 3100 subject contacts, with recruitment rates of 84%-92% across our studies [19,96-102]. Well-established methods from our past studies are used for recruitment procedures as follows:

- Clinic: Nurses identify eligible women at the 1st prenatal visit (eg, appointment schedule and electronic health record) and refer them to the study team for screening. A study flyer with study contact information and a QR code is included in the clinic's prenatal packet and posted in exam rooms.
- Community: Study flyers are posted in local areas (eg, daycares and churches) and hospitals, and shared at community events (eg, farmer's markets and celebratory events).
- Social media: Study information is shared on Facebook, Instagram, X, YouTube, and study websites.

Using well-established procedures from our past studies [19,96-102], interested participants, regardless of recruitment method, are screened for eligibility. If interested, participants scan a QR code that directs them to a REDCap survey to complete a screening questionnaire or they send a message by email, text, or voicemail, and a trained study staff member will reply to complete the screening questionnaire over the phone.

The staff member reviews the participant's responses to determine eligibility. The inclusion criteria are as follows: age range 18-45 years; singleton pregnancy with ≥8 and <18 weeks gestation; any parity; any race or ethnicity; BMI of 24-45 kg/m^2 (>40 with provider consent); have not gained >25% of total GWG (based on BMI and IOM guidelines) from prepregnancy to the date of enrollment [103]; able to read or understand English; access to a computer or phone; able to attend sessions either on-site or remotely; randomization to conditions; no absolute contraindications to PA (and presence of relative contraindications only with health care provider consent to participate); and not a current heavy smoker (>20 cigarettes per day) [19,69-71] . The exclusion criteria are as follows: outside the age, BMI, gestation, or GWG range; not able to participate (cannot read or understand English, no access to a phone or computer to attend sessions remotely, and cannot use a device or service assistance); absolute contraindications to PA [69-71] or relative contraindications to PA noted by the participant's health care provider as precluding study participation; current

heavy smoker (>20 cigarettes per day) at study entry; and multiple pregnancy. Eligible women are scheduled for the preintervention assessment. Women not meeting the eligibility criteria are thanked for their time and given information on other studies that may be of interest.

Safety Considerations

Prior to enrollment, a study team member informs the participant's health care provider about their potential participation and obtains consent from each provider. The provider completes the consent form (hard copy or REDCap link) confirming eligibility for participation, and the participant is officially enrolled. This process is repeated at mid-study (eg, between the 2nd and 3rd trimesters) to ensure the participant does not have any new medical conditions that may impact study participation.

Because this study includes pregnant women, a vulnerable population as defined by the National Institutes of Health, there is a Data Safety and Monitoring Board with experts in obstetrics and gynecology, prenatal weight gain, PA and nutrition interventions, and fetal growth that will: (1) review the study methodology and procedures, data on recruitment, enrollment and adherence to the inclusion/exclusion criteria, and participant's progress through the study; (2) assure the safety of the study participants; and (3) make recommendations to the research team. Adverse events that the Data Safety and Monitoring Board will be notified of and oversee include: (1) insufficient GWG: indicators of insufficient GWG are weight loss of less than 3% in a week or 0% weight gain in a 4-week cycle [104]; (2) depressive symptomology: all women regardless of initial preintervention assessment scores will be given resources on managing depressive symptoms and a comprehensive list of available resources and supportive services, and depressive symptoms will be monitored monthly [105]; and (3) absolute or relative contraindications to exercise [69-71].

Participants in the intervention group complete verbal assessments of pregnancy symptoms (eg, mild muscle cramping, headaches, and symptoms of labor) and contraindications to exercise (eg, bleeding, severe abdominal cramping, nausea, etc) during activity sessions. The study safety protocol includes steps to understand symptoms, ratings of perceived exertion, and responses if appropriate, including stopping the activity, seeking medical attention, and calling a participant's emergency contact and provider. If a woman experiences a contraindication to PA in pregnancy that precludes her continued participation, she will remain in the study and complete measures as appropriate (intent to treat) but will not engage in PA until provider consent to return to activity is obtained. We also monitor changes in health status and health symptoms. For example, women who develop gestational diabetes during the study will remain in the study and receive the standard of prenatal care by their obstetrician or health care provider, in which an established standard of care plan is provided for the treatment and management of gestational diabetes.

Ethical Considerations

This study has been approved by the Pennsylvania State University Institutional Review Board (IRB; STUDY00019075), and Arizona State University is an IRB-approved participating site (SITE00001437). All members of the study team have appropriate CITI training certifications. Any and all changes made to the protocol will be communicated to participants and other relevant individuals or parties immediately. All study participants provide their informed consent prior to enrollment into the study with the option to decline enrollment or stop participation at any time. Data collected are deidentified, and access is only granted through lock and key as well as secure accounts with passwords. Participants are compensated up to US $250 in gift cards for either Target or Walmart. Compensation is provided based on the completion of study milestones, such as completing the pre- and postintervention assessments, allowing electronic health record data to be extracted, and attending and completing more than 85% of study sessions and the measurement protocol. Both the intervention and control group participants can receive the same amount of compensation. This study is registered at ClinicalTrials.gov (NCT05807594).

Randomization Procedures

A trained staff member randomizes each participant after the preintervention measures via a randomization module in REDCap [88]. The study's biostatistician has developed the randomization scheme using variable-size random permuted blocks to ensure the number of subjects in each group is balanced after each set of *B* randomized subjects, where *B* is block size. The biostatistician programs the REDCap module, and the remaining study staff do not have access to the randomization scheme. Randomization to control (n=72) and intervention (n=72) groups uses 1:1 allocation; subjects are entered consecutively. Randomization is stratified by prepregnancy BMI status (<29.9 vs ≥30 kg/m^2). A staff member calls each woman to inform her of study assignment. She is then provided with study information and education materials for her group assignment. The investigator is blinded to intervention assignments.

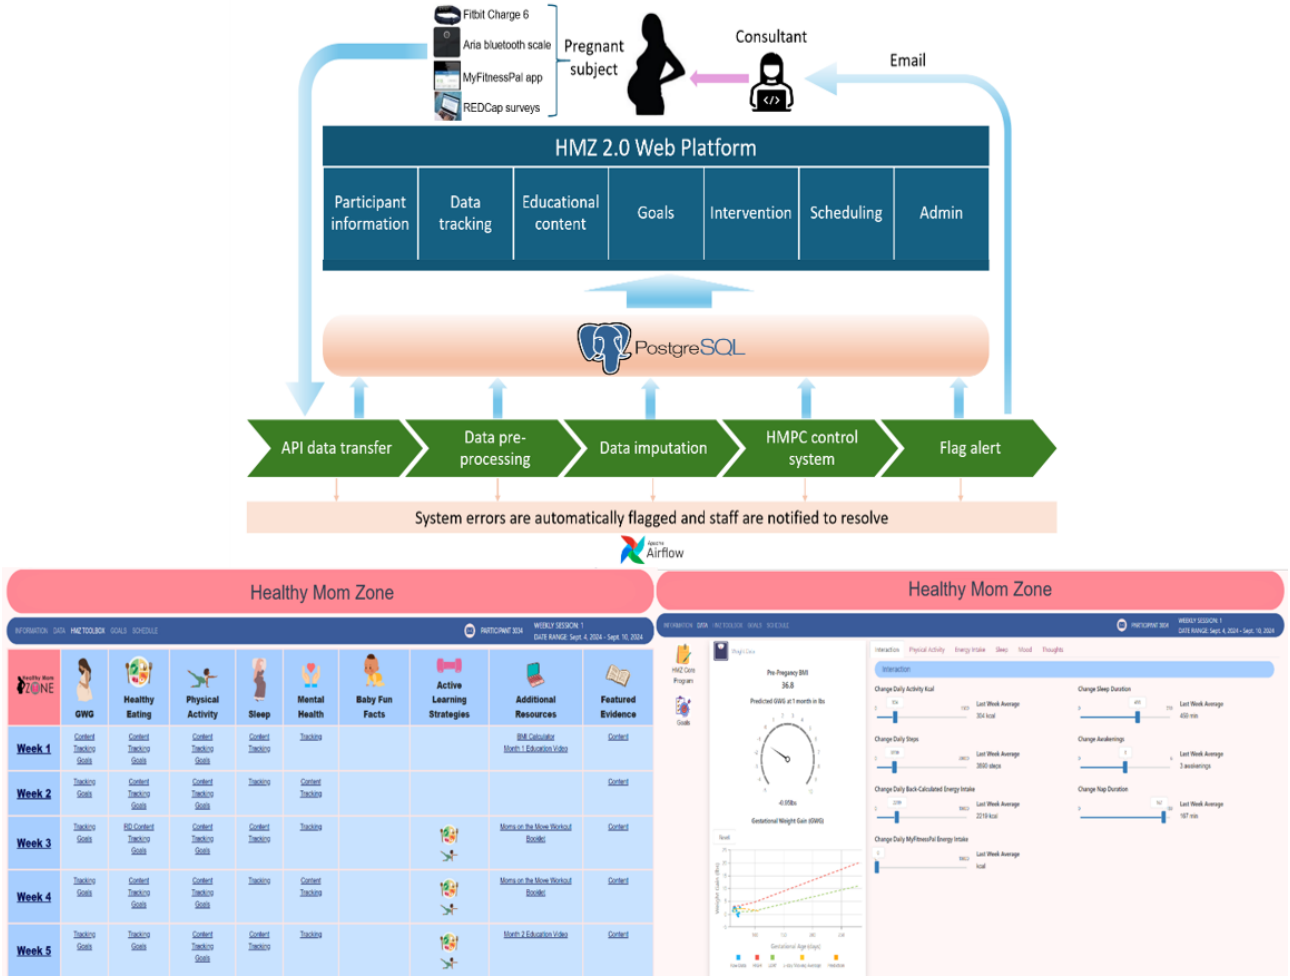
Treatment Conditions

Intervention Condition

Women randomized to the intervention group receive the HMZ 2.0 intervention, described in detail above in the section "HMZ 2.0 Intervention Description," which includes the baseline intervention (education, personalized behavior coaching or counseling, goal setting or action planning, and self-monitoring) and adaptive intervention dosage changes (for the participants who need them). This baseline intervention continues through the duration of the study. Each week over the course of the study, GWG is monitored and evaluated against the recommended upper and lower bounds of the IOM GWG guidelines [1]. Depending on each participant's response to the baseline intervention (eg, GWG within or above guidelines) and her forecasted GWG, the automated control system may recommend a dosage change to adapt the intervention. This adaptive dosage begins after the first 4 weeks of the baseline

intervention (to allow the participants to get used to the intervention and reduce burden) and includes EI and PA active learning interactive components that "step-up" the intensity of the dosage. Dosage change recommendations are automatically delivered through the HMZ 2.0 digital platform (architecture of the platform is described above); staff implement the recommended dosage change with the participant. As illustrated in Figure 6, there are up to five dosage "step-up" adaptations that can be recommended by the automated control system to regulate GWG.

Figure 6. Healthy Mom Zone (HMZ) 2.0 digital platform architecture and website examples. API: application programming interface; HMPC: hybrid model predictive controller.



Attention Control Condition

Consistent with guidelines for comparator groups [106], all women in the study receive prenatal care offered by recruitment sites with routine provider visits, counseling about prenatal behaviors (eg, no smoking), and clinical oversight of health. To match attention to the intervention group, women in the control group receive (for the first 4 weeks of the study) one-on-one weekly education sessions delivered by trained study staff, and thereafter, they receive monthly education content delivered as asynchronous videos and get check-in support from study staff (eg, phone, text, and email) for the remainder of the study. Content includes topics, such as preparing for labor or delivery; benefits of behavioral pain management strategies (eg, mindfulness-based relaxation, imagery, music, massage, and deep breathing) to regulate pain after childbirth with nonpharmacological approaches [107]; and baby or child safety, health and development, behaviors, and nutrition. Content is drawn from evidence-based guidelines and materials designed by members of the study team for a patient-provider toolbox to reduce opioid pain management use after childbirth [107], as well as The American Academy of Pediatrics, The March of Dimes, The Centers for Disease Control, and The American College of Obstetrics and Gynecology [108-111]. The matched control group education content is also provided to the intervention group as supplemental material.

Both the intervention and control groups receive the same measurement protocol and frequency of measurement to understand and compare the impact of the intervention on primary and secondary study outcomes. Data are collected from each participant daily (GWG: Aria Wi-Fi scale [112]; PA, sedentary behavior, or sleep: Fitbit Charge 6 monitor [112], logs for device wear time, and PROMIS Sleep Disturbance [113,114] assessment; and self-reported hydration behaviors); weekly (self-reported online in REDCap; social cognitive determinants and EI diet quality: MyFitnessPal app on 2 weekdays and 2 weekend days) [19,115]; and monthly (self-reported online in REDCap; eating behaviors [19,116,117], psychosocial measures, cognition, pain, and temperament measures).

Control Optimization Trial Procedures

Control systems methodology [51-54] in a novel Control Optimization Randomized Controlled Trial (RCT) [51] is used to test the efficacy of the enhanced HMZ 2.0 intervention with a novel digital platform and a new automated control system to regulate GWG and influence secondary outcomes. This idiographic approach uses individual dynamic models (integrating behavioral and energy balance models) informing how each woman responds to HMZ 2.0 to make personalized decisions about intensifying dosages to regulate GWG. We are not aware of any other studies using this unique strategy to regulate GWG. Women start the intervention with an "open-loop" experimentation phase and receive the HMZ 2.0 baseline intervention (dosages are not yet adapted during this time). Semiphysical models estimated using concepts from system identification [85,118-120] allow individual energy balance and behavior models to be built for each subject [51]. Model and dosage personalization is further enhanced by leveraging our team's expertise in time-varying dynamic systems (systems that show changes in statistical properties over time) and multilevel models that integrate individual- and group-based dynamics and missing data issues [56-68]. Model components are measured with real-time data procedures to predict corresponding deviations from each woman's target GWG range: overweight, 6.8-11.3 kg total and 0.23-0.32 kg/wk; obese, 5.0-9.1 kg total and 0.18-0.27 kg/wk [1,2]. Model estimation is used to confirm individual models and identify if certain constructs provide maximum impact for the control system. The goal of this open-loop phase is to arrive at a set of personalized dynamic models that capture the effects of dosage augmentations, gestational age, and the baseline intervention. Once the models are identified and the controller commissioned, models will not be updated, but the tuning parameters can be adjusted, if necessary. While there is no set threshold of data compliance for building individual models (models can be built with as little as 50% missing data handled with maximum likelihood estimation) [56-68], we will rely on strategies to achieve high compliance (90%; 10% missing data) similar to that in our feasibility study [19].

These personalized individual energy balance and behavior models are used in the "closed-loop" experimentation phase for the rest of the study period during which a woman's responsivity to HMZ 2.0 is considered and dosages are adapted to regulate GWG. Continuous mHealth data are automatically linked to the control system, which considers GWG over a prediction horizon to minimize discrepancies between a woman's observed GWG and her goal [1,2]. It considers the anticipated rate of GWG change as predicted with the individual model. Currently trained with data from the feasibility trial [19] and pilot data collected on HMZ 2.0 participants, the control system uses the values of each woman's modifiable factors (eg, PA or EI kcals) in the current week to simulate ways in which these behaviors can be "controlled" or altered to drive GWG closer to the goal in the following week. We are cognizant of potential system identification issues that may arise with limited data available from each subject. If needed, selected parameters from the energy balance models can be constrained to be invariant across subjects to borrow strengths from other subjects and aid model estimation [121,122]. We will identify the optimal balance between control system performance (how well it can produce desired effects as efficiently as possible) and robustness (how well it can produce desired performance under disturbances and uncertainty; eg, poor compliance, change in responsiveness to dosages, and measurement variability) [10,51]. The controller has tuning parameters that allow adjustment of how fast or slow the control system makes recommendations to enable a judicious balance between effectiveness and responsiveness. Computations are performed with toolkits in MATLAB (MathWorks) and IBM ILOG CPLEX Optimizer. Study staff work with subjects to address concerns or technical issues. We will also explore how the individual subject data may inform modifications to the maternal energy balance and behavior model [10,19] and infant birth weight model [11,18].

Primary and Secondary Outcomes

Table 1 summarizes the HMZ 2.0 measurement protocol and timepoints. More details of the primary and secondary outcomes are provided below.

Table 1. Healthy Mom Zone 2.0 measurement protocol and timepoints.

Variable measure	Timepoint
Energy balance model outcomes	
GWG[a] /weight (primary outcome)	
High precision adult scale (10 s)	Pre- and postintervention
Aria Wi-Fi Smart Scale (15 s)	Pre- and postintervention and daily
Prenatal records: total GWG	Pre- and postintervention
PA[b] and sedentary behavior	
Fitbit Charge 6: activity kcal (passive)	Pre- and postintervention and daily
ActiGraph GT3X: activity min (passive)	Pre- and postintervention and daily
PA log: monitor wear time (1 min)	Pre- and postintervention and daily
Resting metabolic rate	
Predicted equation	Pre- and postintervention and daily
EI[c]	
EI kcal: back-calculation method	Pre- and postintervention and daily
EI diet quality: MyFitnessPal app (5 min)	Pre- and postintervention and monthly
PA or EI social cognitive determinants	
Attitude, subjective norm, perceived behavioral control, and intention (3 min)	Pre- and postintervention, daily, and weekly
Behavioral, normative, or control beliefs (2 min)	Pre- and postintervention and monthly
Retrospective self-regulation (1 min)	Pre- and postintervention, daily, and weekly
Secondary outcome measures	
Sleep behaviors	
Pittsburgh sleep quality index (2 min)	Pre- and postintervention and monthly
FitBit Charge 6: sleep behaviors (passive)	Pre- and postintervention and daily
Sleep log: sleep behaviors (30 s)	Pre- and postintervention and daily
PROMIS Sleep Disturbance (30 s)	Pre- and postintervention and daily
Eating behaviors	
3-factor eating inventory: cognitive restraint, disinhibition, and hunger (3 min)	Pre- and postintervention, weekly, and monthly
Maternal-infant labor or delivery and adverse pregnancy outcomes	
Diagnoses of gestational diabetes, insulin use, preeclampsia, and depression	Postintervention only (at delivery)
Labor or delivery issues and other complications	Postintervention only (at delivery)
Infant APGAR score and mode of delivery (vaginal or cesarean)	Postintervention only (at delivery)
Infant birth outcomes	
Birth weight (adjusted for gestational age at delivery), length, sex, gestational age at delivery, and date of birth in the electronic health record	Postintervention only (at delivery)
Clinical and safety protocol measures	
Height	
Stadiometer (5 s)	Preintervention only
Blood pressure	
Screen for preeclampsia (2 min)	Preintervention only
Demographics, medical history, and obstetric history	
Age, race or ethnicity, income, education, medical or pregnancy history, etc (7 min)	Pre- and postintervention
Depressive symptoms and monitoring health	

Variable measure	Timepoint
Center for Epidemiological Studies Depression Scale (3 min)	Pre- and postintervention and monthly

[a]GWG: gestational weight gain.

[b]PA: physical activity.

[c]EI: energy intake.

Primary Outcome

Participant GWG

Weight and GWG are assessed daily at preintervention, during the intervention, and at postintervention at home using the Fitbit Aria Wi-Fi Smart Scale [112] (weights are wirelessly uploaded to an online program). GWG is standardized, and the target weight gain is determined for each woman based on the BMI status (overweight, 14.1-22.7 kg; obese, 11.3-19.1 kg) [1,2]. For the criterion measure to determine when to adapt the intervention, weight gain is calculated to determine if a woman is gaining less than her goal, at the exact amount of her goal, or more than her goal. GWG over the course of the study is calculated as the last measured weight during the study subtracted by the first measured weight during the study. Weight at enrollment is measured, and prepregnancy weight and GWG from the first prenatal visit to the last predelivery weight are abstracted from clinical records.

Energy Balance and Behavior Model Primary Constructs

PA and Sedentary Behavior

PA and sedentary behavior are assessed daily at preintervention, during the intervention, and at postintervention. Participants wear the wrist-worn Fitbit Charge 6 [112] 24 hours per day from the preintervention assessment until the end of the postintervention assessment. The Fitbit Charge 6 allows for continuous passive (low subject burden) PA assessment in the energy balance model [12] to predict GWG. The device measures total kcal, activity kcal, steps, and minutes in sedentary, light, or moderate PA. The waist-mounted ActiGraph GT3X [123] is worn at pre- and postintervention and for the first 2 weeks of the open-loop phase during waking hours to assess PA and sedentary behavior (activity kcal, steps, and minutes in sedentary, light, or moderate PA). Participants track their PA and monitor wear time by completing a self-report PA log and the Leisure Time Exercise Questionnaire [124] daily for cross-validation of the Fitbit data [125].

EI Behavior: Back-Calculation Estimation

EI is estimated daily at preintervention, during the intervention, and at postintervention from measured weight (Aria Wi-Fi scale) [112], PA (Fitbit Charge 6 activity monitor) [112], and resting metabolic rate (RMR), with k=1, 2,… N relating to day 1 to day N. T is the sampling time (T=1 day) [8,12,68-71], and RMR is estimated daily as follows:

$$eRMR = 0.1976W^2 - 13.424W + 1457.6 \quad \textbf{(1)}$$

The noise in weight is small relative to the total weight, but the extent of this noise can affect the calculated rate of GWG per day, so a 5-day moving average filter is used to preprocess (smooth) measured weight before “true” daily EI is estimated [117-119]:

Our team effectively used this back-calculation method for estimating EI in the HMZ proof-of-concept study [42] and feasibility-initial impact randomized trial [8,10,19,43-45].

Secondary Outcomes

Secondary Energy Balance and Behavior Model Constructs

The following aspects are considered:

- Theory of Planned Behavior [15,126]: Involves healthy eating or limiting unhealthy eating, PA attitude, subjective norm, perceived behavioral control, intention, and beliefs. The Theory of Planned Behavior constructs in the dynamic model of energy balance and behavior [13-17] inform individualized model-based interventions for each intervention participant. Participants complete online surveys daily at pre- and postintervention and during the open-loop phase, and daily and weekly during the intervention to assess their attitude, perceived behavioral control, subjective norm, intention to eat healthy and limit unhealthy eating, and participation in PA. Participants complete a one-time online survey at pre- and postintervention and monthly to assess their beliefs about eating healthy, limiting unhealthy eating, and participating in PA.
- Retrospective self-regulation for EI or healthy eating and PA [17]: Retrospective self-regulation in the dynamic model of energy balance and behavior [13-17] informs individualized model-based interventions for each intervention participant. Participants complete two 6-item online surveys daily at pre- and postintervention and during the open-loop phase, and weekly during the intervention to determine how good they are at regulating their EI or healthy eating and PA and how these behaviors impact GWG over the course of pregnancy.

