Abstract

Background: Metabolic disease is increasingly impacting women of reproductive age. In pregnancy, uncontrolled metabolic disease can result in offspring with major congenital anomalies, preterm birth, and abnormal fetal growth. Pregnancy also accelerates the complications of metabolic diseases in mothers resulting in an increased risk of premature cardiovascular events. Despite the convincing evidence that preconception care can largely mitigate the risks of metabolic disease in pregnancy, there are few data about how to identify the highest-risk women so that they can be connected with appropriate preconception care services.

Objective: The aim of the study is to determine the maternal phenotype that represents the highest risk of having adverse neonatal and maternal pregnancy outcomes.

Methods: This will be a prospective cohort study of 500 women recruited in early pregnancy. The primary outcome is a composite of offspring born small for gestational age (SGA) or large for gestational age (LGA) (customized birthweight ≤10th and ≥90th centile for gestational age). Secondary outcomes are (1) composite of adverse neonatal birth outcomes (SGA, LGA, major congenital abnormalities, preterm birth [<37 weeks' gestation]) and (2) composite of new maternal metabolic outcomes (gestational diabetes, diabetes in pregnancy, type 2 diabetes [T2D] or prediabetes; gestational hypertension, preeclampsia, eclampsia or new essential hypertension after pregnancy; and gestational weight gain ≥20kg or new overweight/obesity at the 12-18 months postpartum visit). A multivariable logistic regression analysis will be conducted to identify candidate predictors of poor pregnancy outcomes due to metabolic disease. From this model, model coefficients and the associated 95% CIs will be extracted to derive the risk score for predicting the delivery of LGA/SGA offspring (primary outcome) and composites of adverse neonatal outcomes and maternal outcomes (secondary outcomes).

Results: Seed funding for the project was acquired in November 2022 and subsequent funding was acquired in May 2024. The first participant was recruited on March 23, 2023. At the time of manuscript submission, 402 participants have been recruited. Data analysis has not yet been performed. Results are expected to be published in the first half of 2027.

Conclusions: This is a prospective observational cohort study that intends to identify the metabolic disease risk factors, or combination of factors, that are most likely to cause adverse maternal and fetal health outcomes. These characteristics will be used to develop a risk calculator which will assist in identifying the highest risk women and in triaging them to appropriate services. The study has been approved by the institutional Human Research Ethics Committee (HREC/90080/MH-2022).

KEYWORDS

preconception; large for gestational age; small for gestational age; pregnancy outcomes; metabolic disease; diabetes; obesity; hypertension

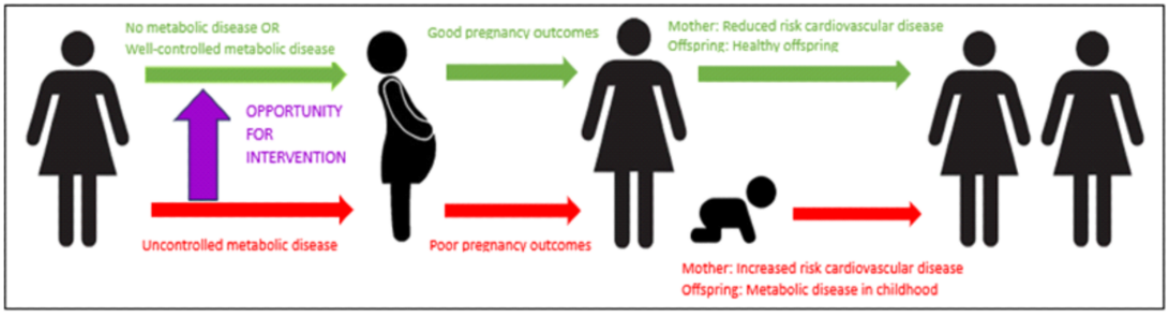
Introduction

The offspring of mothers with pre-existing metabolic diseases—obesity, diabetes, and hypertension—have an increased risk of significant congenital anomalies and premature birth compared with the offspring of mothers without metabolic disease [1]. These offspring are also twice as likely to develop obesity, diabetes, and hypertension in childhood [2]. For the mothers, pregnancy accelerates the complications of metabolic diseases, resulting in an increased risk of premature cardiovascular events including ischemic heart disease, stroke, and death [3]. Although the consequences of uncontrolled metabolic disease in pregnancy are entirely preventable, our current clinical services are not effective. This is because the highest-risk women are often not identified prior to pregnancy and because high-risk women frequently have poor access to appropriate care.

The women who are most at risk of adverse consequences of metabolic disease in pregnancy are women of low socioeconomic status, women who have experienced trauma, and women living in rural and remote areas [4]. Major barriers for these women accessing and using preconception services include (1) failure to be identified as "high risk" by a health care provider prior to pregnancy; (2) accessing a suitable referral pathway; (3) attending clinic appointments especially if limited by remoteness or finances; and (4) accepting care for metabolic diseases which are often stigmatized diseases and may have implications for the women's place in her family or wider cultural group. Ironically, there are well-developed services for preconception care of women with severe metabolic disease. However, these services are generally based in tertiary maternity hospitals in metropolitan cities. Due to geographical factors and because referral pathways and clinic entry criteria are often unclear, these services are often used by high socioeconomic status women with a relatively low risk of adverse pregnancy outcomes.

We hypothesize that the mothers and offspring at the highest risk of the adverse consequences of metabolic disease are predictable based on the phenotype of the mother prior to pregnancy. Despite the high fetal morbidity that can be associated with metabolic syndrome, little has been done to identify and capture at-risk individuals at a preconception or early antenatal stage. The aim of this study is to develop risk calculators that best predict (1) a mother's risk of having a neonate with abnormal fetal growth (large for gestational age [LGA] or small for gestational age [SGA]); (2) a mother's risk of having a serious adverse neonatal outcome; and (3) a mother's risk of developing new metabolic disease after pregnancy (Figure 1). We will translate this to a user-friendly mobile app that will allow any health care worker to access and triage women to appropriate preconception care.

Figure 1. Schematic of the rationale for research study.



Methods

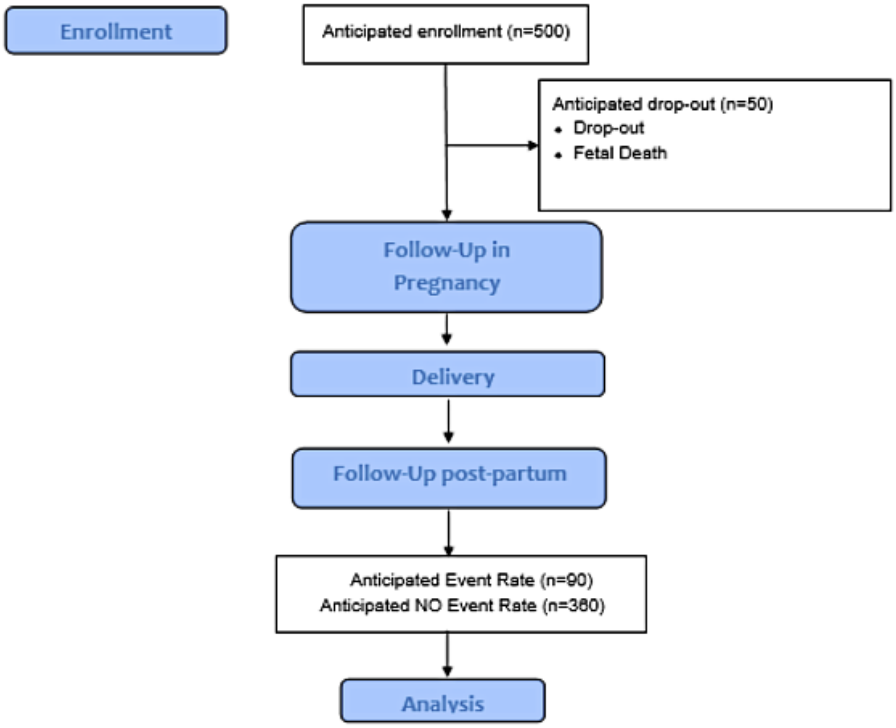
Study Design and Setting

Study phase I is a multicenter prospective observational cohort study. Study phase II involves the development of risk calculators from the observational cohort established in phase I. The study was prospectively registered with the Australian New Zealand Clinical Trials Registry (ACTRN12623000037606).

The observational cohort study will recruit 500 women who have been referred to either a public or a private tertiary maternity hospital (Figure 2). Both hospitals are tertiary referral centers based in metropolitan Melbourne Australia, and collectively manage >8000 births per year. The recruiting maternity hospitals accept referrals from the entire state of Victoria, such that the hospital populations comprise of metropolitan women and a smaller group of women living in regional and rural areas.

The first participant was recruited on March 23, 2023. The projected timeline for recruitment is that the last participant will be recruited in June 2025. It is anticipated that the last participant will have completed all study visits by June 2026.

Figure 2. Flowchart of the anticipated study cohort.



Eligibility and Recruitment

Inclusion Criteria

Eligibility for the study will be women aged 18 years and older with pregnancies of 20±4 completed weeks of gestation who provide written consent and are attending a prespecified study site for maternity care. The study will include those with multifetal pregnancies, chronic disease, and those using medications of any type. Women from non–English speaking backgrounds will be included and telephone interpreting services and cultural liaison officers will be used as required.

Exclusion Criteria

Women will be excluded from the study if they do not have maternity care at one of the prespecified study sites before 20±4 completed weeks of gestation. Women will also be excluded if they do not wish to provide informed consent or are unable to provide informed consent. This may be due to the inability to read and write, intellectual disability, or a severe active mental illness. It is anticipated that fewer than 1 out of 1000 women screened at maternity hospitals would fulfill this criterion.

Withdrawal Criteria

Participants are free to withdraw from the study at any time through revocation of consent (patient preference) or via ceased communication with the recruitment site (lost to follow-up). All data collected prior to the withdrawal of consent will be included in the analysis. Participants who start with maternity care at the recruiting hospitals and then move to seek maternity care elsewhere may continue to take part via telephone/telehealth study visits. Participants who have a pregnancy or neonatal loss will not continue in the study, but information collected until this point will be included in the analysis.

Recruitment Procedure

Women will be recruited when they attend maternity care visits between 16 and 24 weeks' gestation. Initial contact will be made by the maternity care provider. Subsequent contact will be made by a dedicated study nurse/doctor at the time of the standard maternity care visit. All participants will receive standard individualized antenatal care based on their clinical needs.

No study activities will be performed before eligibility has been assessed and informed consent has been formally documented. To encourage attendance at clinical visits, parking and meal vouchers will be provided. At the final visit, women will be provided with a comprehensive summary of their metabolic health and a plan for appropriate long-term follow-up.

Expected Outcomes

Primary Outcomes

Metabolically prone offspring defined as a composite of offspring with birthweight ≥90th centile (LGA) and offspring with birthweight ≤10th centile (SGA) based on population-based charts [5,6].

Secondary Outcomes

A composite of adverse neonatal outcomes includes the following:

- Offspring with birthweight ≥90th centile on population-based charts (LGA).
- Offspring with birthweight ≤10th centile on population-based charts (SGA).
- Offspring with major congenital abnormalities.
- Offspring born preterm (<37 completed weeks' gestation).

A composite of new maternal metabolic disease that develops during pregnancy or <18 months postpartum is defined below:

- Gestational diabetes (GDM) as per the International Association of the Diabetes and Pregnancy Study Group (IADPSG)/World Health Organization (WHO) definition (reference); or diabetes in pregnancy as per WHO/IADPSG definition; or previously undiagnosed type 2 diabetes as per American Diabetes Association/WHO definition; or prediabetes as per American Diabetes Association definition (Table S1 in Multimedia Appendix 1).
- Gestational hypertension; or pre-eclampsia; or eclampsia; or new essential hypertension after pregnancy (Table S2 in Multimedia Appendix 1).
- Gestational weight gain ≥20 kg or new overweight/obesity after pregnancy (BMI ≥25 kg/m^2 and body weight increase of ≥5 kg compared with prepregnancy weight) at the 12-18 months postpartum visit.

Clinical Assessments

A schedule of assessments and measurements is presented in Table 1.

Table 1. Summary of study activities.

	Visit 1 (20, SD 4 weeks gestation)	Visit 2 (36, SD 4 weeks gestation)	Visit 3 (Peripartum)	Visit 4 (12-18 months postpartum)
Informed consent and eligibility	✓	✓

Collect 75g OGTT[c] result		✓		✓
Collect obstetric ultrasound results		✓		
Collect maternal and neonatal mouth swabs for epigenetic analysis		✓	✓	
Collect obstetric medical records including the birth summary		✓	✓	
Collect height and weight data from the childhood development book (“Baby book”)		✓		✓

[a]HbA_{1c}: hemoglobin A_{1c}.

[b]CRP: C-reactive protein.

[c]OGTT: oral glucose tolerance test.

Medical History and Medications

At the first visit, a full medical history will be taken by a trained clinician including past medical history and surgical history. Outcomes of previous pregnancies will be recorded including outcome of the pregnancy, gestation, pregnancy complications, and (if relevant) birthweight and neonatal complications. Current medications including dose, and dosing schedule will be

recorded. Smoking, alcohol, and recreational drug use will be recorded.

Blood Pressure

Blood pressure will be measured after 5 minutes of rest in a seated position using an appropriately sized cuff on the bared left upper arm supported at heart level. Auscultatory readings with an aneroid sphygmomanometer and stethoscope or automated oscillometric readings with a single read per activation device will be collected by trained operators**.**

Weight, Height, and Waist Circumference

Weight will be measured by a trained technician on calibrated digital scales with an accuracy of ±0.01 kg. Participants will be asked to wear light clothing but no shoes. Height will be measured by a trained technician using a standing stadiometer with an accuracy of ±0.5 cm. Waist circumference will be measured with an accuracy of ±0.5 cm using a standard tape measure according to the WHO guidelines (at the end of a normal expiration, at the midpoint between the lower margin of the last palpable rib and the top of the iliac crest, as the average of 2 measurements). BMI will be calculated by dividing weight in kg by height in meters squared.

Bioimpedance Analysis

Bioimpedance will be performed using the DC-430MAS Tanita Dual Frequency Body Composition Analyser. Data obtained from bioimpedance analysis will include fat mass (%), fat mass (kg), free fat mass (kg), muscle mass (kg), and bone mass (kg).

Laboratory Assays

Phlebotomy is a low-risk procedure. At each visit, the required blood samples will be taken for glucose, insulin, C-peptide, high-sensitivity C-reactive protein, and leptin using an aseptic technique. Samples will be mixed by inversion and centrifuged at 4 °C. Plasma from the tubes will be aliquoted into 5 microtubes with 2 spare microtube samples. Plasma samples will be batched for analysis to minimize interassay error. The sample will be stored at –80 °C before analysis. Spare tubes will only be used in the event of a processing error.

Samples will be tested by commercial laboratories accredited by the National Association of Testing Authorities (Australia) and The Royal College of Pathologists of Australia for compliance with National Pathology Accreditation Advisory Council (Australia) standards and ISO (International Organization for Standardization) 15189. Test results were interpreted in accordance with normative reference values. The study database allows the management of the samples.

Calculated Insulin Resistance

Homeostasis model assessment of insulin resistance (HOMA-IR) values will be calculated by the equation (fasting insulin [µU/mL] × fasting glucose [mM])/22.5. Insulin resistance is defined by a HOMA value >4 (reference).

Oral Glucose Tolerance Test Results and Other Forms of Testing for Gestational Diabetes

The 75-g oral glucose tolerance test (OGTT) is a standard of care to screen for GDM at 24-28 weeks' gestation in Australia. A 75-g OGTT may also be performed at 10-20 weeks of gestation if there are risk factors for GDM. A diagnosis of GDM may also be made using other methods such as HbA_{1c} (hemoglobin A_{1c}), glucose readings from a period of fingerstick monitoring, or by evaluating continuous glucose monitoring CGM) metrics. If the woman is considered to have GDM by the treating clinical team, she will also be given this diagnosis for the purpose of the study. All medications used to treat GDM will be recorded.

For all such women, a 75-g OGTT or some other form of testing for diabetes should be repeated >6 weeks' post partum and these results will also be collected.

Obstetric Ultrasound

Obstetric ultrasounds are routinely performed in Australia to assess fetal morphology at 20-22 weeks' gestation. The fetal morphology scan report will be collected from all participants. Fetal growth scans may be performed at 28, 32, or 36 weeks for obstetric indications. If growth scans are performed, the estimated fetal weight and abdominal circumference will be collected from ultrasounds that have been formally reported. The reported customized growth centiles are based on GROW customized charts which are customized for known constitutional variables (maternal height, weight, ethnic origin, and parity) but not pathological factors such as smoking and diabetes. This method of customization has been demonstrated to classify the greatest number of offspring at risk of perinatal mortality [7-9]. Any congenital anomalies reported on ultrasound will also be recorded.

Obstetric Discharge Summary

All neonates born at recruiting maternity hospitals have a standard obstetric discharge summary on discharge from the hospital. Neonatal information collected will include date of birth, gestation at delivery, birthweight, birthweight centile, sex, Apgar's score, neonatal complications (hypoglycemia, jaundice, congenital anomalies [major/minor], and others). Maternal information will include mode of delivery, and maternal pregnancy complications (GDM, gestational hypertension/preeclampsia, and others).

Cheek Swab (for Epigenetic Analysis)

Swabs will be taken from mother and baby using a sterile regular flocked dry swab using a kit supplied at 36 (SD 4) weeks of gestation. These samples will be self-collected by rubbing the swab against the inside of the cheek 10 times and reinserting the swab into the plastic applicator. Samples will be given to nursing staff before discharge. The swabs will be sent to pathology for long-term storage until all samples are collected.

Sample Size

We estimate recruitment of 500 participants over 24 months, with an estimated dropout of 5% inclusive of dropouts due to fetal/neonatal death. The primary outcome variable of interest is LGA/SGA offspring (yes/no) due to the known association with short- and long-term metabolic consequences and the fact that most babies with congenital anomalies and prematurity will have abnormal fetal growth. By definition, LGA (<90th centile for gestational age) and small for gestational age (>10th centile

for gestational age) occurs in 20% of the population. With 475 participants (500 minus 25 dropouts), we would expect 95 offspring of interest compared with 380 normal-weight offspring.

Sample size calculation for the multivariable prediction modeling was conducted using the pmsampsize package in Stata (version 17.0; StataCorp) according to the 3 criteria (shrinkage, overfitting, and precision). From prior data, it is anticipated that the primary outcome of interest (presence of LGA/SGA offspring) will occur in 20% of the population. Åmark et al [10] reported an area under the receiver operating characteristics curve (AUC) of 0.8 from a logistic regression-based prediction model. Therefore, a minimum sample size of 440 is required with at least 88 events to ensure the expected shrinkage required is 10% or less (to minimize the potential overfitting), and a small absolute difference of 0.05 in the model's apparent and adjusted Nagelkerke R^2 value.

We anticipate that ≈20% of women will develop a maternal metabolic disease of interest including ≈15% who develop diabetes, ≈5% who gain excessive weight (>20 kg), and ≈15% who develop a hypertensive disease of pregnancy. Given the anticipated overlap of these conditions, ≈20% (n=90) of women will have at least one maternal metabolic disease of interest (secondary outcome).

Methodology

Data Collection

Study data are collected using paper case report forms. These paper documents will be kept in a locked cupboard accessible only to local research staff. Patient information is collected and stored by the investigators in a confidential REDCap (Research Electronic Data Capture system; Vanderbilt University), with password protection and restricted access. This will include patient information transcribed from the hospital's electronic medical record. REDCap is a secure, web-based app designed for research studies, providing a validated data entry interface, audit trails for data tracking, automated export procedures, and secure procedures for data import [11]. Internet access to the REDCap database will use a secure server located at the University of Melbourne, Australia (REDCap consortium host). Access will be limited to local research staff, approved data administrators, and project statisticians.

All biological samples will be labeled with a reidentifiable study number. The electronic study information will be stored in a dedicated, limited-access clinical database. Only study investigators and key study staff will have access to the database. Biological samples will be stored at –80 °C until all samples are collected. They will then be processed in batches by the local pathology network according to standard protocols.

Epigenetic samples (buccal swabs) will be stored at –80 °C until all samples are collected. DNA will then be extracted using standard processes for DNA extraction, and samples will be prepared for shipping. Methylation analysis will occur at an external genomics facility [12,13]. Once processed, data will be interpreted with the assistance of appropriate clinicians at Murdoch Research Institute. These samples are hypothesis-generating only and will not be included in the prediction modeling.

Data Management

Management of comprehensive and valid records will be the responsibility of each site. To ensure a systematic approach to data collection, the same team of study nurses will work between the sites using the same protocol and standard operating procedures. Data integrity will be maintained through a review of the collected data prior to, during, and after each study visit. Medication and adverse event data will be reviewed during each study visit. In addition, every 3 months the study coordinator will review the data collected to ensure completeness and consistency of data. Any data discrepancies will be queried with the participant by email or telephone within 4 weeks of being noted. All data, including the attendance of study visits, will be captured on a REDCap database. This will ensure that the study can meet regular deadlines required for process reporting as required by the Human Research Ethics Committee.

Data and Safety Monitoring

We anticipate very few study-related adverse events or serious adverse events. The only anticipated adverse events are phlebotomy-related side effects (ie, bruising, bleeding, vasovagal syncope) and a negative psychological response to clinical visits (ie, having weight measured). These events will be circumvented by having provided participants with a full and comprehensive review of study visits at the time of enrolment and prior to each study visit.

Reports of measurements taken at the time of clinical visits including weight and bioimpedance data, and the results of laboratory tests that are clinically relevant, will be made available to participants. Results that are not clinically relevant will not be disclosed to participants as they will not impact clinical care and may be difficult to interpret (ie, lack of reference ranges in pregnant women). Any concerning results will immediately be relayed to the treating maternity team. All other results will be reviewed within 1 week. The outcomes of participants will be discussed with the chief investigator each month. Any systematic problems with data management and adverse event monitoring or reporting will be rectified. REDCap queries will be addressed monthly by the study coordinator and reviewed quarterly by the study statistician.

Ethical Considerations

This is a prospective observational cohort study that intends to identify the metabolic disease risk factors, or combination of factors, that are most likely to cause adverse maternal and fetal health outcomes. No study-related adverse events are anticipated. The study has been granted ethics approval from the Royal Melbourne Hospital Human Research and Ethics Committee (HREC/90080/MH-2022) and recruitment is ongoing. Each participant will provide written informed consent before any study activities are undertaken and participants are free to withdraw consent at any time. Confidentiality will be maintained and only group data will be presented. Dissemination will be through peer-reviewed publications at national and international conferences, national and international obstetric medicine societies, and specialist colleges.

Statistical Methods

This study will follow the Transparent Reporting of a Multivariable Prediction Model for Individual Prognosis or Diagnosis reporting guidelines for prognostic studies [14]. Summary characteristics of the study cohort will be described using means (with SD) or medians (with IQRs) for continuous variables, depending on the shape of the distribution, and numbers and percentages for categorical variables.

A risk calculator will be developed to determine the risk of an abnormally grown fetus (ie, the primary outcome of the study). Participant data will be split randomly into either training (70%) or validation (30%) datasets according to standard prediction model methods. Multivariable logistic regression analysis will be conducted to identify candidate predictors of poor pregnancy outcomes due to metabolic disease. After starting with the most comprehensive model that includes all potential risk factors for an LGA or SGA offspring (ie, the primary outcome). These include categorical variables including maternal SES (based on postcode), maternal parity, maternal smoking status, maternal obesity class, maternal preexisting diabetes, maternal preexisting renal disease, essential hypertension, use of antihypertensive medication, use of metformin, gestational hypertension, preeclampsia/eclampsia, previous LGA/SGA offspring, major congenital anomaly, and continuous variables including maternal age, maternal gestational weight gain, maternal glycemic control (HbA_{1c}), total daily dose insulin, maternal systolic blood pressure, maternal diastolic blood pressure, birthweight of previous offspring, fasting glucose, plasma insulin, plasma C-peptide, plasma leptin, HOMA-IR.

A backward selection method will be performed to determine which combination of risk factors generates the most parsimonious predictive model. The number of candidate variables will be limited to data collected in the dataset. From this parsimonious model, model coefficients and the associated 95% CIs will be extracted to derive the risk score for predicting the delivery of LGA/SGA offspring. Internal validation of the model will be performed using 5-fold cross-validation and bootstrap validation. The performance of the model will be assessed using the AUC and calibration slope.

A similar approach will be taken for the secondary outcomes, and these models will be used to develop risk calculators for a composite of neonatal adverse outcomes and a composite of maternal adverse outcomes. Ongoing statistical input will be provided by the University of Melbourne.

Results

This project was funded by a National Health and Medical Research Council Investigator Grant awarded in November 2021 (CIA Price 2022-2026; 2007957), and by a Translational Challenge Grant from the Ramsay Hospital Research Foundation awarded in April 2024 (CIA Price 2024-2027; 2023/TCG/0038). The first participant was recruited on March 23, 2023. At the time of manuscript submission, 402 participants have been recruited. The projected timeline for recruitment is that the last participant will be recruited in June 2025. Therefore, it is anticipated that the last participant will have completed all study visits by June 2026. Data analysis has not yet been performed. Results are expected to be published in the first half of 2027.

Discussion

Why Predict Adverse Pregnancy Outcomes?

Uncontrolled maternal metabolic disease can profoundly impact both maternal and neonatal outcomes. Major congenital anomalies due to maternal metabolic disease are a common cause of neonatal death and long-term disability. For example, the risk of a major congenital anomaly such as congenital heart defect or spina bifida is 25% with suboptimally controlled diabetes (HbA_{1c} >10%) compared with 3% with well-controlled diabetes (HbA_{1c} <7%) [15,16]. Similarly, preterm birth can result in long-term neurodevelopmental issues and poor academic outcomes [17].

Even in children born at term, abnormal fetal growth can result in a long-term predisposition to metabolic disease. Around half of children born LGA (>90th centile for gestational age) or SGA (<10th centile for gestational age) [16] go on to develop metabolic syndrome (obesity, dysglycemia, and hypertension) by school age [2] with subsequent deterioration of metabolic disease in early adolescence [18]. This occurs due to a combination of factors including altered body composition at birth, altered appetite at birth, and atypical organ development including a lower endowment of cardiac myocytes, pancreatic beta cells, and nephrons [19].

For women, metabolic disease during pregnancy is an independent risk factor for later cardiovascular disease [20]. In the decade after preeclampsia, a meta-analysis including 200,000 women demonstrated a 4-fold increase in the relative risk of developing chronic hypertension and a 2-fold increase in the relative risk of ischemic heart disease and stroke [21]. For women who develop GDM, the lifetime risk of T2D is increased by 7-fold [22]. Lee et al [23] found that all-cause mortality was increased in women who were obese during pregnancy (BMI>30 kg/m^2) versus normal BMI after adjustment for confounding factors (hazard Ratio 1.35, 95% CI 1.02-1.77). Pregnancy loss due to late first-trimester miscarriage or stillbirth is also associated with increased cardiovascular disease in the mother, likely because pregnancy unmasks an underlying endothelial dysfunction [15].

Why Existing Prediction Models Are Inadequate

There are very few studies that have aimed to predict adverse pregnancy outcomes based on the maternal phenotype, and most of these have used maternal characteristics in combination with obstetric tests such as biomarkers in blood or ultrasound [24-27]. To the investigator's knowledge, there has only been one study that has used maternal prepregnancy characteristics to predict the risk of poor pregnancy outcomes [28].

The Generation R study group used easily obtainable maternal preconception characteristics including age, ethnicity, parity, BMI, and smoking status to model the risk of offspring born LGA/SGA. Basic models demonstrated an AUC of 0.63 (95% CI 0.61 to 0.65) and 0.64 (95% CI 0.62 to 0.66) for preterm birth/SGA and LGA, respectively. Interestingly, more complex

models involving sociodemographic and dietary details only led to small improvements in the model [28].

However, the Generation R study was a population-based prospective cohort study that aimed to identify early and genetic causes and casual pathways leading to abnormal growth and development of the offspring [29]. Risk prediction modeling in this study focused on all potential causes of LGA and SGA in a whole population cohort. This study did not specifically focus on LGA/SGA in the context of metabolic disease, nor did it consider the metabolic outcomes of the mother. Women with metabolic disease are known to be at higher risk of adverse pregnancy outcomes than the general population [30]. This cohort requires information about the risk of poor pregnancy outcomes both for themselves and their offspring.

Within an established pregnancy, Frick et al [31] found that LGA offspring (>95th centile) could be predicted based on increasing maternal BMI, diabetes status, and the presence of chronic hypertension. However, this prediction was less accurate in non-Caucasian women, in smokers, and in nulliparous women. In parous women, LGA offspring were predicted based on the birth-weight Z-score of previous offspring, a prior history of GDM, and a decrease with interpregnancy interval. This study then refined the prediction model using early fetal ultrasonography [31].

A population-based study from Ontario Canada (n=634,290) found that it was possible to predict and prevent severe maternal morbidity with moderate discrimination. Those women who had poor short-term pregnancy outcomes were older, had more medical comorbidities, and conceived using assisted reproductive technologies [32]. Similarly, Akinci et al [33] reported that in a small cohort (n=164), prepregnancy obesity, greater gestational weight gain, and a fasting glucose level (>5.5 mmol/L) on the 75-g OGTT predicted the development of metabolic syndrome in postpartum women with moderate to high discrimination.

What the Metabolic Health and Mother and Baby Health Outcomes Study Will Contribute

There are very few studies that use maternal characteristics to predict both maternal and fetal/neonatal pregnancy outcomes, even though they are inextricably linked. There are also few studies that consider the impact of metabolic disease as a whole rather than focusing on individual components of metabolic disease- hypertension, obesity, or dysglycemia.

We anticipate the Metabolic Health and Mother and Baby Health Outcomes (MAMBO) project will be able to fill this gap by developing a risk prediction tool that (1) considers how multiple maternal metabolic risk factors interact to result in adverse pregnancy outcomes, and (2) considers both maternal and neonatal pregnancy outcomes.

A risk calculator that can be used as a mobile app would provide health care workers with a simple effective tool to objectively calculate pregnancy risk and to triage women to appropriate services based on a standard dataset. Health care providers would require very little background knowledge to use the risk calculator. However, the tool would produce personalized data about the risks of an adverse pregnancy outcome. This would assist health care workers in effectively communication with the woman, her family, and with other health care providers.

Limitations

Ideally, the MAMBO cohort would have been recruited prior to conception. However, this would have required a very large sample size to allow for women who did not conceive in a specified timeframe and for additional dropouts due to the lag time between recruitment and conception. Therefore, the pragmatic decision was made to recruit women at 20±4 weeks' gestation. Existing data demonstrates a strong correlation between maternal anthropometric data and biomarkers in early pregnancy and the prepregnancy period [34].

The MAMBO cohort consists entirely of women attending major metropolitan maternity hospitals. Although these hospitals accept referrals from primary care and smaller hospitals that provide maternity care for women living in rural and remote locations, nonmetropolitan women are likely to be underrepresented in this cohort. Women from minority culture groups and women from non–English speaking backgrounds may also be less likely to participate in a prospective cohort study. To address these issues, translators and cultural liaison officers will be made available. We will aim to pair study visits with usual maternity care appointments. The final clinical study visit can be performed by phone if necessary.

Outcomes and Significance

Growing numbers of women are impacted by metabolic disease when they pursue pregnancy. However, women of low socioeconomic status, non-English speaking backgrounds, and women living in rural and remote areas are less likely to access preconception care services. Therefore, these women are at a greater risk of short-term adverse pregnancy outcomes, and long-term due to metabolic programming in the infant and unmasking of endothelial dysfunction in mothers.

The development of a risk calculator that predicts the women most likely to have poor pregnancy outcomes may assist in preventing these adverse pregnancy outcomes. It would allow women to be triaged by any health care professional and would ensure that the highest risk women are identified and have the opportunity to be referred to high-quality preconception care services and to receive information on how to prevent adverse health outcomes for themselves and their offspring. The risk calculator also has the potential to act as a platform that assists health care professionals in providing lower-risk women with basic preconception care information.

Conclusions

Currently, the women at the highest risk of adverse pregnancy outcomes due to metabolic disease are the least likely to access preconception health interventions. The MAMBO project intends to bridge this gap by developing a risk prediction tool that allows any health care practitioner to accurately assess risk, and to triage women to appropriate preconception care services. In this way, we aim to prevent adverse maternal and fetal health outcomes.

Acknowledgments

We gratefully acknowledge the women and their families who agreed to participate in the MAMBO study. SP is supported by a National Health and Medical Research Foundation (NHMRC) investigator grant (2007957). This study is supported by a Translational Challenge Research grant from Ramsay Hospital Research Foundation (2023/TCG/0038). Funders had no role in study design, data collection, analysis, or manuscript preparation.

Data Availability

The datasets generated during this study are available from the corresponding author on reasonable request.

Abstract

Background: Oral health is a significant indicator of general health, well-being, and quality of life. The prevention of oral health problems requires periodic inspection of the oral cavity. Routine oral health examinations at the individual level appears to be one way to deliver quality oral health care but are too often missed as an opportunity for improved oral health in the nondental health care setting in India. This is because of limited training and inaccessible or lack of specialized oral health assessment tools.

Objective: This study will focus on the development, validation, and implementation of the Basic Oral Health Assessment Tool (BOHAT) to improve the oral health assessment capabilities of nondental health care professionals and thus contribute to improved overall health outcomes of the Indian adult population.

Methods: This study will be a mixed methods, multistage study conducted in 3 stages. The study will be conducted with 708 nondental health care professionals in 33 Primary Health Centers (PHCs) of Mangalore Taluk, Karnataka. Ethical approval was sought from the institutional ethics committee of Manipal College of Dental Sciences Mangalore. Informed consent will be obtained from every participant prior to the study. A literature review and qualitative interviews will be used for item and domain generation with respect to BOHAT, and an expert panel review and pilot testing will be used to refine the items and domains. Finally, statistical analyses will be conducted to validate the reliability and consistency. The second phase will involve capacity building and user experience exploration through comprehensive training for nondental health professionals using audio and visual aids, with hands-on learning methodologies including relevant feedback processes in the form of focus group discussions. The third stage will check the effectiveness of BOHAT regarding the changes in knowledge, attitudes, and practices through pre- and posttraining questionnaires, which will then be followed by a retention analysis 3 months later.

Results: As of January 20, 2025, the study is in its preliminary phase: "Substage A: Item and Domain Development." We have received institutional ethics committee and Institutional Protocol Approval Committee approval for the study. Data collection procedures have not started yet. The study is progressing as per the planned timeline.

Conclusions: The BOHAT study holds considerable potential to promote oral health care through collaborative and interdisciplinary approaches. It will facilitate early diagnosis, timely referrals, and comprehensive care by integrating assessment actions for oral health into routine practices of nondental primary health care professionals.

Introduction

Oral health is a significant indicator of general health, well-being, and quality of life [1]. The functioning of the oral cavity, teeth, and orofacial structures, which enables people to perform fundamental bodily activities like eating, respiration, and speaking, is commonly referred to as oral health, and it undergoes changes throughout the various stages of life, from early childhood to advanced age [2,3]. Oral health problems can have a significant effect on people's quality of life, interpersonal connections, general well-being, and self-esteem [4]. Therefore, emphasizing the importance of preventive measures and early detection of oral diseases becomes crucial in mitigating the likelihood of developing subsequent challenges impacting both oral and overall health.

Oral health assessments serve as a good indicator of disease risk, the proper management of existing disease, and even the improvement of health outcomes because of appropriate oral health care [5]. Prevention of oral health problems requires periodic inspection of the oral cavity. Routine oral health examinations at the individual level appear to be one way to deliver quality oral health care but are too often missed as an opportunity for improved oral health in the nondental health care setting [6]. Health care professionals, from the allopathic doctor (physician and surgeon) to Ayurveda, yoga, naturopathy, Unani, Siddha, and homeopathy (AYUSH) practitioners; nurses; auxiliary nurse midwives; and community health workers (CHWs) [7], are very essential for the delivery of holistic health care but have limited capacity to comprehensively assess oral health issues and subsequently intervene because of significantly limited training on its own as well as inaccessible or lack of specialized supportive tools adapted to suit the population. This might ultimately delay the diagnosis and institution of appropriate interventions for oral health conditions in such patients and increase the possibility of further disease progression, which will then compromise overall health outcomes.

The separation between oral health and general health care practices may contribute to the insufficient integration of oral health assessments into routine health care protocols, limiting the overall effectiveness of health care delivery. Screening of oral health, early detection and triage of oral health issues, and immediate referral to dental specialists ultimately require the integration of frontline health care professionals [8]. Several instruments for health care providers to evaluate oral health have been developed over time. A few of these tools are the Holistic Reliable Oral Assessment Tool (THROAT) [6], Revised Oral Assessment Guide [9], Oral Health Assessment Tool (OHAT) [10], and Oral Assessment Guide [11]. However, the tools in current use lack reference pictures, challenging the completeness, relevance, and clarity of wording [12]. The Federation Dentaire Internationale and International Consortium for Health Outcomes Measurement collaboration developed a preliminary standard core set of oral health outcome measures for adults with a primary focus on periodontal disease and caries. The subsequent action is to conduct a validation and feasibility study in different clinics seeking to fine-tune the Adult Oral Health Standard Set more, and studies to do that are ongoing [13].

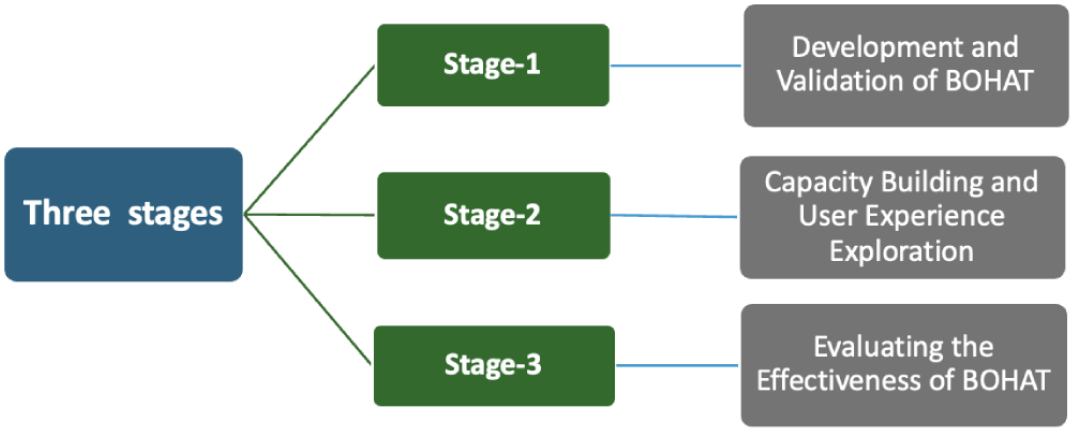
To bridge this gap, this research aims to develop, validate, and implement a Basic Oral Health Assessment Tool (BOHAT) that is tailored for use by nondental health professionals working with populations aged 18 years and older in India. BOHAT will be a screening tool for health professionals who are not dentists, to enable rapid identification of the need to refer patients for dental consultation. This tool will further empower nondental health care professionals to perform effective oral health assessments, thereby addressing an emerging critical need for holistic health care approaches at large. This study will focus on the development, validation, and implementation of BOHAT to improve the oral health assessment capabilities of nondental health care professionals and thus contribute to improved overall health outcomes of the Indian adult population.

Methods

Stages

This study will be a mixed methods, multistage study conducted in 3 stages. Stage 1 focuses on the development and validation of the tool. Stage 2 involves capacity building and user experience exploration, and stage 3 aims to check the effectiveness of BOHAT using a pre-post intervention study (Figure 1).

Figure 1. Multiple stages of the study. BOHAT: Basic Oral Health Assessment Tool.



Study Setting

The study will be carried out in Primary Health Centers (PHCs) located within Mangaluru Taluk of Dakshina Kannada District. This selected study setting will enable insights into the applicability and effectiveness of the developed tool, BOHAT, under Mangaluru Taluk's health care infrastructure. In this approach, oral health assessment practices will be examined more precisely and contextually in relevance to the geographic area selected. PHCs in this region will be the primary sites for data generation, data collection, pilot testing, validation studies, and execution of training programs for nondental health professionals. Approval to conduct the studies in PHCs will be obtained from the District Health Officer, Dakshina Kannada, Karnataka.

Sampling Technique and Sample Size

The sampling technique used in this study is census sampling or complete enumeration, which includes all 708 nondental health care professionals working in the 33 PHCs of Mangalore Taluk. This covers professionals from both urban (10 PHCs) and rural (23 PHCs) areas, ensuring that this target population is widely and appropriately represented.

Nondental health care professionals, including allopathic doctors (physicians and surgeons), AYUSH practitioners, nurses, auxiliary nurses, midwives, and CHWs [7]. Within the urban PHCs, there are 216 nondental health care and allied health care professionals, while the rural PHCs have a workforce of 488 nondental health care and allied health care professionals. The inclusive nature of this study aims to involve all 708 nondental health professionals across all 33 PHCs in Mangalore Taluk who provide their consent for participation.

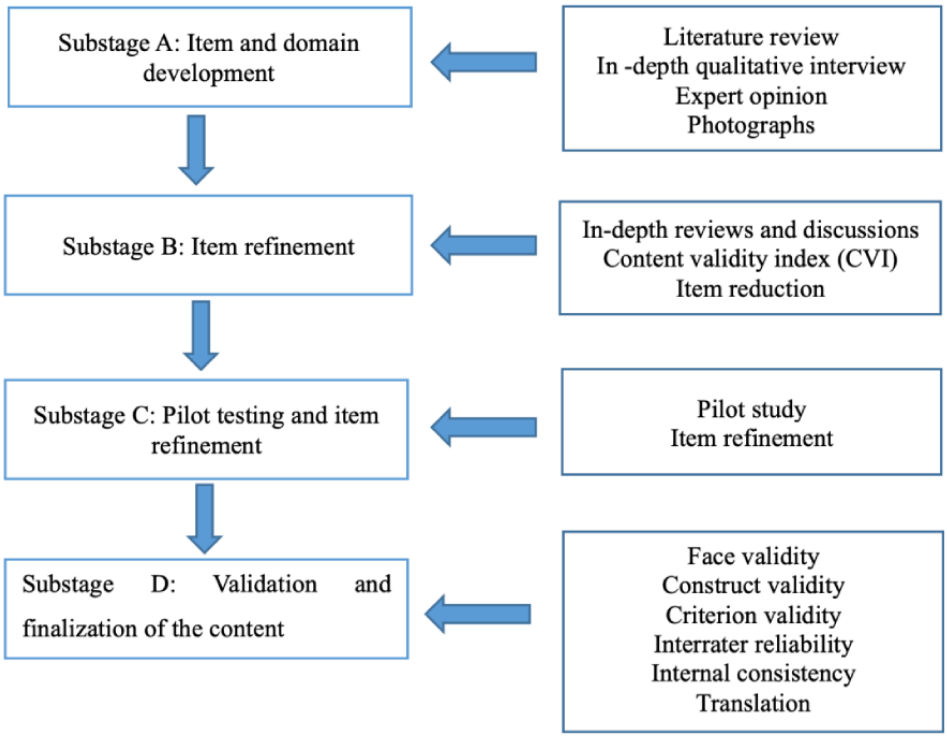
Study Framework

BOHAT will be designed as a paper-based instrument with the inclusion of reference pictures. These reference images serve as visual aids to enhance and facilitate the oral health assessment process**.**

Stage 1: Development and Validation of BOHAT

Stage 1 has 4 substages (Figure 2).

Figure 2. Conceptual framework for the development and validation of the Basic Oral Health Assessment Tool (BOHAT).



Substage A: Item and Domain Development

A literature search will be conducted to obtain data on oral health, oral hygiene, and common dental problems among Indian adult population. An in-depth qualitative interview will be undertaken with nondental health professionals to explore the challenges and complexities inherent in oral health assessment. Additionally, this approach aims to identify key domains that should be incorporated into the BOHAT. Collaboration with oral health care experts from public health dentistry, oral medicine and radiology, oral pathology, oral surgery, periodontics, endodontics, and prosthodontics will identify relevant and essential oral health problems specific to the Indian adult population.

Photographs for BOHAT will be sourced from patients availing of camps organized by the Department of Public Health Dentistry, Manipal College of Dental Sciences, Mangalore. These photographs will cover a vast spectrum of conditions and scenarios pertaining to oral health, thereby presenting a sample of what nondental health professionals might encounter during their assessments. Prior to photographing, proper ethical consent will be obtained from the patients. The photographs will be taken personally by the principal investigator after completing training in intraoral photography. This will help maintain uniformity so that image collection and image capture follow standardized procedures.

The photographic setup for the intraoral photos will include a Canon EOS 90D camera with a Canon EF 100mm f/2.8L Macro IS USM lens. Adequate lighting in the mouth will be provided using a Canon MR-14EX II Macro Ring Lite, which provides lighting without any harsh shadows and gives the best chance of even illumination. The images will have a resolution of 32.5 megapixels and will be saved in both RAW and JPEG formats. This ensures they will provide sufficient detail and can be modified to suit the intended use. The minimum and maximum ISO standards will be set between 100 and 200, aperture will be set at f/22 to ensure enough depth of field, and the shutter speed will be set between 1/125 and 1/200 seconds in order to minimize motion blurs. The custom white balance will be by intraoral light. Each photo will be captured from a distance between 30 cm and 40 cm, and since the ring flash will be used, a fixed distance will be sustained. Each file will be numbered, kept in encrypted digital storage, and secured to ensure data integrity.

Images will be identified and selected by subject matter experts according to the relevance, clarity, and appropriateness of content in relation to the goals of BOHAT. Each image will be critically evaluated to ensure that the wide spectrum of oral health conditions and scenarios that the nondental health care professionals may come across during assessment is captured. This includes ensuring there is sufficient detail and contextual setting in the images for both normal and pathological conditions. Images will further be categorized based on the diagnostic significance, such as specific oral issues like dental caries, periodontal diseases, or mucosa lesions. Selected images will then be further checked for quality assurance to ensure they are educationally valuable, appropriate for educational purposes, and meet ethical standards.

Substage B: Item Refinement and Item Reduction

The items on the BOHAT will undergo rigorous examinations, review, and engagement with the expert panel so that remarks on issues related to clarity, relevance, and appropriateness are captured. Items will also be subjected to systematic refining through discussions of the panels with respect to clarity, relevance, and appropriateness. To evaluate the test's content validity, the content validity index (CVI) will be computed to

measure the relevance of each item. Items with a low CVI (eg, item-level CVI<0.78) will be revised to improve their validity, or only the most relevant items will be retained. There will also be feedback from various stakeholders to enhance the contextual and functional appropriateness of the tool.

Substage C: Pilot Testing and Item Refinement

We will approach 20 nondental practitioners to pilot test the tool for its usability and clarity. This feedback will be used to provide input on the validity and reliability of the tool. Based upon the results of the pilot testing, these improvements will fill in the gaps before formal validation occurs. Descriptive statistics along with qualitative coding of each feedback will be used for initial evaluation of the tool's performance.

Substage D: Measurement Properties and Finalization of the Content

Consensus-Based Standards for the Selection of Health Measurement Instruments Taxonomy

Development and validation will be based on the COSMIN (Consensus-Based Standards for the Selection of Health Measurement Instruments) taxonomy [14]. The COSMIN framework will ensure that this newly developed tool adheres to high methodological standards and permits a rigorous assessment of its primary measurement properties including validity, reliability, and responsiveness.

Validity Testing

For face validity, feedback will be obtained from dental professionals, nondental health professionals, and other stakeholders to establish whether the tool is easy to read, accurate, and relevant. A qualitative assessment will follow, to ensure that the tool is fit for purpose and feasible for end users.

For content validity, content experts will assess the CVI of each item for relevance, clarity, and representativeness. These experts will provide CVI scores as a basis for revision, ensuring objectivity through systematic thresholds, for instance, an item-level CVI≥0.78.

Construct validity of BOHAT will be thoroughly assessed to confirm the extent to which the measure assesses oral health assessment capacity for nondental health care professionals. Exploratory factor analysis will be conducted to determine the underlying structure of the tool by grouping items into the dimensions of knowledge, attitudes, and practices (KAP) of oral health assessments. The appropriateness of the factor structure will be considered with the help of statistical tests such as the Kaiser-Meyer-Olkin test as well as the Bartlett test of sphericity. Confirmatory factor analysis will then validate the identified structure. A root mean square error of approximation ≤0.08 and comparative fit index ≥0.90 will be used to assess fit.

To determine criterion validity, each BOHAT item will be assessed against standardized criteria derived from the World Health Organization (WHO) oral health survey [15]. Each item will be directly mapped to the corresponding items or domains in the WHO oral health survey. For instance, the items measuring dental caries, periodontal health, and oral hygiene status will be benchmarked against the WHO criteria on such conditions. BOHAT and the WHO oral health survey will be administered to the same sample of participants. The sensitivity and specificity parameters will be determined as a statistical measure or estimate of validity for each considered BOHAT item in comparison with the WHO criteria for oral health conditions. Sensitivity and specificity values will show the diagnostic accuracy of the items.

Positive and negative predictive values will provide measures representative of usable or functional utility for each variable under study. Reference variables that form a strong connection with either a positive or negative outcome might be derived from those that create the curves and an area under them in the receiver operating characteristic (ROC) curve using the area under the curve (AUC) as an overall measure of accuracy, such that AUC values ≥0.8 indicate good performance. Items with low sensitivity or specificity will either be reconsidered or removed to obtain the most diagnostically relevant and accurate items.

Reliability Testing

For internal consistency, the Cronbach α will be computed and used as a measure of internal consistency with respect to the degree to which something is being measured as intended. The Cronbach α ranges from 0 to 1. An α near 1 indicates a high internal consistency of the items. Standardization of the scoring criteria for BOHAT, on a consensus basis through collective opinion and expert opinion on subject matter issues, will allow uniformity and objectiveness in assessments.

For interrater reliability, different nondental health professionals will independently use BOHAT with the same patients, and the scores will be checked for their agreement. The ratings proposed by different raters may be statistically analyzed using metrics like the Cohen kappa or the intraclass correlation coefficient (high values [≥0.75] represent excellent agreement).

For test-retest reliability, BOHAT will be evaluated among the same participants at specific intervals to estimate score stability. This will be done using metrics reflecting continuity across time intervals such as intraclass correlations.

Responsiveness of BOHAT

Evaluating the responsiveness of BOHAT will be a vital element in determining the validity of the training for augmenting the oral health assessment skills of nondental health professionals. Differences in scores before and after the training will be assessed using the pre- and posttraining questionnaires as compared with the participants' self-reported changes in confidence and competence of conducting oral health assessments. Focus group feedback will also be analyzed to obtain a sense of perceived skill improvements by participants. Distribution-based methods will be used to evaluate changes in pre- and postintervention scores, including calculation of the effect size (Cohen *d*) to measure the magnitude of change and the standardized response mean to evaluate BOHAT responsiveness to detect clinically meaningful changes. Statistical comparisons of pre- and posttraining scores will be conducted using paired *t* tests or Wilcoxon signed-rank tests. Additionally, minimal clinically important differences will be

determined using ROC curve analysis to interpret thresholds of change in the BOHAT that are considered clinically significant.

Translation of BOHAT

Although BOHAT is primarily in the English language, compliance will ensure proper adaptation of BOHAT for application in Kannada-speaking regions. Adjustments could include providing explanations on linguistic and cultural settings whenever there is a need for clarification. The procedure will likely correspond to the systematic approach provided for the back-translation model by Brislin [16] and comprise the steps outlined in the following sections.