Maternal Health

Participants complete the following measures at preintervention, during the intervention, and at postintervention:

- Diet composition or quality and eating behaviors: Participants use the MyFitnessPal online app on 2 weekdays and 2 weekend days at pre- and postintervention, weekly during the first 2 weeks of the open-loop phase, and once a month during the intervention to assess their diet composition and quality. This information aids in personalized counseling of diet quality for the intervention group [19]. The Three Factor Eating Questionnaire

[116,117] is completed at pre- and postintervention, weekly during the open-loop phase, and monthly during the closed-loop phase and is used to assess 3 dimensions of eating behaviors: dietary restraint (cognitive control of eating behavior), dietary disinhibition, and susceptibility to hunger.

- Sleep behaviors: The Pittsburgh Sleep Quality Index [127] assesses the quality and patterns of sleep and measures subjective sleep quality, sleep latency, sleep duration, habitual sleep efficiency, sleep disturbances, use of sleeping medication, and daytime dysfunction. The PROMIS Sleep Disturbance short-form survey [113] assesses difficulties and concerns with getting to sleep and staying asleep; evaluates the perceptions of the adequacy of and satisfaction with sleep; and measures sleep quality, sleep depth, and restoration associated with sleep. Participants also complete a daily self-report sleep log [128] to measure time to sleep and wake, minutes of sleep, nighttime awakenings, time spent awake after sleep onset, daytime naps, and daytime nap duration, and wear the Fitbit Charge 6 Activity Monitor [112] each night to assess time to sleep and wake, minutes of sleep, nighttime awakenings, and light and deep rapid eye movement sleep.

Maternal and Infant Outcomes

Prenatal, labor, and delivery data will be abstracted from the participant's electronic medical record. Maternal and infant outcomes include: mode of delivery (vaginal or cesarean), adverse pregnancy outcomes (eg, diagnosis of gestational diabetes, insulin use, preeclampsia, depression, labor or delivery issues, and other complications), birth weight, length, sex, gestational age, date of birth, APGAR score, and any complications related to the infant during labor and delivery. In the event that labor or delivery data are missing or unavailable from the medical record, the investigators will obtain information from the participant's self-report.

Implementation Marker Procedures

Our team has ample experience with evaluating program implementation [96-98,129-133], including in the HMZ proof-of-concept study [42] and feasibility trial [19]. The Quality Implementation Framework [49] and Quality Implementation Tool [50] will guide examination of the following markers:

- Subject engagement and participation: Fidelity monitoring evaluations are conducted for each subject and staff after each session. A trained staff observer reviews video recordings of 50% of intervention and attention control sessions and follows a review checklist to measure engagement (degree of subject responsiveness with content, discussion, and activities) [134,135].
- Subject acceptability: Subjects and staff complete weekly checklists to assess attendance (0%-100% attendance at pre- and postintervention assessments; 0%-100% attendance at intervention and attention control sessions), compliance (0%-100% compliance with mHealth tools and surveys during free-living pre- and postintervention sessions and over the course of the study for all subjects; 0%-100% compliance with attention control or HMZ 2.0 activities), and quality and completeness of data (0%-100% of usable data for each subject).
- Dosage exposure is assessed by (1) weekly checklists completed by subjects or staff regarding the amount of program content delivered or received (goal 85%+ coverage) [19]; (2) fidelity monitoring by a trained staff observer who reviews video recordings from the same sample of 50% of video recordings noted above; and (3) tracking of the number of dosage changes determined by the model-based control system, number of days between dosage change recommendation and implementation by staff, and number and type of PA or EI strategies suggested or used.
- Staff engagement: Fidelity monitoring is conducted by a trained staff observer who reviews video recordings from the same sample of 50% of video recordings noted above and follows a checklist to measure engagement (enthusiasm, preparedness, session delivery effectiveness, and responsiveness to the subject).
- Staff burden: Weekly checklists are completed by staff for the amount of time spent preparing for sessions, responding to or following up with subjects, and using the HMZ 2.0 digital platform, and for issues with delivering dosage recommendations to the subjects.
- Study delivery costs: A trained staff member tracks and calculates the time and financial costs of the study. Postintervention semistructured interviews with HMZ 2.0 subjects elicit key facilitators and barriers to study participation. The interview guide has been developed with standard procedures [136,137] from our past studies [10,19,42-45,107,138-140]. Expert feedback will be obtained from key clinician stakeholders (ie, registered dietitians, nurses, obstetrics or gynecology providers, etc) on the strengths and limitations of using the HMZ 2.0 digital platform, potential barriers to scaling-up use in prenatal care (eg, clinician beliefs about technology and connectivity issues), and suggestions for improvements. This valuable feedback will be used to make additional refinements to HMZ 2.0 to scale-up future use by prenatal care clinicians.

Statistical Analysis

For study aims 1 and 2, time series methodology will be used on a subject basis (ie, cubic polynomial spline 3-lag auto-regressive models with maximum likelihood as the estimation method) followed by a fixed effects meta-analytic approach to combine information in order to compare the intervention group to the control group [141-143]. Mixed effects models will be used when the meta-analytic approach does not fit the data [56,62-65]. Potential confounding variables (eg, maternal age, parity, and income; infant sex; and adverse maternal-infant outcomes) [6,144] will be included in the models as covariates when appropriate. We will explore the extent to which prenatal sleep and eating behaviors impact postintervention GWG, PA, or EI and infant birth weight to inform modifications to the maternal energy balance and infant birth weight models. The intent-to-treat principle will be followed. Our statistical approach is robust if data are missing at random (multiple imputation will be considered if missing data are problematic) [145]. Hypothesis tests will invoke a

2-sided significance level of .05. Analyses for the synthesis of mHealth data and the predictive control system are informed by MATLAB toolkits and past experience [51,146,147]. Model personalization will use control-theory models, and requisite computations will be performed for optimal dosage changes [112,113,128,148-150]. For study aim 3, descriptive statistics will be used to examine the percentage and frequency for implementation markers. Formative methods will be used to organize, code, and rank order interview data [136,137]. Study findings will be used to further optimize HMZ 2.0 for effectiveness and scalability. Data will be collected and stored in REDCap [88]. Deidentified data will be exported from REDCap [88] to statistical packages. Subject confidentiality will be maintained with subject IDs. Data security is ensured with Penn State standard procedures.

Power Calculations

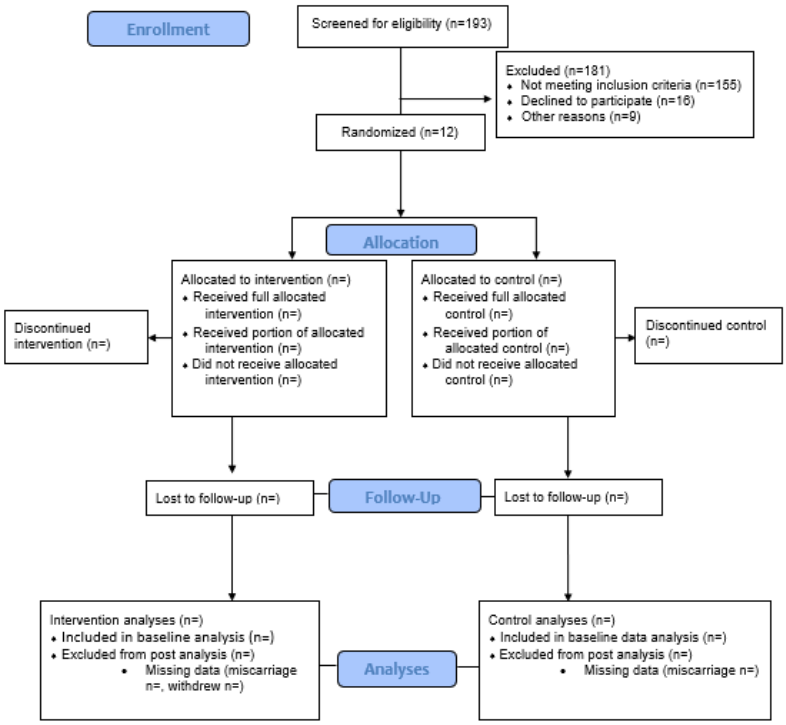
The primary outcome is GWG: absolute difference between the intervention and control groups for the mean change in GWG from the start to the end of the trial. From our feasibility study [19], we found that the difference between the intervention and control groups with respect to the absolute mean change in GWG from the start to the end of the trial was 1.9 kg (SD 4.9 kg), with an approximately 21% relative reduction for the intervention group compared to the control group. We compared the mean change in our feasibility trial [19] to that in several other GWG studies comparing intervention and control groups [29,151-154] and found that the intervention group gained on average 1.8 kg less than controls (range: 1.1-3.1 kg). The sample size of 144 randomized to the intervention (n=72) and control (n=72) groups in the proposed research is informed by our feasibility trial showing a mean difference of 1.9 kg (SD 4.9 kg), a 21% relative reduction in GWG in the intervention group compared to the control group, and a 3% dropout. Given our experience with the feasibility trial [19], the series of refinements that we performed following the feasibility trial (eg, adding content on sleep and eating behaviors given their effects on GWG; modifying all content for remote delivery given 100% compliance found for remote sessions in the feasibility trial; replacing the initial control system to make dosage change decisions with the new, automated, dynamic model-based predictive control system that outperformed the initial system for regulating GWG; and adding the novel HMZ 2.0 digital platform to adapt dosages), and the findings from our HMZ 2.0 pilot study (average weekly GWG over the 4-week study period: 0.3 kg, SD 0.4 kg; overall GWG from pre- to postintervention: 1.2 kg, SD 0.8 kg), we expect the HMZ 2.0 intervention to be more effective. We anticipate that our mean difference will be closer to what a recent study [155] found for the mean difference in GWG between the intervention and control groups (mean 3.6 kg, SD 5.7 kg). Conservatively, considering this larger SD of 5.7 kg and anticipating a larger dropout rate of 10%, the sample size of 144 yields 80% statistical power with a 2-sided significance level of .05 to detect an absolute difference of at least 2.9 kg in GWG between groups. Sample sizes for semistructured interviews are adequate to observe data saturation [136,137,141].

Results

HMZ 2.0 Control Optimization Efficacy RCT

Recruitment began in April 2024 and will continue through May 2027. All data are expected to be collected by December 2027. Currently, we have 193 participant contacts, of which 119 (91%) have been assessed for eligibility and 12 (50% of eligible participants) are enrolled in the RCT (Figure 7). Full results will be uploaded on the ClinicalTrials.gov website at the end of the trial, which is anticipated in January 2028.

Figure 7. Healthy Mom Zone (HMZ) 2.0 CONSORT (Consolidated Standards of Reporting Trials) diagram.



Discussion

Overview

To our knowledge, there are no other adaptive behavioral interventions aiming to regulate GWG with a theory-driven, energy balance model–based predictive control system, highlighting the novelty of our approach. We have made every effort to obtain robust and unbiased results in this trial. We have established the proof-of-concept and tested the feasibility of the intervention dosages, safety protocols, and strategies to retain subjects for this trial. The hypotheses to be tested are based on a sound foundation of preliminary data [10,11,13,14,19,42-45,140]. We have also pilot tested several aspects of HMZ 2.0. Findings from the HMZ 2.0 pilot study showed successful recruitment from multiple methods, excellent participant compliance with the measurement protocol and transfer of data from devices and online surveys to the digital platform, user acceptability of intervention sessions delivered through the platform, and utility of the predictive controller for informing dosage change decisions. We will use a randomized study design for the control optimization trial to test the efficacy of the HMZ 2.0 intervention and automated data pipeline and digital web-based platform compared to an attention control group. Data will be collected from all subjects to measure primary and secondary outcomes with valid and reliable measures. We will show the reproducibility of mHealth measures by having all subjects complete the same measures over time. Intervention content, measurement and implementation evaluation protocols, and intervention materials are available for reproducibility. The HMZ 2.0 digital platform and new model-based predictive control system have been built in MATLAB Compiler for reproduction with limited license restrictions. The HMZ 2.0 digital platform is a central hub for the automated data pipeline and web interface for intervention delivery. The data pipeline uses Apache Airflow for robust and dynamic scheduling and implements a multilayer real-time monitoring system. The web interface leverages the Django framework to deliver a rich user experience with role-based access control. The digital platform greatly improves the efficiency of this collaboration study by facilitating information sharing and reducing the turnaround time among researchers, consultants, and patients. Since both Airflow and Django are readily scalable (eg, through parallelism and caching), this digital platform can easily accommodate scale-up in the future.

Limitations

There are many strengths of this study, including clinical and public health significance, novel methods, introduction of the HMZ 2.0 digital platform and model-based predictive control system with personalized dynamic energy balance models for each subject to automate dosage changes and predict GWG, use of a back-calculation method to estimate EI, pilot data [10,11,13,14,19,42-45,140] to support the rigor and reproducibility of the proposed methods, and strong potential for future scalability. Despite these strengths, participant compliance in RCTs is an ongoing challenge, and thus, we have incorporated strategies (eg, staff support, easy passive data collection, and remote delivery of the intervention) to facilitate compliance. We have also worked through technical aspects of the data pipeline and digital platform to reduce technical challenges. Lastly, there is a risk that the HMZ 2.0 study may be underpowered based on the assumptions used in the sample size estimation, but this is true for any power analysis.

Conclusions

The approach involving the HMZ 2.0 intervention and use of a control optimization trial [46] to examine the efficacy of the intervention in terms of GWG and related maternal-infant outcomes expands the boundaries of GWG interventions, uses novel methods and automated decision making, and has clinical and public health impacts in a high-risk population of pregnant women with overweight or obesity and their offspring. There is excellent potential to further refine HMZ 2.0 in the future to regulate GWG in women of all BMI categories and scale-up HMZ 2.0 for use by clinicians as an adjunct treatment in prenatal care. There may also be a way to optimize the digital platform in the future so that it can be safely and directly used by pregnant women. HMZ 2.0 may also serve as a model for how the control systems methodology and a digital platform can be used to automate dosage change decisions for other behavior interventions such as those involving regulation of diabetes, weight loss, and related health outcomes.

Acknowledgments

The project has been supported by the National Institute for Diabetes and Digestive and Kidney Diseases (NIDDK) through grant 1 R01 DK134863, and support has also been provided through the Office of Behavioral and Social Sciences Research (OBSSR) of the National Institutes of Health (NIH), the National Institute on Drug Abuse (NIDA) through grants R21 DA024266 (roadmap) and K25 DA021173, the United States Department of Agriculture (USDA) National Institute of Food and Agriculture (NIFA) (#2011-67001-30117, A2121 Childhood Obesity Prevention Training Program), and Penn State University (PSU) State Social Science Research Institute and Institutional and Computational Data Sciences. Data Availability

Data cannot be shared publicly because the data collected from human subjects have not been approved for public sharing. Moreover, since the data are of human subjects, a data transfer agreement is needed. Data are available from the principal investigator DSD (dsd11@psu.edu or 814-863-0456) and the Pennsylvania State University Office for Research Protections (orp@psu.edu or 814-865-1775) for researchers who meet the criteria for access to confidential data.

Authors' Contributions

DSD was responsible for intellectual design, framework, and writing of the manuscript, and organized and led a team for co-writing and providing insights on sections. AMP was responsible for co-writing the methods and results, figures, tables, and references, and provided edits to the manuscript. DER was responsible for assistance with the framework of the manuscript, provided insights on control systems engineering aspects of the paper, and provided edits to the overall manuscript. JSS and AMM were responsible for providing insights on the healthy eating aspects of the Healthy Mom Zone (HMZ) intervention and provided edits to the overall manuscript. SC was responsible for providing insights on intervention personalization, data collection, and analysis descriptions, and provided edits to the overall manuscript. CL and DS were responsible for providing insights on HMZ digital platform description and provided edits to the overall manuscript. JMP was responsible for providing insights on HMZ recruitment and retention descriptions, and provided edits to the overall manuscript. AK was responsible for co-writing of the analysis, power, and sample size descriptions, and provided edits to the overall manuscript. OK was responsible for providing insights on control systems engineering aspects of the paper and developing the figures and figure descriptions, and provided edits to the overall manuscript.

Conflicts of Interest

AK owns stock in Merck, a pharmaceutical company. However, Merck was not involved with this particular manuscript.

Abstract

Background: Even in the absence of weight loss, any level of physical activity (PA) can reduce the risk of cardiovascular disease among individuals with obesity. However, these individuals face multifaceted barriers that reduce their motivation and engagement in PA. They prefer programs that are convenient, fun to engage in, and feature people who they can relate to. Yet, there is a paucity of PA interventions that are designed to incorporate these preferences. We designed the web-based PA for The Heart (PATH) intervention to address this gap.

Objective: This study aimed to describe the protocol of a study that aims to examine the acceptability and preliminary efficacy of PATH intervention among insufficiently active adults with obesity aged at least 18 years.

Methods: This is a 6-month pilot randomized controlled trial (RCT), using a parallel design with 1:1 allocation to intervention or control group. The PATH intervention group is given access to the PATH platform, but the resources each participant can access are tailored according to their baseline fitness level. Control group receives a self-help PA handout. Both groups self-monitor their PA using Fitbit (Google) and have Zoom (Zoom Video Communications) meetings twice a month with either the health coach (intervention) or study coordinator (control). The outcomes at 6-months include acceptability, changes in PA, and cardiometabolic risk from baseline to 6-months.

Results: We screened 763 individuals for eligibility and 89 participants were enrolled and randomized to the intervention (45/504, 50.6%) and control arms (44/504, 49.4%). The average age was 48.7 (SD 12.17) years, and most participants were female (81/504, 90.1%), Black (45/504, 50.6%), and non-Hispanic (83/504, 93.3%). No systematic differences in baseline characteristics were observed between the study arms. The 6-month intervention is currently underway, and the completion of follow-up data collection is expected in February 2025, with results to be published soon after.

Conclusions: The PATH intervention offers a promising, evidence-based approach to overcoming the barriers that have hindered previous PA programs for adults with obesity. It can support new and existing programs to foster long-term maintenance of health-enhancing PA.

obesity; physical activity; cardiometabolic risk, body positivity, cardiovascular fitness, self-efficacy

Introduction

Only about 14% of adults with obesity attain the minimum levels of physical activity (PA) recommended by public health guidelines to achieve health benefits [1-3].Low levels of PA contribute to the high population burden of cardiovascular disease (CVD) as they increase the relative risk of stroke, coronary heart disease, and diabetes by 60%, 45%, and 30%, respectively [4-6]. Even in the absence of weight loss, regular PA can significantly reduce the risk of CVD among individuals with obesity [3,7,8]. However, individuals face complex and multifaceted barriers that reduce their motivation and engagement in regular PA for meeting current recommendations [9,10].

Barriers to PA associated with obesity include stigma, shame, poor fitness, and low self-efficacy. These evoke fears of embarrassment and pain, contributing to aversion and avoidance of PA [10-12]. To mitigate these barriers, web-based PA programs targeting adults with obesity have been developed. Preliminary data suggest improved retention for online programs, but the effects on PA are heterogeneous [13]. Limitations of these interventions include the absence of human contact, “one-size-fits-all” strategies, unmet weight-loss expectations, and generic content that fails to address barriers associated with obesity [10,14]. We [15] and others [9,10] have reported that individuals with obesity prefer programs that are convenient, fun to engage in, and feature people who they can relate to with respect to body size, fitness level, and age. Yet, there is a paucity of web-based PA programs that are intentionally designed to flexibly incorporate these preferences [10,16,17].

To address the limitations of previous interventions, our research team designed the web-based PA for The Heart (PATH) intervention. PATH leverages openly accessible platforms, such as YouTube (Alphabet Inc), to provide workout videos that match the specific preferences expressed in our formative studies and the extant literature. In developing PATH, we used an iterative bottom-up approach where our target population was engaged in the selection and rating of the workout videos. Then, highly rated workouts (≥3.5/5 stars) were vetted by the study team for content relevance and safety and then curated on our PATH website in 3 intensity levels (beginner, intermediate, and proficient) to foster gradual progression from low- to high-intensity PA. We added backend features that enable a remote health coach to help users set their PA goals and select a PA regimen that is safe for their fitness level. Each PATH user has a personalized dashboard displaying their recommended workouts and progress toward their PA goals.

We have successfully beta-tested the PATH platform (N=25) and completed a 12-week feasibility study where we met our recruitment goal (N=82) and attained excellent retention (96%). Intervention engagement was high, and the PATH group significantly increased objective moderate to vigorous PA (MVPA) indicating preliminary efficacy [18]. The feedback we obtained from this study included the need to provide resources that can help participants improve their diet, provide feedback on cardiometabolic health indicators, and the need to improve our machine learning algorithm designed to keep the PATH platform up to date.

We used this feedback to further refine the PATH platform by curating nutritional resources focusing on improving diet quality and added a user-facing dashboard with feedback on 5 measures of cardiovascular health including physical activity, blood pressure (BP), weight, heart rate, and sleep efficiency. Also, we optimized the platform’s machine learning algorithm (PATH Fresher) that continually identifies new workout videos that match those preferred by the PATH users to be used in future updates of the platform.

This study describes the latest protocol (version #7, 12/16/2024) of a 6-month pilot randomized controlled trial (RCT), using a parallel design with 1:1 allocation to intervention or control, and designed to assess the preliminary efficacy of the optimized PATH intervention for promoting adherence to PA guidelines among 88 insufficiently active adults with obesity. We hypothesized that participants who are randomized to the optimized PATH intervention will show greater increases in PA at 6 months compared with those assigned to the attention control group. We also hypothesized that the optimized PATH intervention group will have a more favorable cardiometabolic risk profile at 6 months compared with the attention control group.

Methods

Study Design

This is a 6-month, ongoing parallel group RCT including 89 participants with insufficient activity and obesity who are randomized 1:1 to either the PATH intervention or an attention control group. The PATH intervention group are given access to the PATH platform, but the resources each participant can access are tailored according to their baseline fitness level (details described below under optimized PATH intervention).