Forward Translation

The test items will be in English; however, key instructions, terms, and technical language will be translated into Kannada by a well-trained bilingual expert who is a native Kannada speaker. This step will provide nondental health care professionals who are comfortable with Kannada the capacity to understand the use and purpose of the tool with ease.

Review by an Expert Team

To ensure cross-cultural equivalence, all translated versions will be reviewed by a multidisciplinary team. A total of 3 oral health experts and nondental health care professionals who have experience with oral health assessments will check the cultural relevance of the terms and concepts with the research team. We will consult 5 nondental health care professionals for practicality and relevance of the tool in the Kannada-speaking health care setting. Any semantic and conceptual changes required will be undertaken based on their feedback, resulting in a first Kannada version of BOHAT.

Back-Translation

A second professional bilingual translator will then back-translate the preliminary Kannada version into English. This translator will be blinded to the original English version to avoid bias.

Comparison and Revisions

The back-translated English version of BOHAT will be compared with the original English version, during which contradictions or deviations will be detected. Revisions will be made when necessary to ensure that the Kannada clarifications correspond to the meaning of the original English version, hence preserving the integrity of the tool items.

Pilot Testing

A refined version of BOHAT in Kannada will be pilot tested with 20 nondental health practitioners in rural and urban PHCs. Each participant will pilot test the tool and provide feedback on items that appear to be unclear or culturally insensitive. The feedback for clarity and utility of additional Kannada content will help determine whether they can understand and use BOHAT properly. The participants will rate each item on a scale from 1 to 5 for relevance, clarity, and specificity. The feedback from this phase will guide further adaptation toward achieving semantic and content equivalence.

The English version will be the final version of BOHAT, supplemented by additional explanatory material in Kannada for users needing language support. This will ensure that the original tool stays in the intended format in English while remaining culturally relevant and accessible to Kannada-speaking health care professionals in the setting.

Stage 2: Capacity Building and User Experience Exploration

Process

The training modules will have details on the purpose of BOHAT, administration procedure, and interpretation of the results. Experts will be given this module, and for content and face validity, they will be invited to classify the need for each question according to a 3-point Likert scale: “necessary,” “useful but unnecessary,” and “unnecessary.” Depending on the experts’ opinion, the content will be modified. The BOHAT training module will adopt a multimodal mode of learning: audio, visual, and audiovisual modes. This will ensure maximum benefits from training sessions so that better understanding and actual application in oral health assessment practices can be achieved.

The module for the training will include how to navigate the tool, interpret the results, and communicate the findings efficiently to patients. Hands-on training sessions will be conducted regarding using the tool. A focus group discussion will be conducted with nondental health professionals to explore the experiences of the participants, challenges faced by them, and perceptions about BOHAT’s usability.

Training Module

This training module is 4 hours long and will be delivered using a combination of audio, visual, and audiovisual aids. The comprehensive training on common problems of oral health among the adult population in India shall draw upon a variety of subjects to provide the necessary background to a health professional. The module will start with an overview of the role of health professionals in disseminating awareness regarding oral health problems and the importance of dental health in relation to overall health. The epidemiology of oral health in India will be presented with data on the most common oral health problems among adults.

The module will consider specific oral health problems often seen in adults. It will cover in-depth the processes of dental caries, periodontal diseases, and tooth sensitivity; the association between tobacco and oral health; potentially malignant disorders and oral cancer; other oral lesions; and the risk factors and lifestyle factors, like diet and lifestyle, affecting oral health. At the same time, emphasis will be placed on early detection and prevention. The module will cover potential solutions to improve access and further incentivize health professionals to incorporate oral health discussions into their practice. The training will be completed with key takeaways underscoring the importance of oral health awareness and preventive measures. An interactive question-and-answer session will be conducted, and participants will have time to share their experiences and discuss special concerns.

Stage 3: Evaluating the Effectiveness of BOHAT

A validated questionnaire will be used by each nondental health professional before the training session to gauge their baseline KAP regarding oral health assessments. The same questionnaire administered after training will help assess the impact and effectiveness of BOHAT on the KAP of nondental health professionals. The scores obtained from the posttest of BOHAT will be compared with benchmarks as observed by dentists. This comparative assessment aims to establish the effectiveness of BOHAT through the tool's degree of conformance with existing standards in dental practice. Retention analysis 3 months after the posttest will evaluate and measure the retained knowledge and acquired skills from the training sessions. Results of the retention analysis will rate how effective the training was when applied and in the long run to help modify or reinforce the practice of oral health assessment.

Statistical Analysis

Chi-square tests will be used to compare the number and percentage of oral health problems detected in a timely manner by nondental health care professionals before and after the training. Referral frequencies before and after training will be used to measure the changes in early referral behavior. Paired *t* tests or Wilcoxon signed-rank tests will be used to analyze any differences found. We will create a reflected quantitative summary of baseline knowledge, and improvement in the KAP of oral health will be evaluated using validated pre- and posttraining questionnaires. Thematic analysis of the qualitative data obtained through the semistructured interviews and focus group discussions will help provide insights into improvements in collaboration with dental and health professionals.

Data from the training assessment and improvements in competence will be analyzed using paired *t* tests, and the reliability of BOHAT will be assessed using the Cronbach α. Referral logs will subsequently be analyzed to gauge increased accessibility to dental care, and trends over time will be evaluated using longitudinal data analysis methods such as linear mixed-effects models. Finally, retention analysis will be conducted 3 months after the training to examine the sustainability of acquired knowledge and skills measured using KAP questionnaires, and time effects will be analyzed using repeated measures ANOVAs.

Ethical Considerations

The Declaration of Helsinki principles will be followed while conducting the research [17]. Ethical approval was sought from the institutional ethics committee of Manipal College of Dental Sciences Mangalore, Manipal Academy of Higher Education (reference number: 24023). Additionally, the Institutional Protocol Approval Committee of the Manipal Academy of Higher Education provided approval for the study (2300400101). Informed consent will need to be provided by every participant after verbal and written information regarding the study is given to them.

All participant data will be anonymized: Names, addresses, or any other forms of unique characteristic directly identifiable in any data collected will be removed from the data set prior to its analysis. In preparation for data coding, all participants will be allocated an ID code that links to personal details using a secure key held separately. For sensitive data that cannot be anonymized, such as qualitative responses or images, access to identifiable data will be strictly limited to authorized research team members. Electronic data shall be stored on secured, encrypted, password-protected devices. Physical records shall be kept in locked cabinets. There shall be no sharing of identifiable data beyond the research team, and the data shall be used only for research.

Participants will not receive monetary compensation for this study, but they will be compensated for any travel costs associated with their involvement in the study. No identifiable characteristics of the participants will be described in the manuscript, supplemental materials, or images.

Results

Study Status

As of January 20, 2025, the study was in the preliminary phase (Substage A: Item and Domain Development). The study will be carried out for a period of 42 months. We have received institutional ethics committee and Institutional Protocol Approval Committee approval for the study. The research team had a meeting with the District Health Officer, Dakshina Kannada District on January 10, 2025, and the study protocol was submitted to the District Health Officer for review. Data collection procedures had not started yet. The study was progressing as per the planned timeline.

Dissemination

This study will be complemented by in-depth qualitative and quantitative analysis. The results of the study will then be presented at relevant scientific conferences and professional meetings as oral presentations and published in academic journals.

Expected Outcomes

The expected outcomes of the study include timely identification of oral health problems and an increase in early referral behavior. This will improve oral health assessments by nondental primary health care providers and oral health KAP of these nondental primary health care providers, leading to enhanced collaboration with dental and other health professionals and improved training and competency. Increased access to dental care is also expected.

Discussion

Overview

Oral health problems can have a significant effect on people's quality of life, interpersonal connections, general well-being, and self-esteem [4]. It is therefore important to address the role of preventive techniques and early diagnosis of oral pathologies in reducing the risk of developing further oral-health-related complications affecting not just oral but also general health. Therefore, oral health assessments are an important part of estimating disease risk, monitoring existing conditions, and improving oral health [5].

The current educational frameworks for these practitioners do not sufficiently cover oral health topics, leading to gaps in knowledge and practice [18]. Health care providers face problems effectively assessing and addressing oral health issues in the population because of a lack of adequate training and inaccessibility of tools specialized for the Indian population.

The Brief Oral Health Status Examination allows carers to monitor the dental health of patients in aged care institutions who are cognitively challenged as well as those who are not. However, the study was conducted in only one nursing home, and the sample size was small [19]. THROAT is another instrument for the oral evaluation of hospitalized older adult patients with medical conditions [6]. OHAT is an assessment tool designed for people with cognitive impairment and is easy to use by nondental staff, such as nurses and caretakers. Nonetheless, OHAT has drawbacks, including nonsignificant and weak correlations and percent agreements for the saliva, oral cleanliness, and dental pain categories [10]. The Oral Health Screening Tool for Nursing Personnel (OHSTNP) evaluates the functioning of the mouth as well as oral health status for inhabitants in long-term care homes. Although the OHSTNP had high specificity for screening the lips, tongue, gums, tissues, saliva, and oral cleanliness, its sensitivity is low, indicating the need for further improvements in these categories [20].

The Minimum Data Set (MDS) is a standardized assessment tool used extensively in long-term care settings that includes an oral health component. Nevertheless, studies have indicated that oral and dental items in the MDS 2.0 lack validity and often underdetect oral health problems among residents of nursing homes [21]. This limitation highlights the importance of developing an instrument like BOHAT, which can both assess oral health conditions with relative accuracy and, most importantly, provide actionable findings for nondental health care workers. The Dental Hygiene Registration (DHR) is a dental hygiene assessment scale suitable for nurses working in institutions [22]. The DHR index requires individual judgment and attendance by a dental professional. The DHR is not an alternative to examinations by dental professionals but an aid for nurses and other caregivers in their daily work [22]. The Oral Assessment Sheet aims to improve the oral health of older adults who require nursing care using 3 items in each of the following 3 categories: oral hygiene, biting and chewing, and oral function [23]. However, challenges concerning its use for oral assessments by care workers have been highlighted [23]. BOHAT seeks to fill these gaps by providing a more credible and valid assessment framework

Within nondental health care settings in India, a critical issue has emerged surrounding the insufficient attention given to oral health due to a lack of adequate training, lack of tools, and underutilization of health care providers for oral care [24]. The role of AYUSH practitioners as nondental health professionals is often underappreciated or even underutilized in the Indian health care setting. Josyula et al [25] pointed out the discrepancies in role perceptions among various health system actors, indicating that AYUSH practitioners are not fully integrated into the public health framework, which limits their ability to effectively contribute to oral health promotion. This lack of integration is echoed in the findings of Kharbanda et al [18], who emphasized that AYUSH professionals, when appropriately empowered with training, can go a long way in promoting oral health. CHWs have a role in addressing oral health issues, but their effectiveness is hindered by poor training and inadequate resources.

According to Najmunnisa et al [26], CHWs can be empowered to serve as oral health literacy workers, but actual knowledge and attitudes toward oral health are often insufficient for promoting preventive behaviors. Reddy and Singh [27] also noted that a comprehensive spectrum of health-promoting behaviors, including oral health, is central to community well-being. The necessity of integrating oral health education in the training of CHWs has thus been demonstrated by these studies, which have shown positive results after CHWs had appropriate structured training [28]. Promotion of oral health by professionals not trained as dentists and by nurses and midwives has also been documented. Villarosa et al [29] discussed how indigenous health workers promote oral health while a woman is pregnant, and their findings suggest that nondental professionals could positively impact maternal oral health. Likewise, only one study conducted by Garry and Boran [30] considered that, to improve the care of older adult patients, enhanced oral health training needs to be incorporated within the nursing curriculum. With a more concrete educational foundation, oral health outcomes could be improved across a variety of demographics.

The challenges that nondental health care providers face in India are not unique to that country. International studies conducted by McGrath et al [31] and Scrine et al [32] showed that health professionals from all disciplines acknowledge their role in oral health, yet they lack the training and resources to effectively develop programs. Therefore, there is a universal demand for cross-disciplinary collaboration and training to ensure that oral health receives adequate emphasis in broader health initiatives.

Insufficient research has been conducted to determine how oral health assessment tools can be integrated into the routine practice of nondental health care professionals. Furthermore, the existing literature does not adequately address the training needs to attain effective tool use among these professionals. Evidence pertaining to the validation of the oral health assessment tools in varying clinical scenarios and patient populations is also lacking. Finally, there is a lack of literature investigating the effectiveness of enhanced oral health assessments on overall patient outcomes and preventive care. These gaps in research provide the rationale for the development and validation of BOHAT to fill these gaps with a culturally appropriate tool that can be efficiently used by nondental health care professionals in India.

Beyond dentistry, oral health is important for general well-being and good health [33]. Unfortunately, the absence of specialized instrumentation for nondental health care providers often creates a barrier to early detection and treatment of oral health diseases. This calls for a comprehensive and easy-to-use instrument; hence, the need exists for BOHAT. It allows nondental health care professionals to conduct effective oral health assessments, thus addressing the need for holistic approaches to health care.

Challenges and Solutions

A major challenge can be a lack of awareness of the importance of oral health care among nondental health professionals. There is a need to conduct an awareness drive with campaigns aimed at professional groups and the community. Conducting a media campaign on television, radio, print media, and social media regarding the importance of oral health and its interlinkage with general health will be very useful. Another challenge is resources and funding. A possible solution for this challenge can be the exploration of grants aimed at health care innovations and public health improvements. Integration into current health care systems presents yet another possible obstacle. Integration issues can be identified and dealt with by working closely with health care administrators to ensure the integration of BOHAT into existing workflows, developing clear protocols and guidelines on implementation, then piloting the program in a few centers prior to a wider area. There can be difficulties relating to the collection and management of data. These may be overcome by ensuring strong systems for data management and error-free and effective data collection, training health professionals in data entry and management, and digitizing tools for data collection and analyses. For its sustainability, this program will require a long-term sustainability plan that includes periodic training and follow-up support for health professionals. A monitoring and evaluation framework should also be developed to check the program's impact, make necessary adjustments, and create community ownership and involvement to help sustain interest and participation.

Strengths of the Study

The BOHAT study fosters holistic health care that is interdisciplinary in nature by its inclusion of nondental health care professionals, therefore providing the basis for oral health to become part of general health assessments. It builds the capacity of nondental health professionals with training and education for better health outputs. This study aims to enhance the capacity of nondental health professionals in relation to the identification and referral of oral health conditions and increase access to dental care, particularly in underserved areas. This way, early identification and intervention will help prevent the progression of these oral diseases and reduce the health care system burden—improving the quality of life of patients. The research conducted here contributes to many sustainable development goals (SDGs) that pertain to good health, quality education, reduced inequalities, and effective partnerships.

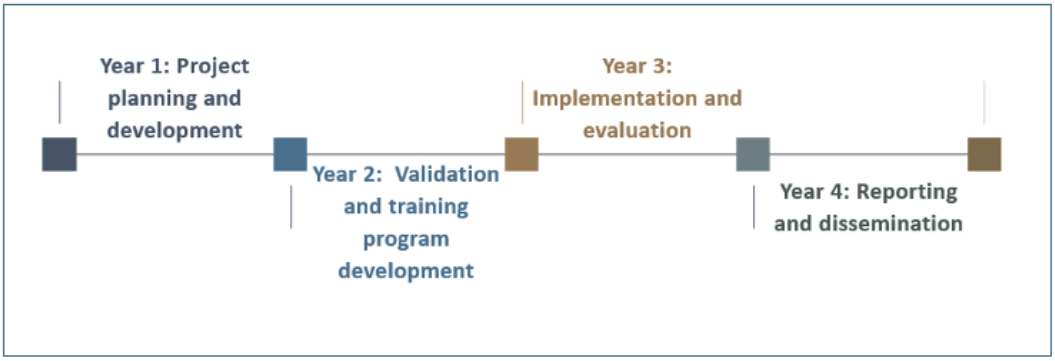
Link to SDGs

Oral health assessments are crucial for identifying problems early and preventing more severe oral and general health conditions [34]. Therefore, BOHAT is linked with many SDGs. BOHAT will support the attainment of several health and well-being SDGs. It will help support SDG 3: "Good health and well-being" by providing a systematic approach for performing oral health assessments [35]. It will help with the early diagnosis and prevention of oral diseases by building the capacity of nondental health professionals, hence promoting health and well-being. This study aligns with SDG 4: "Quality education" by training nondental health care professionals on the use of BOHAT and promoting continued education and capacity building, ensuring that health care professionals have the proper skills to manage oral health [36]. The study will help reduce inequalities in oral health, working in concert with SDG 10: "Reduced inequalities" [37]. Hence, it will reduce health disparities in oral health outcomes but ensure equitable access to quality health care. This will add depth to the exploration of oral health practices within a specified region, like Mangaluru Taluk, and establish ways to reduce health inequalities. Thus, working with the main stakeholders—nondental health professionals, PHCs, and people within the community—shall further stress the importance of partnership in line with SDG 17: "Partnership for goals" [38]. This will help underscore the indispensability of collaborative efforts in securing SDGs.

Research Timeline

Figure 3 shows the research timeline for the proposed study including the order of the main activities and the study milestones over time. The developed timeline spans a duration of 42 months, making sure that each of the stages of implementing such a research project takes place in a highly systematic, organized, and timely manner, making it easy to adapt to changes and solve eventual problems.

Figure 3. Research timeline.



Conclusion

The BOHAT study holds considerable potential for promoting oral health care through collaborative and interdisciplinary approaches. It will facilitate early diagnosis, timely referrals, and comprehensive care by integrating assessment actions for oral health into routine practice by nondental primary health care professionals. This work is a large step toward the

integration of oral health into general health care, by emphasizing general health and well-being and the reduction of health disparities. This study can, therefore, serve as a model for similar efforts elsewhere in the world and help to ensure good oral health outcomes and excellent quality of life for diverse populations.

Acknowledgments

The authors extend their appreciation to Prince Sattam bin Abdulaziz University for funding this research work through project number PSAU/2024/01/922576.

Abstract

Background: Optimal anticoagulation using vitamin K antagonists prevents strokes associated with atrial fibrillation and heart valve replacements. Preparedness for self-monitoring and self-management could improve outcomes, but this remains a challenge.

Objective: This study aimed to outline the methodology for developing and validating the PERSONAE scale, a self-report measure designed to assess the preparedness for self-monitoring and self-management of oral anticoagulation in adult patients.

Methods: This study comprises 2 main phases, and it adheres to the "COnsensus-based Standards for the selection of health Measurement INstruments" (COSMIN) guidelines for instrument development. The first phase involved the conceptualization of the PERSONAE scale, where a comprehensive literature review and a consensus meeting among experts were conducted to draft the initial items. Face and content validity were then established through an expert panel review. In the second phase (ongoing), a detailed sampling methodology will be used, targeting adult Italian patients on long-term oral anticoagulation. According to a performed simulation-based power analysis, the study aims to recruit a sample size of approximately 500 participants by using a combination of convenience and snowball sampling. Data collection will be facilitated through web-based surveys distributed through social media and patient networks, ensuring a wide and representative sample. Analytical procedures will include Mokken scaling analysis for item selection and confirmatory factor analysis to validate the scale's structure. In addition, internal consistency will be assessed using Molenaar Sijtsma statistics.

Results: The scale's content derived from phase 1 (process completed in December 2023) is grounded in a comprehensive literature review and based on the assessments of a panel of 12 health care expert professionals. The PERSONAE scale derived from phase 1 encompasses 20 items reflecting essential behaviors needed to assess the preparedness for self-monitoring and self-management of oral anticoagulation. Each item obtained a content validity ratio higher than 0.67, which is the critical content validity ratio indicating the minimum level of agreement among the experts for an item to be considered essential beyond the level of chance at a significance level of .05 for a 1-tailed test. From January 2024 to May 2024, we conducted the initial round of data collection and use Mokken scaling analysis to select items. A second round of data collection for confirmatory factor analysis was scheduled from June 2024 to September 2024, which will validate the scale's unidimensional structure. We expect to achieve robust psychometric properties, including high internal consistency and validated constructs.

Conclusions: The PERSONAE scale will be a valuable tool to assess patients' preparedness for self-monitoring and self-management of oral anticoagulation. The study's insights into technology-assisted learning preferences will inform the design of future educational interventions to enhance preparedness in adult patients.

KEYWORDS

self-monitoring; self-management; oral anticoagulation; vitamin K antagonists; preparedness; validation

Introduction

Vitamin K antagonists (VKAs), such as warfarin, are a group of medicines used to thin the blood, preventing the formation of harmful blood clots that can lead to stroke [1]. They function by inhibiting Vitamin K-dependent coagulation factors, which are essential for blood clotting. This class of medications is particularly vital for reducing the risk of stroke associated with atrial fibrillation and heart valve replacements, especially when direct oral anticoagulants are unsuitable for certain individuals, such as adults with multiple morbidities [1]. The use of oral anticoagulants globally is on the rise, reflecting an increasing need to manage conditions predisposing individuals to increased thromboembolic risks. Currently, about 2 out of every 100 Italians are on oral anticoagulants [2], including both direct and indirect agents [3]. This increasing prevalence underscores the necessity for regular monitoring of prothrombin time and appropriate dose adjustments, as inadequate monitoring and dose management could lead to serious adverse reactions and complications. Several studies have highlighted the risks associated with insufficient monitoring in the last 2 decades [4,5]. For instance, it was highlighted that patients on warfarin who did not have their prothrombin time regularly monitored were at a higher risk of major bleeding complications [4]. A meta-analysis published in 2020 confirmed that with the rising number of patients on oral anticoagulants, there is a proportional increase in adverse events related to inadequate monitoring [5].

People on long-term oral anticoagulation can use point-of-care testing equipment (POCT) to monitor their blood clotting time, typically measured by the international normalized ratio (INR) [6]. In managing their anticoagulant medication, these individuals have 2 primary options: self-management, where they adjust their medication dosage based on a predetermined dose-INR schedule, allowing them greater autonomy and immediate response to INR readings, or self-monitoring, where they measure their INR levels independently but consult health care providers to make dosage adjustments [7]. This distinction is crucial as self-management empowers patients to take full control of their therapy, potentially improving their adherence and outcomes, while self-monitoring still relies on professional guidance for dose adjustments [8,9].

Numerous studies and systematic reviews have demonstrated that these self-testing approaches are equally effective, if not superior, to routine physician-managed anticoagulation monitoring, providing evidence that patient-led monitoring can enhance therapy management and patient satisfaction [8,9]. For instance, a systematic review reported that patients who self-managed their oral anticoagulation therapy had significantly better control over their INR levels and fewer thromboembolic events than those who relied on professional monitoring [10]. In this context, a solid randomized controlled trial found that self-management was associated with higher patient satisfaction and better quality of life due to increased control over their health [11]. However, the choice between self-management, self-monitoring, and physician-managed care should be individualized based on patient characteristics. Recent researches highlight that health-related quality of life in anticoagulated patients varies significantly, indicating how some patients may benefit more from self-management while others may find self-monitoring or physician-managed care more suitable [9,12,13]. In addition, the quality of anticoagulation control, traditionally assessed by the time in the therapeutic range (%TTR), is enhanced by using recommended coagulometers like CoaguChek XS, which are globally endorsed, particularly in response to the COVID-19 pandemic [14,15].

While self-monitoring and self-management approaches have garnered strong evidence for their effectiveness and cost-effectiveness, a Cochrane review highlighted the need for further research into factors influencing individuals' preparedness for self-testing [8]. These factors include both psychological preparedness and preparedness in terms of objective equipment. Psychological preparedness encompasses patients' self-management knowledge, motivations for medical attention, health literacy, self-efficacy, and perceived and actual support systems [13,16]. Specifically, patients' knowledge about self-management affects their ability to understand and manage their treatment, while motivations for seeking medical attention could influence their commitment to regular monitoring. Health literacy impacts their ability to comprehend medical instructions and make informed decisions, and self-efficacy relates to their confidence in performing self-testing tasks [17]. Finally, perceived and actual support systems are crucial in providing the necessary resources and emotional support for effective self-management. Preparedness in terms of objective equipment involves access to and familiarity with POCT devices and other necessary tools. Evaluating preparedness for self-management and self-monitoring is therefore crucial in tailoring health care delivery, enhancing efficiency, and adequately preparing patients for self-testing [18]. The interaction between psychological preparedness and preparedness regarding objective equipment is critical. Patients who are psychologically ready but lack the necessary equipment, or vice versa, may not effectively self-manage their condition. Therefore, both aspects must be

addressed to ensure successful self-management and self-monitoring.

In Italy, for instance, adopting self-testing is complicated by organizational and professional barriers, such as the cost of POCT devices and concerns regarding the loss of direct control over treatment management [12]. Addressing this gap is essential, as enhancing patient preparedness through targeted interventions could substantially improve the effectiveness and patient outcomes of self-management programs, ultimately transforming anticoagulation therapy practices globally. The PERSONAE scale specifically addresses these gaps by assessing domains of preparedness and providing its comprehensive measure for self-management and self-monitoring. Thus far, no measures of the preparedness for self-monitoring and self-management exist in relation to this population. Therefore, the aim of this protocol is to outline the methodological steps for the development and validation of the PERSONAE scale, a self-report measure intended to assess the preparedness for self-monitoring and self-management of oral anticoagulation in adult patients. The study is currently focused on the Italian adult patient population, carefully considering the scalability and adaptability of the PERSONAE scale for diverse age groups and international settings. In addition, it aims to pinpoint the most favored technology-assisted learning options among patients undergoing anticoagulation therapy. The PERSONAE scale is expected to improve existing self-management protocols and practices by identifying areas where patients may need additional support or resources after a detailed assessment of patient preparedness. The findings from this pioneering research will lay the groundwork for innovative technology-assisted educational programs designed specifically to boost preparedness for self-monitoring and self-management of oral anticoagulation, marking a significant advancement in patient-centered health care solutions.

Methods

Study Design

This methodological, multiphase study comprises 2 main phases to develop and validate the PERSONAE scale for assessing the preparedness for self-monitoring and self-management of oral anticoagulation in adult patients. The protocol adheres to the "COnsensus-based Standards for the selection of health Measurement INstruments" (COSMIN) guidelines for instrument development [19].

Phase 1 focused on conceptualizing the PERSONAE scale through a developmental methodological approach involving 3 primary steps. First, a literature review was conducted to identify all relevant elements related to the preparedness for self-monitoring and self-management of oral anticoagulation (anticipated between May 2023 and July 2023). This review was recently published elsewhere [13]. Second, a consensus meeting among developers was held to examine the findings of the literature review and endorse its synthesis (anticipated time: September 2023). Finally, the situations representing patients' preparedness will be operationalized, and an external panel of experts, including nurses, physicians, and pharmacists, will determine the face and content validity of the newly developed scale (anticipated time: October 2023). Phase 2 focused on the validation procedures. Initially, the PERSONAE scale, containing items with acceptable content validity, was used for cross-sectional data collection from January to May 2024. The Mokken scaling analysis (MSA) procedure will be used to assess how the items in the first version of the scale behave in response to varying levels of the theoretical latent trait (preparedness). MSA is preferred over exploratory factor analysis in this study as it allows selecting items with the highest scalability, leading to a brief, unidimensional measure computed in a single score. Once a stable unidimensional PERSONAE scale is developed, a second round of cross-sectional data collection was performed from June to September 2024 to cross-validate the plausible unidimensional structure of the scale.

Participants and Procedures

In phase 1, a panel of 8-12 experts, comprising nurses, physicians, and pharmacists, evaluated the relevance and clarity of the proposed items derived from the literature review (content validity). The experts provided written consent to use their sociodemographic and professional characteristics for scientific reporting, as content validity is closely linked to the characteristics of the involved experts. This phase cannot be anonymous to ensure transparency, and variables such as sex, age, academic title, experience in studies testing content validity, and experience in oral anticoagulation were collected.

Once adequate content validity was established (December 2023), data collection commenced at the IRCCS (Istituto di Ricovero e Cura a Carattere Scientifico [Institute for Research and Healthcare]) Policlinico San Donato, using 2 cross-sectional data collection rounds using web surveys. A convenience sampling procedure was used, disseminating the web surveys through social media campaigns, newsletters, and flyers of associations involving anticoagulated patients, such as "Associazione Italiana Cardiopatici Congeniti" (AICCA). Participants for the second round were selected based on the same approach, with communication to prevent overlapping responses from participants who completed the survey.

Quality control measures have been implemented to ensure the integrity and quality of the data collection process: automatic data validation checks are included in the survey software to ensure that all responses are complete and adhere to the required format; unique identifiers were used for each participant to prevent duplicate responses in the dataset; and after data collection, statistical analyses were performed to identify any outliers or inconsistencies in the responses, which were then reviewed for accuracy.

Sampling Procedure

The sampling procedure will use a cloud-data recording system and web surveys disseminated through social media campaigns, newsletters, and flyers. The local study coordinator and the principal investigator will manage the sampling procedure following good clinical practice principles. An expected response rate of approximately 60% is anticipated, which is considered adequate [20]. This expectation is based on several considerations, including using targeted engagement strategies such as precontacting potential participants and leveraging

multiple dissemination channels. In fact, this rate aligns with the upper bound of the confidence interval from a recent meta-analysis, which reported an average response rate of 44.1% across 1071 studies in educational research [20]. Studies achieving similar response rates are those that have successfully implemented strategies to engage participants actively.

Sample Size

The sample size for phase 1 will be 8-12 experts. The sample size required for phase 2 to perform the Mokken scaling analysis was determined considering the 20 items derived from phase 1 (content validity phase). A simulation-based power analysis was performed in R (R Foundation for Statistical Computing; library "Mokken"), as shown in Multimedia Appendix 1. The aim of the simulation was to estimate a sample size that would provide sufficient statistical power, set at 0.8, to detect a minimum H coefficient of 0.3, indicative of a moderate scale according to Mokken's hierarchy. The H coefficient in Mokken scaling analysis measures the strength of the hierarchical relationship among items in a scale as it quantifies the extent to which items form a cumulative scale. A custom simulation function was created using R statistical software, with the following parameters defined: 20 items, initial sample (n= 200), number of simulations=100, desired power=80%, minimum H coefficient=0.3, and maximum number of iterations=30. For each simulation iteration, the function generated a matrix of binary data representing responses to the 20 items, with responses simulated under a simple random model (ie, the probability of success was 0.5 for each item). The results from the simulation suggested that a sample size of 500 patients would be needed to achieve the desired power of 0.8 for our MSA. The MSA procedure will help reduce the number of items to the first 10-15 items that define the preparedness for self-monitoring and self-management of oral anticoagulation in adult patients. The required sample size for the second round of data collection will be determined through Monte Carlo simulations, aiming to achieve a power of 0.8 for the confirmatory factor analysis (CFA) model.

Eligibility Criteria

In phase 1, experts must have at least 1 year of experience in managing patients with VKAs, hold at least a master's degree in nursing, pharmacy, or an MD degree, and have proficiency in the Italian language. Exclusion criteria for experts include conflicts of interest regarding the topic. In phase 2, patients aged 18 years and older will be included under oral anticoagulation treatment in an anticoagulation clinic for at least 3 months, with appropriate cognitive functioning and the ability to provide informed consent. Patients will be excluded based on more specific criteria to ensure the homogeneity and reliability of our data: those with a high Charlson Comorbidity Index (CCI>4), indicating severe concurrent medical conditions that could confound the study outcomes; patients undergoing any other experimental treatment affecting coagulation; and those with a history of noncompliance with medical regimens as reported by their health care providers.

Study Procedures for Cross-Sectional Data Collections

Patients who agree to participate will access a web-based survey (SurveyMonkey) through social media channels, mobile messages, or emails. The invitation will include all relevant information about the study's aim, methods, and tasks required for participation. Patients will confirm the inclusion and exclusion criteria during the initial access, and those who do not meet the criteria can opt out.

The data collection tools will include the PERSONAE scale derived from the content validity phase, a sociodemographic and clinical data form, and a graphic rating scale for assessing patients' preferences for technology-assisted learning options. Sociodemographic data will include age, sex, marital status, educational level, and occupation, while clinical variables will encompass time in oral anticoagulation, clinical indication for anticoagulation, %TTR, and history of thromboembolic or bleeding complications in the last 3 months. These clinical variables are consistent with previous research, such as the studies that developed measures of knowledge in the same population [21,22], which examined similar sociodemographic and clinical factors to assess anticoagulation knowledge in the Italian population. This alignment ensures that our data collection is grounded in established theoretical frameworks and allows authors to generate hypotheses relevant to our target population.

Data Analysis

The data analysis will involve the use of various statistical methods to develop and validate the PERSONAE scale.

For the first data collection round, MSA will be conducted using the "mokken" package in R [23]. MSA allows for the hierarchical evaluation of items, and the most relevant items that measure preparedness for self-monitoring and self-management of oral anticoagulation will be selected for the PERSONAE scale [24]. Loevinger's coefficient of homogeneity function will be used to assess the scalability of the items. Monotonicity violations will be checked, and violations below 80 will be consistent with the requirements of a Mokken scale [23,25]. Loevinger's coefficients of homogeneity (H) at the scale, item, and pairs of items level will be computed, where H values equal to or greater than 0.3, 0.4, or 0.5 indicate weak, moderate, or strong scales, respectively [23,25]. Item pairs violating monotonicity will be excluded, and floor and ceiling effects in data distribution will be assessed. Invariant item ordering (IIO) will be performed to further narrow down the pool of questions based on monotone homogeneity [25]. The IIO procedure will remove items one at a time until no significant violations are found. The Htrans (H^T) coefficient will express the accuracy of the IIO selection, and H^T>0.3 will denote proper IIO process and consistent Mokken scales. The final set of questions will be used to calculate ρ coefficients for reliability using the Molenaar-Sijtsma technique [26]. This approach is particularly adequate for assessing reliability in MSA because it provides a robust estimate of the internal consistency for nonparametric scales. The Molenaar-Sijtsma technique is well-suited for evaluating the scalability and reliability of the items within the scale, ensuring that the

PERSONAE scale reliably measures the construct of preparedness for self-monitoring and self-management of oral anticoagulation.

CFA will be used to cross-validate the plausible unidimensional structure of the PERSONAE scale derived from the MSA, theoretically containing 10-15 items, using Mplus 8.1 (Muthén and Muthén, 2017). An unrestricted and unspecified model will be used with a maximum likelihood robust estimation of parameters. A confirmatory factor analysis with covariates will be used to estimate measurement invariance between subgroups if linear relationships between participant characteristics and the scale's total score are detected [27]. Modification indices will be explored to identify items causing a violation of invariance. Items causing invariance will be evaluated for possible deletion from the final scale. The adequacy of confirmatory factor analyses in explaining sample statistics will be assessed using various fit indices, such as chi-square, chi-square/degree of freedom, comparative fit index, Tucker-Lewis index, and root mean square error of approximation [28]. Invariance testing based on different levels of CCI and other potential confounders will be considered if needed and is feasible to ensure that the scale functions equivalently across groups with varying levels of comorbidity and demographics.

Missing data will be managed using an available-case approach for missingness lower than 5% or regression imputations for missingness equal to or higher than 5%, assuming missing at random. The significance level for all analyses will be set at 5%. The software used for the analysis will include Mplus (version 8.1, Muthén and Muthén), IBM SPSS Statistics for Microsoft Windows version 27, and R (version 4.2.1, R Foundation for Statistical Computing).

Ethical Considerations

The present protocol was approved by the Ethical Committee of Ospedale San Raffaele (protocol number 52/INT/2023). Ethical considerations will be carefully adhered to throughout the research process.

In the first stage of the study, which involves experts assessing the content validity [29,30], written informed consent will be obtained from each expert. They will be fully informed about the study's objectives and their voluntary participation in the process. During the second part of the study, data collection will be carried out through anonymous web surveys. As per European Regulation 2016/679 and Legislative Decree 101/2018, this type of study ensures anonymity and does not require individual written informed consent from the participants [31]. However, to ensure transparency and participant understanding, a simple and clear presentation page will be provided to patients before they proceed to complete the web-based questionnaire. This page will explain the study's purpose, the voluntary nature of their participation, and the anonymity of the survey.

The research team will prioritize the confidentiality and privacy of all participants involved in the study, adhering to the ethical principles outlined in the Declaration of Helsinki. Personal data will be handled with utmost care, and all data collected will be stored securely and accessible only to authorized personnel involved in the study. Any potentially identifying information will be removed from the dataset to ensure complete anonymity. Throughout the study, participants' rights and welfare will be protected, and any potential risks will be minimized. The study findings will be reported and disseminated in a manner that preserves anonymity and confidentiality. Researchers will act responsibly, maintaining the highest ethical standards and ensuring that the study is conducted with integrity and respect for the participants' rights and well-being.

Results

The PERSONAE scale development and validation protocol has been fully funded by the "Fondazione Insieme per Vita agli Anni" with additional support from the Ricerca Corrente funding by the Italian Ministry of Health in 2023 (no specific grant number). The summary of the results is shown in Textbox 1.

Textbox 1. Results summarized per main categories.

Conceptual framework

- Defined by the literature summarized in a literature review published elsewhere, describing self-care behaviors in patients on oral anticoagulant therapy [13].

Focus of PERSONAE measure

- Assess how ready patients feel about undertaking and managing the tasks associated with their anticoagulation therapy by translating the behavioral content identified in the review into terms of preparedness (refer to Multimedia Appendix 1).

Item pool drafting

- November 2023

Expert panel for validation

- Date of content validation: December 2023.
- Median age: 36 (IQR 29-45) years.
- Education qualifications: 25% (n=3) with a master of science, 25% (n=3) with a doctor of philosophy, and 50% (n=6) medical doctors.
- Specialties: 16.67% (n=2) in cardiology, 50% (n=6) in nursing, 16.67% (n=2) in pharmacy, and 16.67% (n=2) in internal medicine.
- Experience: All experts with more than 6 years in oral anticoagulation.
- Sex distribution: 66.67% (n=8) females.
- Conflict of interest: None reported (100%, n=12).
- Content: 50% (n=6) in nursing, 16.67% (n=2) in pharmacy, and 16.67% (n=2) in internal medicine.
- Experience: all experts with more than 6 years in oral anticoagulation.
- Sex distribution: 66.67% (n=8) females.
- Conflict of interest: none reported (100%, n=12).
- Content validity ratio (CVR): All 20 items obtained adequate CVR (refer to Multimedia Appendix 1 for additional details).

Scale question

- “How prepared do you feel to independently monitor and manage your oral anticoagulation therapy for each of the following statements?”

Rating scale

- A 5-point Likert scale ranging from 1 (not at all prepared) to 5 (extremely prepared).

Data collection for phase 2

- Ongoing, anticipated completion by September 2024.

Impact of PERSONAE scale

- The PERSONAE scale will offer a comprehensive and validated tool to assess the preparedness of patients for self-monitoring and self-management of oral anticoagulation, aiding clinicians in tailoring interventions. Health care providers can empower patients to take an active role in their anticoagulation therapy, potentially improving treatment outcomes and reducing health care costs by encouraging safe and effective practices of self-monitoring and self-management.

Dissemination of results

- Upon successful validation, the results will be disseminated through peer-reviewed publications and presentations at international conferences. The research team plans to engage with professional societies and patient advocacy groups to promote the implementation of the PERSONAE scale in clinical practice globally.

The conceptual framework was defined by the literature summarized in a literature review published elsewhere, describing self-care behaviors in patients on oral anticoagulant therapy [13]. The focus on preparedness encapsulates the ability to perform specific self-care tasks and integrates the confidence and knowledge necessary to manage treatment proactively. In other terms, the version of the PERSONAE measure derived from phase 1 aims to assess how ready patients feel about undertaking and managing the tasks associated with their anticoagulation therapy by translating the behavioral content

identified in the review into terms of preparedness (Multimedia Appendix 1). Once the pool of items was drafted (November 2023), an expert panel for validating the PERSONAE scale was involved, and it consisted of 12 professionals with diverse qualifications and backgrounds in health care. The process of content validation was performed in December 2023. The median age of the experts was 36 (IQR 29-45) years. Regarding higher education qualifications, 25% (3/12) held a master of science degree, another 25% (3/12) had earned a doctor of philosophy degree, and the remaining 50% (6/12) were medical doctors. Expertise among the panel members varied, with representation from multiple disciplines critical to managing oral anticoagulation therapy. Specifically, 16.67% (2/12) specialized in cardiology, the majority, 50.00% (6/12), were from nursing, 16.67% (2/12) practiced pharmacy, and 16.67% (2/12) were from internal medicine. When considering potential conflicts of interest, it was noted that 100% (12/12) of the experts reported none. All experts had substantial experience with oral anticoagulation, with each member having more than 6 years of experience in the field, which provided a solid foundation for their evaluative contributions. Regarding sex distribution, the panel was predominantly female, with 66.67% (8/12) of the members being women. All content validity ratio (CVR) of the 20 items obtained adequate content validity based on the evaluation of the experts (Multimedia Appendix 1; all observed CVR were equal or higher to the critical CVR, indicating the minimum level of agreement among the experts for an item to be considered essential beyond the level of chance at a significance level of .05 for a 1-tailed test).

The question guiding the self-report assessments derived from phase 1 is: “How prepared do you feel to independently monitor and manage your oral anticoagulation therapy for each of the following statements?” Therefore, the scale is designed for the patients. In the current form of the scale, patients are asked to rate their level of preparedness on a 5-point Likert scale ranging from 1 (not at all prepared) to 5 (extremely prepared). Therefore, the scale prompts patients to consider their proficiency across a spectrum of 20 activities (items) vital to the effective self-management of their treatment, from medication adherence to lifestyle adjustments and the use of technology.

The data collection for phase 2 is ongoing, and it is anticipated to be completed in September 2024. The PERSONAE scale will fill a critical gap by offering a comprehensive and validated tool to assess the preparedness of patients for self-monitoring and self-management of oral anticoagulation. Clinicians will be able to use this scale to identify patients who may benefit from self-testing approaches and tailor interventions accordingly. Health care providers can empower patients to take an active role in their anticoagulation therapy, potentially improving treatment outcomes and reducing health care costs by encouraging safe and effective practices of self-monitoring and self-management.

Upon successful validation, the results will be disseminated through peer-reviewed publications and presentations at international conferences. The research team plans to engage with professional societies and patient advocacy groups to promote the implementation of the PERSONAE scale in clinical practice globally.

Discussion

Principal Findings

This study outlines a methodological approach to developing and validating the PERSONAE scale, a self-report measure aimed at assessing the preparedness for self-monitoring and self-management of oral anticoagulation in adult patients. This novel scale aims to help health care providers discern patients’ preparedness for autonomous oral anticoagulation management, potentially leading to customized treatment strategies that enhance patient independence and treatment adherence. High scorers on the PERSONAE scale might be suitable for self-testing and adjusting their medication. At the same time, those with lower scores could benefit from targeted educational programs to improve their management capabilities, pending further research to establish specific scale cutoffs for optimal outcomes. It is important to note that the practical application of this scale and its cutoff points require empirical testing in future research to assess criterion validity and establish effective thresholds for different patient outcomes.

Phase 1 of the research protocol, based on a developmental methodological approach, was based on a literature review [13], followed by a consensus meeting among developers who have operationalized the literature into 20 measurable items of preparedness, leading to the initial version of the scale as per previous research focused on developing new self-report measures [32,33]. An expert panel consisting of 12 professionals from diverse health care disciplines (cardiology, nursing, pharmacy, and internal medicine) validated the content of the PERSONAE scale in December 2023. The experts, who brought a wealth of experience from their respective fields, ensured that the scale’s content was relevant and applicable to various professionals involved in anticoagulation management. This multidisciplinary approach enriched the scale’s content validity, ensuring comprehensive coverage of the necessary competencies for effective self-management. This phase was instrumental in creating a scale that is scientifically sound and clinically meaningful. This initial phase set a solid foundation for the subsequent validation phase, aiming to confirm that the scale accurately measures preparedness in a way that is predictive of patients’ ability to manage their anticoagulation therapy effectively.

In phase 2, validation procedures will be conducted to ensure the reliability and validity of the scale, and it is anticipated to end in September 2024. This process will require 2 cross-sectional data collections among Italian adult patients currently undergoing oral anticoagulation treatment. The collected data will be used to assess the scale’s psychometric properties and determine its performance in measuring preparedness for self-monitoring and self-management of oral anticoagulation [34]. More precisely, the first cross-sectional data collection will provide the needed power to perform the MSA procedure and determine item behavior in response to varying levels of the theoretical latent trait (preparedness) [35]. The second data collection will be based on the version of the scale updated from the analytics of the first data collection, and a CFA will be used to cross-validate the unidimensional

structure of the PERSONAE scale. Cross-validation helps assess the generalizability of the scale's results and allows researchers to determine if the validity holds true beyond the initial sample used for scale development [36].

Limitations

Several limitations should be acknowledged. First, the sample size for the validation phase was based on a power-based simulation and Monte Carlo simulations, which may have inherent assumptions that could affect generalizability. Expanding future studies to include larger and more diverse populations could enhance the scale's validity across varied demographics and age groups. Second, the use of web surveys for data collection may introduce response biases, particularly biases associated with self-reporting, such as recall bias and social desirability bias. Although measures such as ensuring participant anonymity and confidentiality are planned to mitigate these issues, the influence of these biases cannot be entirely eliminated. In addition, further exploration into potential sources of bias, including sampling biases due to nonrandom selection methods and the impact of the data collection medium on participant engagement and accuracy, is necessary. Limitations stemming from the analysis methods, such as potential confounding factors not accounted for in the statistical models, should also be critically evaluated. Future research should aim to address these limitations by adopting more robust sampling frameworks, using mixed methods for data collection, and applying comprehensive analytical techniques to provide a deeper understanding of the scale's applicability and accuracy.

Comparison With Previous Work

While previous studies have explored various components of oral anticoagulation therapy, such as patient knowledge, health literacy, and self-efficacy in self-management, the PERSONAE scale introduces a unique comprehensive measure [2,7-9,17]. It is the first self-report tool designed to assess both self-monitoring and self-management preparedness among adult patients on oral anticoagulation therapy. This distinction sets the PERSONAE scale apart from existing scales that typically focus on isolated aspects of anticoagulation management. Existing measures often independently evaluate patient knowledge or health literacy, which does not necessarily translate to practical, actionable patient readiness. In contrast, the PERSONAE scale encompasses a broader spectrum of preparedness, integrating aspects of knowledge, self-efficacy, and practical application capabilities into a single measure. This integrative approach not only aids health care providers in identifying well-prepared patients but also pinpoints those who might benefit most from targeted educational interventions. Furthermore, the development methodology of the PERSONAE scale enhances its robustness and applicability. The scale was crafted to ensure scientific soundness and clinical relevance through a rigorous, multiphase approach that included a literature review, expert consensus, and external validation. This methodological solidity supports its potential for widespread adoption and use in clinical settings, distinguishing it further from other tools that may lack such comprehensive validation.

Conclusions

The PERSONAE scale represents a significant advancement in the management of oral anticoagulation therapy. It is the first comprehensive self-report measure specifically designed to assess the preparedness of adult patients for self-monitoring and self-management. This tool will enable health care providers to better identify patients ready to manage their treatment autonomously, possibly enhancing patient outcomes and optimizing therapy adherence. Our study aims to determine the scale's robust psychometric properties, which underscore its reliability and applicability in clinical settings. The PERSONAE scale's ability to encompass a broad spectrum of preparedness, from patient knowledge to self-efficacy and practical application skills, sets it apart from existing tools focusing on narrower anticoagulation management aspects. Looking forward, the PERSONAE scale has the potential to transform patient management in clinical practice globally. By facilitating the identification of patients suited for self-testing, the scale supports tailored educational interventions that can improve self-management skills among those less prepared. This approach promises to enhance patient autonomy and aims to reduce health care costs by improving treatment efficiency and satisfaction. Future research should focus on validating the scale across diverse patient populations to ensure its broader applicability. In addition, integrating the PERSONAE scale into routine clinical practice will be crucial for evaluating its impact on long-term patient outcomes and health care systems. Ultimately, the scale is poised to play a pivotal role in advancing patient-centered health care solutions in anticoagulation therapy.

Abstract

Background: Post–COVID-19 condition is emerging as a new epidemic, characterized by the persistence of COVID-19 symptoms beyond 3 months, and is anticipated to substantially alter the lives of millions of people globally. Patients with severe episodes of COVID-19 are significantly more likely to be hospitalized in the following months. The pathophysiological mechanisms for delayed complications are still poorly understood, with a dissociation seen between ongoing symptoms and objective measures of cardiopulmonary health. COVID-19 is anticipated to alter the long-term trajectory of many chronic cardiovascular and pulmonary diseases, which are common among those at risk of severe disease.

Objective: This study aims to use a single, integrated device—MouthLab, which measures 10 vital health parameters in 60 seconds—and a cloud-based proprietary analytics engine to develop and validate the Aidar Decompensation Index (AIDI), to predict decompensation in health among patients who previously had severe COVID-19.

Methods: Overall, 200 participants will be enrolled. Inclusion criteria are patients in the US Department of Veterans Affairs health care system; "severe" COVID-19 infection during the acute phase, defined as requiring hospitalization, within 3-6 months before enrollment; aged ≥18 years; and having 1 of 6 prespecified chronic conditions. All participants will be instructed to use the MouthLab device to capture daily physiological data and complete monthly symptom surveys. Structured data collection tables will be developed to extract the clinical characteristics of those who experience decompensation events (DEs). The performance of the AIDI will depend on the magnitude of difference in physiological signals between those experiencing DEs and those who do not, as well as the time until a DE (ie, the closer to the event, the easier the prediction). Information about demographics, symptoms (Medical Research Council Dyspnea Scale and Post-COVID-19 Functional Status Scale), comorbidities, and other clinical characteristics will be tagged and added to the biomarker data. The resultant predicted probability of decompensation will be translated into the AIDI, where there will be a linear relationship between the risk score and the AIDI. To improve prediction accuracy, data may be stratified based on biological sex, race, ethnicity, or underlying clinical characteristics into subgroups to determine if there are differences in performance and detection lead times. Using appropriate algorithmic techniques, the study expects the model to have a sensitivity of >80% and a positive predicted value of >70%.

Results: Recruitment began in January 2023, and at the time of manuscript submission, 204 patients have been enrolled. Publication of the complete results and data from the study is expected in 2025.

Conclusions: The focus on identifying predictor variables using a combination of biosensor-derived physiological features should enable the capture of heterogeneous characteristics of complications related to post–COVID-19 condition across diverse populations.

Trial Registration: ClinicalTrials.gov NCT05220306; https://clinicaltrials.gov/study/NCT05220306

KEYWORDS

Aidar Decompensation Index; AIDI; biophysical biomarkers of worsening health; biosensor-based physiological monitoring; cardiorespiratory, metabolic, renal, and neurological complications after COVID-19; early warning signs of clinical decompensation; long COVID; noninvasive monitoring of physiology; postacute sequelae of COVID-19; PACS; rapid assessment tool; risk triaging related to long COVID

Introduction

Severe complications of postacute COVID-19 infection like thrombosis, respiratory failure, and cardiac and vascular damage increase the likelihood of future morbidity and mortality in recovered patients. In one study of individuals who had been hospitalized with COVID-19, nearly a third (14,060/47,780, 29.4%) of individuals who were discharged from the hospital after acute COVID-19 were readmitted, and more than 1 in 10 (5875/47,780, 12.3%) died over a follow-up period of 140 days after discharge [1]. These events occurred at rates 4 and 8 times greater, respectively, than in the matched control group from the general population. In another study, the 6-month incidence of a new hospitalization among patients previously hospitalized with COVID-19 was found to be 29.8% [2]. SARS-CoV-2 infection can also lead to postacute development of substantial cardiac cellular abnormalities and cardiovascular clinical sequelae, including dysrhythmias, ischemic heart disease, heart failure, pericarditis, myocarditis, and thromboembolic disease [3]. Glycometabolic abnormalities are also evident in many survivors of acute COVID-19 and, in some cases, manifest as overt new-onset diabetes mellitus [4].