In addition, the intervention group receive text and or email reminders to log into PATH and do their workouts based on their preferred schedule and will have twice per month online meetings with fitness coaches to monitor progress and review PA goals. The control group receives the Be Active Your Way booklet which is an evidence-based self-help resource for promoting PA [19] and twice per monthly online meetings with the study coordinator to check-in on their progress in the study and maintain contact. The staff members conducting the study assessments are blinded to randomized group allocation.

Setting and Participants

The study is conducted at Emory University, with participants recruited primarily from the Atlanta metro region. Eligibility criteria include reliable access to the internet, age ≥18 years, BMI ≥30 kg/m^2, successful self-monitoring of PA (≥4 days with ≥10 hours wear time) via a waist-worn ActiGraph accelerometer during a run-in period, and classification as insufficiently active according to the PA Guidelines (<150 min of MVPA per week) based on self-reported PA from the Behavioral Risk Factor Surveillance System PA questionnaire [20]. Exclusion criteria include current participation in a lifestyle modification or weight loss study, pregnancy or intention to become pregnant within 6 months, mobility restrictions, use of implantable electronic medical devices, or any condition that requires supervised PA (eg, stroke). Those with any condition that the PA Readiness Questionnaire (PAR-Q+) [21] identifies as requiring primary care provider review before engaging in unsupervised PA will be required to obtain medical clearance before they are enrolled in the study.

Recruitment

Overview

To obtain our target sample (N=89), we leverage resources available to Emory investigators, including Georgia Clinical and Translational Science Institute, Research Match (registry of research volunteers), electronic mailings, announcements on social media sites, and fliers posted in the community. We are also recruiting from primary care practices affiliated with Emory Health care, with an aim to recruit a diverse sample that includes ≥25% men and ≥30% racial and ethnic minorities.

Screening and Online Questionnaires

Individuals who respond to recruitment solicitations are directed to a web link that provides a brief overview of the study and eligibility criteria. Those who are eligible are guided to follow a link to complete 9 brief questionnaires which are outlined with their validation references in Table 1. For participant convenience, the questionnaires are administered via the REDCap (Research Electronic Data Capture; Vanderbilt University) platform so that they can be completed online in one or multiple sittings within 30 minutes. Data from the questionnaires are used for eligibility screening and will eventually allow us to examine the impact of sleep disturbance, health status, stress, and risk of depression on study outcomes. The eligibility criteria are embedded within the online surveys so that the data collection is terminated when a potential participant enters information that makes them ineligible (eg, history of stroke). Those who complete the REDCap questionnaires and remain eligible for the study are scheduled for a 20-minute phone interview, during which the Mediterranean Eating Pattern for Americans [22] screener and the PA questionnaire [20] are administered by an interviewer. Those who do not meet current PA guidelines (<150 min of MVPA per week) are scheduled for a 15-minute phone call to set up the technology that they will be using in the study.

[i]ASCVD: atherosclerotic cardiovascular disease.

[j]MVPA: moderate to vigorous PA.

Technology Set-Up, Informed Consent, and Mediation

Before the technology set-up phone call, we provide potential participants with email instructions on how to install Zoom (Zoom Video Communications; for assessments and coaching), Withings (weight, BP), and Fitbit (PA) apps. During the phone call, the study staff members verified the software installation and provided login credentials for the apps. Next, study staff members review the study procedures and those still interested in the study receive a copy of the informed consent to review and sign via REDCap. Those who consent are asked to complete the All of Us Research Program Lifestyle Survey as well as questionnaires assessing exercise self-efficacy [29], self-regulation [30], PA enjoyment [31], social support [32], and outcome expectancy [33] (Table 1). These validated questionnaires are frequently used to identify facilitators and barriers [29-33] that are known to influence PA and cardiovascular outcomes [38-41]. These questionnaires can be completed in REDCap within approximately 30 minutes and will be repeated at the 6-month follow-up visit. An optional Adverse Childhood Experiences questionnaire will be used to explore difficult childhood experiences that may impact variables of interest in the study. The participants will be asked by the study staff members to give their verbal consent to receive this questionnaire at the end of the study assessment.

Baseline Assessment Via Zoom

Participants who meet all eligibility criteria during screening are scheduled for a baseline assessment via Zoom. Before the assessment, each participant will receive a package with all supplies including a Dry Blood Spot Kit, Fitbit Charge 5, ActiGraph GT3X, Withings Arm BP Monitor, Withings Scale, Perfect Waist Tape Measure, and Stretch Band. During the Zoom visit, the study staff members review the data in the PA readiness questionnaire (PAR-Q+) [21], to ensure that individuals who need primary care practitioner clearance obtain it before they are randomized to the intervention or attention control condition. We use the HIPAA (Health Insurance Portability and Accountability Act)-compliant online Fax (SRFax, Ziff Davis Inc) to send and receive faxes on behalf of participants.

The assessments commence with the study staff members reviewing the waist circumference self-measurement video and guidelines developed by the International Chair on Cardiometabolic Risk [42]. The staff members instruct the participants to go to a private location where they can measure their waist on bare skin using the Perfect Tape Measure. The participant shows the locked tape measure to staff members via the camera. There is evidence for strong correlation coefficients (0.8 to 0.9) between self and technician-measured waist circumference using this method [43-47]. Next, the staff members instruct the participant to wear light clothing and stand on the smart scale footpads with their bare feet to measure weight, percentage body fat, percentage body water, muscle, and BMI. The study team obtains these device-recorded measures via the Withings application programming interface (API) with the PATH platform.

We use the clinically validated Withings Arm BP Monitor for self-measurement of BP [48]. The smart monitor has a one-touch easy-to-read digital screen and a cuff that fits an arm circumference of 22-42 cm (larger cuffs available on request). Staff members will instruct the participant to apply the cuff on the bare left arm, then sit in a chair with both feet resting flat on the floor, with the back straight and supported. After 5 minutes of rest with the left arm resting on a flat surface at heart level, participants will be asked to turn on the BP machine and take 3 measurements at 1-minute intervals. The study team will immediately access the device-recorded BP via Withings API with the PATH platform. Participants with elevated BP (>130/80 mm Hg) will be referred to their primary care practitioner, with a request to update the study team if treatment is initiated. Those with severe hypertension (BP ≥180/110 mm Hg) will be asked to seek urgent medical attention before re-evaluation of their eligibility.

Blood samples for measurement of adipokines (tumor necrosis factor alpha [TNF-α], monocyte chemoattractant protein 1 [MCP-1], interleukin [IL]-1 beta [IL-1β], and IL-6, leptin, and adiponectin) and lipids (low-density lipoprotein [LDL], high-density lipoprotein [HDL], and total cholesterol) are collected via volumetric absorptive microsampling approach using Mitra dry blood spot kits [49]. Study staff members supervise participants collecting the fingerstick sample following the steps outlined in the sample collection tutorial [50]. The samples are mailed by each participant to the laboratory using the included return address. Once at the laboratory, the samples are stored at –80^{o} C and will be processed at the end of the study using established protocols for analysis [51].

Run-In Period

At the end of the baseline assessment, the staff members will instruct participants to wear the ActiGraph GT3X on their waist and Fitbit on their wrist to monitor PA for a 7-day run-in period. The run-in period will help potential participants appreciate study expectations and will provide objective data on baseline MVPA. Individuals will need to wear the Fitbit and ActiGraph GT3X for ≥10 hours on ≥4 days to be eligible in the study [52].

Randomization and Orientation

After the successful completion of the run-in period, nonblinded staff members randomize eligible participants with equal allocation (1:1) to either the PATH intervention or the attention control arm using the REDCap randomization software. Group assignments are generated via a REDCap stratified randomization scheme to achieve a balance between the treatment and control groups regarding age (18-45, 46-64, and ≥65 years), sex (male or female), and race (White or racial and ethnic minorities). The Randomization scheme was developed by the study statistician. After randomization, a study staff member meets with each participant on Zoom to orient them to their randomized group resources. If blinded staff members inadvertently become unblinded, the incident will be noted in the study's log, and they will not conduct end-of-study assessments on the participant. Participants in both groups are

instructed to wear Fitbit on their nondominant hand during the study using a 24-hour wear protocol.

The PATH Intervention

A health coach will provide each participant with a password-protected profile to access the PATH website and a detailed orientation on how to use all the resources included in PATH. In addition, the health coach will meet remotely with each participant twice per month. The PATH intervention provides counsel and guidance to participants in the development of multiple behavior change strategies to promote long-term adherence to the minimum threshold of PA Guidelines (150 MVPA min/week). The Fitbit and Withing APIs are integrated with our PATH platform to enable near-real-time monitoring of the participant's progress. The interface also enables us to capture longitudinal trends in PA and to display the progress toward their PA goal on each participant's dashboard. The coach will work with each participant in the treatment group to develop their PA prescription guided by the FITT-VP (frequency, intensity, type, time, volume, and progression) principle [53], which recommends the frequency, intensity, duration, type, volume, and progression of PA. Although there are no established standards on how to increase PA, available evidence suggests that it is safe to increase MVPA by 10 minutes per week [54]. Although the weekly MVPA goal translates to about 1000 steps of moderate activity per week [55], the participants are asked to target 500 additional steps per week to make sure that the goals are safe for everyone, including those with morbid obesity.

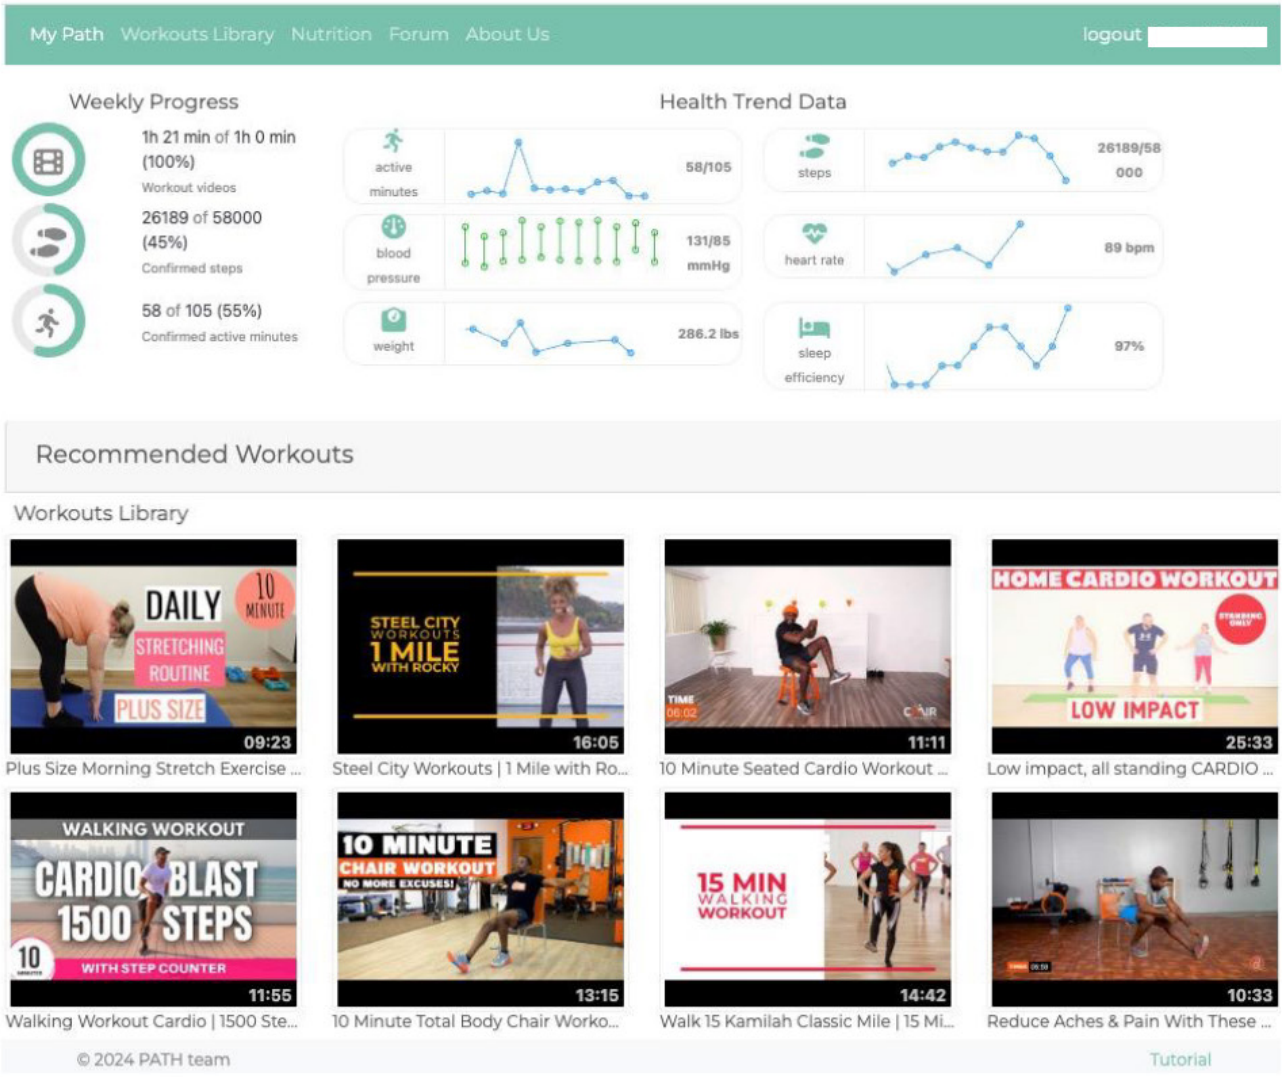
The coach works with each participant to develop a tailored plan geared toward increasing MVPA by ~10 minutes per week with each coaching encounter. Given the scheduled 12 coaching encounters during the 6-month study period, participants at all levels of fitness will have a chance to develop a PA regimen that is adherent to the PA Guidelines. Participants with relatively high baseline PA are advised to target the higher threshold of the PA Guidelines (300 MVPA minutes per week). Our PA prescription process begins by identifying a suitable PATH level for each participant based on their estimated cardiorespiratory fitness level, which is estimated using a predicted maximum rate of oxygen consumption during incremental exercise (VO_2 maximum) [53]. The VO_2 maximum is predicted using a validated, nonexercise prediction model for peak VO_2 whose covariates include sex, age, waist circumference, resting heart rate, and PA index [34].

Individuals with a predicted VO_2 maximum in the ≤35th percentile for their age and gender are considered for assignment to the Beginner PATH level (includes light-intensity PA metabolic equivalents [METs] of <30 METs). Those with VO_2 maximum above the 35th percentile rank are assigned to the intermediate PATH level, which includes moderate-intensity workouts (3.0-5.9 METs) in addition to the Beginner PATH content. Based on our pilot experience, it is unlikely that a participant will be assigned to begin at the Proficient PATH level which includes vigorous-intensity workout videos (≥6 METs). Rather, participants will be given access to the level based on their rating of perceived exertion (RPE) scores at the intermediate level and coach evaluation. The coach can change the PATH level based on their assessment of the participant's capabilities during the meetings.

After assigning the PATH fitness level, the health coach guides each participant in selecting their weekly PA goal and helps them start slowly with a plan to establish regular exercise frequencies of 3-5 days per week. The coach also guides participants to select activities with intensity to help them progress along the PA continuum (ie, from inactive to light PA and then MVPA). To foster safety, participants are instructed to use the RPE Scale [56] as a guide for adjusting the intensity of their PA regimen. The scale ranges from 6 (no exertion at all) to 20 (maximal exertion) and is embedded within each workout video on PATH. The coaches will also help participants set up Fitbit safe heart rate zones based on their fitness levels, with a goal of progressing to the Cardio Zone (70% and 84% of maximum heart rate) by the end of the study.

Participants are asked to use workouts that elicit perceived exertion ratings between 12 and 14 (ie, moderate intensity) on the RPE Scale. The coach reviews progress made every 2 weeks. More intensity is allowed, including the transition to the next PATH level, when most workouts within the assigned PATH level are perceived to be "fairly light" (≤11 on the RPE Scale). If a participant forgets to rate their workouts, their heart rate during the workout sessions is reviewed during the coaching session, and a goal that aligns with each person's capabilities is discussed between the health coach and participant. This method ensures the prescribed regimen is based on ability and fitness status. Although the health coach provides examples of workout videos that could help participants attain their personalized goals, each participant has access to all resources within their PATH level and is encouraged to select a regimen that includes their preferred workout videos and other types of PA appropriate for their fitness level. The workouts that are recommended by the health coach and those selected by each participant as favorites are featured on their PATH dashboard alongside the self-monitoring data (Figure 1).

Figure 1. Participants' physical activity for the heart platform dashboard.



The PA prescription is revised during the online meetings with the coach to reflect the progress made toward the study goal. Those who attain adherence to the PA Guidelines within the first 3 months will achieve the study goal and their plan for the remaining 3 months will be to maintain the improved PA regimen. However, each participant can opt to continue with a gradual increase in PA duration and intensity. To simplify access and support maintenance of PA, the workout videos are organized into categories (eg, walking, dance, and steps aerobics) and can be sorted by duration and METs. To reduce the risk of injury, the amount and intensity of PA are increased gradually, with emphasis on duration followed by intensity per the American College of Sports Medicine [53]. The coach, in consultation with the principal investigator (PI), may discontinue or modify any participant's PA prescription in response to the potential for harm, participant request, or improving or worsening disease. To complete the PA prescription, participants are asked to suggest their preferred schedule for receiving motivational PA reminders (eg, "Remember to work out on PATH today! Exercise doesn't have to leave you exhausted for it to make a difference in your health — M. Richardson"). The short motivational messages are randomly selected from a bank with >270 vetted messages. Also, participants are asked to provide a schedule for the Zoom meetings with a health coach to monitor progress and revise PA goals. During the study, the participants are encouraged to share their experiences on the PATH community forum to foster community and social support. An end-of-study survey will capture feedback on participant experiences and the most helpful aspects of the PATH intervention resources.

The Control Condition

After randomization, study staff members schedule a Zoom meeting with each control group participant where they are guided to use their tracker and Be Active Your Way Guide [19]. They also schedule a check-in meeting with them every 2 weeks, with the intention to keep the contact between the groups as similar as possible.

Protocols for Both Treatment and Control Arms

During the twice per month meetings with intervention and control groups, the participants receive early morning reminders to empty their bladder and step on the scale before meeting with the study staff members who supervise BP measurements on Zoom. These data are used to monitor trends in BP, weight, and body composition during the study period. Both the intervention

and control arms receive an email with a brief PDF addressing 1 diet component every 4 weeks. The diet information is also available to them as modules on the PATH platform (control group access on PATH is limited to the nutritional resources). At the end of the 6-month study assessments, both control and intervention group participants are given the option to continue using the PATH platform at their convenience without any interaction with the coaches.

Study Outcomes

Indicators of PATH Fresher Algorithm's Effectiveness in Identifying Workouts That Match User Preferences

Effectiveness of the PATH Fresher algorithm will be indicated by its ability to analyze PATH users' data, spin up new browser sessions in the background to activate the YouTube recommender system, and select new workouts like those highly rated (≥3.5/5 stars) by study users. At the end of the study, the coaches will vet the new workouts recommended by the PATH fresher algorithm. The acceptance of ≥50% of the top twenty recommended workouts for inclusion in PATH will indicate the effectiveness of the PATH fresher algorithm. The systems usability survey [37] will be completed by participants to survey satisfaction with the PATH platform.

Acceptability of the Disseminated Educational Resources Focusing on Improving Diet Quality

The resources will be curated from an extensive library of standard behavioral treatment content previously developed and validated by the SMARTER study team [57,58]. Their acceptability will be indicated by 70% of the participants rating the materials as helpful via a researcher-developed end-of-study survey (Multimedia Appendix 1).

Measures of PA and Adherence to PA Guidelines

The efficacy of PATH in enhancing adherence to PA guidelines will be evaluated at 6 months using MVPA data collected using the Actigraph GT3X device [59] worn on the waist for 7 days at 6 months. Adherence to PA guidelines will be defined as achieving ≥150 minutes of MVPA per week. Percent change in adherence will be calculated as follows: ([postintervention MVPA–baseline MVPA]/recommended MVPA×100). Between-group differences in % change in adherence and the proportion of individuals who attain the recommended MVPA will be evaluated. Established and novel methods will be used to process ActiGraph data which will be considered valid if ≥4 days with ≥10 hours of wear time are measured [59]. ActiGraph GT3X nonwear time was defined using the Choi wear time validation algorithm [60]. Fitbit valid data were indicated by ≥4 days with ≥500 steps per day as recommended by Thorndike et al [61] and Bizhanova et al [62]. Sustained PA engagement will be evaluated via Active Zone Minutes data collected via Fitbit Charge 5 and will be analyzed via the adherence strategy described above. Validation studies suggest that Fitbit is ideally suited for long-term self-monitoring of PA due to its user-friendliness and extensive use in RCTs [63].

Measures of Cardiovascular Outcomes

Cardiovascular outcomes will be indicated by change from baseline to end of 6-month study post intervention in CVD risk score calculated using the 2013 Atherosclerotic Cardiovascular Disease Risk Calculator [35]. The algorithm provides sex- and race-specific estimates for the first CVD events. The scores range from 0% to 100% with higher scores representing poor cardiovascular health status. The composite risk factors included in the algorithm are age, total and HDL cholesterol, systolic blood pressure (including treated or untreated status), diabetes, and current smoking status. These will be measured using the protocols outlined under baseline assessment. The main outcome will be between-group differences in risk score change from baseline. We will use the same strategy to evaluate changes in independent risk factors for CVD (secondary outcomes): waist circumference, weight, BP, Life's Essential 8, hemoglobin A_{1c} (HbA_{1c}), adiponectin, and lipids (total, low-density lipoprotein, and HDL cholesterol).

Sample Size Justification

Given our repeated measures study design, we anticipate some participant attrition. To ensure sufficient sample size with complete assessment through 6-months follow-up, we plan to enroll 88 participants (44 per treatment group) retaining at least 76 participants (38 per treatment group) assuming a 14% attrition through the 6-month follow-up based on attrition rates observed in the literature [64]. When estimating within-group changes to describe the effect of PATH on study outcomes using either proportions or means, with at least 38 participants per treatment group (76 total), we would have at least 80% power to detect small-to-medium effect sizes for the efficacy of the PATH intervention. For PA, this corresponds to a mean difference of 20 minutes of MVPA or 13.3% absolute change in terms of adherence to PA guidelines. For CVD risk factors, linear contrasts from either linear or generalized linear mixed modeling will be specified and estimated to compare the treatment groups on the 6-month change in CVD risk scores and risk factors at test wise (Bonferroni-adjusted) significance level of .05.

Statistical Analysis

Data will be analyzed using SAS (version 9.4; SAS Institute) to conduct exploratory data analyses for data screening, including missing data assessment, as well as repeated measures modeling, and modeling of attrition. Mplus (version 8.8; Muthén and Muthén) will be used for mediational analyses to explore possible mechanisms of action of the PATH intervention. Data will first be carefully screened with the results of these preliminary analyses informing the final analysis strategies to be applied to address study aims and exploratory analyses. Although hypotheses are stated as directional, hypothesis testing will be nondirectional with the significance level set to .05 and CI estimation at 95%. The randomness of missing data will be investigated using information on participant characteristics to help discern patterns in the missing data, identify possible missing data mechanisms, and inform strategies to handle missing data. If data are not missing at random, we will apply multiple imputations and 2 extreme case scenarios (worst or best case) to address missing data. If nonrandom missingness is suspected, we will use selection or pattern mixture modeling to explore the sensitivity of results to the assumed missing data patterns.

An intent-to-treat (ITT) approach will be used to test the efficacy of the PATH intervention on the distal outcome of adherence to the PA guidelines over time. Since key study end points are assessed at multiple time points, repeated measures modeling (eg, linear or generalized linear mixed modeling methods and or marginal modeling using generalized estimating equations as appropriate, both assuming a normal error structure) will be used to test the efficacy of the PATH intervention on the measures of adherence to the PA guidelines over time (baseline [0 months], and 6 months [long-term] follow-up). To test the hypothesis that the PATH intervention group will have greater adherence to PA guidelines compared with the attention control group, linear contrasts will be specified and estimated to compare adherence to PA guidelines between the treatment groups at 6 months relative to baseline values, respectively. The test wise significance level will be set to .05 (Bonferroni-adjusted). Point and interval (95% CIs) estimates based on linear contrasts will also be computed as both unstandardized and standardized effect sizes of the efficacy of the PATH intervention.

Analysis Strategy to Compare the Effects of the PATH Intervention on CVD Risk Factors

A similar repeated measures modeling approach as outlined above will be used to evaluate the efficacy of the PATH intervention compared with the attention control condition on CVD risk factors including CVD risk score, weight, BP, waist circumference, HbA_{1c}, and lipids at 6-month follow-up. These measures of CVD risk are either interval or ratio scaled, and a normal error structure (or following a suitable data transformation) will be assumed when modeling. As necessary, generalized linear mixed modeling assuming a binomial error will be applied to model CVD risk factors dichotomized based on clinically meaningful cut points. To test the hypothesis that the PATH intervention group will have a greater reduction in CVD risk score versus the control group, linear contrasts will be specified and estimated to compare the treatment groups on the change in CVD risk scores at 6-months follow-up relative to baseline values at a test wise significance level of .05 and CI estimation at 95%.

Data Management

Overview

All technologies to be used in this study, including the AWS web hosting platform, PATH website, Twilio, SR Fax, ActiGraph GT3X, Fitbit, and Withings apps were reviewed and approved by Emory University's Enterprise Information Security Team. The entire data collection infrastructure, including the REDCap and PATH platforms, were tested by the study team before it was deployed for data collection. Data will be stored on a password-protected computer with access limited to the staff members who monitor participants' adherence and safety, and the data management team. Access to the master list of participant names and ID numbers will be limited to the staff members who conduct the screening and intervention procedures as they need to interact with these individuals on a name basis. The staff members who do not interact with participants are blinded to name and treatment assignment. The primary outcomes will be shared in scientific conferences and peer-reviewed publications. Investigators seeking to use the deidentified data will sign a data user agreement with Emory University.

Plans to Monitor the Data to Ensure Safety of Participants and Data Integrity

A data safety and monitoring plan will be implemented to ensure the safety of all participants involved in the study and to ensure the validity and integrity of the collected data. The PI and biostatistician (in conjunction with the project coordinators and staff members), will be responsible for the execution of this plan under the oversight of a safety officer and the institutional review board (IRB). The safety officer will act in an advisory capacity to the PI and the National Institutes of Health program director. All adverse events will be documented in REDCap and reported in publications. Major adverse events will be reported to IRB following established protocols. To posttrial care or compensation for harm will be provided. The SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) checklist is provided in Multimedia Appendix 2.

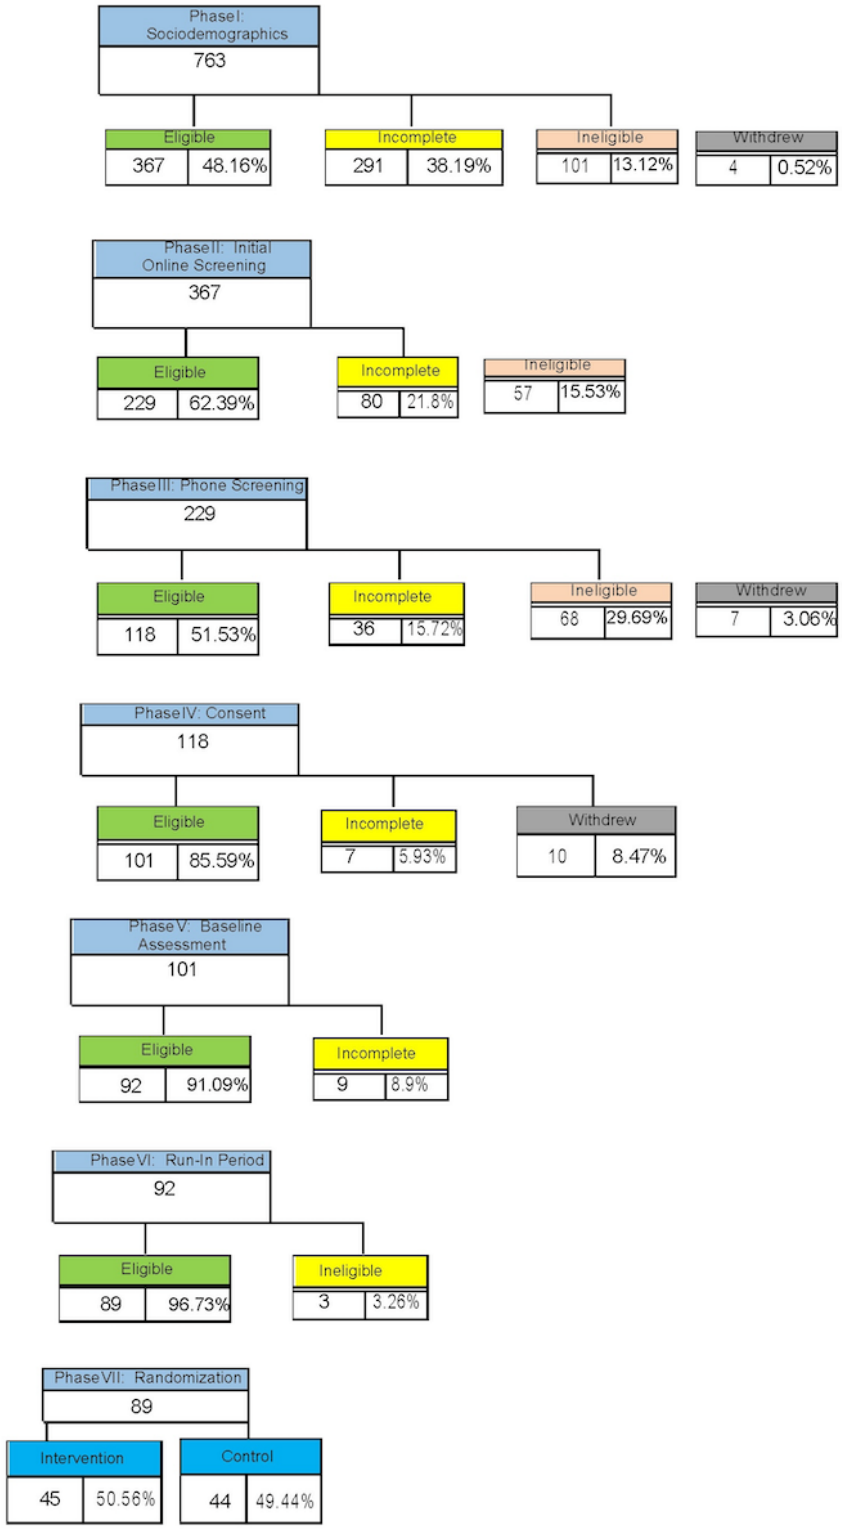
Ethical Considerations

The Emory IRB approved the study protocol before beginning the study (IRB approval #STUDY00005168). Written informed consent is obtained from all participants before participation in study procedures. Data is collected using the encrypted and password-protected REDCap and PATH platforms. Identifiable data is only stored in REDCap and is deidentified before being exported for analysis. Confidentiality will be ensured by the use of a simple ID number, which is not encoded to denote other variables. Participants received US $100 compensation and were allowed to keep their Fitbit tracker and Smart Scale for their participation in the study.

Results

We screened 763 individuals for eligibility and 89 participants were enrolled and randomized to the intervention (45/504, 50.6%) and control arms (44/504, 49.4%). The average age was 48.7 (SD 12.17) years, and most participants were female (81/504, 90.1%), Black (45/504, 50.6%), and non-Hispanic (83/504, 93.3%). No systematic differences in baseline characteristics were observed between the study arms. The 6-month intervention is currently underway, and the completion of follow-up data collection is expected in February 2025, with results to be published in the Spring of 2025. Figure 2 presents the CONSORT (Consolidated Standards of Reporting Trials) flow diagram with the screening, enrollment, and randomization details.

Figure 2. The CONSORT flow diagram.



Discussion

Anticipated Findings

The significance of addressing physical inactivity in adults with obesity cannot be overstated. The PATH intervention is testing a novel strategy for addressing the multifaceted barriers to PA among adults with obesity. Our study protocol is grounded in the understanding that traditional PA programs often fail to engage this population because they do not address their unique barriers to PA including stigma, poor fitness, low self-efficacy, unmet weight loss expectations, and limited access to relatable exercise programs [10,15]. By engaging users via tailored workout videos, online coaching, and digital self-monitoring tools, the PATH intervention offers a scalable, participant-centered, and highly accessible solution to address barriers to PA engagement among individuals with obesity. The weight-neutral messaging included in PATH programming is

intentionally designed to help participants focus on getting active without being discouraged by limited weight loss progress.

Preliminary evidence from formative studies suggests that the PATH intervention is promising in promoting PA engagement and adherence among adults with obesity [18]. The integration of personalized online coaching with a highly accessible and user-friendly web-based platform addresses key limitations of previous web-based and mobile health (mHealth) PA interventions, which often lacked the individualized support necessary to sustain long-term behavior change [10,14,16]. Our approach in this RCT aligns with that used in recent studies that have highlighted the importance of combining technology with human interaction to promote engagement and adherence in PA programs [14,18]. Moreover, the use of validated smart digital tools (eg, Fitbit tracker, Withings scale, and BP monitor) that are interfaced with the user-facing dashboard on PATH facilitates near–real-time accurate monitoring of multiple cardiovascular health indicators without increasing participant burden. These tools enable the coaches to offer timely feedback and appropriate support during online coaching sessions, helping the participants maintain PA engagement over time.

If successful in promoting PA adherence, the PATH intervention could provide a practical, scalable option that health care providers can recommend to patients who struggle with PA adherence, especially those with obesity. Because PA has been shown to reduce the risk of CVD even without weight loss [8], the PATH intervention has the potential to play a critical role in improving health outcomes in this high-risk population. The program's weight-neutral messaging encourages the participants to focus on being active with the goal of achieving cardiovascular health benefits, even if no weight loss is attained. This careful messaging is intended to mitigate unmet weight loss expectations, which are a major impediment to long-term adherence to PA in this high-risk population [12].

Understanding the mechanisms of action underlying the efficacy of PATH is highly significant. In this study, we are examining factors such as self-efficacy, social support, and outcome expectations to gain more insights into how the PATH intervention facilitates behavior change. These data will inform further refinement and optimization of the PATH platform. The next phase of optimization could leverage novel digital health technologies such as artificial intelligence for enhanced personalization to further improve the engagement and efficacy of the PATH intervention. This presents a promising opportunity for providing a more tailored and engaging experience for users, which aligns with the growing trend of technology-enhanced preventive health solutions.

This study has a few limitations that are worth acknowledging. The relatively small sample size may limit the generalizability of findings, and our eligibility criteria may favor participants with higher levels of digital literacy and access to technology. Future research should focus on addressing these limitations by conducting larger-scale trials that evaluate long-term efficacy and sustainability of PA adherence, with proactive strategies to reach populations with limited digital access. Our next logical step will be to conduct a full-scale RCT which will be adequately powered to examine if the PATH intervention can increase long-term PA and cardiometabolic health in adults with obesity. After large-scale efficacy trials, comparative effectiveness studies may be needed to determine how PATH performs relative to other web-based, in-person, or hybrid PA interventions to identify the most effective strategies for promoting PA adherence in adults with obesity. In addition, evaluating the cost-effectiveness of PATH compared to traditional PA programs or other web-based or mHealth interventions is also necessary to examine its value as a sustainable solution in real-world settings.

Moreover, future research should explore how the PATH platform can be further tailored to meet the needs of specific subgroups, such as older adults, individuals from diverse cultural backgrounds, or those with comorbidities like diabetes or hypertension. This will enhance the intervention's relevance and effectiveness for a broader range of individuals. Then, future studies can explore how the PATH intervention can be availed to health care systems to facilitate seamless referral of sedentary high-risk patients by clinicians, making PATH a more practical tool for promoting PA in routine clinical practice. Currently, there are very few options for structured PA programs that health care providers can refer their patients to beyond physical therapy.

Conclusion

In conclusion, the PATH intervention offers a promising, evidence-based approach to overcoming the barriers that have hindered previous PA programs for adults with obesity. For instance, most of the existing supervised PA programs, such as cardiac rehabilitation are usually short-term and address recovery to a baseline–rather than long-term maintenance of health-enhancing PA. By incorporating user preferences, human support, and a flexible, scalable web-based platform, the PATH intervention is poised to significantly improve PA adherence and reduce the risk of CVD in this high-risk population. If the PATH program proves to be efficacious in promoting PA among individuals with obesity, it could be an option for referral at the end of cardiac rehabilitation to promote and maintain a regular PA regimen. The findings from this RCT will contribute valuable insights to the field of research focusing on behavioral interventions to manage obesity, with potential implications for reducing the burden of obesity-related diseases. This aligns with the broader goal of preventive health care models that emphasize lifestyle modification as a cornerstone for managing chronic diseases [12,65].

Abstract

Background: The nonmedical use of prescription opioids (NMUPO) in young adults in the United States is concerning and is robustly influenced by many psychosocial factors. Given the advantages of flexibility, wide coverage, and real-time responses and assessment, using social media appears to be a promising and innovative approach to delivering psychosocial intervention to young adults. However, few theory-based social media interventions are available for NMUPO targeting this at-risk population.

Objective: Guided by the information-motivation-behavioral skills model, the proposed research aims to address critical gaps by theoretically exploring psychosocial content associated with NMUPO among young adults via formative assessment. These findings will then be used to develop and evaluate the feasibility and preliminary efficacy of a peer-led social media intervention to reduce NMUPO among young adults.

Methods: The proposed study will comprise serial research activities. First, formative research will be conducted through semistructured interviews among 30 young adults engaged in NMUPO. Qualitative data will be synthesized using a pragmatic approach for identifying psychosocial content associated with NMUPO. Second, qualitative findings will be used for developing a peer-led social media intervention to reduce NMUPO among young adults by integrating promising psychotherapy principles and incorporating them with well-trained recovery coaches. Third, the social media intervention will be evaluated through a 12-week randomized controlled trial among 70 young adults (n=35, 50% in the intervention group and control group) engaged in NMUPO via mixed methods, including pre- and postintervention surveys, social media paradata (eg, time-series reactions to posts) collection, and ecological momentary assessment during the intervention. The control group will not receive an intervention but will complete the pre- and postintervention surveys. The primary outcomes will be feasibility, usability, and acceptability, while the secondary outcomes will be psychosocial and behavioral measures, such as past–3-month NMUPO, intention, psychological distress, self-efficacy, resilience, and coping strategies.

Results: The proposed study was funded in May 2024. Social media campaigns have received responses from a total of 379 individuals, with 24 (6.3%) identified as eligible. As of February 10, 2025, we have completed formative interviews with 8 eligible participants.

Conclusions: The proposed study will be one of the first efforts to develop and deliver a theory-based peer-led intervention on social media, incorporating empirical findings on the psychosocial mechanism of NMUPO. The findings of the proposed study

will provide valuable insights into opioid risk reduction for young adults through an innovative approach. If the tested trial is found to be feasible, the proposed study will contribute to future scaled-up and fully powered psychosocial interventions among young adults and other key populations at risk for NMUPO.

KEYWORDS

nonmedical use of prescription opioids; opioid misuse; young adults; social media; psychosocial intervention; randomized controlled trial; mixed methods

Introduction

Background

The nonmedical use of prescription opioids (NMUPO) is a critical public health concern in the United States, and young adults are particularly susceptible to this behavior. NMUPO refers to the aberrant use of prescription opioids in a manner other than as prescribed [1-3]. Substance use literature has paid increasing attention to NMUPO owing to its adverse consequences. National US data have shown a substantial increase of opioid-related overdose deaths, from <5000 in 1999 to >100,000 in 2023 [4,5]. NMUPO has also led to extensive medical costs in the United States (US $78.5 billion annually) [6]. Young adults (aged between 18 and 25 y) are at a high risk for NMUPO. In 2019, 5.5% of young adults in the United States engaged in past-year NMUPO, compared to 2.3% to 3.5% for other age groups. This rate was even higher among those who were not enrolled in college (6.3%) [7]. Besides the risk of overdose and dependence, NMUPO is associated with other negative outcomes, including health-jeopardizing behaviors (eg, driving under the influence), sexual risk behaviors, and suicide attempts [1,8-11]. In response to this issue, many US jurisdictions have launched initiatives to monitor prescription opioids [12]. Despite an obvious reduction in the prescribing rate (eg, 47% in 2019 to 38% in 2023) [12], NMUPO-related deaths remain high (>100,000 in 2023). Notably, NMUPO is strongly linked with the initiation of heroin and synthetic opioid use (eg, fentanyl) in young adults, posing a substantial risk for the development of substance use disorder (SUD) and overdose [13]. Hence, interventions targeting young adults are urgently needed to address NMUPO, and those should be delivered beyond the college population [14].

Interventions for NMUPO in young adults should take psychosocial factors into account. NMUPO literature has identified several important psychosocial factors associated with NMUPO in young adults, including perceived stress (eg, academic strain and traumatic stress), psychiatric distress (eg, depression and anxiety), perception of risk, peer and family influences, and sensation seeking [15-18]. Tam and his colleagues' previous research on NMUPO in college students has indicated several additional factors that reduce risk for NMUPO, such as psychological resilience, positive coping, outcome expectancies, and self-esteem [10,19-21]. Importantly, psychosocial factors robustly contribute to NMUPO. A meta-analysis study revealed that pooled effect sizes of psychosocial factors on NMUPO (odds ratios 2.14-2.45) were higher than those of somatic symptoms (odds ratio 0.81-1.76), which are traditionally viewed as major NMUPO determinants [22]. These findings indicate that interventions should be guided by a structured framework between psychosocial factors and health actions for NMUPO.

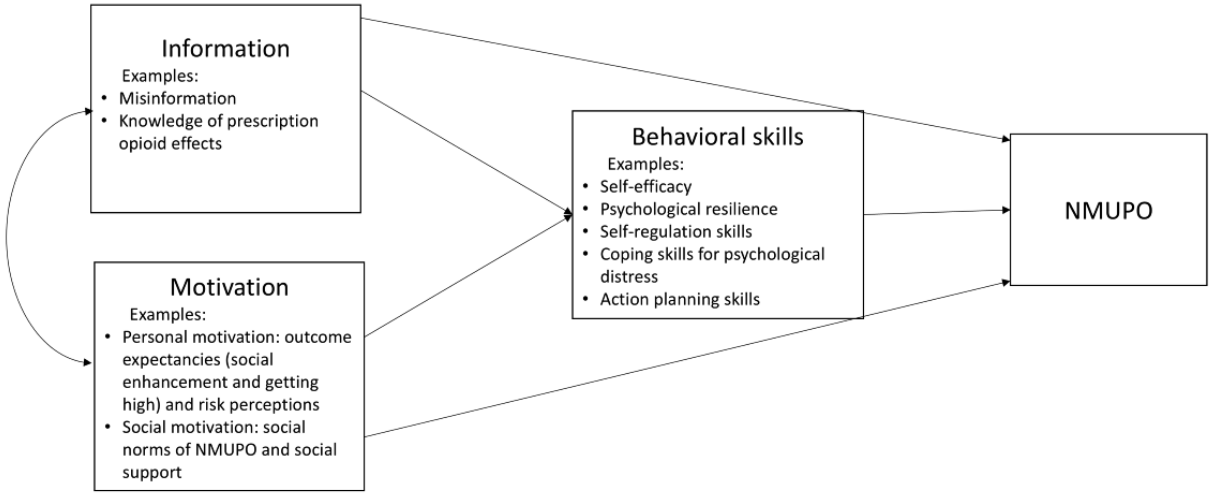
There are a handful of interventions that have been recently developed to address psychosocial aspects of NMUPO in young populations [23-25]. Although these programs have shown some efficacy, they encounter numerous challenges. First, most programs have been adapted from existing substance use interventions that were not originally designed for NMUPO. For example, some content specific to opioids (eg, the risk for overdose and pain relief expectancy) are absent from these programs, yet these factors significantly contribute to health action related to NMUPO. Second, most programs were delivered in schools and failed to target young adults who did not attend college or were difficult to reach. Third, the flexibility of these interventions was limited because they were delivered by professionals in an in-person setting. Furthermore, literature on substance misuse prevention in young adults has revealed several drawbacks to the in-person context, such as limited trust and fear of being stigmatized [26]. These challenges highlight the critical need for an innovative intervention that is based on psychosocial theory, tailored to the NMUPO context, and flexible in real-world settings.