Risks of complications are higher among patients with comorbidities like congestive heart failure, chronic obstructive pulmonary disease, asthma, chronic kidney disease, diabetes, and hypertension [1,5,6]. Thus, although the current rate of new COVID-19 infection has dropped, the risk of morbidity, mortality, and organ dysfunction among the survivors of COVID-19 infection is high, especially among those with preexisting illnesses. Compelling evidence suggests that the pandemic may lead to new-onset kidney disease (and other noncommunicable chronic diseases including diabetes, cardiovascular disease, and neurological disease) in the millions. Given the scale and the chronic nature of several of its sequelae, post–COVID-19 condition (also known as “long COVID” or “postacute sequelae of COVID-19”) will reverberate with us for decades and will have broad and deep social and economic impact long after the COVID-19 pandemic abates [7]. Thus, it would be appropriate to infer that the next wave related to COVID-19 may not necessarily be a new strain but rather the surge of hospitalizations due to postacute complications. Developing strategies to prevent decompensation among high-risk survivors of COVID-19 has emerged as an unmet need.

One approach to the prevention of decompensation is to monitor for worsening in physiological parameters after hospital discharge. However, collecting such data longitudinally for prediction poses several challenges. First, only a limited number of parameters can be easily collected (eg, blood pressure, heart rate, oxygen saturation, etc), although additional parameters such as heart rate variability and lung function may provide additional prognostic data. Second, even if patients or families are able to collect these parameters longitudinally, there is no automated, validated method to analyze those data concurrently and provide a quantitative assessment of decompensation risk over time. These limitations hinder the sensitivity and thus the utility of current approaches to using physiologic parameters to predict decompensation risk among patients after COVID-19.

The overall objective of this study (trial registration: ClinicalTrials.gov NCT05220306) is to use a handheld, multisensor device—MouthLab, which measures 10 vital health parameters in 60 seconds—and a cloud-based proprietary engine to develop and validate the Aidar Decompensation Prediction Index (AIDI). MouthLab measures oral temperature, single-lead electrocardiogram, heart rate, breathing rate, heart rate variability, respiratory flow morphology, oxygen saturation, pulse rate, and basic lung function (forced expiratory volume in the first second and peak expiratory flow rate). The study will collect MouthLab data from patients previously hospitalized with COVID-19 (“severe COVID-19”) in order to identify decompensation predictor variables. These variables will be used to develop the AIDI to accurately predict decompensation events (DEs) related to post–COVID-19 condition. Index development will follow best practices in machine learning and algorithmic development, where the main outcome is any COVID-19–related event that leads to an emergency department (ED) visit, hospitalization, or the need for escalated care (new diagnosis or change in intervention to manage the chronic conditions). These DE cases will help inform the final set of predictor variables to develop the AIDI. In the future, early prediction and real-time risk triaging using the AIDI may support better clinical decision-making, thus preventing complications, controlling disease progression, and improving outcomes. The aim of this paper is to describe the protocol for this study to develop and validate the AIDI.

Methods

Study Design

This is a national, longitudinal, observational study. Potentially eligible patients will be identified using the US Department of Veteran Affairs (VA) Corporate Data Warehouse (CDW) and the COVID-19 Shared Data Resource. A total of 200 patients who have a history of “severe” COVID-19 infection in the previous 3-6 months and at least 1 of the specified comorbidities will be recruited. Severe COVID-19 is defined as requiring hospitalization for acute COVID-19 or its complications.

Participants will be required to use the MouthLab device twice daily and to complete monthly surveys administered remotely either by phone or through a web portal. Data will be used to develop a machine learning–based algorithm to detect DEs among patients in the postacute COVID-19 phase.

Study Setting

The VA is the largest integrated health system in the United States, with over 9 million patients enrolled. VA delivers care to US military veterans across 171 VA Medical Centers and 1113 outpatient care sites across the United States and Puerto Rico, Guam, and other US territories [8]. Nearly 50% of enrolled veterans are aged 65 years or older; 91.1% are male and 8.9% are female; and overall, veterans bear a greater burden of physical and mental health comorbidities than nonveterans [9,10].

Sample Size

To develop the AIDI algorithm, the study will collect longitudinal parameters that lead up to a DE with the MouthLab device. Because the actual multiparametric changes are unknown and are, in fact, the outcome of the study, the study aims to obtain as much data as possible from those who experience a DE. For this study, we estimate that 100 individual DEs would be sufficient to create a statistical algorithm to predict decompensation. The ultimate goal is to have the algorithm produce no false negatives (ie, if someone is at risk of decompensation while the algorithm says that they are not) and less than 10% false positives (ie, if someone is *not* at risk of decompensation while the algorithm says they are). That is, we do not want to miss any DEs at the cost of having some nonevents classified as being risky.

Al-Aly Z et al [11] observed that the risk and associated burden of pulmonary and extrapulmonary manifestations increase across the disease spectrum of acute COVID-19 infection (from nonhospitalized individuals to hospitalized individuals and then to those admitted to intensive care). The study implemented a comparative approach to examining postacute sequelae in individuals who are hospitalized with COVID-19 versus individuals with seasonal influenza (using a high-dimensional approach and through examination of prespecified outcomes). Results suggested that there is a substantially higher burden of a broad array of postacute sequelae in the individuals who are hospitalized with COVID-19, which provides features that differentiate post–COVID-19 condition (both in the magnitude of risk and the breadth of organ involvement) from postinfluenza viral syndrome [11]. A study by Mainous et al [2] demonstrated a hospitalization rate of 29.8% among survivors of “severe COVID-19.” Given that the AIDI study has defined “decompensation” more broadly than hospitalization alone, we anticipate higher decompensation rates among our study population. Conservatively estimating 1 DE per any participant, with an event rate of 60%, we would need 168 participants to complete the study in order to capture 100 DEs. Since we anticipate up to 15% dropout, we will aim to recruit 200 participants.

Eligibility Criteria

The inclusion and exclusion criteria are shown in Textbox 1.

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Aged 18 years and older
- Were hospitalized for treatment of acute COVID-19 or its complications in the prior 3-6 months
- At least one of the following comorbidities:
  - Hypertension
  - Asthma
  - Chronic obstructive pulmonary disease
  - Heart failure
  - Chronic kidney disease
  - Diabetes mellitus
- English fluency
- Comfortability with using technology
- Basic literacy with electronic platforms

Exclusion criteria

- Any motor disability that would impede the use of the MouthLab device as required with the left hand
- Pregnancy
- Cognitive deficits that would impede the ability to provide informed consent
- Alzheimer disease or other dementia
- Pacemakers and implantable cardioverter-defibrillators

Recruitment

This study will recruit participants from across the country who receive care at the VA. A waiver of the Health Insurance Portability and Accountability Act (HIPAA) and informed consent for screening will be obtained for recruitment. Three modes of recruitment will be used. First, eligible patients will be identified via the CDW and sent letters with information about the study and a number to call if they are interested in learning more. Second, those who have authorized the VA through any partnership programs (eg, COVID-19 research volunteer registry) to receive communication on research opportunities may be contacted for this study. Third, study flyers will be posted at three of the VA's post–COVID-19 condition clinics. The selection process will include best efforts to ensure equitable inclusion of different races, ethnicities, and age groups among the participants.

Ethical Considerations

The protocol was approved by the Central Institutional Review Board of the Veterans Healthcare Administration, on December 21, 2022 (1720625-1). Since this is a multisite study, individual institutional review boards at the VA Bedford Healthcare System and the VA Providence Healthcare System also reviewed and approved the study. Informed consent will be obtained from all eligible participants prior to shipping the MouthLab device, administering baseline surveys, and collecting any patient data. Upon obtaining consent, the research team will also obtain HIPAA authorization. No study-related tasks will be performed before obtaining both consent and HIPAA authorization. A member of the research team will send the informed consent form (ICF) to the patient via DocuSign and read through the form with the participants on the WebEx (Cisco) consent call. The person obtaining consent will review the ICF in depth and solicit all questions before the participants sign the ICF via DocuSign. Participants will receive an executed copy via email, and those who prefer to sign a physical copy will be mailed a consent form. This approach will allow participants sufficient time to follow up with questions and discuss before officially signing the consent form. Participants will receive US $85 at the end of months 1-5. At the end of month 6, upon the completion of study tasks (survey and device return), participants will receive US $175. The total potential compensation is US $600, paid by check.

Study Timeline

The timeline of the study is provided in Table 1.

In addition to MouthLab and survey data (Table 2), data will be collected from the CDW on patient demographics, comorbidities, medications, and potential DEs. The main DEs of interest are any COVID-19–related events that lead to an ED visit, hospitalization, or the need for escalated care (new diagnosis or change in intervention to manage the chronic conditions).

The study will collect information about the index hospitalization, related to COVID-19 either as a primary or secondary diagnosis, from the CDW. This information will include medications (including oxygen therapy), vitals, and the use of mechanical ventilation. Additionally, the index hospitalization will be classified as an intensive care unit–level admission or not.

Evaluation of DEs

Data on outcomes (DEs) will be collected at the end of the data collection period via the CDW, records obtained from non-VA hospitalizations and ED visits, and monthly and end-of-study surveys.

A DE is defined as a complication related to organ dysfunction induced by SARS-CoV-19 that establishes the need for a change in treatment or intervention. To identify these events, we will first identify all new diagnoses and treatments, including medications, health care visits, and changes in level of service (eg, outpatient, inpatient, and hospital at home), for each patient during the study period using national CDW data. The data reviewed will be limited to those linked to relevant service types (eg, emergency care, urgent care, primary care, cardiology, and pulmonology). A study staff member will review these outcomes with guidance from the principal investigator or other team member with medical training to establish which are highly likely, somewhat likely, and not likely to be related to COVID-19. The full set of outcomes (Table 3) will be used as one outcome in one approach to the development of the predictive algorithm, and the subsets of highly likely and somewhat likely DEs will be used in a second approach to development.

Table 3. Study outcomes.

Outcomes	Instrument or measure
Primary outcomes	
All-cause, higher-level health care use (hospitalization, ED[a], or urgent care visits within the VA[b] system)	Participant self-reporting, confirmed through EMRs[c]
All-cause health care use (within and outside the VA system)	Participant self-reporting, confirmed through record requests and EMRs
Highly likely COVID-19–related health care use	As evaluated by the PI[d] and subinvestigators
Highly likely and somewhat likely COVID-19–related health care use	As evaluated by the PI and subinvestigators
Secondary outcomes	
Highly likely and somewhat likely COVID-19–related health care use	As evaluated by the PI and subinvestigators
Highly likely COVID-19–related diagnoses, treatment, use, and medication	As evaluated by the PI and subinvestigators and confirmed in EMRs

[a]ED: emergency department.

[b]VA: Department of Veteran Affairs.

[c]EMR: electronic medical record.

[d]PI: principal investigator.

Data Blinding

Participants and physicians are blinded to the data from the MouthLab device. Participants will be informed that they are not restricted from seeking any level of care. There will be no medical intervention provided during or after the study as a consequence of any unfavorable trends in the MouthLab data, as these data are not being surveilled during the study.

Participant Data Protection

The confidentiality of participants will be maintained throughout the study. All participants will be assigned a unique subject ID by the data analyst. The crosswalk that matches the participant ID to the participant's name will be secured behind the VA firewall. Any data that may be published in abstracts and scientific journals or presented at medical meetings will reference the unique participant ID or will be aggregated, so to not reveal the participant's identity. Patient identifiable information such as name, address, email address, and phone number will only be used to support device shipment and return–related activities. Participants' unique identifiers, rather than personal information, will be connected to their device and survey data as well as any other data obtained from the electronic medical record. To protect participants' privacy, the Aidar Connect dashboard will not collect any patient identifiable information during registration, and pairing of MouthLab devices will be performed against the participants' IDs.

Safety Monitoring

During the monthly health surveys sent via the VA Office of Research and Development Qualtrics platform, participants will report any potential adverse events (AEs) that are possibly related to their COVID-19 diagnosis, as well as to any hospitalizations or medical care use. Study coordinators will follow up with participants to gather more information and have participants sign a Release of Information if needed. The investigator or study coordinator will determine whether the AE or serious AE meets the criteria for reporting; submit to the sponsor and VA Central Institutional Review Board all associated information and documentation related to each AE or SAE; and execute corrective actions as necessary.

Statistical Analysis

Feature Engineering and Selection

For each patient, baseline readings will be based on their first few MouthLab measurements. The number of observations used to establish the baseline will depend on the variability in each patient's reading. We will then summarize the patient's parameters obtained from the MouthLab data collection. At each time t, we will include the most recent observations, changes since the last reading, trends, variability in values, and comparison to the patient's baseline. Additionally, we will include information about demographics, symptom scores, other clinical characteristics, as well as key comorbidities. We anticipate that variable interactions will be important. Given the cohort size and the number of different features, regularization will be applied to avoid overfitting.

Outcome Modeling

We will define the outcome as patients experiencing a DE within τ time units (DEτ). For different values of τ, we will deploy a series of more sophisticated models in order to explore the predictive ability of different approaches, as detailed below. We will split up the data into training and testing datasets based on the time of enrollment. We anticipate an 80:20 split; in other words, we will set aside 20% of the data to evaluate the model performance. For each τ, we will construct a training dataset consisting of multiple overlapping time segments for each patient, which we refer to as the observation period (eg, 2 weeks), and multiple nonoverlapping time segments leading up to the outcome for the patients that experience the outcome, one of which contains the outcome.

Second, we will explore several other machine learning algorithms, including classification trees, random forest, and boosting approaches, to understand whether these more flexible modeling approaches have an advantage over the logistic regression approach. The output of any of these approaches is a predicted probability of a DE occurring within the following τ days given observations of a fixed observation interval (eg, up to 30 previous measurements, or ~2 weeks). As stated earlier, the goal is to develop the AIDI to predict worsening health. The detailed analysis laid out above will allow us to understand the ability of early prediction, that is, the critical time frame just prior to decompensation during which the probability of hospitalization becomes increasingly predictive.

The initial exploratory analysis will inform the selection of proper features for the analysis. We will model the patient's risk of hospitalization as a function of their physiological values, short-term changes in those values, changes from the baseline, etc. The initial exploratory analysis will inform features such as the appropriate time ranges (eg, should short-term changes be captured since the last reading or over the last 24 hours).

Performance Evaluation

In case of a lower-than-expected number of observed outcomes, or smaller differences than expected between those who experience the outcome and those who do not, we may revert from our 80:20 split to use cross-validation to measure performance. In that case, we will evaluate the algorithm using the leave-one-out cross-validation technique. We will implement this approach by leaving out one patient at a time (corresponding to potentially multiple observation periods to avoid fitting the model on data from the same patient as the model is being evaluated). The leave-one-out cross-validation technique facilitates cross-validation evaluation of the algorithm structure to assess its robustness to changes. This validation step will remake the algorithm for every patient left out of the algorithm development iteration. In short, this approach fits each algorithm using all available data except for (in our case) the data of one patient and then summarizes whether the algorithm predicts the correct classification of decompensation or nondecompensation for each observation period. This process is repeated over all available patients. For each τ, we will summarize the accuracy, false positives, and false negatives.

The resulting predicted probabilities of decompensation will then be translated into the easy-to-communicate AIDI, where there is a linear relationship between the risk score and the AIDI. At the conclusion of phase 3, the final COVID-19 DE detection performance of the AIDI will be evaluated using standard measures including sensitivity, specificity, and positive predictive value across a wide range of risk cutoff values. Overall, AIDI DE detection performance and lead time statistics will be examined across study populations as well as within subgroups. If necessary, to improve prediction accuracy, data may be stratified based on biological sex, race, ethnicity, or underlying clinical characteristics into subgroups to determine if there are differences in performance and detection lead times among the groups.

Results

Recruitment began in January 2023, and the first patient was enrolled in January 2023. At the time of manuscript submission, 204 patients have been enrolled. Publication of the complete results and data from the study is expected in 2025.

Discussion

Expected Findings

The AIDI study seeks to address a substantial challenge, that is, to develop an affordable, scalable, technology-assisted remote monitoring solution to facilitate early identification of abnormalities and timely intervention by clinicians to improve quality of life, functional status, and health outcomes and, ultimately, to reduce the burden of post–COVID-19 condition in the United States and elsewhere. We hypothesize that monitoring participants for 6 months and capturing critical cardiorespiratory parameters on a daily basis in conjunction with subjective and clinical data will enable the development of an index, the AIDI, that will empower high-quality clinical care using the MouthLab device as a rapid and early assessment tool. The outcomes of this research have the potential to redefine the care delivery for COVID-19 and potentially other conditions in the future, as well as push the boundaries of prevention and care beyond traditional care settings into the home.

Limitations

Self-selection bias may be a limitation of this study as participation is voluntary, and participants already comfortable with using technology might be especially motivated to participate in digital intervention studies. Patients who are particularly ill may not enroll due to difficulty managing the device, and those without cellular service will not be able to participate.

Strengths

Fully remote study procedures will enhance the accessibility of eligible research participants living in rural or remote locations away from large metropolitan areas. The MouthLab device has built-in SIM cards offering cellular data, thus requiring no other accessory, such as mobile phones, to transmit data to the Aidar Cloud. Using a web application dashboard will allow easier visualization of MouthLab data from all participants, providing us with the opportunity to intervene immediately in the event of absent data or noncompliance.

Conclusions and Future Work

The findings from this study will result in a predictive algorithm (AIDI) to predict decompensation among high-risk patients who previously had severe COVID-19. In the short term, this could be applied to monitoring such patients during the hospital-to-home transition or for longer periods at home. In the long term, we will adapt and validate the AIDI for monitoring other conditions. Our work will generate insight and guidance for scalable and easy-to-use digital monitoring solutions for remote management of chronic diseases to control disease progression, limiting the impact of comorbidities and, ultimately, improving health outcomes among high-risk populations.

Acknowledgments

The study used data from the Department of Veteran Affairs (VA) COVID-19 Shared Data Resource.

This clinical trial is funded in part with federal funds from the Department of Health and Human Services; Office of the Assistant Secretary for Preparedness and Response; and Biomedical Advanced Research and Development Authority, under contract 75A50121C00062. The clinical trial will be completed by the VA under contract with Aidar Health, Inc. and supported with resources and the use of facilities at the VA Bedford Medical Center and the VA Informatics and Computing Infrastructure (VA HSR RES 13-457).

The content is the sole responsibility of the authors and does not necessarily represent the official views of the VA, the National Institutes of Health, the Department of Health and Human Services, or the US Government.

Data Availability

Datasets generated or analyzed during the study described by this protocol may be made available from the corresponding author on reasonable request.

Authors' Contributions

JM and SE acquired the funding. JM and SE conceptualized the study with input from VGV. JM, JAP, and VGV drafted the paper with input from LKW, KL, and AJL. All authors contributed to reviewing and editing the final version.

Conflicts of Interest

Two authors (JM and SE) are employees of Aidar Health, Inc., which is the company that manufactured the technology being used in the research study (device and the software platform).

Abstract

Background: Transitioning into the first year of clinical practice as a nurse or changing specialties in the nursing career presents a critical phase for novice nurses characterized by excitement, apprehension, and the phenomenon of “transition shock.” Within perioperative nursing, this transition phase takes on distinctive challenges. However, there is a lack of empirical evidence on transition programs and arrangements.

Objective: This study aimed to evaluate the current transition-to-practice (TTP) arrangements available to new graduate and novice nurses within Australian perioperative nursing settings.

Methods: This study uses an exploratory mixed-method, multilevel triangulation with a sequential phase design to address 4 research questions. Phases 1 to 3 will use document analysis, surveys, and semistructured interviews to establish the findings of the research questions. Phase 4 will use meta-inference and triangulation to aggregate and analyze the data from all preceding phases. These findings will be the foundation for developing a framework to inform future TTP arrangements. This robust framework will embed empirical evidence, existing literature, and sound learning and teaching pedagogy. Results emerging from this study will be reported using the Good Reporting of Mixed Methods Study guidelines.

Results: This project received approval in June 2023. Following this, Human Research Ethics Committee approval was sought for phases 1 and 2, and recruitment began. As of August 2024, phase 1 has collected 50 responses and phase 2 has collected 69 responses. Data collection for phase 3 is projected to commence in May 2025 once data from phases 1 and 2 have been analyzed. Phase 4 is projected to occur in 2026. Each phase is anticipated to have a results manuscript submitted for publication once data are analyzed and written up.

Conclusions: The findings of this study will provide an in-depth exploration of TTP arrangements within perioperative nursing in Australia and provide a framework to guide the future development of TTP arrangements.

Introduction

Transitioning from undergraduate nursing studies or other nursing specialties into perioperative nursing is a pivotal phase in a nurse's career journey. This critical period in a novice nurse's career is often filled with excitement, nervousness, and apprehension. It is not uncommon for novice nurses to experience transition shock during this period, a term that describes a state of emotional and physical shock [1]. Novice nurses often describe transition as feeling like they are "drowning", "terrified," or "scared to death" [1]. Within the specialized field of perioperative nursing, transition challenges take on a unique dimension. Perioperative nurses play a vital role in surgical settings, where precision, attention to detail, and seamless care coordination are paramount. Professional health care organizations recognize the unique nature of critical care environments, such as perioperative nursing, that require specialized clinical competence and an understanding of the environment [2,3].

Transition shock in novice nurses arises from the sudden shift from a structured, academic environment to the complex and high-pressure demands of real-world practice, which often differ greatly from their expectations [1]. Without the support systems novice nurses rely on as students, novices can feel isolated, anxious, and insecure in their abilities. The disconnect, paired with high responsibility and fear of making mistakes, contributes to self-doubt, stress, and sometimes burnout in the early months of their job [1].

It is common practice for novice nurses to gain employment opportunities that offer the prospect of completing structured transition-to-practice (TTP) arrangements [4]. TTP arrangements serve as vital conduits connecting the theoretical knowledge acquired during undergraduate nursing education with the knowledge and skill requirements of real-world clinical practice. TTP arrangements play a pivotal role in nurturing the growth of novice perioperative nurses by providing mentorship, tailored training, and a supportive environment where new graduates can gain hands-on experience and develop the competence and confidence necessary for successful nursing practice [5,6].

A lack of empirical evidence regarding TTP arrangements within the perioperative nursing setting was noted during the literature search [7]. Transition arrangements and the impacts of transition shock are well defined within the literature [5,6]; however, there was a paucity of empirical literature that discussed the perioperative TTP arrangements. Most of the literature identified were discussion pieces [7]. Second, the "Educating the Nurse of the Future" report described the significant variability between TTP arrangements and their providers [8]. In this report, it was identified that there is no set standard for the length of transition arrangements, the content taught, how the content is taught, or the other supporting mechanisms available to novice nurses.

This study will address the 2 critical gaps in the literature and transition practices, as identified above. This paper provides a detailed overview of the methods to be used and a discussion of how the study will systematically investigate current practices in transition arrangements and the efficacy of these arrangements. It seeks to explore the perspectives of novice perioperative nurses and perioperative nurse educators regarding transition arrangements.

Methods

Study Aim

The proposed research study aims to evaluate the current TTP arrangements available to new graduate and novice nurses (hereafter referred to both groups as novice nurses) within Australian perioperative nursing settings and draw on these findings to develop recommendations and a theoretical framework to guide the design, development, and implementation of future transition arrangements within the perioperative nursing specialty.

Study Objectives

The following research objectives stem from the research aim and have been used to guide the development of the research questions. The research objectives are (1) to develop an understanding of the transition to practice arrangements in the perioperative environment; (2) to engage key stakeholders to share their opinions, expertise, and experiences on transition arrangements within the perioperative nursing environment in Australia; (3) to undertake critical analysis of the transition arrangements available in Australia to support novice nurses entering perioperative nursing; and (4) and to develop a framework and model that provides evidence-based educational, social, and holistic transition arrangements for novice nurses entering perioperative nursing.

Research Questions

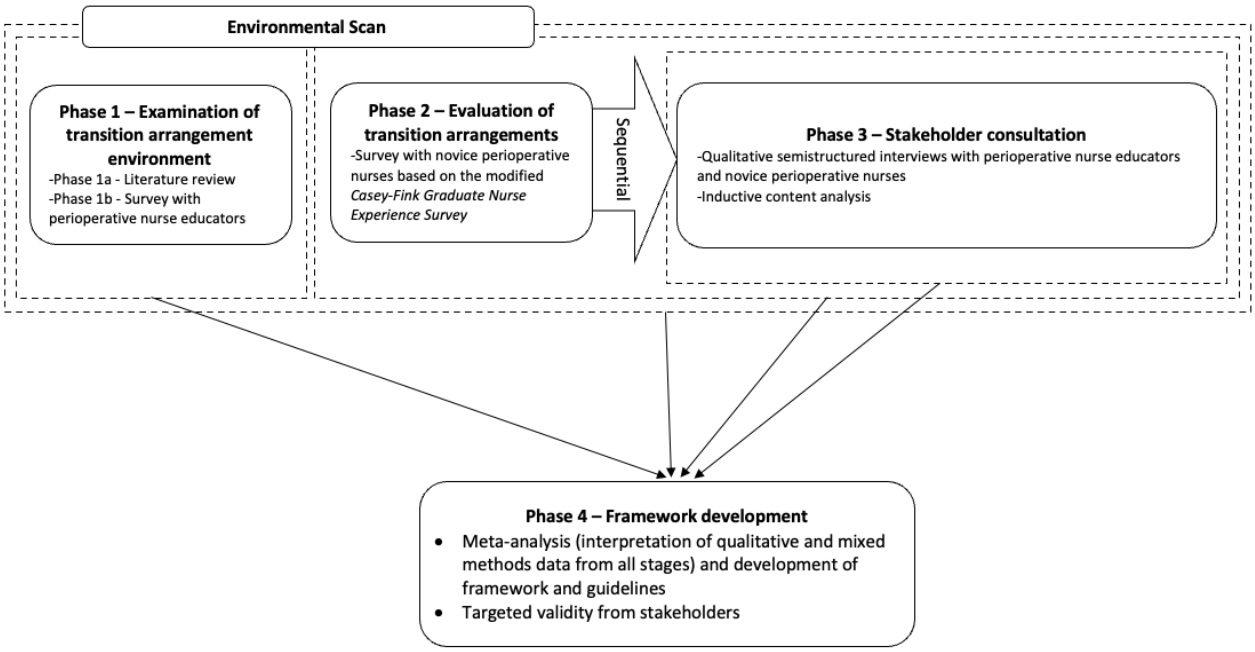
The following research questions (RQs) are designed to meet this study's aims and objectives:

- RQ1: What are the current TTP arrangements available to novice perioperative nurses within Australian health care organizations?
- RQ2: What are the content, methods, and educational philosophies used within these TTP arrangements?
- RQ3: How effective are TTP arrangements in supporting novice perioperative nurses and guiding them throughout the transition period?
- RQ4: What support do novice perioperative nurses undertaking TTP arrangements require to become competent and confident clinicians?