Psychosocial Theoretical Framework for an NMUPO Intervention

To guide an intervention addressing psychosocial aspects of NMUPO, a theoretical framework (Figure 1) was developed based on the information-motivation-behavioral skills (IMB) model [27]. The IMB model has been applauded for its strength in considering a straightforward path diagram for health behavior changes [28]. This model emphasizes that health behavior changes are driven by 3 arrays of psychosocial constructs—information, motivation, and behavioral skills. Information refers to knowledge contributing to a prerequisite for enacting the changes (eg, misinformation of opioids). Motivation includes 2 belief components: personal motivation (eg, outcome expectancies and risk perceptions) and social motivation (eg, social norms and support). Behavioral skills stand for cognitive capacities (eg, self-efficacy and resilience) and behavioral skill sets necessary for adopting the changes (eg, coping or self-regulation skills) or for managing barriers (eg, stress management) [27,28]. Information and motivation can directly affect the target behavior as well as indirectly affect it

through the acquisition of adjacent behavioral skills. Such a well-structured framework offers clear guidance for intervention practices and suggests that intervention delivery could benefit from targeting information and motivation factors in the initial sessions, along with enhancing the role of behavioral skill training gradually in the intervention. For instance, initial efforts ought to address misinformation and outcome expectancies of substance use, and, as the intervention progresses, sessions should facilitate action by helping participants develop planning strategies and coping skills. Indeed, existing evidence has shown the efficacy of IMB-guided interventions in reducing substance use (ie, tobacco and illicit drugs) [29-32]. Thus, the IMB model is an ideal theoretical choice for developing an intervention for NMUPO.

Figure 1. Theoretical framework for the proposed study. NMUPO: nonmedical use of prescription opioids.



Social Media as a Promising Platform for an NMUPO Intervention Targeting Young Adults

The rapid development of social media technologies provides a novel tool for substance use interventions. Increasing substance use literature has highlighted the significant potential of social media, in which individuals can obtain substance use knowledge, communicate their experiences and thoughts of substance use problems, and seek out social support from peers with similar problems through available networks or groups [33,34]. It is worth noting that social media offers distinct merits in addressing existing challenges in interventions for NMUPO in young adults. First, recent research has validated the use of social media to reach people who engage in NMUPO from multiple venues across the United States [35,36]. Ubiquitous connectivity enables interventions to deliver content remotely to young adults who are not enrolled in college and, therefore, not able to access traditional models of education on safe substance use. Second, social media allows interactive posts in multiple formats (eg, texts, images, polls, and videos) and with customized functions (eg, internet-based goal setting tools and notifications) without time restrictions. This can facilitate exposure to intervention content at the time when participants choose to engage [37]. Third, social media technologies are applicable to timely measurements, such as ecological momentary assessment (EMA) and paradata (eg, auxiliary data of engagement [frequencies of shares, comments, and "likes," etc] analyses) [38,39], which allow tracking of intervention usability and acceptability on specific modules in real time. Extant literature has shown that EMA has been applied in intervention research for substance use reduction and psychosocial improvements [40]. Fifth, social media is extremely popular among young adults. The latest national data indicate that 72% of US adults use social media, most of whom are young adults (84%) who use it daily (70%) [41].

Another notable feature of social media is that it is significantly favorable for the peer role model, which has been a robust intervention approach for reducing substance use, particularly among young adults [42]. Existing evidence has demonstrated that social media interventions are effective in promoting behavior change for stigmatizing behaviors, including substance use, with perceived peer influence and support playing an important role in the change [43]. Accordingly, emerging peer-led intervention programs have been initiated on popular social media platforms among young adults (ie, Instagram [Meta Platforms, Inc], Facebook [Meta Platforms, Inc], Snapchat [Snap Inc], and Twitter [subsequently rebranded X; X Corp]) and have indicated good feasibility and preliminary efficacy in reducing various substance use behaviors (eg, risky drinking, cigarette use, and cannabis use) [37,42-47]. Notably, promising findings have also been reported for NMUPO reduction. Young et al [45] conducted a pilot study of a peer-led trial on Facebook for patients with chronic pain, who were randomly assigned to the peer-led intervention group or the control group (with no peer leaders) The preliminary results suggested higher engagement and more discussion on NMUPO and coping in the intervention group than in the control group. Taken together, the advantage for the peer role model with other promising aspects, social media appears to be a promising platform for NMUPO intervention among young adults, and such programs would be strongly powered by psychosocial theory–guided content and peer-led modules.

The Aims of This Study

Overview

This study proposes to develop and pilot-test a theory-guided, peer-led social media intervention on Instagram as well as examine its feasibility and preliminary efficacy among young adults engaged in recent NMUPO via a randomized controlled trial (RCT). The assessments will use mixed methods to collect various types of data, including qualitative assessment of semistructured interviews; psychometric measures in pre- and postintervention surveys; real-time paradata on social media platforms; and brief, timely measures in EMA surveys during the intervention. The specific aims are mentioned below.

Aim 1

Aim 1 involves conducting a formative study to inform a theory-based social media intervention for NMUPO among young adults in the United States. By collaborating with 4 peer leaders trained as "recovery coaches," the proposed study will recruit 30 young US adults (aged 18-25 y) who engage in NMUPO from social media (eg, Instagram) and conduct in-depth semistructured interviews to explore psychosocial content associated with NMUPO. The interviews will be guided by the IMB model.

Aim 2

Aim 2 involves developing a theory-based social intervention to reduce NMUPO among young adults. The intervention will be developed upon findings from the formative study and based on several promising strategies (eg, peer support group, ambivalence resolving techniques, interactive training modules, internet-based goal setting, and video modeling). It will be delivered via Instagram private groups by peer leaders, with close supervision provided by experts and clinicians in the fields of health psychology and addiction medicine.

Aim 3

Aim 3 involves testing the feasibility and preliminary efficacy of the theory-based social media intervention with a randomized controlled design for NMUPO among young adults. Participants who engage in recent NMUPO will be randomly assigned to 1 of the 2 parallel groups, including the intervention group (35/70, 50%) and control group (35/70, 50%), using a 1:1 allocation ratio. The intervention will be evaluated in terms of feasibility, usability, acceptability, engagement, dose, and preliminary efficacy using mixed methods (eg, surveys, EMA, paradata, and semistructured interviews). During the intervention, EMA (a prompt every 2 days) will assess the acceptability and usability of individual modules. Preliminary efficacy will be tested on behavioral outcomes (ie, past-month NMUPO) and psychosocial factors (eg, outcome expectancy, self-efficacy, action or coping planning, resilience, and psychiatric symptoms).

Methods

Research Settings and Participants

Research Platforms

The proposed formative and intervention study will be conducted on Instagram, which is a popular social media platform for young US adults (71% use) [41,48] and home to many support groups for substance use prevention and reduction [49,50]. Recruitment sites will expand to Snapchat and Facebook (>65% use) [41], which are identified as useful recruitment sources for substance use prevention in young US adults [51,52]. As a pilot study for a cross-platform trial, the module prototypes will be developed based on Instagram features available on other platforms (eg, live streaming, voting polls, group chatting, and multimedia posting). Recent interventions developed on these features indicated efficacy on behavioral changes, including drug use [37,45,46,53-56].

Peer Leaders

The study will engage 4 peer leaders who are serving in recovery programs at substance use–related associations or communities for young adults (ie, Gamecock Recovery at the University of South Carolina). The study takes advantage of this model in various aspects, including recruitment and intervention development or delivery. Eligible leaders will be those who are (1) aged between 18 and 25 years, (2) formally trained as a recovery coach (>40 h), (3) have had successful recovery from opioid misuse or opioid use disorder, and (4) use social media (eg, Instagram, Facebook, and Snapchat) on a daily basis. The health psychologist and addiction treatment experts and doctoral-level clinical psychology trainees at the Integrated Care for Recovery (I-CaRe) Training Center at the University of South Carolina will provide training and ongoing support for the peer leaders. e-gift cards will be provided to compensate for their time (US $2 for each recruitment; US $30/h for intervention).

Participants and Recruitment

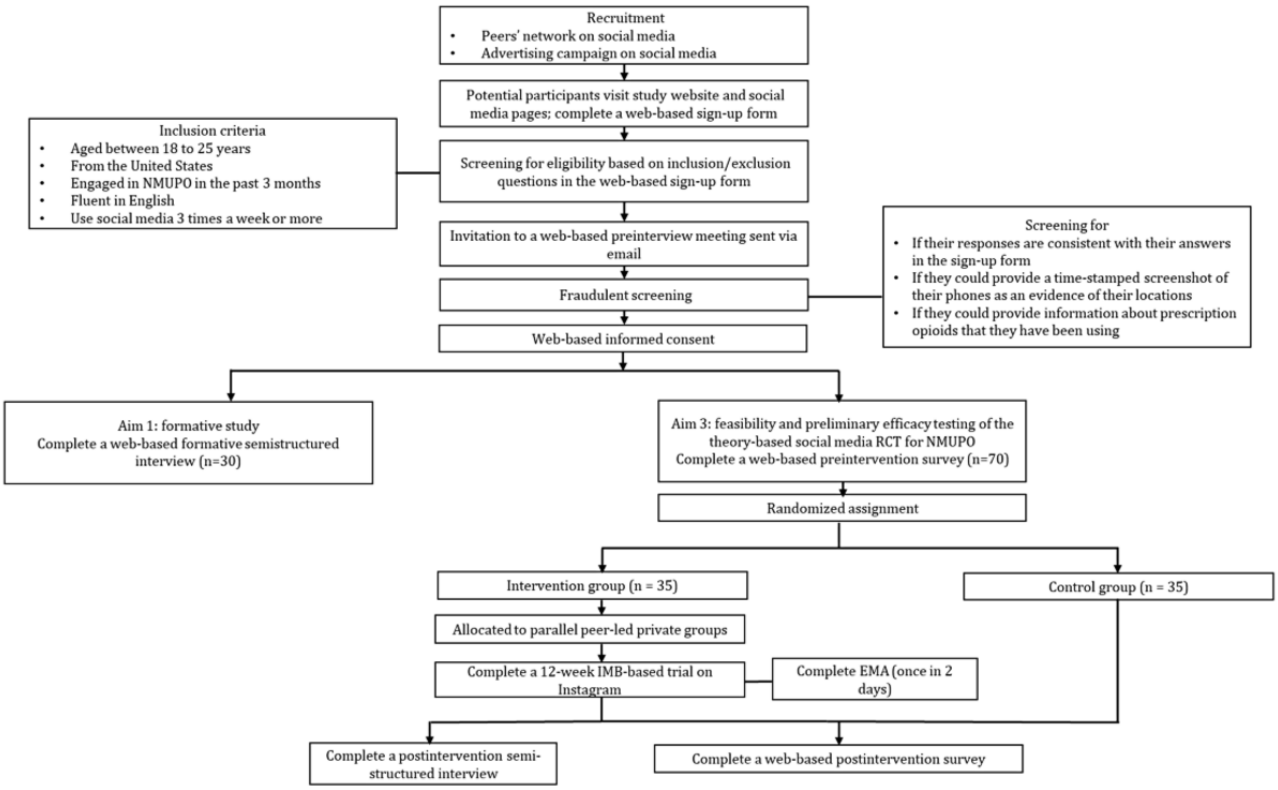
Participants for the formative study and intervention trial will be those who meet the following inclusion criteria: (1) aged between 18 and 25 years, (2) US residents, (3) engaged in NMUPO in the past 3 months, and (4) using Instagram at least 3 times a week in the past 3 months. NMUPO refers to the occurrence of the following behaviors (1 time or more): (1) taking a prescription opioid without a prescription, (2) taking more doses than prescribed, and (3) using opioid for a nonmedical reason (eg, getting high) [1-3]. Individuals will be excluded if they report (1) receiving substance use interventions in the past 3 months, (2) being diagnosed with SUD, or (3) not being proficient in English. We anticipate a total sample size of 100, with 30 for the formative study and 70 for the intervention trial.

The entire recruitment procedure is presented in Figure 2. Recruitment will be conducted using two strategies: (1) peer outreach and (2) advertising campaigns. For the peer outreach approach, peer leaders will distribute recruitment advertisements via online social networking (eg, posting advertisements on their social media accounts and inviting subscribers to repost the advertisements). Peers can also send direct invitations to young adults who they personally know to be eligible for the study. For advertising campaign approaches, we will target the accounts (on Instagram or Facebook) of colleges, local young adult communities (eg, trade unions), and substance use support groups. Upon approval from their group administrators, we will post advertisements in the groups. In addition, we will develop

targeted advertising using Ads Manager (Meta Platforms, Inc) [57]. The advertisements will display research-relevant images, hashtags, and headings, which are tailored to engaging content for young adults. To ensure appropriateness, the advertisements will be reviewed by a community advisory board. The advertisements for aim 3 will be improved in line with formative research. The Ads Manager will also determine the range of the advertisement campaign in terms of age, time, and locations (ie, the United States). The designed advertisements will be delivered in various formats dependent on the platforms, such as linear posts within personal feeds on Instagram, news feeds on Facebook, and stories on Snapchat. To ensure representativeness, recruitment will be stratified based on key demographics (eg, gender, race or ethnicity, and education) in line with the latest US national data on NMUPO [58]. The advertisements will navigate potential participants to a web-based sign-up survey on REDCap (Research Electronic Data Capture; Vanderbilt University), which is a secured web-based platform monitored by the University of South Carolina. The prescreening survey will include questions in terms of age, past–3-month NMUPO (National Institute on Drug Abuse [NIDA]–Modified Alcohol, Smoking and Substance Involvement Screening Test [59]), US residency, use of social media, and SUD diagnosis or treatment history. Participants who are identified as eligible will provide their preferred contact method (eg, Zoom [Zoom Communications, Inc]) in the survey for a brief preinterview online meeting with the study team for a fraudulent screening. Such a screening will be conducted by checking for inconsistencies in their responses, requesting time-stamped screenshots to prove their locations, and asking for information (eg, brand names) of prescription opioids that they have been using. Eligible participants with no fraud responses will then be invited to complete web-based informed consent. Young adults enrolled in the study will be provided with instructions for interviews (aim 1) or intervention (aim 3).

Our recruitment approaches are considered feasible according to existing data. Feasibility research examined the advertising campaign approach on Facebook to reach young adults engaged in NMUPO, showing that it successfully recruited 689 participants over 2 weeks (91% past-year misuse) [35]. The US national data indicate that the majority of young people with NMUPO do not have SUDs (2801/3257, 85.9%) [60]. Previous substance use studies indicated retention rates of 75% to 93% among young adults reached by social media [46,53,61].

Figure 2. CONSORT (Consolidated Standards of Reporting Trials) flowchart of the proposed study. EMA: ecological momentary assessment; IMB: information-motivation-behavioral skills; NMUPO: nonmedical use of prescription opioids; RCT: randomized controlled trial.



Study Design and Procedures

Aim 1: Formative Study

Young adults who are social media users (eg, Instagram and Facebook) and indicate NMUPO will be invited to web-based 60-minute individual semistructured in-depth interviews. The interview guide will be based on the IMB model and aim to (1) identify NMUPO patterns (eg, drug classes and individual behaviors), (2) understand psychosocial factors contributing to reducing NMUPO, (3) extract vivid examples related to psychosocial content, (4) identify planning processes and coping skills facilitating the change, (5) assess the feasibility and acceptability of social media to manage NMUPO, and (6) review recruitment advertisements. This will provide the foundational knowledge and materials to develop specific content (eg, video and posts) for the intervention. The interviewers will be trained research assistants from the fields of psychology or public

health. As suggested by the guideline of qualitative research [62], the sample size will be 30 young adults.

Interviews will be audio recorded, transcribed, and coded using a pragmatic approach. The framework analysis [63] will be performed via a deductive process, including five key steps: (1) familiarizing the data, (2) developing a coding scheme, (3) condensing and structuring the data, (4) rearranging the coded data and comparing patterns, and (5) mapping and interpretation [64]. A codebook will be developed based on step 2 as a guide for coding. Coding disagreements will be resolved through group discussion. Data analysis will be conducted on NVivo (version 11.0; Lumivero). Interrater reliability will be assessed throughout the coding process with a goal of ≥0.80 [65].

Aim 2: Intervention Development

Intervention Strategies

The intervention will apply various principles in psychotherapy. The intervention materials (texts, videos, and images) and activities will be developed using the findings from the formative study. To address particular factors in the IMB model, it will be based on peer support for behavioral change, motivational interviewing (MI) [66], cognitive behavioral therapy (CBT) [67], and solution-focused therapy (SFT) [68], which have been widely applied in substance use interventions [69-71]. Peer support is promising for facilitating social support and skill coaching [72]. MI is used to resolve cognitive ambivalence (eg, positive expectancies of substance use vs the benefits of making change), which is particularly beneficial for promoting motivation [73]. CBT is widely applied to distress management by reframing negative thoughts and facilitating adaptive coping [74]. SFT emphasizes a focus on problem-solving and is favorable for setting concrete goals (action planning) [75,76]. This content and these activities will be packed in different modules.

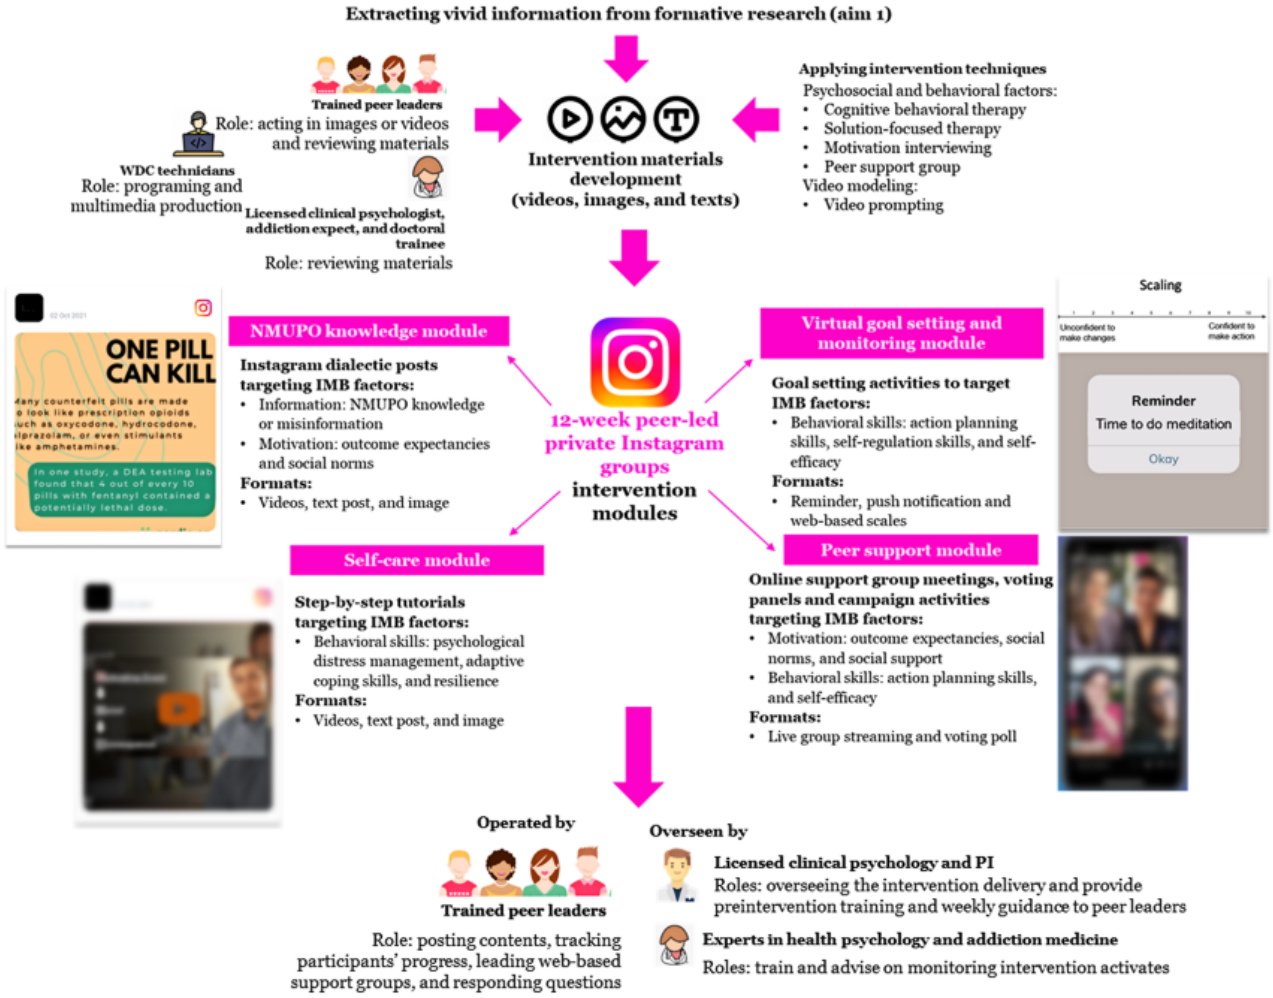
Incorporating inputs from peer leaders, the video content will follow a video prompting strategy [77]. Videos will feature peer leaders and involve breaking tutorials into steps, allowing young adults to learn and rehearse cognitive and behavioral skills in a sequential fashion. For example, guided by CBT, a peer leader may lead participants may lead participants to reflect on the context, thoughts, and consequences, related to their last experience of NMUPO, and then practice adaptive responses (eg, positive reframing and replacement behaviors). Video prompting has been effective for skill coaching in young adults [78].

Intervention Components

Overview

The proposed intervention components are guided by the IMB-based conceptual framework (Figure 1), with each component targeting specific factors derived from 3 psychosocial constructs (ie, information, motivation, and behavioral skills). As outlined in the framework, the pacing of intervention is structured to prioritize addressing information and motivation factors during the initial phases, while later sessions progressively promote behavioral skill training that contributes to psychological distress management and NMUPO reduction. Incorporating Instagram functions, the intervention platform is proposed to consist of four intervention modules, including (1) NMUPO knowledge module, (2) self-care module, (3) internet-based goal setting or monitoring module, and (4) peer support module (Figure 3). These are planned, and final content will be informed by or modified in line with the formative research. The research team will work closely with the community advisory board and peer leaders to ensure appropriate content and language. The intervention will last 12 weeks according to previous social media trials (typically 8-12 wk) [37,44,79-86]. Clinicians will review the intervention materials and ensure the scope is appropriate. Content will be prompted daily as suggested by the IMB model (eg, initially focus on information and motivation factors and gradually enhance the role of behavioral skills).

Figure 3. Planned intervention modules and strategies. I-CaRe Training Center: Integrated Care for Recovery Training Center; IMB: information-motivation-behavioral skills; NMUPO: nonmedical use of prescription opioids; PI: principal investigator; WDC: Web Development & Communication.



NMUPO Knowledge Module

A self-paced psychoeducation module will be developed targeting information and motivation factors. This module will provide the latest information about prescription opioids (eg, illicit manufacture and the role of fentanyl, naloxone, and xylazine) and the harms of NMUPO, introduce the benefits of use reduction, and clarify misconceptions. Each component will display vivid stories drawn from the formative study and delivered via multiple formats, including images, videos, and text. Participants can react to the posts by leaving comments or by liking the posts. The majority of the content will be based on MI strategies (eg, ambivalence resolution). This media campaign strategy, combined with prevention education, has been identified as an essential approach for reducing NMUPO in young adults [25].

Self-Care Module

This module will provide tutorial materials on behavioral skills for managing psychological distress and identifying strengths to make changes. Material formats (videos, texts, and images), duration, and content will be determined by the findings from the formative study. For example, serial 3-minute tutorial videos will introduce CBT strategies for reframing negative thoughts (eg, "I'm a total failure") and exploring intrapersonal or interpersonal strengths (eg, resilience). Tutorials will be step-by-step based, allowing participants to role-play and rehearse, presented with vivid examples extracted from the formative research (aim 1). Such a self-guided CBT component has proven effective in reducing psychiatric distress [87].

Internet-Based Goal Setting or Monitoring Module

This module aims to enhance action planning skills to reduce NMUPO. Specifically, it will assist young adults with setting personalized goals associated with NMUPO reduction and tracking progress toward meeting the goal. Web-based activities will be developed using SFT strategies. For example, the video will guide using scaling questions, which help participants identify their confidence levels to stop NMUPO and make a realistic plan based on it. Participants will then be instructed to explore barriers and their corresponding coping strategies for moving up the scale. Peer leaders will track their progress and provide support via online support group meetings. In addition, tutorials will instruct participants to set daily reminders or notifications on their devices (eg, mobile phone) to monitor the progress. This virtual self-monitoring has been a promising strategy to manage psychiatric distress and substance use [88].

Peer Support Module

This module will provide interpersonal activities for discussing NMUPO, sharing strategies, monitoring progress, providing social support, and increasing self-efficacy to take action, with themes based on the aim 1 findings. Activities include weekly (30 min) online support groups, discussion polls, and campaign activities. Online support groups are live video meetings led by peer leaders and assisted by doctoral-level clinical psychology trainees at the I-CaRe Training Center, who will be overseen by a licensed clinical psychologist and principal investigator (PI), under supervision from experts in health psychology and addiction medicine (SH and AHL). Each meeting will discuss personal practices related to content in that week. Peer leaders will use techniques (eg, active listening, insights, and interpretation) [26] to facilitate cohesion and provide feedback. Discussion polls will be voting activities (eg, selecting adaptive coping skills), aiming to stimulate discussions. Campaign activities will be held weekly with target-orientated themes (eg, "#healthy coping challenge") to boost posting. Participants will be encouraged to leave comments and peer leaders will promptly provide feedback.

Intervention Encouragement and Monitoring

Several strategies that are shown to be useful for enhancing engagement will be used [82,84,89-92]: (1) reminder notifications (via Instagram or emails); (2) prompt replies to participants' messages; and (3) biweekly prize draws of US $25 gift cards for those who post, attend meetings, and reply on the panels. The intervention will be overseen by PI and a licensed clinical psychologist at the I-CaRe Training Center, under supervision from experts in addiction medicine and psychotherapy for SUD. They will provide preintervention training (eg, skills in MI or CBT techniques and findings from aim 1) and weekly guidance to peer leaders. They will also advise on referrals to link participants to licensed mental and behavioral health professionals in their states of residence if necessary. The doctoral-level psychology trainees at I-CaRe Training Center will support intervention delivery by (1) ensuring conversations are intervention related and banning inappropriate content; (2) promptly replying to participants' comments; and (3) monitoring participants' safety (eg, emotional reactions to the posts and in the online group meetings) and offering referrals for outside psychological services, if needed. They will also be responsible for reporting adverse events to the PI if observed.

Aim 3: Intervention Feasibility and Preliminary Efficacy Evaluation Study

RCT Design

The intervention modules will be tested through an RCT design using mixed methods in 70 young adults who engage in NMUPO [93]. The primary purpose is to determine acceptability, usability, feasibility, and initial efficacy. Participants reached by peer leaders or advertisements on social media will be navigated to a screening survey on REDCap and scheduling a meeting with the research team for informed consent. Participants will be required to comply with the user safety agreement. Participants will be randomly assigned to the parallel intervention (35/70, 50%) or control group (35/70, 50%) using computer-generated random numbers. Participants are blinded to the randomized assignments. Intervention group will be guided to join Instagram peer-led private groups (n=10-15 each). Participants will be asked to provide their Instagram accounts to their assigned peer leaders for participating in intervention activities. Peer leaders will set up private and independent groups via their Instagram accounts and will send direct invitations to their assigned participants to join groups. Once group membership is confirmed, peer leaders will post intervention materials and lead group activities according to the plan as developed in aim 2. Private groups will synchronously deliver intervention packages over 12 weeks. To ensure confidentiality, participants will be assigned unique study IDs, which will be used for data collection and intervention activities. The intervention group will participate in data collection through multiple formats, including Instagram paradata, pre- and postintervention surveys, EMA surveys, and postintervention semistructured interviews.

The control group will not engage in any intervention activities but will complete the pre- and postintervention surveys.

Web-Based Pre- and Postintervention Surveys

The web-based pre- and postintervention surveys will be developed and administered on REDCap [94] to measure demographic variables as well as psychosocial and behavioral factors outlined in the IMB-based conceptual framework. Factors include NMUPO behaviors (past–3-month NMUPO) and information- and motivation-related factors (ie, NMUPO knowledge, NMUPO risk perception, outcome expectancies, self-efficacy, psychological distress, resilience, and other substance use). Web-based surveys will be conducted among participants in both the intervention and control groups. Participants will receive survey links via inbox messages to the Instagram accounts they provide for the study. The preintervention survey will be sent 2 weeks before the intervention (baseline), and the postintervention survey will be sent in the week immediately following the intervention (12-week follow-up). The survey will be self-administered and take approximately 20 to 30 minutes to complete. If participants cannot complete the surveys at one time, they can save their responses, and the platform will generate a code that allows them to resume the survey within the same week. The survey will also provide forward and back buttons, allowing participants to review and change their responses before they submit their surveys. Study IDs and filling time will be collected for determining duplicate entries. e-gift cards will be provided for the completion of surveys (baseline and 12 weeks; US $30 each).

Use of EMA

EMA will be used through brief evening surveys to screen the prompt acceptability and usability (the Usefulness, Satisfaction, and Ease of use questionnaire) [95] and the dose of particular modules in the intervention group. The EMA survey will be conducted once every 2 days during the intervention. The daily EMA is widely used in behavioral trials [39]. Data will be collected via a 20-second survey on a smartphone app (ExpiWell), which is user-friendly and customizable for EMA development and implementation [96]. A prompt will be sent

at the moment for assessment and tailored for the intervention materials in the past 2 days. A reminder will be provided if no response is made in 30 minutes. For safety purposes, if an EMA occurs during an incompatible activity (eg, driving), participants will be instructed to ignore or postpone the prompt.

Postintervention Semistructured Interviews

At week 12, participants will join semistructured interviews measuring (1) feasibility, usability, and acceptability and (2) reactions to the content, format, concepts, visual presentation, assessments (survey and EMA) and adaptation to other platforms. The interview guide will be based on mobile health (mHealth) studies [97]. The interview will be audio recorded and take approximately 60 minutes via an online meeting application (eg, Zoom).

Measures

Mixed Methods Measures for Primary Outcomes: Intervention Feasibility Outcomes

Multiple forms of data will be collected within 12 weeks during the intervention for the intervention feasibility evaluation.

Feasibility, Acceptability, and Usability

Mixed methods will be used. Acceptability will be assessed using EMA on Likert items that rate how helpful the module is (1=not at all to 5=extremely). Usability will be measured using EMA on the Usefulness, Satisfaction, and Ease of use questionnaire [95], which assesses perceived usefulness, satisfaction, and ease of use for the module. At week 12, participants will join semistructured interviews measuring (1) feasibility, usability, and acceptability and (2) reactions to the content, format, concepts, visual presentation, assessments (survey and EMA), and adaptation to other platforms. The interview guide will be based on mHealth studies [97].

Engagement

Paradata on participants' interactions with specific modules will be collected, including their frequency of reactions (ie, comments, "likes," questions, and replies on specific posts) and personal posts to Instagram groups [37]. Retention will be assessed by calculating the percentage of participants engaging in the group at varying time points. Data will be collected in real time.

Dose of Intervention

Participants' engagement in particular intervention modules will be measured in EMA surveys as guided by dose operationalization for mHealth interventions [98]. Dose for specific modules will be assessed in three domains (1 yes or no item each): (1) intervention actions (if viewing a post), (2) participant actions (if practicing a skill or completing an assignment), and (3) behavioral target actions (if adopting skills outside of the intervention).

Web-Based Surveys for Demographic Variables and Secondary Outcomes: Psychosocial and Behavioral Outcomes

The web-based surveys will measure demographic factors and psychosocial and behavioral factors outlined in the IMB-based conceptual model (Figure 2).

Demographic Characteristics

In the baseline preintervention survey, participants will be asked to report their background information regarding gender (ie, man, woman, transgender, or other), race or ethnicity (eg, White or African American or Black), age (y), socioeconomic status, education, family or household characteristics, and physical health status (Patient Health Questionnaire-15) [99].

NMUPO Measurement

The past–3-month NMUPO will be measured using relevant items from the Tobacco, Alcohol, Prescription medication, and other Substance use tool [100]. The scale includes 2 sections, with a screener followed by a brief assessment. The screener contains 1 item asking the frequency of NMUPO (ie, used just for feeling, more than prescribed, or without a prescription) with 5 response options (daily or almost daily, weekly, monthly, less than monthly, or never). Participants with a response other than "never" will be led to the brief assessment, including 3 dichotomous questions regarding their level of use, dependence, and concern from others related to the past–3-month NMUPO. The sum score of the brief assessment will be calculated, with a higher score indicating a greater level of NMUPO.

NMUPO Knowledge

Information about NMUPO and relevant topics, such as misconceptions, the role of fentanyl, naloxone, and xylazine, will be assessed using the NMUPO knowledge scale [61]. This scale will be developed according to the measure in POP4Teens and the formative study. This scale is proposed to include 15 statements related to opioids or NMUPO. Participants will be asked to determine if a statement is true or not (0=false and 1=true). Responses will then be rated by the research team, with higher scores indicating better knowledge of NMUPO.

Outcome Expectancies

Beliefs on positive or negative consequences of engaging in NMUPO will be assessed using a scale adapted from the Behaviors, Expectancies, Attitudes, and College Health Questionnaire [101]. A total of 50 items will be scored on a 5-point Likert-type scale ranging from 0 (not at all) to 4 (very often or always), with higher sum scores standing for the greater level of expectancies. The scale consists of 8 dimensions related to specific expectancies of opioids, including pain reduction, tension reduction, academic preference, emotion enhancement, social enhancement, guilt and dependence, cognitive impairment, and physical discomfort.

NMUPO Risk Perception

Perceived susceptibility and severity of engaging in NMUPO will be assessed using the Perceived Risk Scale for Prescription Drug Abuse [102]. This scale includes 5 items with 4 rating options (1="strongly disagree" and 4="strongly agree"). The

sum score will be generated, with a higher score indicating a greater level of perception risk for NMUPO.

Action Self-Efficacy and Coping Self-Efficacy

Perceived control on making actions to stop or reduce NMUPO or confidence on coping with barriers against the actions will be assessed using an adapted version of the Self-Efficacy Scale [103]. A total of 6 items will be rated on a 5-point Likert scale (1=strongly disagree and 5=strongly agree) and can be organized into 2 subscales (coping self-efficacy and action self-efficacy) with 3 items each. The sum scores will be generated for each subscale, with higher scores indicating greater levels of self-efficacy.

Psychological Distress

Depression and anxiety symptoms in the past 2 weeks will be assessed using the Patient Health Questionnaire-9 [104] and Generalized Anxiety Disorder-7 [105], respectively. The Patient Health Questionnaire-9 is composed of 9 items asking the frequency of depressive mood experiences (eg, “feeling down, depressed, and hopeless”), while the Generalized Anxiety Disorder-7 comprises 7 items assessing the frequency of feelings of nervousness or worry (eg, “not being able to stop or control worrying”). Two scales have 4 response options ranging from 0 (not at all) to 4 (nearly every day). Sum scores for 2 scales will be generated, with higher scores indicating greater levels of depression or anxiety.

Resilience

The Connor-Davidson Resilience Scale will be used for assessing psychological resilience [106]. This scale has 25 items asking about personal capacities in response to stress, including tenacity, tolerance of negative affect, positive acceptance of change, and positive view of adversities. Items will be rated on a 5-point scale (1=not at all and 5=nearly all the time). The sum score will be generated, with a higher score indicating a greater level of resilience.

Other Substance Use

The engagement in the use of alcohol, illicit drugs, and cigarettes in the past 3 months will be assessed using the NIDA-Modified Alcohol, Smoking and Substance Involvement Screening Test [59]. The scale includes 12 dichotomous items (0=no and 1=yes) asking if a participant has engaged in using or misusing any of 12 individual substances.

Data Analysis

The intervention trial will use multiple data analytic methods according to the format of the data.

Qualitative Analyses

Postintervention interviews will be audio recorded, transcribed, and coded using a pragmatic approach. The framework analysis [63] will be performed via a deductive process, including five key steps: (1) familiarizing the data, (2) developing a coding scheme, (3) condensing and structuring the data, (4) rearranging the coded data and comparing patterns, and (5) mapping and interpretating [64]. A codebook will be developed based on step 2 as a guide for coding. Coding disagreements will be resolved through group discussion. Data analysis will be conducted by the PI and graduate assistants on NVivo (version 11.0). Interrater reliability will be assessed throughout the coding process with a goal of ≥0.80 [65]. Analyses for postintervention interviews will synthesize the comments on feasibility, acceptability, and usability of the intervention, as well as summarize suggestions for improvements.

Quantitative Analyses

Bivariate Analyses

Data of web-based surveys (ie, before and after intervention) will be screened for missing data, outliers, and normality. If data are not missing (completely) at random or have a high missing rate (>5%), multiple imputation will be used [107]. Transformations will be conducted if violating normality (square root for moderate skew or log for greater skew). Attrition tests will be used (ie, chi-square tests and ANOVA) on demographics and outcomes at baseline. Descriptive statistics will be reported on primary (feasibility outcomes) and secondary outcomes (psychosocial and behavioral outcomes).

Multivariate Analyses

Preliminary outcomes from baseline and 12 week will be tested using repeated measures analysis of covariance, controlling for demographics. EMA data will be tested using multilevel modeling (ie random-coefficient regression model) to examine intervention usability and acceptability, capable of incorporating tests of time-serial characteristics, including linear trend over time and cyclicity. Before multilevel modeling, unconditional means models will be tested for between- and within-participant variation in each measure and determination of appropriate within-person error covariance structure [108].

Mixed Method Analysis

Qualitative and quantitative data on feasibility will be triangulated with a complementary proposition [109], in which the qualitative findings will provide in-depth understanding for the quantitative results in terms of intervention feasibility outcomes.

Power Analysis

The primary aim is to evaluate the feasibility, acceptability, and usability of the intervention to support a future large-scale RCT. According to the guidance for pilot intervention studies [110], it is suggested a minimum sample of 30 per group for the feasibility evaluation. In terms of the aim for the preliminary efficacy evaluation (ie, secondary outcomes of psychosocial and behavioral factors associated with NMUPO), we estimate an effect size according to a previous review on digital interventions for illicit drug use [111] and found small-to-medium effect sizes (Cohen d=–0.17 to –0.34) with a 6-month follow-up assessment. G-power analysis [112] estimated a sample size of 10 to 35 per arm for an RCT (repeated measures analysis of covariance). According to previous mHealth trials for substance use with retention rates ranging from 75% to 93% [46,53,61], a sample of 70 appears to be feasible and provides adequate power for proposed analytic plans. Despite a small sample size, this is appropriate for the aim of developmental research.

Project Timeline

A detailed study timeline is shown in Table 1.

Table 1. The project timeline.

	Year 1	Year 2	Year 3	Year 4	Year 5
Phase 1: formative study (aim 1)	✓	✓			
Literature review and assessment development (ie, surveys and semistructured interviews)	✓				
IRB[a] submission	✓				
Peer leader recruitment, participant recruitment and assessment, and community advisory board establishment	✓				
Transcription and data analysis or extraction		✓			
Phase 2: intervention development (aim 2)		✓	✓		
Development of multimedia files or features based on data from formative research		✓			
Establishment of IMB[b]-based intervention module packages		✓	✓		
Development of prototype for social media groups and pages (ie, Instagram [Meta Platforms, Inc])			✓		
Peer leaders' and administrators' training (doctoral clinical psychology trainees)			✓		
Phase 3: intervention feasibility and preliminary efficacy evaluation study (aim 3)			✓	✓	
Participant recruitment, preintervention assessment, and randomized controlled trial assignment			✓		
Delivery of intervention			✓		
EMA[c] surveys and paradata collection			✓		
Postintervention assessment and interviews				✓	
Data analysis				✓	
Revisions based on participants' feedback				✓	
Dissemination and disclosure of research findings				✓	✓
Preparation and submission a research proposal for a large-scale intervention effectiveness evaluation with a randomized controlled trial design				✓	✓

[a]IRB: institutional review board.

[b]IMB: information-motivation-behavioral skills.

[c]EMA: ecological momentary assessment.

Ethical Considerations

All data (ie, qualitative and quantitative) and materials (including video, images, and comments) collected or generated in the proposed study are deidentified and stored on a password-protected drive to ensure confidentiality. Intervention materials will be only delivered in private Instagram groups, which are not accessible to public users. Before their participation, all participants are provided with informed consent that explains the study's purposes, voluntary nature, and confidentiality. Participants are allowed to withdraw from the study at any time. Participants will receive e-gift cards for the completion of formative interviews (US $50) and each intervention assessment (preintervention and postintervention; US $30 each). The prorated incentive will be given according to the completion of EMA during the intervention period (eg, US $25 e-gift card for a 100% completion; US $15 for a 67% completion). Biweekly random prize draws of US $25 gift cards for these who post, attend meetings, and reply on the panels. At the end of the intervention, US $60 e-gift cards will be provided to participants who complete 90% of tasks during the intervention.

As a multiphase study, the protocol is reviewed by the research ethics boards in a sequential manner. A protocol for a formative interview study (aim 1) has been submitted to relevant institutional boards for review. Detailed information on the ethical approval and recruitment progress is provided in the subsequent sections. The protocol has been developed and reviewed in accordance with the SPIRIT (Standard Protocol Items: Recommendations for Intervention Trials checklist; Multimedia Appendix 1). The protocol of the formative study (aim 1) has been approved by the Institutional Review Board for Human Research at the University of South Carolina (#Pro00135306).

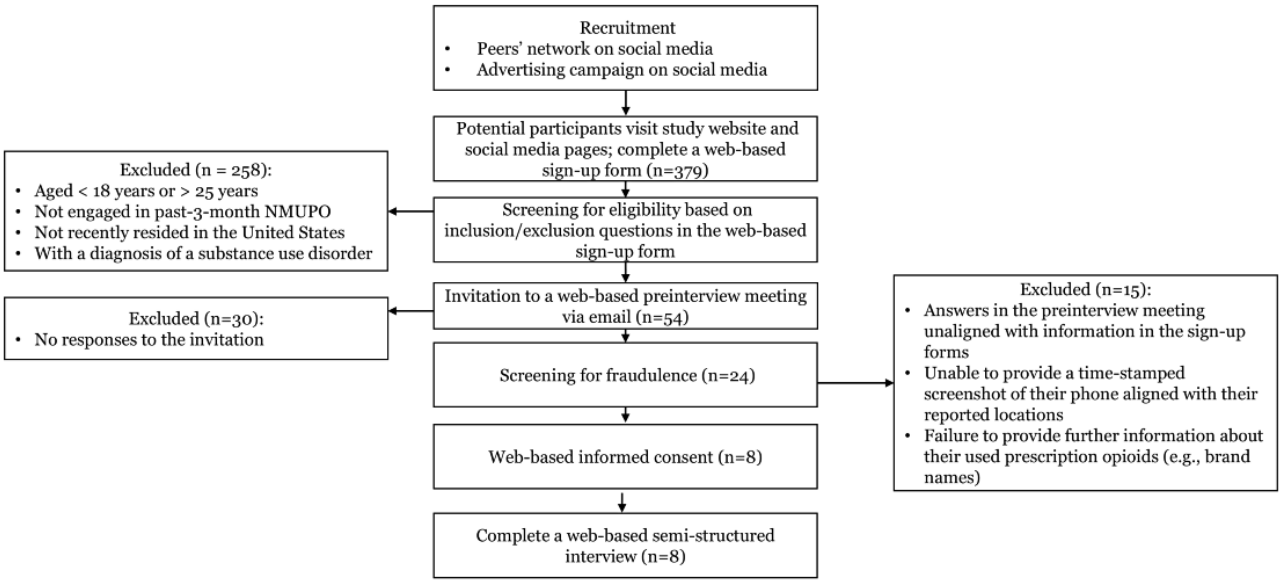
Results

The protocol was funded in May 2024 by the NIDA under the award number 1K01DA058768-01A1. The research team has

developed a social media campaign (eg, Facebook and Instagram) to facilitate recruitment for formative qualitative interviews. As of February 10, 2025, the study has received 379 responses, with 24 (6.3%) completing screening interviews. In total, 8 participants who are identified as eligible for the study have consented and completed formative interviews (Figure 4).