Design

This study uses an exploratory sequential mixed-method, multilevel triangulation design (Figure 1). This methodology combines both qualitative and quantitative data to yield a deeper understanding of the research questions [9]. By mixing qualitative (subjective) and quantitative (objective) research, the researcher is provided with the flexibility to explore complex issues and answer multifaceted research questions, thus bridging the divide between the 2 individual research approaches [10]. Several multifaceted research questions need to be answered within this study, which would not be feasible by using only quantitative or qualitative data sources.

Figure 1. Overview of the exploratory mixed-method, multilevel triangulation design with sequential phases.



This research study has 4 phases (Figure 1). The sequential design will be applied between phase 2 and phase 3 [11]. Phase 1 involves document analysis and surveys to establish the existing TTP arrangements for perioperative nursing in Australia. Phase 2 involves surveys with novice perioperative nurses to determine the effectiveness of TTP arrangements. The findings from these phases will inform the development of interview questions for phase 3. Phase 4 of this study will involve a meta-analysis of all the data collected, which will be used in the development of a framework. An overview of this research design is represented in Figure 1, illustrating the research questions being addressed and the primary method used at each phase. Ethics approval will be sought for phases 1 and 2, as these will run concurrently, and for phase 3.

Phase 1: Transition-to-Practice Arrangement Analysis

The first phase of the study will address RQ1 (what are the current TTP arrangements available to novice perioperative nurses within Australian health care organizations?) and RQ2 (what are the content, methods, and educational philosophies used within these TTP arrangements?) using document analysis techniques and a mixed methods survey. As most health care organizations do not publicly publish their transition arrangements, a survey was designed to collect data about TTP arrangements from perioperative nurse educators. The research team had access to their local TTP arrangements; however, surveying perioperative nurse educators will ensure that this study is not geographically confined. Using 2 data collection methods ensures sufficient results are obtained to understand the TTP arrangements used within the Australian perioperative environment.

Participants, Sample Size, and Recruitment

Data will be collected from 2 separate sources. First, the document analysis, which seeks to explore and understand TTP arrangements from within Australia. These TTP arrangements will be purposefully selected to ensure completeness and that they are currently used in novice perioperative nurses' training and transition support.

Second, a survey will be undertaken with a convenience sample of Australian perioperative nurse educators. Sample size calculations indicate an ideal sample size of 28 participants will be required using a confidence level of 95% and a margin of error of 5%) [12] to capture adequate responses to generalize TPP arrangement practices in Australia. Perioperative nurse educators who participate in this survey must be currently used within an Australian perioperative department in a role that allows them to provide nursing education, management, or support to novice perioperative nurses. Participants will be recruited through snowball sampling techniques and social media such as LinkedIn, Facebook (Meta), and Twitter (rebranded as X) [13]. In addition, professional nursing organizations and peak bodies for perioperative nursing will be approached to disseminate the survey.

Data Collection and Analysis

Manual searching of gray literature search engines, professional organizations, and health service websites will be used to identify suitable TTP arrangements for the document analysis component of this phase. Data collection for the document analysis and survey will be completed using a fit-for-purpose online survey. The survey tool was designed based on the authors' scoping literature review findings [7]. The survey instrument will collect data regarding the duration of TTP arrangements, modality, pedagogy and content taught, assessments, efficiency, and barriers. The survey will remain open until the required sample size is reached, or until all recruitment strategies have been used.

The document analysis tool and survey will collect both qualitative and quantitative data. Qualtrics StatsIQ will be used for descriptive statistical analysis and frequencies for quantitative data. Qualitative data will be analyzed using Braun [14] and Clarke's [15] 6-step guide to thematic analysis. NVivo

(Lumivero) software will be used for data management and coding of qualitative data. The findings from this phase will be used to inform the semistructured interviews for phase 3.

Phase 2: Survey Phase

Phase 2 of the project will use an online survey to address RQ3 (How effective are TTP arrangements in supporting novice perioperative nurses and guiding them throughout the transition period?) by exploring the effectiveness of TPP arrangements within perioperative nursing from the novice nurse perspective. By doing this, the researcher will understand the efficacy of TTP arrangements within perioperative nursing. Understanding transition practices, particularly from the novice nurse experience, is essential as novice nurses are integral to transition arrangements. Transition arrangements should be designed around novice nurses' learning and organizational needs and resources.

Participants, Sample Size, and Recruitment

A convenience sample of novice perioperative nurses who have recently completed a TTP arrangement within perioperative nursing will be sought for this study phase. It is anticipated these participants will be familiar with the transition arrangement they undertook. A 3-year inclusion criterion is set based on Benner's Novice to Expert Theory [16]. Nurses within the perioperative specialty with over 3 years of experience are often considered competent and an expert and no longer novices [16].

Significant missing data were noted when attempting to calculate sample sizes for this phase. An accurate estimate of the current population of novice perioperative nurses in Australia was unable to be achieved without making several assumptions that may lead to inaccurate sample size calculations. As the purpose of this phase is to inform the interview development of the next phase (interview phase), therefore a purposive, convenience sample will be the aim for this survey, where all reasonable recruitment strategies will be undertaken and the survey will remain open for 12 months.

Recruitment will be conducted through social media and snowballing, through professional organizations such as the Australian College of Perioperative Nurses, at conferences, and through university contacts to disseminate to graduate perioperative nursing students.

Data Collection and Analysis

Data will be collected using the revised Casey-Fink Graduate Nurse Experience Survey [17]. The survey tool was modified with the written permission of the survey tool authors. Adjusting the survey allows contextualization to the Australian perioperative nursing setting and enables the inclusion of further questions relating to participants' experiences during the transition. The Casey-Fink Graduate Nurse Experience Survey examines novice nurse transition across 8 domains, these being Role Confidence, Organize and Prioritize Care, Support, Role Satisfaction, Stress and Burnout, Resilience, and Organizational Commitment and Preceptorship [17].

Data will be analyzed using SPSS (IBM Statistics) software [18]. Descriptive and inferential statistics will be completed, including reliability testing (Cronbach α), linear regression, and factor analysis (varimax rotation) [19,20]. The NVivo software [15] and Braun and Clarke's [14] 6 steps of thematic analysis will be used to analyze the open-ended qualitative survey questions. The findings from this phase will be used to inform the semistructured interviews for phase 3.

Phase 3: Interview Phase

In phase 3, semistructured interviews will be conducted to address RQ4 (What support do novice perioperative nurses undertaking TTP arrangements require to become competent and confident clinicians?). These interviews will involve 2 cohorts: novice and perioperative nurse educators. The aim of phase 3 is to comprehensively examine the components of transition arrangements essential for success from the perspective of these 2 sample groups. This approach will also facilitate an exploration of the similarities and differences in the perspectives of the 2 cohorts.

Participants, Sample Size, and Recruitment

A total of 8-12 participants from each cohort will be sought to complete semistructured interviews. Purposive sampling techniques will be used to ensure a suitable breadth of participants. Continuous comparative analysis will be used throughout the interview process to examine data saturation. Participants must meet the eligibility requirements of novice perioperative nurses and perioperative educators, as defined in the above phases, to participate in phase 3.

Recruitment for phase 3 will commence in the previous 2 phases. Both cohorts will have the option to express their interest in participating in follow-up interviews after the completion of their survey. To maintain the confidentiality of participants and their survey responses, participants who choose to enroll for follow-up interviews will be redirected to a separate survey to collect their names, contact details, and cohort group. The study will use social media and snowball if insufficient participants are recruited through this method.

Data Collection and Analysis

A data collection instrument will be developed for phase 3, following the sequential completion of phases 1 and 2. The findings from these earlier phases will inform the development of the interview tool and semistructured interview questions. Before delving into a detailed exploration of TTP arrangements, a comprehensive understanding of the content, methods, and philosophies within TTP arrangements and the experiences of novice perioperative nurses must be obtained.

The interviews will be audio recorded and transcribed verbatim before data analysis is undertaken. NVivo software [15] will be used for thematic analysis using Braun and Clarke's [14] 6-step guide. This process will be applied to both cohorts, and the results will be compared and triangulated to uncover the experiences and perspectives related to TTP arrangements of novice perioperative nurses and experienced perioperative nurse educators. Differences and similarities between the cohorts will be carefully examined and presented.

Phase 4: Meta-Inference and Framework Development

The final phase involves the analysis of data and findings from the previous 3 phases. Data will undergo meta-inference analysis and triangulation to establish the findings directly aligned with the research aims, objectives, and questions. These findings will form the foundation for developing a framework to guide the design, development, and implementation of future perioperative nursing TTP arrangements. This framework will be embedded in the empirical evidence uncovered by this study, existing literature, and adult learning principles. Targeted validity checking will be used to ensure rigor and congruence of the research findings.

Peer Reviews

This study has completed 2 peer reviews. The initial review occurred during the confirmation of candidature milestone for Doctor of Philosophy students. This review encompassed 2 independent reviews from experts in their field. The second review was conducted as part of the approval process by the CQUniversity Human Research Ethics Committee for both phases 1 and 2 of the study.

Ethical Considerations

As this study spans 4 phases, ethics approval will be obtained in 2 applications. The initial ethics application encompasses phases 1 and 2 and has been approved by the CQUniversity Human Ethics Research Committee under approval number 0000024139. The subsequent ethics application will be submitted once data analysis from phases 1 and 2 is completed and a semistructured interview protocol has been developed for phase 3.

Results

This project received approval in June 2023. Following this, Human Research Ethics Committee approval was sought for phases 1 and 2, and recruitment began. As of August 2024, phase 1 has collected 50 responses and phase 2 has collected 69 responses. Data collection for phase 3 is projected to commence in May 2025 once data from phases 1 and 2 have been analyzed. Phase 4 is projected to occur in 2026. Each phase is anticipated to have a results manuscript submitted for publication once data is analyzed and written up.

The results from this study will be disseminated locally and at relevant national and international conferences. The findings from this study will also be disseminated in peer-reviewed nursing journals. Media releases will be undertaken as opportunities arise. In addition, this study will be published and disseminated as a thesis document to meet the requirements of the Doctor of Philosophy program.

Discussion

International Significance

In examining the international implications of this study, it is evident that the findings should hold significant relevance on a global scale, reflecting the shared challenges encountered by novice nurses worldwide as they transition into specialized fields [21].

Identifying and exploring gaps in empirical evidence regarding TTP arrangements within perioperative nursing is not unique to Australia; many countries grapple with similar challenges in standardizing and evaluating TTP programs [7]. By addressing these gaps, this study will offer insights that extend beyond national borders, providing a comparative perspective on the effectiveness of transition practices.

Furthermore, the development of a framework and model based on evidence-based educational, social, and holistic transition arrangements has implications beyond Australian perioperative nurses. Components of the framework could be used to inform the development of TTP arrangements internationally. In addition, aspects of this study can be replicated internationally to identify common trends and differences between countries in TTP arrangement practices. The challenges novice perioperative nurses face are likely shared globally, making a well-informed framework adaptable and applicable in different countries to enhance the quality of transition programs.

Available Evidence

It could be argued that TTP arrangements from other specialty areas could be used within the perioperative nursing realm to support novice nurse assimilation; however, perioperative nursing requires a unique skill set and specialized knowledge that is incomparable to other nursing contexts [3,22]. For this reason, a rigorous literature review was undertaken to establish the existing body of literature related to TTP arrangements within perioperative nursing. The literature review identified a paucity of empirical evidence, with most research on perioperative TTP arrangements consisting of discussion and editorial papers [7]. In addition, most papers described the TTP arrangement they offer rather than provide an evaluation of the TTP arrangements. Papers that evaluated TTP arrangements frequently measured efficacy by participant retention postcompletion [7]. In addition, an Australian national report also identified that TTP arrangements are unregulated and unmonitored [8]. This has led to significant variability between TTP arrangements and their providers.

The lack of empirical evidence and the variability between TTP arrangements provide the rationale and justification of this study. The aims, objectives, and RQs developed are aimed to address these gaps and limitations. It will also provide a guiding framework for TTP arrangement design, development, and implementation within perioperative nursing.

Methodological Discussion

Integration (with or without method integration) is an essential element within mixed methods methodology [10]. This differs from multimethod research, where various methods are used, but data or data analysis are not required to be integrated [10]. Within this study, mixed methods are adopted as the methodology for a multitude of reasons. Mixed methods are frequently used in evaluation research as the research questions are often multifaceted, such as phases 1 and 2 within this study [9]. The third phase of this project requires data collection from multiple sources, as novice perioperative nurses and

perioperative nurse educators are key participants in this topic. The mixed methods methodology is well suited to collecting and mixing multiple data sources from various participant cohorts [9,10].

The mixed methods methodology uses significant formalization approaches to ensure rigor and accuracy of results [10]. Numerous mixed-method designs are available for the researcher to use to provide a pragmatic and appropriate approach to their research. This study uses an exploratory mixed-method, multilevel triangulation design with sequential phase design to achieve the desired research aim and objectives [9,10]. Using this design, the researchers can collect data in distinct phases and sequentially. Each phase of this study requires a differing method due to the lack of perioperative nursing TTP literature. In addition, phase 3 of this study relies on the findings from phases 1 and 2. The findings from phases 1 and 2 are related to the characteristics of TTP arrangements and the experiences and efficacy of these arrangements. Using these findings, an interview tool can be developed for phase 3 to explore TTP arrangements in great depth.

Implementation Challenges and Limitations

The researchers have identified several potential challenges and limitations that may affect this study. The use of online surveys, generalizability, and the methodology will be discussed herein. By identifying these challenges and limitations in the early phases of the study, mitigation strategies can be enacted to prevent or minimize their impact.

The use of online surveys presents a potential implementation challenge. It is estimated that online surveys attract response rates anywhere from 15% to 60% [23]. Regarding this study, it may suggest that the surveys of phases 1 and 2 may not receive the desired number of participants. The implication of this challenge is minimized as sound plans for participant recruitment have been included in the research methods. In addition, the survey will remain available online until an appropriate number of participants is reached. It is also observed within online surveys that some responses may be fraudulent [23]. Fraudulent refers to multiple responses from the same participant, or the tool might be inappropriately and opportunistically used. This may cause misrepresentation in the data collected and affect the findings. This study overcomes this challenge by ensuring that participants must complete a reCAPTCHA before accessing the survey, placing a cookie on participants' browsers to prevent surveys from being completed more than once by the same participant, and preventing search engine indexing [12].

Sample size and generalizability considerations have been incorporated into this study and the methods. However, capturing all potential demographic participants and participant experiences in a study is difficult. Furthermore, it is difficult to ascertain the population sizes of the participant cohorts within this study. The researcher used their own experiences to establish an estimated total population size that was used for sample size calculations. Therefore, the components of this study may not apply to all perioperative novice nurses. Generalizability has been addressed by ensuring accurate sample size calculations for the relevant phases of the study. In addition, it has been addressed by the recruitment strategies and analysis strategies.

Finally, the mixed methods methodology presents some unique challenges. In particular, the length of the study can be greater than a single-method study [10]. This is particularly relevant within this study as phase 3 is sequential from phases 1 and 2; therefore, the project length will be increased. In addition, there is potential difficulty in reconciling and triangulating differences in data. Data sets that may emerge from this research could be noncongruent. However, this will lead to further discussion possibilities [10]. A delimitation of this method is that data sets from each phase can often be cross-validated and confirmed, adding to the validity and trustworthiness of the research.

Acknowledgments

This research project is supported by the Centaur Memorial Fund for Nurses – Higher Research Degree Scholarship. Generative AI was not used in the preparation of this manuscript.

Data Availability

Data sharing is not applicable to this article as no data sets were generated or analyzed during the preparation of this protocol.

Abstract

Background: With the existence of various frozen embryo transfer (FET) methods currently used in the field of assisted reproductive technologies, the debate surrounding which of these is superior remains. All FET protocols aim to prime the endometrium and time embryo transfer during the window of implantation. Current methods include the true natural cycle FET (tNFET), modified natural cycle FET, artificial cycle FET, and ovulation induction. Each of these harbors, distinct advantages and disadvantages, namely, surrounding the timing of transfer and flexibility conferred through this process. More recently, a newer approach has been used whereby the need to monitor or trigger ovulation is circumvented, with luteal phase support commenced once a certain follicle diameter and endometrial thickness criteria are met but before ovulation. However, the research into this protocol has certain important limitations that our study seeks to address.

Objective: This study aims to assess the feasibility of a progesterone-modified natural cycle protocol for FET. The primary outcome will be the presence of a corpus luteum on ultrasound scans on the day of embryo transfer. The secondary outcomes will include the number of clinic visits required per patient undergoing the protocol, biochemical pregnancy rate, and clinical pregnancy rate.

Methods: We will conduct a prospective cohort study, recruiting 20 women undertaking FET at the Public Fertility Care of The Royal Women's Hospital in Melbourne, Australia. These women will be matched to a control group who have undergone the tNFET protocol within the preceding 12 months of the study start date.

Results: This project received ethics approval on July 17, 2024, with commencement of the study in September 2024, aiming for a duration of completion of 9 months. The completion of the follow-up and submission of the study for publication are anticipated for September 2025.

Conclusions: After this preliminary study, the aim would be to progress to a noninferiority randomized controlled trial to compare the progesterone-modified natural cycle protocol for FET to the tNFET.

KEYWORDS

frozen embryo transfer; fertility care; reproductive health; infertility; progesterone-modified natural cycle protocol; in vitro fertilization

Introduction

Frozen embryo transfer (FET) has been increasingly used over recent decades in Europe [1,2] and Australia [2]. With advancements in cryopreservation techniques and increasing use of FET, debate still exists around the optimal method of endometrial preparation to achieve the best possible pregnancy rates and improve various maternal and neonatal outcomes. The most widely used protocols for endometrial preparation include the natural cycle FET (NFET), artificial cycle FET (AFET), and ovulation induction methods [3], with the latter two protocols usually reserved for anovulatory women. While the true NFET (tNFET) relies on monitoring for a surge of endogenous luteinizing hormone (LH) and rise in progesterone (P4) as markers of ovulation to time P4 supplementation start and embryo transfer, the AFET protocol involves exogenous hormone (estrogen, followed by P4) administration to mimic the natural cycle and prime the endometrium. Furthermore, while the AFET confers greater flexibility in terms of timing FET precisely, there is evidence to suggest lower overall implantation rates and higher miscarriage rates from this technique [4]. The literature also suggests there may be a higher rate of obstetric complications for both mother and fetus, including pre-eclampsia [5] and fetal macrosomia [6]. Therefore, the advantage of tNFET centers on avoiding excessive exogenous hormone administration and the resulting adverse events (AEs) linked to AFET. However, the inflexibility conferred by the tNFET in terms of the need to closely monitor endometrial thickness, follicle size, and hormone levels may require multiple blood tests and 7-day in-vitro fertilization clinic availability. Further, the ovulation induction protocol involves the expense and invasiveness of using medication without removing the need for a 7-day service or the need for blood tests. Therefore, a protocol that achieves ovulation and gives a degree of flexibility to the timing of embryo transfer would be highly appealing to both patients and in-vitro fertilization clinics.

To address these challenges, some clinics use the modified NFET (mNFET) protocol where exogenous human chorionic gonadotropin (hCG) is administered to trigger ovulation when a dominant follicle of typically 17 mm or more is detected, thereby conferring some flexibility in scheduling FET while still relying on the woman's natural cycle [7]. Retrospective cohort studies have shown favorable outcomes in both the tNFET and mNFET as compared to the AFET [8]. Notably, two recent randomized controlled trials (RCTs) showed similar rates of pregnancy in the mNFET as compared to the tNFET, with higher implantation rates in the mNFET cohort [7,9]. However, at least one study has reported better outcomes with tNFET [10], and the most recent Cochrane systematic review on cycle regimens of FET did not compare tNFET and mNFET [3].

To further explore the potential flexibility conferred by the mNFET method while mitigating the lack of flexibility in scheduling the transfer, a prospective case series proof-of-concept study by Weiss et al [11] has trialed a novel approach whereby timing the FET to the endogenous LH surge is circumvented. Instead, P4 luteal phase support (LPS) via vaginal pessary is commenced once a mature follicle of >12 mm is identified in ultrasound scans and the lining of the endometrium is sufficiently thick at >7 mm, with FET scheduled 2-5 days from this point, depending on the stage of the embryo at the time of cryopreservation. It appears that this P4-modified natural protocol for FET (P4mNFET) provides a simultaneous advantage of both retaining a natural cycle, with authors suggesting ovulation took place regardless, as well as conferring greater flexibility for the scheduling of embryo transfer without compromising clinical pregnancy rates. It should be noted that the authors report a degree of variation in the timing of P4 initiation in relation to the last ultrasound scan without any further blood tests. Importantly, no AEs were reported from this study of 42 participants. A more recent retrospective cohort study comparing this method to AFET demonstrated comparable outcomes in terms of clinical pregnancy, miscarriage, and live birth rates between the methods [12]. A further single-center retrospective cohort study reported similar results when comparing outcomes from patients undergoing FET cycles within the natural and artificial protocols, as compared to a P4mNFET protocol [13]. Taken together, P4mNFET may confer greater flexibility to clinicians and patients in timing FET, negating the requirement to await ovulation, with comparable outcomes.

Overall, this study aims to provide greater flexibility in timing transfer by providing participants with vaginal pessaries of P4 to be used before FET and, subsequently, confirming the absence of elevated endogenous P4 on the day of P4 supplementation start and confirming the presence of a corpus luteum on an ultrasound scan. It is hypothesized that the potential advantages of this P4mNFET protocol, over triggering and manipulating ovulation, may include the increased flexibility in the timing of commencing P4 without the requirement of a large follicle, the elimination of the importance of pinpointing the exact timing of ovulation, and the potential cost-saving to the patient and clinic as a result of these components. It is anticipated that the outcomes of this pilot cohort study may inform the planning and development of a subsequent noninferiority RCT to further reinforce the utility of such a protocol.

Methods

Study Type

The proposed study will adopt a pilot cohort methodology consisting of 12 weeks of intervention and follow-up monitoring of participants for primary and secondary outcomes. Secondary outcomes will be compared with retrospective data from the tNFET control group.

Participants

The study population will consist of 20 women undertaking FET cycles at the Public Fertility Care of The Royal Women's Hospital (RWH), Melbourne, Australia. The recruitment process will commence at this location, whereby clinicians and nursing teams will be invited to screen the patients they interact with for eligibility for the study. These staff members will be trained on appropriate screening according to the study protocol and will be delegated by the principal investigator. Eligible patients will then be approached for study by team members who are not directly involved in potential participants' clinical care and, therefore, will not have had any clinical interactions with the participant. All patients will be provided with a patient informed consent form (Multimedia Appendix 1) to ensure they are familiar with the protocol requirements and understand their rights as participants. Additionally, they will be provided with a patient information document created by the research team (Multimedia Appendix 2) to assist with patient education surrounding the use of the P4 pessary during the study.

Inclusion criteria consist of women with regular cycles defined as 21-35 days, women younger than 40 years at the start of a cycle, and women whose BMI ranges from 18 to 35, inclusively.

The exclusion criteria include anovulatory women, women who are 40 years or older at the start of the cycle, and women who have preexisting contraindications to exogenous P4 supplementation, such as those with liver disease or thromboembolic disease. The exclusion criteria will also include the use of additional LPS (eg, subcutaneous), women with uterine pathology, including congenital malformations of the female reproductive tract, endometrial polyps, intrauterine adhesions, adenomyosis, and leiomyoma. Regarding the retrospective element of the study, patients for whom inclusion criteria information is lacking will not be included in the study.

The control group will consist of retrospective data from 20 women, matched against inclusion and exclusion criteria, within the Public Fertility Services of the RWH data bank. These controls would have undergone tNFET at the service provider within the preceding 12 months of the study start date.

All participant data will be stored securely in the database of the RWH Reproductive Services Unit (RSU), ensuring the security of patients' confidential information. Furthermore, on completion of the study, all patient information will be securely stored within the hospital server with restricted access for a minimum of 15 years, with custodial responsibilities given to the principal investigator.

Outcome Measures

The primary outcome will be the presence of corpus luteum with a characteristic "ring of fire" appearance on the transabdominal ultrasound on the day of embryo transfer.

The secondary outcomes consist of the number of clinic visits required per patient undergoing this protocol, the biochemical pregnancy rate defined as the detection of βhCG in serum or urine [14], and the clinical pregnancy rate defined as the ultrasonographic visualization of one or more gestational sacs [14].

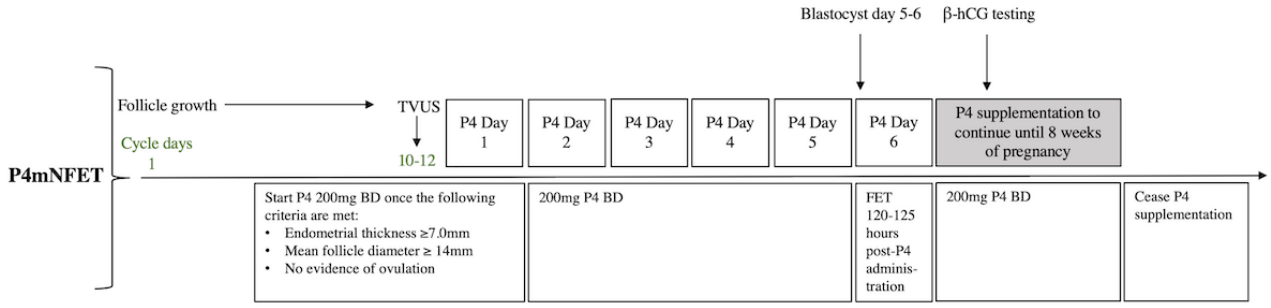
Randomization

This is a pilot prospective cohort study without randomization.

Intervention: P4mNFET Protocol

Participants will undergo active treatment for 2-8 weeks, with a follow-up period of up to 12 weeks or gestation. For a patient with a 28-day menstrual cycle, on days 10-12 (Figure 1), a transvaginal ultrasound will be performed to evaluate for an appropriate endometrial thickness of 7.0 mm and a mean follicle diameter of 14.0 mm. If these ultrasound criteria are met, the patient will undergo blood tests for estrogen, LH, and P4 on the same day; should levels of P4 be under 5 nmol/L, exogenous P4 supplementation via vaginal pessary will then commence on the same day, with FET scheduled 120-125 hours post P4 administration. P4 pessary, ORIPRO (Orion Laboratories Pty Ltd T/A Perrigo Australia, Balcatta, Western Australia), at a dose of 200 mg twice daily, will be the only form of LPS for patients undergoing P4mNFET. Following FET, serum hCG will be taken 10 days later. If positive, LPS via P4 pessary at 200 mg twice daily will continue to 8 weeks' gestation with a pregnancy scan between 6-7 weeks. If negative, the patient will be advised to cease LPS. In the instances where P4 levels are greater than 5 nmol/L, the patient will be removed from the study.

Figure 1. Visual representation of the patient journey with P4mNFET protocol. FET: frozen embryo transfer; hCG: human chorionic gonadotropin; P4: progesterone; P4mNFET: progesterone-modified natural cycle protocol for frozen embryo transfer; TVUS: transvaginal ultrasound.



Control: tNFET Protocol

The control group will consist of patients, matched to the inclusion and exclusion criteria, who would have undergone tNFET at the RWH RSU. Patients undertake an ultrasound on days 10-12 of their cycle for those with a 28-day cycle. Upon detection of a dominant follicle of 18 mm or more and an endometrial thickness of 7 mm or more, serum LH and P4 are taken. An LH surge is defined as >25 IU/L in the context of P4 <5 nmol/L. Ovulation is defined as a P4 >5 nmol/L. LPS, in the form of a vaginal ORIPRO 200 mg pessary (Orion Laboratories Pty Ltd T/A Perrigo, Australia), is commenced on day 1 post ovulation, and embryo transfer is carried out 6 days post LH surge.

Statistical Analysis and Sample Size

Given the qualitative and binary nature of the primary outcome, no statistical testing is proposed for this. Secondary outcomes will undergo *t* tests and Mann-Whitney *U* tests for data that are normally and not normally distributed, respectively. Should there be significant variation in the key baseline variables between the study and the control group, a multivariate analysis will be performed.

Safety Monitoring and Reporting

Safety oversight for the study will be carried out under the direction of the independent safety monitor working within the framework of the Data and Safety Monitoring Board Charter to ensure an objective assessment of the safety and efficacy of the study. AEs deemed secondary to the administration of the pessary will be monitored and reported accordingly by either the investigators or the independent safety monitor, from administration to the end of follow-up. Relevant physical examinations or investigations will then be carried out to ensure the effects of the AE are managed accordingly. The primary investigator will record the AE appropriately into the patient's medical record or study shadow file.

Integration and Dissemination of Findings

On completion of the study, primary and secondary outcomes will be disseminated to investigators, ensuring the confidentiality of patient information. Findings will be synthesized and communicated to colleagues of the RWH RSU and Human Research Ethics Committee, as well as in further peer-reviewed publications related to the RCT that may be conducted following the completion of this cohort study. Additionally, findings will be communicated confidentially in potential presentations at national and international conferences.

Results

This project was conceived in November 2023. It was subsequently approved by the RWH Human Research Ethics Committee on July 17, 2024. Local governance approval was granted on August 28, 2024.

Commencement of the study began in September 2024, aiming for a duration of completion of 9 months, and completion of follow-up and submission of the study for publication in September 2025.

Discussion

Overview

We have designed a pilot cohort nonrandomized study to assess the feasibility of a novel P4mNFET protocol that circumvents the need to monitor for an endogenous LH surge to pinpoint ovulation to schedule FET. This protocol, therefore, may combine the advantages of the tNFET, AFET, and mNFET into one protocol that provides greater flexibility for the timing of transfer with fewer requirements for surveillance and no impact on pregnancy outcomes.

Anticipated Challenges

As with any study of this kind, some challenges are anticipated with patient recruitment. The research team aims to mitigate this via appropriate counseling and use of our patient informed consent form, which is in a question-and-answer format.

The second challenge may be the accuracy of the retrospective data for the control group. This is an inherent issue with all retrospective studies. However, it is anticipated that key secondary outcomes will be accurately reported.

Limitations

As with any study, there are limitations to acknowledge. First, cohort studies lack the same level of rigorous methodology as an RCT. However, based on the results of this pilot, we aim to proceed with a noninferiority RCT to compare this novel protocol to tNFET. Second, the retrospective nature of the control group may be associated with issues related to data entry.

Implications

The implications of this study are that it may inform the future of FET. If primary outcomes are met such that the presence of the corpus luteum is maintained with P4mNFET, then a noninferiority RCT will be carried out to formally compare the two methods. Moving forward, this P4mNFET protocol may provide clinics the opportunity to perform FET with greater scheduling flexibility and comparable outcomes to established methods while potentially leading to cost-saving and increased efficiency.

Acknowledgments

Generative artificial intelligence was not used in the writing or conceptualization of this protocol.

Abstract

Background: Type 1 diabetes (T1D) is a growing global health concern, with a notable rise in incidence in Saudi Arabia. Despite the potential benefits of early detection through screening programs, such initiatives are currently lacking in Saudi Arabia and other Arab countries.

Objective: This study aims to evaluate the feasibility, acceptability, and cost-effectiveness of a T1D-screening program targeting high-risk individuals, specifically children with a first-degree relative diagnosed with T1D.

Methods: The VISION-T1D program is a prospective cohort study focused on the early detection of presymptomatic T1D by screening children aged 2-18 years. The primary screening method involves testing for islet autoantibodies, including insulin autoantibodies, glutamic acid decarboxylase autoantibodies, insulinoma associated-2 autoantibodies, and zinc transporter-8 autoantibodies. Optional genetic testing, including human leukocyte antigen phenotyping and the genetic risk score, is offered. Outcomes include the feasibility of the screening process, prevalence of early-stage T1D, psychological impacts, educational intervention effectiveness, progression rates to stage-3 T1D, and economic viability.

Results: The VISION-T1D program began in May 2024. As of December 2024, a total of 176 families have been enrolled. Data collection will continue until April 2025, with final data analysis projected for mid-2025.

Conclusions: The VISION-T1D study provides a practical approach to T1D screening tailored to the health care landscape of Saudi Arabia. The insights gained from this pilot program will inform the development of a national, population-based screening initiative designed to reduce diabetic ketoacidosis at diagnosis, improve long-term outcomes, and alleviate the economic burden of T1D. The VISION-T1D initiative could also serve as a scalable and sustainable model that can be adopted internationally, contributing to global efforts to manage and prevent T1D.

KEYWORDS

islet autoimmunity; type 1 diabetes mellitus; T1D; screening program; antibody detection by agglutination–polymerase chain reaction; PCR; ADAP; human leukocyte antigen; genetic risk score

Introduction

Background

The incidence of type 1 diabetes (T1D) is rising globally, with Saudi Arabia reporting a surge to 31.4 per 100,000 youths annually, making a nearly 9-fold increase over the past decade [1,2]. This trend is compounded by high rates of diabetic ketoacidosis (DKA) at diagnosis [3], ranging from 40% to 77%, the highest in the Arab region [4,5]. DKA at T1D onset is associated with significant morbidity, mortality, and long-term complications [6-9]. DKA also imposes a substantial economic burden through direct and indirect medical costs [10-12]. Early detection by T1D screening is crucial in reducing DKA incidence and mitigating the health and economic impacts [13,14].

T1D pathogenesis involves a complex interplay of genetic predisposition and environmental factors, resulting in the autoimmune destruction of pancreatic β-cells [15,16]. Individuals with a first-degree relative (FDR) affected with T1D have a 15-fold higher lifetime risk of developing T1D compared to the general population [13]. Screening for islet autoantibodies identifies presymptomatic stages (stages 1 and 2) at least in children, adolescents, and young people, enabling timely interventions that may alter disease progression [13,17-19]. Individuals with multiple positive islet autoantibodies have a 99% lifetime risk of progressing to clinical stage-3 T1D, with 84% developing insulin-dependent diabetes within 15 years of seroconversion [18-20]. Screening programs in several countries have successfully reduced DKA at diagnosis, improved long-term outcomes, and lowered health care costs [13,14].

Despite successful screening initiatives in other countries, Saudi Arabia and neighboring Arab countries lack such programs. Moreover, most prior efforts have been confined to research settings, leaving a gap in knowledge about real-world implementation in health care settings [14,18,20,21]. The VISION-T1D protocol (NCT06513247) aims to bridge this gap by evaluating the feasibility and cost-effectiveness of a pilot, T1D-screening program for FDRs of individuals with T1D in Saudi Arabia. Aligned with Saudi Arabia's National 2030 Vision, which prioritizes health improvement and the reduction of chronic disease burden, the VISION-T1D initiative aims to establish a robust framework for broader, population-based, T1D-screening implementation in Saudi Arabia. Furthermore, it could also serve as a scalable and sustainable model for international adoption, thereby contributing to global efforts to manage and prevent T1D.

Study Objectives

Primary Objectives

The primary objectives are as follows:

- Evaluate the feasibility of implementing a pilot, T1D-screening program for early detection in FDRs of patients with T1D in Saudi Arabia.
- Determine the prevalence of stages-1, -2, and -3 T1D among FDRs of patients with TID in Saudi Arabia.

Secondary Objectives

The secondary objectives are as follows:

- Examine the psychological impacts of T1D screening on caregivers, including changes in anxiety, depression, distress level, and health-related quality of life before and after receiving screening results.
- Evaluate the effect of early detection on reducing DKA incidence at stage-3 T1D onset.
- Analyze the cost-effectiveness of implementing a T1D-screening program in Saudi Arabia.
- Evaluate the natural history of T1D progression in identified presymptomatic individuals, tracking time to clinical onset and changes in health outcomes over time.
- Examine the effectiveness of educational interventions on caregivers' knowledge of T1D screening and early identification.
- Investigate the genetic predisposition to T1D within our population through human leukocyte antigen (HLA) testing and validate the genetic risk score (GRS) 2 in the Saudi population.

Methods

Study Design and Setting

The Vision-T1D study is a prospective cohort designed to screen children aged 2-18 years who have an FDR with T1D (index case). Participants are recruited from the University Diabetes Centre (UDC) at King Saud University Medical City (KSUMC) in Riyadh, Saudi Arabia. The diagnosis of T1D in index cases is based on the American Diabetes Association criteria [22], and T1D classification is determined by a clinical diagnosis from a specialized endocrinologist, with or without confirmatory islet autoantibodies testing. Exclusion criteria included index cases diagnosed with other forms of diabetes and non-Saudi children due to different ethnic and genetic backgrounds.

Ethical Considerations

The study was approved by the Institutional Review Board of King Saud University Ethics Committee (approval: E-248566). The pilot phase began in May 2024, with 1 year dedicated to recruitment and screening. All procedures were conducted in accordance with the ethical standards of the Declaration of Helsinki and national research ethics guidelines.

Informed consent was obtained from all participants or their legal guardians prior to data collection. Privacy and confidentiality were maintained according to GCP standards. Participants identified as at risk or presymptomatic for T1D

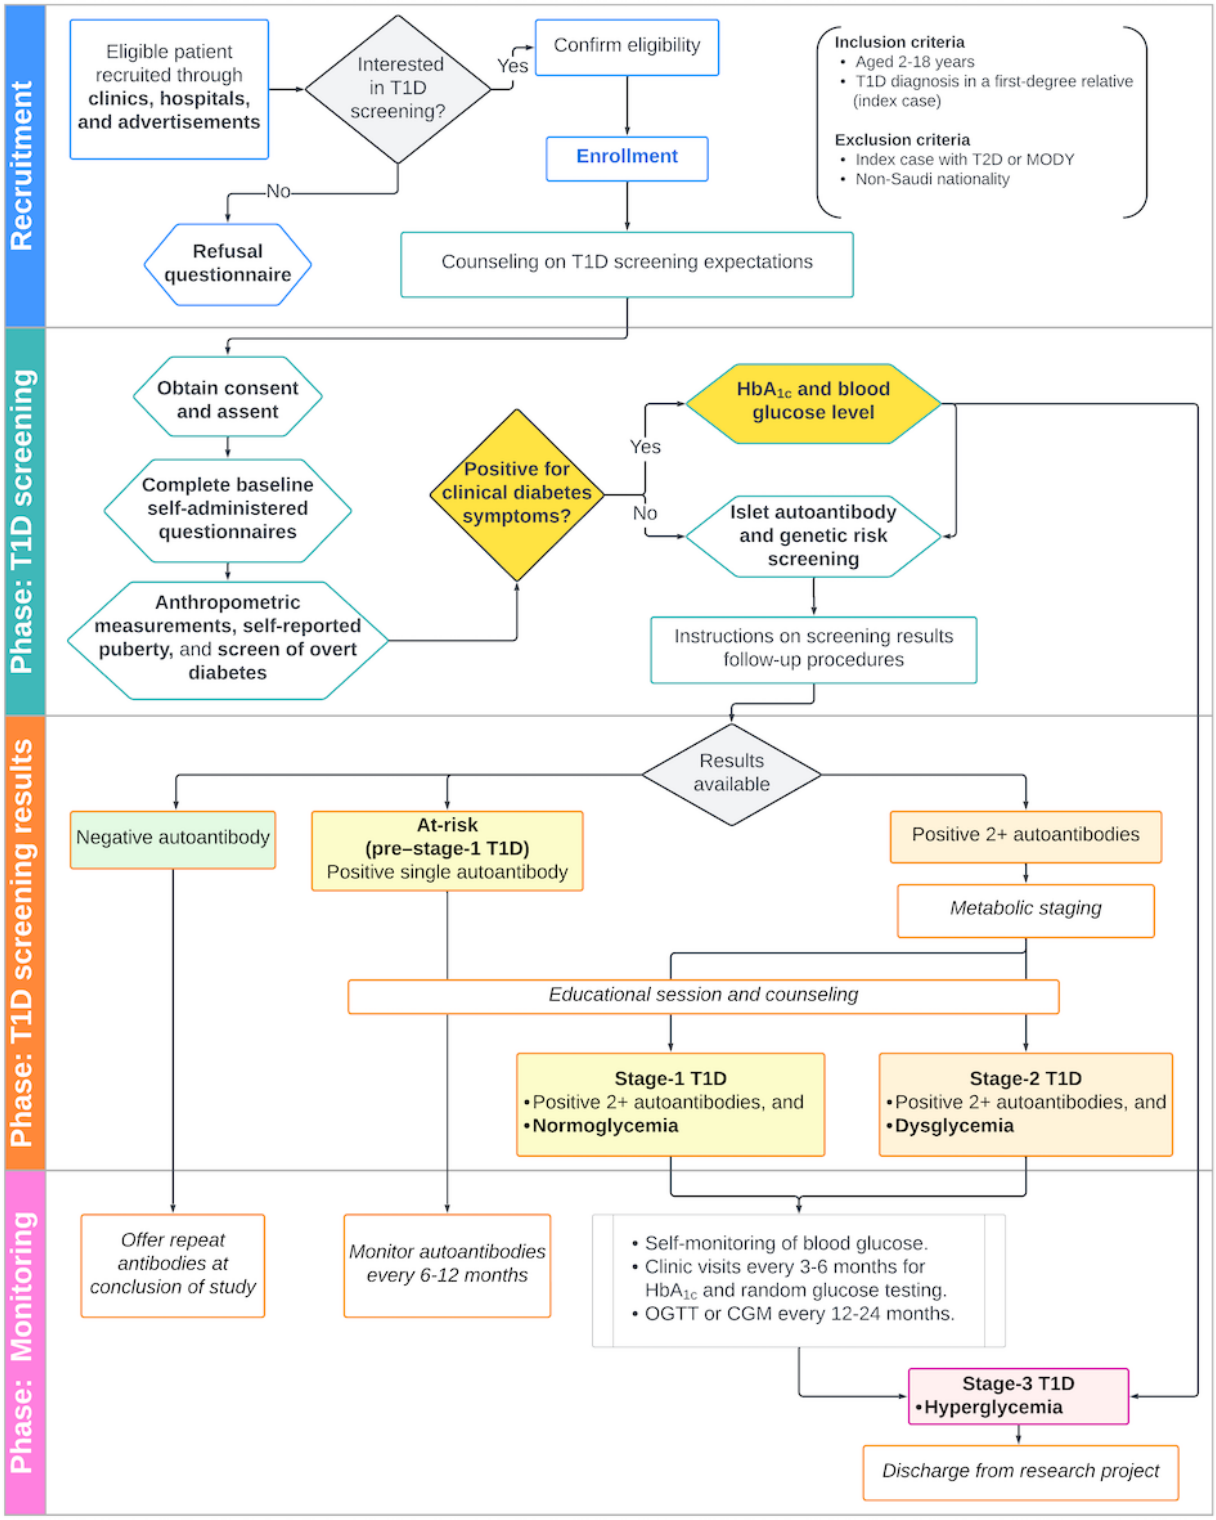
will enter a 4-year clinical follow-up phase, culminating in a total study duration of 5 years.

Participants did not receive financial compensation for participation. However, We have received funding for the project as described in the acknowledgment section.

Study Process and Interventions

The VISION-T1D study consists of 3 well-structured phases: screening, results communication and counseling, and long-term clinical follow-up. Each phase is designed to provide tailored interventions, ensuring appropriate care, monitoring, and education for children and their families (Figure 1).

Figure 1. The study flowchart. CGM: continuous glucose monitoring; HbA_{1c}: hemoglobin A_{1c}; MODY: maturity-onset diabetes of the young; OGTT: oral glucose tolerance test; T1D: type 1 diabetes; T2D: type 2 diabetes.



Phase 1: T1D Screening

Families are recruited and scheduled for an enrollment and screening visit, where they receive comprehensive counseling about participation and education on T1D screening. Upon obtaining informed consent and assent, participants undergo baseline assessments, including completion of questionnaires and the collection of blood samples for islet autoantibody testing. Optional genetic screening for HLA phenotyping and GRS analysis is also offered to evaluate genetic predisposition to T1D. To enhance recruitment, a home testing option is provided, allowing families to conveniently perform finger-prick testing and data collection at home.

Phase 2: Results Communication, Education, and Metabolic Staging

After screening results are available, a research physician reviews the findings. Participants who test positive for islet autoantibodies are invited to a follow-up visit that includes personalized counseling, targeted educational interventions, and additional metabolic staging to determine their T1D stage. Participants with negative islet autoantibody results are notified by the research staff and are invited for repeat autoantibody screening at the conclusion of the long-term follow-up period (approximately 4-5 years later).

Phase 3: Long-Term Clinical Follow-Up

Participants identified as having presymptomatic T1D (stage 1 or 2) or those at risk based on autoantibody markers enter a 4-year clinical follow-up phase. During this period, regular monitoring of disease progression is conducted through metabolic assessments and psychological evaluations. Participants receive continuous support tailored to their risk level and diagnosis.

This systematic, 3-phase approach ensures that participants receive appropriate care, counseling, and monitoring based on their screening outcomes.

Phase 1: T1D-Screening Procedures and Data Collection

Recruitment and Enrollment

Active and passive recruitment strategies are used. Research staff identified potential participants by reviewing patient lists from KSUMC diabetes clinics and pediatric endocrinology inpatient records. Recruitment materials, including advertisements with QR codes, are shared via the UDC and on social media platforms. The QR codes were linked to an introductory video explaining the study and eligibility criteria, along with a contact submission form. Families who decline participation are asked about the reason for refusal.

Informed Consent

Eligible families are scheduled for T1D-screening visits, where informed consent and assent are obtained. A comprehensive educational approach was developed to ensure participants receive standardized information and fully understand the T1D-screening process. This included an animated video and an educational booklet. The video, in Arabic, explains the screening program and key concepts, such as T1D pathophysiology, its stages, and clinical presentation. It emphasizes the benefits of early detection in preventing DKA and improving long-term outcomes; outlines the screening process; and provides an overview of current and emerging T1D treatments, including insulin therapy and disease-modifying interventions. The educational booklet complemented the video, using infographics to illustrate T1D pathophysiology, stages, symptoms, and benefits of screening. It also outlined study expectations and provided key study contact information.

Intervention: T1D Screening

Islet Autoantibodies Screening

The program uses antibody detection by agglutination–polymerase chain reaction (ADAP) assay, a cutting-edge technology developed by Enable Biosciences. The assay measures islet autoantibodies [23-27], including insulin autoantibodies, glutamic acid decarboxylase autoantibodies, IA-2 autoantibodies, and zinc transporter 8 autoantibodies, using dried blood spots on filter paper. The ADAP assay offers notable advantages over other assays for large-scale analysis, such as cost-effectiveness, high sensitivity and specificity, and minimal sample volume requirements. These features make it suitable for large-scale applications, including home testing [25-27].

Genetic Risk Screening

This pilot study integrated optional HLA phenotyping and GRS testing to deepen the understanding of T1D pathogenesis in the Saudi population. Analyses will be conducted by Enable Biosciences, the Barbara Davis Center for Childhood Diabetes, and delegates [28,29]. These tests are used for research purposes only.

HLA Phenotyping

Testing focuses on identifying high-risk HLA genotypes associated with T1D, particularly variants in the HLA region (MHC class II alleles), which account for over 50% of T1D heritability [13]. This approach aims to provide insights into T1D risk associations in the Saudi population, especially in participants with negative islet autoantibodies. HLA typing is performed using oligonucleotide probes for *HLA-DRB1*, *DQA1*, and *DQB1* alleles as previously described [30].

GRS Testing

The GRS aggregates the cumulative contribution of multiple genetic variants into a single score estimating an individual's genetic predisposition to T1D [29,31-33]. This study uses GRS2, an advanced version that incorporates HLA haplotypes, non-HLA loci, and interactions between HLA variants [34]. Testing is conducted using a Kompetitive allele-specific polymerase chain reaction (PCR) assay, as described earlier [35,36]. The Kompetitive allele-specific PCR assay is a cost-effective and efficient alternative to the traditional DNA array and imputation-based methods. It successfully genotypes 60 of the 67 single nucleotide polymorphisms in GRS2, with the remaining single nucleotide polymorphisms excluded due to genotyping challenges. This study represents one of the first applications of GRS2 in FDRs of patients with T1D and the first validation of its use within the Saudi population.

Specimen Collection

Blood samples are collected via fingerstick or venous sampling onto dried blood spot filter paper, based on participant preference. For families opting for home testing, parents collect sample cards and detailed instructions from the clinic, perform the testing at home, and return the samples for processing. All collected samples are stored at –80 °C before being batched and shipped to the United States for analysis.

Measures

Demographics and Clinical Characteristics

Families complete a self-administered questionnaire upon enrollment to collect baseline demographics and clinical characteristics. Information includes the age, sex, medical history, and current medications of the participating child, as well as family demographics such as parental age, marital status, number of siblings, education levels, family income, residential region, and family medical history focused on diabetes or autoimmune diseases among FDR and any self-reported parental comorbidities. For the index case with T1D, the questionnaire captures clinical details, including the relationship to the participant, age at diagnosis, current age, insulin regimen, history of DKA at onset or recurrent DKA, and diabetes-related complications. If multiple FDRs have T1D, similar information is collected for each.

Clinical T1D Screening

Participants are screened for overt diabetes symptoms, such as polyuria, polydipsia, polyphagia, and unexplained weight loss. Research staff conduct point-of-care hemoglobin A_{1c} (HbA_{1c}) and random blood glucose tests if any symptoms are reported. Participants with abnormal blood sugar levels are referred to a research physician for further evaluation, which may include an oral glucose tolerance test (OGTT) and counseling. Those meeting the diagnostic criteria for stage 3 T1D will receive standard medical care and education for new-onset diabetes.

Health Literacy

The Single-Item Literacy Screener tool evaluates parental health literacy using a 5-point Likert scale. A score of 4 or higher indicates adequate health literacy, while a score of 3 or lower suggests limited literacy [37-39].

T1D-Screening Acceptability Assessment Scale

This self-administered tool evaluates caregivers' acceptability of the T1D-screening program through 10 items rated on a 5-point Likert scale. Domains include affective attitude, the ethicality of the screening, perceived effectiveness, self-efficacy, opportunity costs, communication, burden, and general and cultural acceptability. Total scores range from 10 to 50, with higher scores indicating greater acceptability [40].

Psychological Measures

A set of validated Arabic tools assess caregiver stress, anxiety, depression, and quality of life at baseline, after results disclosure, and during long-term follow-up.

Anxiety Symptoms

The Generalized Anxiety Disorder 7-item scale screens for generalized anxiety over the past 2 weeks using a 4-point Likert scale. A score of 8 or more indicates possible generalized anxiety disorder, with 92% sensitivity and 76% specificity [40,41].

Depressive Symptoms

The Patient Health Questionnaire-9 screens for depression. A score of more than 10 suggests possible major depressive disorder, with a sensitivity and specificity of 88% [42-44]. Research staff will screen responses indicating suicidal ideation and prompt immediate referral to emergency care.