Formative interviews (aim 1) are expected to be completed by May 2025. The completion of formative qualitative analyses and intervention module development (aim 2) is anticipated by May 2027. A protocol for an intervention study (aim 3) will be submitted to the Institute Review Board for Human Research for review in early 2027. Upon receipt of an approval, the recruitment of the RCT will be initiated in late 2027, and the intervention will be conducted in early 2028. The intervention feasibility and preliminary efficacy (aim 3) will be finalized by the middle of 2028. Data analyses and manuscript development of the intervention will be completed by the end of 2029.

Figure 4. Recruitment progress for the formative study (aim 1) as of February 10. NMUPO: nonmedical use of prescription opioids.



Discussion

Anticipated Findings

In response to the growing evidence on psychosocial aspects of opioid addiction and relevant disorder concerns in the United States, this proposed study aims to apply a psychosocial theoretical framework and peer role model techniques to develop and implement an evidence-based intervention for reducing NMUPO risk in young US adults. The intervention will be established through a serial research activity, from a formative semistructured in-depth interview study to feasibility evaluation of a 12-week interactive peer-led trial. By leveraging the merits of social media, the proposed intervention study will be powered by adopting innovative approaches, including a tailored recruitment strategy (eg, paid advertisement campaigns), intervention delivery that transcends time and space constraints, and the application of mixed methods and time-series assessments (eg, paradata and EMA measures). As one of the first attempts to deliver peer-led interventions on social media specifically targeting NMUPO, the findings from this mixed methods design will offer valuable insights into the use of innovative approaches for reducing opioid risk among young adults. In line with previous intervention studies for NMUPO on social media [45], we anticipate that our intervention will yield high feasibility outcomes. In particular, the mixed methods assessments for the intervention group will demonstrate (1) high feasibility, acceptability, and usability on all intervention modules among young adults across 12 weeks and (2) high engagement, especially for the modules in the interactive formats, such as discussion polls and live streaming group meetings. We also anticipate significant preliminary intervention efficacy on the NMUPO-related and psychosocial behavior outcomes. Compared to the control group, the intervention will report (1) decreases in past–3-month NMUPO and other substance use (eg, alcohol, illicit drugs, and cigarettes), (2) decreases in psychological distress, (3) changes in outcome expectancies (eg, increased physical discomfort and decreased pain reduction), (4) increases in NMUPO knowledge and NMUPO risk perception, and (5) increases in resilience and self-efficacy (ie, action and coping).

Notably, the proposed intervention will be developed and implemented based on qualitative findings on the psychosocial mechanism of NMUPO, incorporating tailored psychotherapy strategies, such as CBT, MI, and peer role models. As highlighted in recent research, NMUPO in young adults is robustly driven by psychosocial factors, with influences comparable to biological and medical factors, which are traditionally viewed as prominent determinants [22]. However, scant theory- and evidence-based intervention programs have been designed to empower psychosocial skills for young US adults, especially for those who have engaged in NMUPO but do not develop addiction or SUDs. As a pilot trial, our feasibility evaluation will contribute to emerging practices of opioid use disorder prevention within social media settings, particularly through the implementation of peer-led groups [45,46]. In addition, preliminary efficacy on psychosocial measures will contribute to the growing literature on psychosocial aspects of NMUPO and offer clinical evidence for using psychosocial

intervention to manage the risk of opioid misuse in the young population. The success of the proposed trial should underscore the potential of leveraging social media as a feasible tool for delivering secondary prevention programs targeted at group-based psychosocial skill training for young people at high risk of SUD.

The proposed study has several methodological limitations. First, the generalization of our findings will be limited by the convenient sampling approach. Second, because most evaluations in this study will be based on self-reported measures, results could be subject to response bias (eg, social desirability and recall bias). Third, our EMAs could impose additional burdens on participants due to the frequent prompts for assessments in real time. Fourth, our efficacy findings could be limited in assessing long-term effects given a pre- and postevaluation design. Fifth, since the planned content for all peer-led groups will be identical and delivered concurrently, our analyses could not examine the efficacy of specific intervention modules. Sixth, given a program will be delivered on Instagram, our findings will be limited to Instagram users, and the format and presentation of the intervention content will be constrained by the platform's available features and functionality. Seventh, our peer leaders could also have limitations. They are recruited solely from local agencies within a single state (South Carolina). In addition, although they will be supported by clinicians (eg, licensed clinical psychologists and physicians in addiction medicine), their service may be subject to disparities in the quality of support. To address those, our future plan is to conduct a scaled-up cross-platform social media RCT study with a design of the multiphase optimization strategy and longitudinal measures. The intervention will be provided by a team of peer leaders, comprising recovery coaches with expertise in opioid misuse from various states across the United States.

The proposed intervention might encounter several potential challenges related to social media, including inefficient recruitment (eg, scams) and intervention delivery affected by the policy changes to social media platforms. Several contingency plans will be used if these occur. To address recruitment challenges, the eligibility of participants will be thoroughly evaluated by a 2-step approach. Young adults who have signed up for participation via social media will be navigated to complete a screening survey regarding their age, current NMUPO, history of SUDs, and their preferred online meeting methods. The research team will then contact the participants by their preferred methods and evaluate their eligibility in person. In addition, the recruitment plan will be supplemented by additional in-person approaches, including a snowball strategy (ie, allowing participants to invite eligible peers), and an outreach approach (ie, advertising at local young adult communities, colleges, and associations). To address the policy challenges to social media, the research team will transfer multimedia files to a publicly available but password-secured platform (eg, Discord [Discord Inc]), which also allows member reactions, and implement all interactive activities (eg, live streaming) via alternative social media applications (eg, WhatsApp [Meta Platforms]).

Guided by a theoretical framework, the proposed intervention study is dedicated to reducing NMUPO behaviors and the risk for opioid-related addiction and disorders by empowering psychosocial competencies among young adults via the application of social media. The proposed program is informed by substantial literature on NMUPO in young adults and formative qualitative findings of psychosocial mechanisms associated with NMUPO behavior management. Findings from rigorous methods are anticipated to inform a future scaled-up RCT study to optimize intervention content and effectiveness of a fully powered cross-platform social media intervention.

Study Dissemination

To promote the academic and social benefits of the proposed intervention study, several strategies will be used to disseminate the study findings. First, the findings will be published in international and national scientific journals and presented at national and international scientific meetings or conferences held by SUD research institutes. Second, the access to the deidentified data will be available for registered users through our selected data repository, the Interuniversity Consortium for Political and Social Research, with high security standards. Third, documentation and support materials regarding the intervention will be available at ClinicalTrials.gov and compatible with its protocol registration data elements. Fourth, we will capitalize on social media and professional networks that can increase the research and accessibility of findings, such as webinars, files, and videos available on websites and publicly available channels (eg, YouTube [Google LLC]), to increase the visibility and impact of the scientific publications and presentations. We hope that the anticipated success of the proposed intervention will prompt policy attempts for prescription drug intervention and treatments. The lessons learned from the proposed study and the intervention strategies tested can be scaled up to reduce NMUPO risk in young adults and other high-risk populations.

Acknowledgments

This protocol reported in this paper was supported by the National Institute on Drug Abuse (1K01DA058768-01). The content solely reflects the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Data Availability

The (deidentified) datasets generated or analyzed during this study will be available in the Data Sharing for Demographic Research data repository hosted at the Interuniversity Consortium Political and Social Research.

Authors' Contributions

CCT is the principal investigator of this project and led the study design as well as manuscript development. AHL, SH, SDY, and XL contributed significantly to the conception and design of the study. SDY and XL contributed significantly to the editing of the manuscript. All authors reviewed and provided comments to improve the manuscript and final approval of the manuscript.

Conflicts of Interest

SY is an advisor to digital health startups and a consultant to SBIRs grant to help opioid use disorder researchers. The remaining authors have no conflict of interest to declare.

Abstract

Background: Dementia is a global health priority with significant challenges due to its complex nature and increasing prevalence. Health systems worldwide struggle to address chronic conditions like dementia, often providing fragmented care. However, information about how health systems respond to the needs of people with dementia and their carers, and the quality of care provided, is scarce in low- and middle-income countries.

Objective: This study aims to assess the quality of the health system to provide diagnosis and care for people with dementia and their carers in Peru. In order to do this, the study will explore the response of the Peruvian health system to people with dementia and their carers, and explore the experiences of people with dementia of receiving their diagnosis, management, and quality of care for this condition.

Methods: This study is part of a research program called “IMPACT Salud: Innovations using Mhealth for people with dementia and Co-morbidities,” aimed at strengthening health systems to provide care for people with dementia and their carers. The study has a descriptive, cross-sectional design that uses a qualitative methodology, including stakeholder interviews and documentation review, and consists of 2 substudies, a health system assessment (HSA) and an exploration of the patient journey. The first substudy uses an HSA methodology suitable for low- and middle-income countries, conducting 160 structured interviews with 12 different stakeholder types across 3 levels of the health system (micro, meso, and macro) in 4 Peruvian regions, each with distinct geographical and urbanization profiles. The second substudy uses a patient journey methodology, which involves conducting 40 in-depth interviews with people with dementia, carers, and health care workers from the same 4 regions. The insights into the people with dementia patient and caregiver experience within the health system from the interviews will be used to produce a

patient journey map. The analysis will be guided by the high-quality health system framework, and the findings from the HSA and patient journey will be structured using the domains included in the framework through the lens of quality of services.

Results: Data collection began in March 2024. As of the end of September 2024, a total of 156 interviews from the HSA and 38 interviews from the patient journey study have been conducted across 4 regions.

Conclusions: This study will provide a national, multilevel insight into the current operation of the Peruvian health system, including an analysis of the quality of services provided with regard to dementia diagnosis, management, and care from the perspectives of stakeholders, patients, and their carers.

Introduction

Background

Health systems worldwide face the challenge of addressing chronic conditions, which in low- and middle-income countries (LMICs) is exacerbated due to resource scarcity. LMICs often respond to diseases in isolation through vertical programs [1]. A global and integrated response to chronic conditions is needed to provide high-quality care for individuals with complex conditions [2]. Dementia is one such chronic condition, characterized as a complex disorder involving psychosocial dysfunction and vulnerability due to brain disease [3]. Dementia is a generic term that describes progressive cognitive and behavioral decline severe enough to interfere with daily life and independent function [4] and is a global health priority given its enormous human and economic costs.

Globally, the number of people with dementia is increasing. According to the World Health Organization, there are approximately 50 million people with dementia, projected to reach 75 million by 2030 [4]. Studies indicate that women are more likely to develop dementia than men [5]. Furthermore, around 60% of people with dementia live in LMICs, which are aging rapidly and have limited capacity to support them [5]. In Peru, in 2022, the Ministry of Health (MoH) attended to 13,066 people with Alzheimer disease and other dementias [6].

Health systems in LMICs are not well equipped to address dementia, often resulting in inadequate or nonexistent care. Specific challenges for the health systems and people with dementia include developing effective diagnostic services, managing cognitive and behavioral decline, handling multiple comorbidities, caregiver burden, widespread stigma, and lack of awareness about dementia. The concept of tracer conditions can help facilitate understanding the complexity of health systems and the challenges LMICs face [7,8]. Using tracers in health systems research is based on the premise that focusing on carefully selected health problems allows for the identification of weaknesses within the system and facilitates more direct insight of its performance [7,8].

Dementia affects multiple aspects of individual and family well-being, serving as an indicator of multimorbidity in both people with dementia and their carers. People with dementia have twice the number of chronic physical and mental conditions compared to those without dementia [9,10]. Dementia shares risk factors with many other common chronic diseases, including health-related behaviors (eg, unhealthy diet, smoking, and physical inactivity), as well as obesity, hypertension, diabetes, depression, and social isolation. Together, these factors account for 35% or more of the population-attributable risk (proportion of new cases of dementia due to the noted exposures). In Latin America and the Caribbean, this percentage can reach 56%, due to a combination of cultural, political, and economic factors [11].

In a broader context, addressing dementia does not mean working with a disease in isolation but rather a broader set of system-wide responses, both within and outside health care delivery structures, which can in turn contribute to achieving global goals such as Universal Health Coverage and the Sustainable Development Goals [12-16]. Abundant literature has pointed out significant deficiencies in protection systems that are relevant for addressing dementia. In Peru, despite having a specific law that addresses dementia (law no. 30795: Law for the Prevention and Treatment of Alzheimer's Disease and Other Dementias) [17], people with dementia are affected by the fragmented health care systems, shortage of human resources, limited specialized services, minimal or nonexistent long-term care, and a siloed approach to addressing diseases and health conditions.

In the vast majority of cases [18-22], support available for individuals with chronic conditions in Peru, including dementia, comes from family members, predominantly women [23], who commonly lack access to information and primary or specialized dementia care services. A study across various LMICs identified high psychological stress and caregiver burden, particularly among female carers of people with dementia [24]. Studies, such as those by Papastavrou, recognize caregiving for people with dementia as highly stressful for families, potentially leading to depression, panic disorder, anxiety, or substance use like psychotropic drugs, alcohol, and nicotine.

To date, few studies have addressed dementia in South America. Notably, the 2023 Pan American Health Organization report [25] indicates that only Chile has a national dementia plan, with underreporting in LMICs potentially reaching 90%. The 10/66 Dementia Research Group study [25] highlights the high cost

of dementia for health systems and the negative mental health impacts on women in LMICs, who are often primary caregivers for people with dementia [26]. This underscores the need for further research on dementia diagnosis and care in LMICs and for directing it effectively toward impactful decision-making. This landscape highlights the urgent need for improved dementia diagnosis strategies in Peru and LMICs, considering the unique challenges posed by limited resources, illiteracy rates, and caregiver burden. Task-shifting approaches recommended by the World Health Organization could help bridge the gap in dementia care [4]. Additionally, addressing the social and economic impacts of dementia requires a multifaceted approach, involving collaboration between health care providers, policy makers, and community organizations. To understand the potential for such improvements on dementia diagnosis and care in Peru, a thorough exploration is needed of the existing health system and the problems that people with dementia and their carers face in daily life from a multistakeholder perspective. For these reasons, this study aims to assess the readiness to diagnose and treat dementia, as well as the quality of dementia services, in the Peruvian health system from the perspective of various stakeholders.

The study has 2 overarching objectives, which are addressed by 2 parallel substudies, respectively: a health system assessment (HSA) and an exploration of the patient journey within the health system.

Substudy 1: HSA

The HSA aims to understand the diagnosis and treatment needs of people with dementia and their carers in Peru and resources available for this, including the readiness of the health system to implement innovative mobile health (mHealth) tools for the screening and diagnosis of dementia. It will address the following research questions (Textbox 1).

Textbox 1. Research questions.

- What is the existing capacity of health workers to provide care to people with dementia and what is the quality of this care?
- What are the preconceived barriers and enablers for engaging with interventions using mobile health (mHealth) technology?
- What are the main system barriers and facilitators for the uptake of mHealth tools for supporting people with dementia and carer dyads?

Substudy 2: Patient Journey

This substudy aims to understand the journey of people with dementia to being diagnosed and receiving management for dementia and to identify opportunities to improve the diagnosis and management of dementia for people with dementia. It will address the following research questions (Textbox 2).

Textbox 2. Research questions.

- What are the experiences and challenges of providing care and unmet needs of people with dementia, their carers, and health workers?
- What are the most common barriers and facilitators to being diagnosed with dementia from the perspective of people with dementia, their carers, and health workers?
- What are the most common barriers and facilitators to receive or provide treatment and management of dementia from the perspective of people with dementia, their carers, and health workers?

Methods

Context

The IMPACT Salud research program comprises 4 distinct work packages (see Table 1), which have the overarching goal of strengthening the health system in Peru through sustainable, integrated, community-delivered, technology-enabled innovations. The expected outcomes of the overall program include improving access to diagnosis of dementia and development of a feasible and acceptable mHealth intervention for people with dementia and their carers. The first work package, the focus of this protocol manuscript, is a descriptive cross-sectional qualitative study, consisting of an HSA and an exploration of the patient journey through interviews and documentation review in order to inform future work packages of the program. The HSA will collect information on the structure and organization of the Peruvian health system, the political environment, financing, data collection and information systems, availability and affordability of medications and tests, barriers to diagnosis and treatment, service delivery in prevention and management issues, training and capacity to provide care, medical technologies and infrastructure, and perceptions of and experience with using mHealth technology.

Table 1. Work packages that comprise IMPACT Salud.

Work packages	Objective
1	Evaluate health system readiness to diagnose, treat, and support people with dementia and carers
2	Develop and implement a mobile health–enabled system for the diagnosis of dementia
3	Determine the feasibility of an intervention to treat and support people with dementia and their carers
4	Assess the economic burden of dementia and related comorbidities in Peru and estimate the costs of rolling out the diagnosis tool at a national level

This information will be collected from diverse stakeholders from different institutions, including not only health services provision, eg, civil society and municipalities, among others, but also from policy and practice documentation. The patient journey study will complement the information gathered from the HSA from a more centered perspective of people with dementia and their carers. The insights into the experiences of both people with dementia and carers within the health system will inform the development of a journey map that visualizes these experiences. The findings from the HSA and patient journey will inform other work packages of the program and will allow for the identification of opportunities for using mHealth technology for dementia diagnosis improvement and management intervention.

Setting

Study Regions

The IMPACT Salud program is working across 4 sites in Peru (see Table 2). These include Lima, the nation's capital with over 10 million inhabitants [27], situated along the central coast. Lima holds significant importance as the country's primary city, burdened with the highest incidence of noncommunicable diseases [28]. Notable for its social disparity and cultural heterogeneity, Lima is a dynamic research locale. The second city, Huancayo, has over half a million residents [29] and is positioned in the central highlands at an elevation of 3200 meters above sea level. A pivotal hub for the economic growth of the central region, Huancayo attracts migrants from the jungle and southern highlands, primarily engaged in providing diverse services for citizens and agricultural activities. The third city, Iquitos, serves as the primary urban center in the jungle, hosting almost half a million inhabitants [30]. Characterized by diverse indigenous populations, Iquitos can only be accessed via river and air transport, resulting in an economy marked by high transportation costs. Lastly, Tumbes, located in Peru's northern most region with 265,844 residents [31], operates as a border economy due to its proximity to Ecuador. With a warm, rainy climate, Tumbes is currently experiencing heavy rainfall attributed to the “El Niño-Southern Oscillation” climatic phenomenon.

Table 2. Characteristics of the study sites or locations. Source: Instituto Nacional de Estadística e Informática (INEI)-2017—Repositorio Único Nacional de Información en Salud (REUNIS) [27-30].

Sites	Population, n	Region	Illiteracy rate in the department (15+), %	Completed high school in the department (15+), %	Most spoken language in the department	Quintile of dementia care in Peru
Lima (Metropolitan)	8,894,412	Coast	2	50.2	Spanish	1
Huancayo	545,615	Highlands (Andes)	5.3	45.5	Spanish	3
Iquitos—Maynas	149,773	Amazon Jungle	5.4	50.1	Spanish	1
Tumbes	2,154,962	Coast	4.1	48.3	Spanish	4

Health Care System

The Peruvian health care system is fragmented and complex, with health care provision and financing depending on multiple public and private entities under the oversight of the MoH. Within this fragmentation, the 2 main public health care providers are the MoH and the Social Security System (EsSalud), the last one depending financially on the Ministry of Labour and Employment Promotion [32].

This study will primarily work with the MoH, which serves 74.5% of the population [33]. Since 2007, there has been a coordinated and decentralized health system [34], which has resulted in the creation of regional health directorates and management for each region that, independently, are responsible for implementing MoH's regulations.

For the purpose of this research, we categorize the health system into 3 levels: micro, meso, and macro. The micro level encompasses primary health care services, along with any supplementary systems or organizations at the local level. The meso level includes secondary health care services and regional directorates. Finally, the macro level encompasses tertiary health care services, national directorates of the MoH, and specialized bodies.

Design

The HSA follows a Rapid Assessment Protocol (RAPIA) methodology for data collection, targeting access to care for individuals with chronic diseases in LMICs [35]. The RAPIA framework is being used for its structured approach to data collection, designed to generate information from both primary and secondary sources, including structured interviews with participants across various levels of the health system within the 4 representative regions. The interview questions were adapted to gather information on dementia, modifying the focus on medications and emphasizing inquiries about the care provided to people with dementia by their caregivers. Key attributes of this methodology include its patient-centric focus, cost-effectiveness, and provision of valuable insights for decision-makers. The rapid assessment methodology is implemented via structured interviews following a standardized questionnaire, supplemented with a review of secondary sources of information (eg, policies and national statistics), to explore 11 themes related to the Peruvian health system across the 3 levels of the health system (macro, meso, and micro). This framework will facilitate the understanding of the needs and available resources for patients with dementia and their carers. Similarly, to understand the experiences of people with dementia in receiving their diagnosis and the subsequent management of their condition, we will use the “patient journey” methodology.

This approach is used by health care managers to identify gaps in the touchpoints between the health care system and the patient throughout the care process, such as the admission process, physical care, and appointment reminders [36]. In LMICs, "patient journeys" for noncommunicable diseases provide valuable insights for decision makers aiming to prioritize interventions and optimize disease management [36]. To carry out the "patient journey," we will conduct in-depth qualitative interviews with individuals with dementia, their caregivers, and health care professionals. This follows an example of a study on understanding poststroke care management [37]. Based on the patient journey interviews, a patient journey map will be developed to visualize the experience of people with dementia, carers, and health care workers within the health care system.

Participants and Selection Criteria

Overview

Table 3 details the different types of participants across the 2 substudies and the criteria used for purposive selection of participants. In the HSA, 14 types of key actors are participating across the macro [4], meso [3], and micro [7] levels. The patient journey involves 3 types of key actors: people with dementia, their carers, and health care workers. The aim is to achieve a comprehensive coverage of health care system stakeholders pertinent to the theme of dementia.

Table 3. Key actors and inclusion criteria.

Level	Target institution and key stakeholder role	Inclusion criteria
Substudy 1		
Macro	• (1) Ministry of Health (eg, Mental Health Strategy, Non-Communicable Diseases Strategy, Integrated Health Insurance (SIS) Department, Planning and resources) • (2) Ministry of Financing (eg, Presupuesto por Resultados) • (3) Social Security (EsSalud) • (4) Ministry of Women and Vulnerable Populations • (5) Key opinion leaders (eg, nongovernmental organization representatives, representatives of health organizations)	• 18 years of age or older • Occupy the specified role in the Peruvian provinces of Lima, Huancayo, Iquitos, or Tumbes
Meso	• (6) Regional directorates of health • (7) Health workers of mental health public hospitals, general hospitals, and specialized memory clinics (eg, including psychologists and therapists) • (8) Nursing homes run by District Municipalities	• 18 years of age or older • Occupy the specified role in the Peruvian provinces of Lima, Huancayo, Iquitos, or Tumbes
Micro	• (9) Grass-root organizations and elderly community centers (Centro del Adulto Mayor) • (10) Community leaders and community health workers • (11) Health care workers (eg, physician, nurses, technicians, pharmacies) from primary health care facilities and community primary mental health care facilities (Centro de Salud Mental Comunitario)	• 18 years of age or older • Occupy the specified role in the Peruvian provinces of Lima, Huancayo, Iquitos, or Tumbes

Micro	• (12) People with dementia and carers	• Only for people with dementia; people with a mild dementia diagnosis who meet the following criteria:
		  • Status of dementia: people will be asked for a self-reported diagnosis of dementia. Where this is not possible, the carer will be asked to confirm. This diagnosis had to be performed by a physician in a health facility.
		  • Level of functionality: the Pfeffer Functional Activities Questionnaire (PFAQ), Spanish version, will be applied with potential participants (n=31); participants must score below 6 to participate.
		  • People with dementia should also have at least one chronic comorbidity, such as hypertension, diabetes, depression, and anxiety, among others.
		• Carers: people who are formal or informal carers, including family members that are responsible for taking care of the people with dementia. They need to have been with the people with dementia in the process of diagnosis and management and are self-recognized as carers of the people with dementia. We will also include carers of people with severe stages of dementia

Substudy 2		
N/A[a]	• (1) People with dementia	Same as substudy 1
N/A	• (2) Carers	Same as substudy 1
N/A	• (3) Health care workers	General health practitioners and neurologists

[a]N/A: not applicable.

Sampling Method

Across the HSA and patient journey substudies, we aim to include 200 participants in total across the 4 sites through purposive sampling to recruit the required range of stakeholders across the health system. The inclusion criteria are detailed in Table 3, and the target sample size is provided in Table 4. These numbers will allow for gathering sufficient information from all regions to understand differences across the 4 settings and levels. For recruitment of people with dementia, there are specific inclusion criteria related to the stage of dementia and level of functionality. A community mapping exercise was conducted in each region to identify relevant organizations and groups from which to recruit potential participants. The purposive sampling was focused on identifying participants who represented each stakeholder type across each level of the health system as outlined in Table 4 and continued until all stakeholder types had been recruited.

Table 4. Sample size.

	Huancayo	Iquitos	Lima	Tumbes	Total
Substudy 1					
Macro[a]	—	—	—	—	20
Meso	15	15	15	15	60
Micro	20	20	20	20	80
Substudy 2					
People with dementia and carers	6	6	6	6	24
Health care workers	4	4	4	4	16

[a]The precise breakdown of participants is unclear for the 4 provinces.

Fieldwork Team

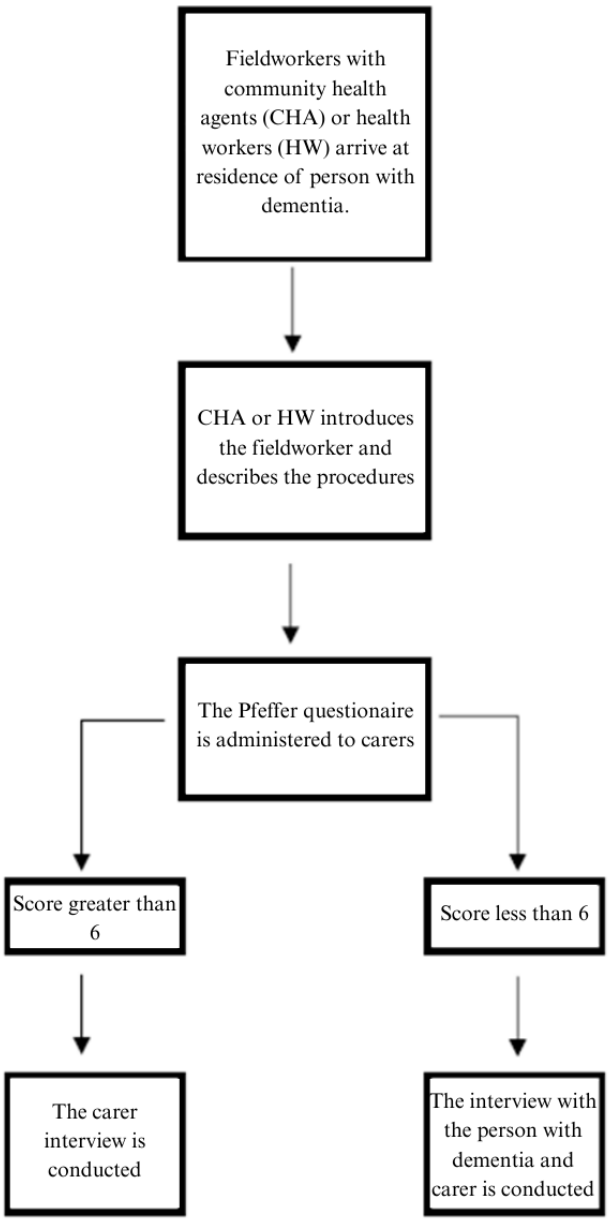
Field workers in each site were selected for their expertise in conducting qualitative interviews, their health care sector experience, and residency in the designated city of work. A total of 11 field workers have been engaged, with 9 assigned to micro- and meso-level interviews and 2 for the macro-level. A dedicated team of 2 or 3 researchers has been formed for each site, alongside a coordinator. Fieldwork team members attended 2 comprehensive training sessions, combining in-person and virtual formats. Training topics encompassed participant recruitment protocols, ethical considerations in elderly populations and dementia care, implementation of informed consent and assent procedures, an introduction to dementia from biomedical perspectives, and familiarization with the data collection materials. Upon completion of training, field workers received an operational manual detailing standardized operating procedures for data collection.

Data Collection Procedures

The study received institutional support from MoH and follows a staggered data collection approach. The process commences with higher management levels progressively authorizing interviews at operational tiers such as first-level health centers. Identification of persons with dementia (diagnosed by a health center) and their carers is facilitated through community health agents, health care center workers, and health care facility administrations. They introduce the fieldwork staff, who then administer the Pfeffer Functional Activities Questionnaire [38,39] to assess the people with dementia's functional abilities for daily activities and their possibility to participate in the interview. Scores below 6, indicating no clear impairment of functional activities, prompt interviews with both the caregiver and the person with dementia. In such cases, an informed assent is sought from the person with dementia, with informed consent obtained from the carer in their representative capacity. Figure 1 summarizes the procedure for conducting interviews with people with dementia. For other actors, specific informed consent procedures are followed prior to initiating data collection. Detailed information regarding recruitment can be found in Multimedia Appendix 1.

For the HSA, interview information will be recorded in notes on a printed version of the interview questionnaire and captured with handheld recorders. These notes will then be entered into the REDCap (Research Electronic Data Capture; Vanderbilt University) software, developed by Vanderbilt University. In this case, interviews will not be transcribed; only the recordings will be used as backup. This is due to the format of the RAPIA methodology, which advocates for a rapid analysis of information, prioritizing the perspectives of various actors rather than delving deeply into them; hence, a detailed analysis of the testimony is not necessary. On the other hand, for the patient journey, the interviews will be recorded and subsequently transcribed verbatim and coded in an Excel spreadsheet. Following coding, the information will be shared in order to seek its validation at a meeting with people with dementia and careers who were interviewed.

Figure 1. Procedure for conducting interviews with people with dementia.



Data Collection Materials

Questionnaires with closed and open-ended questions will be used to perform the structured interviews conducted in the HSA. These instruments were originally designed to assess health systems with regard to access to insulin [35]; subsequently, they have been applied for exploring chronic diseases and neglected tropical diseases [1]. Drawing from these previous experiences, they have been adapted for this study, with questions amended or added to capture information on several key thematic areas to assess the readiness of the Peruvian health system for diagnosing and managing dementia. These thematic areas are informed by the RAPIA guidelines mentioned earlier and are outlined in more detail in Table 5, including sections and topics of the structured interview questionnaire; an example of the structured questionnaire is also provided in Multimedia Appendix 2. As per the RAPIA guidelines, interview data will be supplemented with a document review of relevant technical standards, laws, regulations, national plans, care protocols, clinical guidelines, and other materials that are publicly available. In the patient journey, we will use semistructured interview guidelines for the in-depth interviews with people with dementia, carers, and health care workers. The guidelines will explore topics to understand the diagnosis and management process of dementia and identify opportunities for improvement. The interview guide is structured into 3 stages: prediagnosis, diagnosis, and treatment [40]; an example is provided in Multimedia Appendix 3. In these stages, the number of interactions with health care personnel, the time between appointments, the emotions associated with the encounters, among others, will be collected.

Table 5. Sections and topics of the questionnaire in the health system assessment.

Type of data	Components
General information	• Place and date • Contact information • Demographic information • Workplace and time • Occupational category
Health system structure and organization	• Units or departments responsible for people with dementia • Preparation of health personnel • Preparation to attend comorbidities • Services and organizations centered in people with dementia
Relevant policies	• Public policies and relevant policies for people with dementia
Financial issues	• Sufficient funding for prevention, diagnosis, and treatment in people with dementia • Barriers or difficulties for find funding for people with dementia • Programs or financial contributions for people with dementia and careers
Data collection and information systems	• Date registration for people with dementia • Statistic information available about people with dementia and comorbidities
Service delivery in prevention and management	• Knowledge of the available tests for people with dementia • Medications for people with dementia • Peruvian political medication for people with dementia • Knowledge of the available medication for people with dementia • Barriers or difficulties in the access of medication, tests and technology for people with dementia
Barriers for diagnosis	• Current barriers to dementia assessment • Current barriers to dementia attention • Current barriers of dementia care
Training and capacity to provide care	• Training, knowledge and capacity of health care workers in the provision and management of dementia care
Medical technology	• Infrastructure to support internet access • Infrastructure to support use of mHealth
Perceptions of and experience with using mHealth technology	• Knowledge of the tools for the dementia diagnosis • Opinion about mobile applications for disease diagnosis

Analysis Procedure

The analysis of substudy 1 HSA will follow a deductive process using coding reliability thematic analysis [41], with the aid of a structured codebook to index the information collected within the domains proposed by the high-quality health system (HQHS) framework developed by Kruk. The HQHS framework was designed to take into account the challenges of LMICs and allows for a comprehensive evaluation of service quality beyond mere access, emphasizing patient-centered care and trust in health care systems. The framework will allow us to organize and structure the results of our substudies in order to create an overall overview of the health system and the quality of services provided to people with dementia and their carers. The relevance of using this framework lies in its ability to integrate general aspects, such as access to health care centers and the number of consultations, with the patient's perception of the service's utility when describing service quality. In contrast, the analysis of the patient journey in substudy 2 will be inductive, following a framework analysis approach [42]. Analyses for both substudies will be carried out in parallel until the final phase, at which point they will be integrated to enhance the HQHS framework. The detailed analytical procedures are outlined below.

Substudy 1 will follow a 3-step process, conducted initially by 2 researchers working together on data from one site first to agree on understanding of codes and then moving to work independently on interviews from the additional sites subsequent to this. Throughout the process, the team overseeing the study will meet regularly to discuss the coding of data into the various categories and thematic areas in order to confirm understandings and address any disagreements in data coding placement (Textbox 3).

Substudy 2 will consist of 4 phases (Textbox 4).

The findings will be reported in accordance with the checklist proposed by the COREQ (Consolidated Criteria for Reporting Qualitative Research) reporting guidelines for qualitative studies [43].

Textbox 3. Phases of the analysis for substudy 1.

- First, the data from the structured interviews and document review will be coded into the 11 themes proposed by Rapid Assessment Protocol (RAPIA; Table 5), where each theme will be structured according to the interviewees and the regions they represent.
- Next, the data from stakeholders as coded into the RAPIA themes will be cross-referenced with the components and subcomponents of the high-quality health system framework.
- The final step will involve integrating relevant information from substudy 2 into this matrix.

Textbox 4. Phases of the analysis for substudy 2.

- The first phase will involve developing an analytical framework based on codes derived from initial familiarization with the data. This familiarization process will consist of 4 meetings (one meeting per site) in which 3 researchers will listen to the interview transcripts and propose categories for analysis. The categories resulting from the first meeting will be used in the subsequent meetings, where their relevance will be evaluated.
- The second phase will involve coding all the data into the identified codes.
- The third phase will consist of summarizing data from the codes into overarching categories that represent key milestones identified as significant within the patient experience, as well as those identified by their carers and health care workers.
- These overarching category summaries will serve as the foundation for creating a patient journey map to visualize the data and for describing the subcomponents and components of the high-quality health system framework as identified in substudy 1.
- The draft patient journey map will be presented to a subsample of substudy 2 participants in each region to sense check the understanding of their experiences and inform a final version of the map and to feedback into the refinement of the overall analysis.

Ethical Considerations

The research protocol, data collection materials, and consent were initially reviewed and approved by the institutional review board (IRB) at Universidad Peruana Cayetano Heredia (UPCH) on July 20, 2023 (IRB number 209080). Subsequent amendments were approved by UPCH on October 30, 2023, and May 13, 2024, and an extension was granted on June 18, 2024, allowing data collection until June 2025. The protocol and consent forms were also approved by the Imperial College Research Ethics Committee (IRB number 6784708) on February 29, 2024, with a further amendment approved on June 11, 2024. The study will be conducted in accordance with the recommendations for physicians involved in research on human subjects adopted by the 18th World Medical Assembly, Helsinki 1964, and later revisions. Participation in the interviews will be completely voluntary; potential participants will be provided with information about what taking part will involve, and signed consent will be sought for each participant prior to collecting any data.

All invited participants have the option to decline the invitation or withdraw from the study at any time. No monetary or material compensation has been provided, other than a brochure containing general information about dementia. All collected data will be anonymized prior to analysis, in order to protect confidentiality.

In addition to the considerations mentioned earlier, specific measures to ensure ethical safeguards and to abide by local legislation will be taken in the cases of people with dementia and their carers. Assent and dissent will be respected from people with dementia, verbally or nonverbally. Also, carers who function as proxy decision makers will also be consulted about consent when the potential participant has not been able to give full consent.

Results

The IMPACT Salud program was funded in October of 2022, but the study was launched in Peru in November 2023. In the meantime, ethical approval and pilots were conducted before the implementation of both substudies. The pilot study took place from July to September 2023. The implementation of both substudies began in March 2024. As of September 30, 2024, 192 individuals have been interviewed as part of the HSA and the patient journey study from the cities of Iquitos, Huancayo, Tumbes, and Lima. Transcription and data systematization in REDCap will occur simultaneously with the administration of questionnaires and interviews. The analysis phase is scheduled to take place from October 2024 to January 2025.

Discussion

Principal Findings

This study, with its focus on both HSA and understanding the patient journey, will generate comprehensive insights into how dementia is diagnosed and managed across the diversity of the Peruvian health care system. The findings will be organized in 3 core themes from the HQHS framework, such as the process of care, quality impacts, and foundations. It is anticipated that this will reveal areas of strength in dementia care as well as areas where there are issues with quality of provision or lacking provision. This might include, for example, structural issues with financial resourcing, training of health care workers, or the existence of standardized policies and protocols. It is anticipated that there may be divergence between the experiences of stakeholders at different levels of the health system, as well as across the different regions in which the study is being conducted. Furthermore, the study will reveal insights into the facilitators and barriers to using mHealth technology in Peru for supporting better diagnosis and management of dementia.

To date, few studies have holistically addressed dementia in South America. This work aims to serve as the foundational step in a series of studies across LMICs, particularly in Latin America, assessing health care system readiness to effectively diagnose, manage and provide care for people experiencing dementia and chronic comorbidities. As the burden of dementia and associated conditions rises among older populations in LMICs [44-46], there is a dearth of data on health care system preparedness. Additionally, the study will also address the needs of other work packages as part of the IMPACT Salud program (see Table 1).

It is important to note that using health care system evaluations from high-income nations for public health decisions in LMICs is cautioned against due to considerable disparities in home care systems, health care professional readiness, belief and health literacy, technology and infrastructure availability, as well as the political stability essential for sustained quality care. As such, this research endeavors to provide updated insights into the intricate workings of health care systems in Peru, potentially driving reforms in the health care sector. Furthermore, it aims to foster alignment among stakeholders and amplify the impact of reforms on dementia patients' lives. A notable antecedent of health care systems' responses to dementia is the STRIDE project that engages 7 countries (Mexico, Brazil, India, Indonesia, Jamaica, Kenya, and South Africa) [47]. There is one publication of this study in Mexico, and STRIDE, like IMPACT Salud, involves actors from civil society, such as the Alzheimer's Association of Mexico, its allied associations, and researchers. However, STRIDE does not directly include the participation of patients and carers as project participants, as its goal is to improve the implementation of public policies rather than gathering the needs and experiences of people with dementia in the health care system [48]. A comparative analysis of findings between these projects is planned, aiming to elucidate differences and similarities. The results of this research also aim to provide input for the development of Comprehensive Care Guidelines for individuals with Alzheimer disease and other dementias, a task that the MoH has pending since its proposal in the 2018 regulation of the Law for the Prevention and Treatment of Alzheimer's Disease and Other Dementias [17].

Also, the study has a particular focus on carers due to the significant impact of caring for a person with dementia on their mental health. Carers are 4 times more likely to experience depression and 3 times more likely to experience anxiety [49,50]. For these reasons, it is important to explore the needs of carers and possible opportunities to better support them and reduce any burden they experience. The intervention that will be adapted [51] in work package 3 of the IMPACT Salud program (Table 1) will have carers as its focus, aiming to provide guidance and tools with the aim of improving the quality of life of people with dementia and the mental health and quality of life of their carers.

Study Strengths and Limitations

The RAPIA methodology offers a diverse, multilevel, and national perspective to assess the health system, in this case having dementia as a tracer condition in Peru. While the patient journey complements this by providing insights from a patient-centered perspective about the health care system's functionality.

The HQHS framework will enable the analysis to be organized to identify structural issues (such as access, political support, and availability of qualified health care personnel), as well as relative or subjective issues contingent upon each dementia patient, caregiver, and health care provider (such as trust and service quality).

The decision of using a combination of methodological approaches is based on their focus on the end user of the health system, namely persons with dementia and their carers. Furthermore, the RAPIA methodology has the quality of being flexible to the context, allowing the addition of topics to the interview and new questions to the questionnaire [35]. Finally, the methods offer replicability benefits for researchers and health system specialists in terms of time and costs to implement.

The approach proposed in this study involves examining the macro view while also taking into account the daily lives of people living with dementia. By staying focused on these, we aim to propose solutions in the health system that have a tangible impact on people's lives. The study includes 4 sites with diverse characteristics in terms of population size, ecosystem, mother tongue, and number of people with dementia attended by MINSA; this will allow comparing the quality of the health system and experiences of people with dementia and carers, as well as opportunities in 4 highly diverse contexts within Peru.

While the study has adopted existing robust methodologies for HSA and understanding patient experience, there are potential limitations with applying these in practice. To date, the study has faced difficulties in recruiting dementia patients who meet the inclusion criteria. Our data so far indicate that most patients seek diagnosis late, resulting in worse cognitive decline than expected (a score of less than 6 on the Pfeffer functional test). This issue is compounded by the view of dementia as a normal part of aging, which discourages symptomatic individuals from seeking health care. We have partially addressed this by conducting more interviews with carers in cases where patients themselves do not meet the inclusion criteria.

Furthermore, while the setting for the research includes 4 sites with diverse characteristics to represent the various sociodemographics and cultures of Peru, this is not exhaustive, and there may be factors related to the diagnosis and management of dementia that remain unidentified by this study.

Additionally, the HQHS framework has been used previously with a survey to share information from some domains or subdomains [52]. However, there is not much published research using this framework with qualitative data, so there may be some challenges faced with this during the analysis phase.

Conclusions

This study will provide a national, multilevel insight into the current operation of the Peruvian health system, including an analysis of the quality of services provided. The findings will be structured in 3 core themes from the HQHS framework (process of care, quality impacts, and foundations) in order to

share information about dementia diagnosis, management, and care from the perspectives of stakeholders, patients, and their carers.

Dissemination

The dissemination strategy of the IMPACT Salud program is focused on sharing the study findings with a wide variety of audiences, including the patient and carer community, health care providers, and policy makers. A variety of dissemination formats are planned, including online and in-person meetings and webinars, policy briefs and briefing notes, social media, and news communication and scientific formats including peer-reviewed journals and conferences. We will also use the project web page [53] to share information for these different audiences in a friendly format.

Acknowledgments

This study is funded by the UK National Institute for Health Research (NIHR) Global Health Policy and Systems Research Programme (grant number NIHR150287). The views expressed are those of the authors and not necessarily those of the National Health Service, the NIHR, or the Department of Health and Social Care. The funder had no role in the design or conduct of the study; review or approval of the manuscript; or decision to submit the manuscript for publication. JH and GM work at The Centre for Development, Evaluation, Complexity and Implementation in Public Health Improvement (DECIPHer), which is funded by the Welsh Government, through Health and Care Research Wales.

Data Availability

The datasets generated or analyzed during this study will initially be available in anonymized format from the study investigators (MLP, JH, SCF, and CB) upon reasonable request, in accordance with participants' informed consent and IRB requirements. No publicly accessible repository is currently used for data sharing, but this will be developed as part of the IMPACT Salud study and more information will be available on the study website [53] in due course.

Authors' Contributions

JH, MLP, CB, JJM, and MGL worked in the first version of the protocol. FTS, MLP, JH, and DRV worked to prepare the first draft of the protocol for publication. All authors reviewed the questionnaires for the HSA and the journey map as well as reviewed and approved the current protocol. Members of the IMPACT Salud Study Group: Cecilia Anza Ramirez; María Verónica Belón Hercilla; Julio Leonardo Albitres Flores; Mariela Margarita Villegas Chavez; Javier Eduardo Sanchez Calderon; Kelly Milagros Tello Lizarraga; Lee White; Ángeles Cano Cárdenas; Matías Vega; Ioana Dobre; Martina Cesarina Edith Guillermo Roman; Pablo Fonseca; Marco Da Re