Health-Related Quality of Life

The EQ-5D-5L tool from the EuroQol Group measures health across 5 dimensions—mobility, self-care, usual activities, pain or discomfort, and anxiety or depression—each rated on 5 levels. The EuroQol Visual Analogue Scale allows participants to rate their overall health from 0=worst to 100=best [45]. The results are scored using a value set specific to Saudi Arabia, providing a comprehensive quality of life score [46].

Distress

The Subjective Units of Distress Scale measures anxiety and discomfort on a 0-100 scale, with higher scores indicating greater distress. The Subjective Units of Distress Scale is widely used and validated in clinical settings for assessment and monitoring of changes over time [47-49].

Anthropometric Measurements

Baseline assessments will include weight, height, BMI, and self- or parental-reported pubertal status [50].

Phase 2: Result Disclosure, Education, and Metabolic Staging

Results Disclosure

Participants receive written reports explaining the results, estimated risk of progression, long-term follow-up recommendations, and key contact information. The process of sharing results varies based on screening outcomes:

Participants With Negative Results

Families of participants who test negative for islet autoantibodies are contacted by the research staff to receive their results report. They are instructed to contact the research team if T1D develops in the future and are invited for repeat antibody testing at the end of the follow-up phase.

Participants With Positive Results

Families of participants who test positive for multiple islet autoantibodies are invited to a one-to-one counseling visit with a research physician to discuss the result, followed by a group education and metabolic staging to determine their T1D stage.

Participants With Equivocal Results

Families of participants with a single autoantibody are invited for a one-to-one counseling session with a physician to discuss the result. They then join the same group educational session as those with positive results.

Genetic Testing Disclosure

Genetic testing results are shared with families only upon request to avoid unnecessary alarm given the elevated baseline risk among FDRs and the lack of validated Saudi population–based genetic risk estimation. When shared, these results are presented in a dedicated educational session designed to help families understand the complexities of genetic predisposition to T1D.

Educational Curriculum for Participants With Positive or Equivocal Results

The educational curriculum was developed based on a comprehensive robust educational framework and expertise [51]. It is delivered in small group sessions by experienced endocrinologists, diabetes educators, and dietitians. The curriculum covers key topics such as T1D pathophysiology, disease progression stages, and the importance of early detection. Participants learn to identify their specific stage and risk of progression and recognize factors that influence clinical diabetes onset. The curriculum highlights insulin's role as the primary treatment for clinical T1D (stage 3), addressing common concerns and misconceptions. Participants are also trained to monitor their condition by recognizing early T1D symptoms, performing blood glucose checks, interpreting results, and determining when insulin therapy or medical advice is needed.

The program underscores nonpharmacological strategies for reducing the risk of T1D progression through healthy eating and lifestyle modifications and provides an overview of current and future T1D research. The psychological and emotional aspects of receiving T1D screening results are also addressed, and access to support is provided.

Psychological Support

The psychological and emotional impact of T1D risk disclosure is carefully addressed throughout the process. Families experiencing significant psychological burdens are offered counseling sessions and access to professional psychological support. Additionally, all families can self-refer to these services as needed. These measures are designed to alleviate stress, promote resilience, and ensure families feel supported during the follow-up period.

Metabolic Staging

Participants with multiple positive islet autoantibodies undergo metabolic staging to determine their T1D stage. This includes HbA_{1c} measurement, fasting glucose, 2-hour OGTT, or continuous glucose measurement (CGM) if OGTT is not feasible.

OGTT Measurement

Performed after an overnight fast of at least 8 hours. Participants consume a glucose solution dosed at 1.75 g/kg (up to 75 g). Serum glucose levels are measured at fasting baseline and 120 minutes after ingestion.

HbA_{1c} Measurement

Serum samples will be processed in the laboratory per American Diabetes Association–recommended standards.

CGM Measurement

Used as an alternative for participants unable or unwilling to complete an OGTT. CGM glucose profiles over a 2-week period will be reviewed for staging.

Phase 3: Long-Term Monitoring and Clinical Follow-Up

Monitoring for Disease Progression

Participants with positive single or multiple autoantibodies will enter a 4-year follow-up phase. During this period, regular assessments are performed to monitor T1D disease progression, track time to clinical onset, and observe any changes in metabolic staging. Monitoring intervals vary by stage and risk level [18,20]. Participants progressing to stage-3 T1D will transition to standard care.

Self-Monitoring of Blood Glucose

All participants with multiple positive islet autoantibodies results will be instructed to perform self-monitoring of blood glucose testing at home twice over a 2-week period after receiving their results, including one fasting test and one 2-hour postprandial test after a heavy meal. This testing should be repeated every 1-3 months and during any illness. Participants will be provided with contact information and guidance on when to seek medical advice.

Stage-1 Monitoring

Participants categorized as stage-1 T1D (positive autoantibodies with normal glycemia) will have clinic visits every 6 months for HbA_{1c} and random glucose testing. An OGTT or CGM will be performed every 24 months or earlier if there is a 10% or more rise in HbA_{1c} from baseline.

Stage-2 Monitoring

Participants categorized as stage-2 T1D (positive autoantibodies with dysglycemia) will have more frequent clinic visits every 3 months for HbA_{1c} and glucose testing. An OGTT or CGM will be performed annually or sooner if there is a 10% or more rise in HbA_{1c} from baseline.

Monitoring for Single Autoantibody Results

Participants with a single autoantibody undergo metabolic assessment only if symptoms develop. For children younger than the age of 6 years, autoantibody screening will be repeated within 6 months for confirmation, then annually throughout the study. For children aged 6 years or older, annual screening will be conducted for the duration of the study. Autoantibody monitoring will be discontinued if a participant seroconverts to a negative status. No physician visits are required, and families are encouraged to contact the research team if T1D symptoms arise in the future.

Monitoring for Participants With Negative Autoantibodies

All participants who test negative for autoantibodies will undergo follow-up autoantibody testing at the conclusion of the 5-year study period.

Other Monitoring Measures

Clinical Measurements

Weight, height, and BMI are assessed annually for participants with positive autoantibodies.

Psychological Assessment

Parents of children with positive autoantibody results will undergo psychological assessment within one week of receiving screening results. Assessments are repeated during follow-up at 6 and 12 months to track changes over time.

Outcome Definitions and Metrics

Feasibility Metrics

The feasibility of the screening program will be evaluated using the following key metrics.

- - Recruitment rates: The proportion of eligible participants successfully recruited into the study.
  - Screening refusal rates: The percentage of eligible participants who decline participation.
  - Completed screening visit rates: The percentage of participants completing the initial screening visit (phase 1).
  - Completed counseling visit rates: The percentage of participants with positive autoantibody results who complete the counseling session and educational curriculum (phase 2).
  - Completion of long-term follow-up: The percentage of participants with presymptomatic T1D who complete their monitoring visits during the 4-year follow-up period (phase 3). Participants progressing to clinical T1D before the study conclusion will transition to standard clinical care and be considered as having completed follow-up.

Prevalence of Presymptomatic T1D at Screening

Metabolic staging performed during the screening results visit (phase 2) will classify participants into the following stages.

- - Stage-1 T1D: Presence of two or more islet autoantibodies with normal glycemia. Criteria include HbA_{1c} <5.7%, fasting blood glucose <100 mg/dL, and a 2-hour OGTT <140 mg/dL. For CGM users, values >140 mg/dL should be less than 10% of the time over 10 days of continuous wear.
  - Stage-2 T1D: Presence of two or more islet autoantibodies with dysglycemia. Criteria include HbA_{1c} between 5.7% and 6.4%, fasting blood glucose between 100-125 mg/dL, and a 2-hour OGTT between 140-199 mg/dL. For CGM users, values more than 140 mg/dL should be between 10% to less than 20% of the time over 10 days of continuous wear.
  - Stage-3 T1D: Clinical onset of T1D marked by one or more islet autoantibodies and hyperglycemia. Criteria include HbA_{1c} 6.5%, fasting blood glucose levels 126 mg/dL, and a 2-hour OGTT 200 mg/dL. For CGM users, values >140 mg/dL must occur at least 20% of the time over 10 days of continuous wear.
  - At risk (pre–stage-1 T1D): Defined as the presence of a single islet autoantibody with normal glycemia.
  - Isolated genetic predisposition: Defined as the presence of positive genetic risk markers without accompanying islet autoantibodies.

Incidence of DKA

The incidence of DKA at the clinical onset of T1D will be tracked during the long-term follow-up phase (phase 3). DKA occurrences will be captured from clinical records and follow-up visits.

T1D Progression Rate

The annual progression rate to stage-3 T1D will be tracked in participants testing positive during the follow-up phase (phase 3) and categorized based on their initial stage.

Effectiveness of Educational Interventions

The effectiveness of the educational curriculum will be evaluated using pre- and postintervention tests completed by caregivers. These tests are developed to measure changes in knowledge related to the curriculum's objectives, providing a comprehensive assessment of the intervention's effectiveness in preparing caregivers for presymptomatic T1D management.

Health Care Resource Use for Cost-Effectiveness Analysis

Health care resource use will include both program-related and external health care resources. Program-related costs will encompass autoantibody testing, metabolic profiling, results notification visits, and educational or follow-up visits. Non–program-related costs will include diabetes clinic visits (eg, consultations with physicians, educators, nutritionists, or psychologists), emergency department visits for diabetes or DKA, hospitalizations for diabetes, laboratory and imaging studies, and prescription medications for diabetes management either inpatient or outpatient.

Statistical Analyses

Sample Size

The target enrollment is 1300 participants (or 322 families), based on the feasibility of recruiting 70% of eligible families from the UDC clinic cohort. The estimated seropositivity rate for islet autoantibodies among children with an FDR diagnosed with T1D is estimated at 5% to 15%, with a 90% significance level and 80% power. Considering that the UDC serves approximately 450-500 children with T1D, and that the typical Saudi family has 4-6 children younger than the age of 18 years, this sample size is calculated to be sufficient. Recruitment will be expanded to FDRs outside the UDC cohort if the family target is met without reaching the participant's goal.

Statistical Analysis

Descriptive statistics will report continuous data as mean (SD) for normally distributed variables and categorical data as frequency and percentage (N, %). Feasibility metrics and T1D stages will also be summarized as percentages.

To evaluate the psychological effects of T1D screening on caregivers, pre- and postscreening levels of anxiety, depression, and distress will be compared using paired 2-tailed *t* tests or Wilcoxon signed-rank tests, depending on data distribution. The effectiveness of educational counseling will be analyzed similarly, comparing pre- and postintervention test scores. Longitudinal changes in the psychological measures will be evaluated using repeated-measures ANOVA or mixed effects models to track patterns over time.

For participants with presymptomatic T1D, progression rates to stage 3 will be analyzed using Kaplan-Meier survival analysis. Time to event will be calculated from screening age to age at stage-3 T1D diagnosis or last follow-up. Cox proportional hazards models will assess factors associated with disease progression, such as baseline autoantibody titers, genetic risk scores, and demographic variables.

At the 1-year follow-up, cost-effectiveness will be assessed by reporting total costs for all screened participants, cost per child screened, and cost per case detected. The incremental cost-effectiveness ratio calculations will compare outcomes for screened children with controls diagnosed with stage-3 T1D in the general population. The incremental cost-effectiveness ratio will incorporate potential benefits, such as reduced DKA incidence and improved HbA_{1c} levels, while adjusting for control characteristics like age and FDR status.

Results

The VISION-T1D pilot screening program was funded and launched in May 2024, with the initial screening phase scheduled to conclude in April 2025. As of November 2024, a total of 176 eligible families had enrolled, representing approximately 39.1% of the target sample size of 322 families. Final data analysis for the initial screening phase is projected for mid-2025.

Discussion

The VISION-T1D protocol outlines a comprehensive approach to assess the feasibility and impact of a T1D screening among FDRs of individuals with T1D in Saudi Arabia. This model is tailored to address the unique demographic, cultural, and health care characteristics of the Arab region, aiming to deepen understanding of the prevalence and patterns of autoimmunity in at-risk populations. The data generated will provide valuable epidemiological insights to inform future health care policies and targeted interventions.

A key strength of this study is its focus on translating screening programs from the research setting to practical, real-world implementation. It provides a detailed roadmap for integrating T1D screening into health care systems, addressing scientific and operational complexities, particularly within the Arab region. The use of culturally sensitive consent materials, diverse educational methods, and clear protocols ensures that participants and caregivers are well informed, supported, and empowered to manage their health proactively. Additionally, the adoption of the ADAP assay—a cost-effective, sensitive, and low-sample-volume technology—enhances scalability and operational efficiency, making the program accessible for large-scale applications.

This study addresses significant unmet needs in T1D care and research in the Middle East, offering critical insights into genetic predispositions and disease progression in the Saudi population. One of the program's pivotal contributions is the early identification of candidates for T1D prevention therapies. Early detection through screening will facilitate timely intervention with disease-modifying therapies that can delay or prevent the onset of clinical T1D. This proactive approach aligns with global health strategies advocating for prevention and early intervention to mitigate the long-term burden of chronic diseases. Furthermore, this initiative lays the groundwork for the future of prevention trials in Saudi Arabia, contributing to the development of a sustainable infrastructure for T1D research and management.

The study also tackles logistical challenges, such as recruitment, sample analysis, and generalizability, through a combination of recruitment strategies, robust educational tools, and systematic follow-up procedures. While reliance on international laboratories for sample analysis introduces potential delays, the program is designed with long-term sustainability in mind, including plans to establish a centralized laboratory for the ADAP assay in Saudi Arabia.

Despite its strengths, the study has limitations. Focusing on FDRs may restrict generalizability to the broader population, as prior exposure to T1D within the family could influence the acceptability of the screening program. Additionally, cultural and social factors specific to Saudi Arabia may shape perceptions and behaviors related to T1D screening and management, potentially affecting intervention outcomes. Furthermore, the relatively short follow-up period, constrained by funding, limits the ability to assess long-term outcomes and the program's sustainability. Extended follow-up would provide a deeper understanding of the enduring effects of early detection and educational interventions on disease progression and management. Future extensions of this study are based on funding availability or collaborations with national screening programs may allow for prolonged follow-up.

In conclusion, this study represents a critical advancement in addressing the challenges of T1D screening and management of presymptomatic T1D. By integrating innovative screening technology with a robust educational framework and systematic follow-up, this program demonstrates the potential to enhance health outcomes while offering a scalable and sustainable approach to managing presymptomatic T1D. The outcomes garnered from this research will provide a foundation for implementing practical T1D-screening programs and establishing a framework adaptable to similar initiatives in neighboring Arab countries. By addressing both scientific and operational challenges, this study serves as a valuable resource for policy makers, health care providers, and researchers striving to integrate effective T1D management strategies into routine health care practice, ultimately improving the quality of care for at-risk populations.

Acknowledgments

This investigator-initiated study received funding from Sanofi and the University Diabetes Center at King Saud University Medical City for funding this study.

Authors' Contributions

The study was conceptualized by ISA and RAA, who also led the design of the protocol framework, supervised the research process, and provided overall research direction. Methodology, data curation, and formal statistical analysis plans were developed collaboratively by RAA, ISA, and YA, with additional contributions from JS and KA. Data collection plans, strategic guidance, and investigation, including participant recruitment and data collection, were carried out by ISA, MM, KA, MA, SA, AAA, and RAA. DS and CTT were responsible for the provision of laboratory technology and the analysis of blood samples. Funding was secured by RAA, ISA, JS, and MM. ISA and RAA collaborated on the literature review, drafting, revisions, and final submission of the manuscript. All authors reviewed and approved the final version of the manuscript.

Conflicts of Interest

The authors declare that there is no conflict of interest regarding the publication of this paper. DS and CTT were employed by Enable Biosciences. DS and CTT are shareholders of Enable Biosciences. CTT are inventors of the antibody detection by agglutination–polymerase chain reaction (ADAP) patent licensed from the University of California, Berkeley to Enable Biosciences. The ADAP assay used in this study is a product in development. This does not alter our adherence to journal policies on sharing data and materials.

Abstract

Background: The synthesis of evidence in health care is essential for informed decision-making and policy development. This study aims to validate The Umbrella Collaboration (TU), an innovative, semiautomatic tertiary evidence synthesis methodology, by comparing it with Traditional Umbrella Reviews (TUR), which are currently the gold standard.

Objective: This study aimed to evaluate whether TU, an artificial intelligence—assisted, software-driven system for tertiary evidence synthesis, can achieve comparable effectiveness to TURs, while offering a more timely, efficient, and comprehensive approach. In addition, as a secondary objective, the study aims to assess the accessibility and comprehensibility of TU's outputs to ensure its usability and practical applicability for health care professionals.

Methods: This protocol outlines a comparative study divided into 2 main parts. The first part involves a quantitative comparison of results obtained using TU and TURs in geriatrics. We will evaluate the identification, size effect, direction, statistical significance, and certainty of outcomes, as well as the time and resources required for each methodology. Data for TURs will be sourced from Medline (via PubMed), while TU will use artificial intelligence—assisted informatics to replicate the research questions of the selected TURs. The second part of the study assesses the ease of use and comprehension of TU through an online survey directed at health professionals, using interactive features and detailed data access.

Results: Expected results include the assessment of concordance in identifying outcomes, the size effect, direction and significance of these outcomes, and the certainty of evidence. In addition, we will measure the operational efficiency of each methodology by evaluating the time taken to complete projects. User perceptions of the ease of use and comprehension of TU will be gathered through detailed surveys. The implementation of new methodologies in evidence synthesis requires validation. This study will determine whether TU can match the accuracy and comprehensiveness of TURs while offering benefits in terms of efficiency and user accessibility. The comparative study is designed to address the inherent challenges in validating a new methodology against established standards.

Conclusions: If TU proves as effective as TURs but more time-efficient, accessible, and easily updatable, it could significantly enhance the process of evidence synthesis, facilitating informed decision-making and improving health care. This study represents a step toward integrating innovative technologies into routine evidence synthesis practice, potentially transforming health research.

Introduction

Background

The synthesis of evidence in health care is a knowledge-acquisition process designed to transform extensive volumes of data into manageable information to support decision-making based on the best possible evidence. It aims to integrate information from multiple sources on complex topics in a comprehensive, precise, transparent, and easily understandable manner. These principles ensure that synthesized evidence is accessible and useful to all stakeholders, including health care professionals, policy makers, and patients [1].

Evidence synthesis plays a pivotal role in knowledge translation (KT) [2], serving as a bridge between research and health care. Consequently, evidence synthesis is essential for the development of health policies and informed decision-making [3].

The role of all stakeholders in health decision-making underscores the importance of their ability to access, understand, and evaluate health information adequately [4]. A persistent challenge in KT is the low level of statistical and health literacy among the general population and health professionals, which significantly complicates effective health management [5,6]. Therefore, it is crucial to democratize access to high-level health information and to promote active participation of all stakeholders in decisions affecting health care [7].

The evolution of evidence synthesis methodologies has led to the development of tertiary synthesis, designed to condense knowledge from multiple systematic reviews with or without meta-analyses (SR/MA). This synthesis, often referred to as Umbrella Reviews now referred to as Traditional Umbrella Reviews (TUR) to distinguish them from the experimental methodology under study, The Umbrella Collaboration (TU), builds upon the concept of primary studies (individual studies with participant samples) and secondary studies (systematic reviews and analysis of those primary studies). Tertiary synthesis represents a third level, named with other terms such as overviews, meta-epidemiological studies, meta-analyses, meta-synthesis, and meta-reviews also describing this approach [8,9]. Tertiary synthesis has gained prominence in contexts where broad research questions are posed, rapid results are needed, and resources for extensive systematic reviews are limited. TURs follow a structured methodological process that involves several clearly defined stages [9-14]. Although organizations like Cochrane Collaboration [14] and the Joanna Briggs Institute (JBI) [11] have developed and continually updated detailed methodologies for these reviews, there remains considerable divergence in how TUR authors implement these steps in practice. This methodological freedom leads to significant variations among different TURs in terms of rigor and approach.

The urgency for high-quality, timely information during crises like the SARS-CoV-2 pandemic has highlighted the critical need for faster evidence synthesis methods, even if it means accepting certain limitations in comprehensiveness, detail, and precision [15]. This demand has driven the development of innovative approaches such as TU, which leverages artificial intelligence (AI)-assisted software to facilitate tertiary evidence synthesis under human oversight. While AI tools such as PICO (Population, Intervention, Comparison, and Outcome) Portal, DistillerSR, Covidence (Veritas Health Innovation), and Rayyan (Rayyan Systems Inc) have already improved secondary evidence synthesis by streamlining data management and analysis [16], technologies like large language models (LLMs), including ChatGPT, are beginning to demonstrate potential for conducting systematic reviews autonomously, though human supervision remains essential to mitigate risks such as errors and hallucinations [17]. Despite these developments in secondary synthesis, the application of AI and software engineering in tertiary synthesis is still in its early stages, with no dedicated software currently available. TU is at the forefront of this field, pioneering the integration of AI and software engineering with human oversight to ensure accuracy and minimize technology-induced errors. As AI continues to evolve, it is likely that fully automated processes for both secondary and tertiary synthesis will emerge, potentially revolutionizing clinical research and practice. However, building confidence in these technologies will require ongoing development and rigorous validation.

The Umbrella Collaboration (Patent Pending)

TU is primarily a software-driven system engineered to streamline tertiary evidence synthesis, relying on programmed algorithms to automate the majority of its functions. The core of the system is built on a software infrastructure that processes and synthesizes data from SR/MA abstracts stored in MEDLINE. While AI plays a crucial role, particularly through the use of LLMs and machine learning (ML), it is used selectively within the broader software framework to enhance specific tasks.

LLMs are used in generating related search terms, expanding upon human-generated queries to enhance the comprehensiveness of literature searches. Any LLM can be adapted to TU software, up to date we have used ChatGPT 4 [18]. This function is crucial in broadening the scope of the searches while ensuring that the results remain relevant and precise. The AI component is designed to support, not replace, human oversight, ensuring that the final selection of literature is both accurate and comprehensive [19]. To mitigate the risk of AI-generated hallucinations due to insufficient data, TU

primarily operates as a stable, auditable software system. The use of AI is limited to the search term expansion phase, where it suggests synonymous terms for the keywords provided by the human reviewer.

All AI-generated search terms are subject to human validation before being incorporated into the search strategy. The human reviewer evaluates the relevance and appropriateness of each AI-suggested term, ensuring that only those that align with the research objectives are retained. This manual oversight serves as a critical safeguard against inaccuracies or misleading AI-generated suggestions, maintaining the methodological integrity of the evidence synthesis process.

As the TU database grows, ML will be integrated to further refine and optimize the software's performance. Training the system on an expanding dataset is expected to enhance its ability to select, categorize, and analyze relevant research, thereby improving both efficiency and accuracy over time. This approach allows TU to evolve, continuously improving its utility in evidence synthesis through the iterative learning process [20].

Overall, TU represents a hybrid model where traditional software engineering and targeted AI applications work in tandem. This balance ensures that while the software performs most functions automatically, AI enhances specific tasks, such as search term generation and future predictive analysis, under strict human supervision. This strategic integration of AI elements within a primarily software-driven system ensures the reliability and precision of the evidence synthesis process.

The outcomes generated by TU will be presented through an interactive web application designed to enhance accessibility and comprehension for a broad range of stakeholders, including those without advanced statistical expertise. The use of graphical formats and clear language aims to facilitate the interpretation of findings by diverse audiences.

In addition, the platform supports continuous updates, automatically integrating new SR/MA data every 24 hours, thereby ensuring the most current and reliable evidence synthesis. This approach aligns with the concept of Living Systematic Reviews (LSRs) [21], which advocate for frequent updates to maintain relevance in rapidly evolving fields. While Cochrane Collaboration recommends updating LSRs monthly [22], TU is designed to surpass this standard by ensuring updates are incorporated daily, providing near real-time evidence synthesis.

The daily updates provided by TU are expected to enhance its efficiency, allowing for a more dynamic and continuously updated evidence synthesis process. Pilot tests have demonstrated TU's capability to complete tertiary evidence synthesis projects within hours, a significant reduction in time compared to traditional methods (unpublished data). If validated by the upcoming research, this advancement could demonstrate TU's potential to streamline the synthesis process, delivering rapid yet reliable results while upholding the highest standards of accuracy. Should these findings be confirmed, TU may emerge as an invaluable tool for accelerating the pace of evidence-based research.

TU is designed to maximize computational efficiency while maintaining methodological rigor. Unlike TURs, which require extensive manual data extraction and synthesis over months, TU automates critical steps in the tertiary synthesis process, significantly reducing execution time.

In terms of computational complexity, TU does not perform direct statistical meta-analyses but instead extracts and synthesizes pre-existing systematic reviews and meta-analyses. This approach ensures that the computational load remains minimal compared to methodologies that require full-scale meta-analyses or real-time data processing. The most computationally intensive process within TU is the search term expansion using AI, which is constrained to generating synonymous terms based on human-input keywords. This AI function operates on a lightweight model that does not require high-performance computing resources.

A key distinction of TU is that it assists in the entire tertiary review process, rather than being limited to isolated stages. Compared to existing approaches such as DistillerSR, Covidence, and Rayyan, which focus on specific tasks like study screening or data extraction, TU integrates a complete methodology for tertiary evidence synthesis. This includes search term expansion, literature retrieval, synthesis automation, and structured result visualization. While other tools provide assistance in certain steps, TU ensures a fully automated, structured, and reproducible workflow for umbrella reviews.

To our knowledge, there are currently no automated systems specifically designed for tertiary evidence synthesis that comprehensively address and assist in the entire synthesis process. While several tools exist for systematic review automation—such as DistillerSR, Covidence, and Rayyan—these primarily focus on secondary evidence synthesis (ie, systematic reviews) and are not designed to facilitate tertiary synthesis methodologies like umbrella reviews.

In addition, no previous tool has undergone a formal assessment or validation for automated tertiary synthesis, as TU is the first system explicitly developed for this purpose. Unlike existing software, TU does not merely automate isolated steps (such as literature screening or data extraction) but provides a structured, end-to-end approach for tertiary evidence synthesis. This distinction highlights the novelty of TU and underscores the need for this study to formally assess its performance compared to TURs.

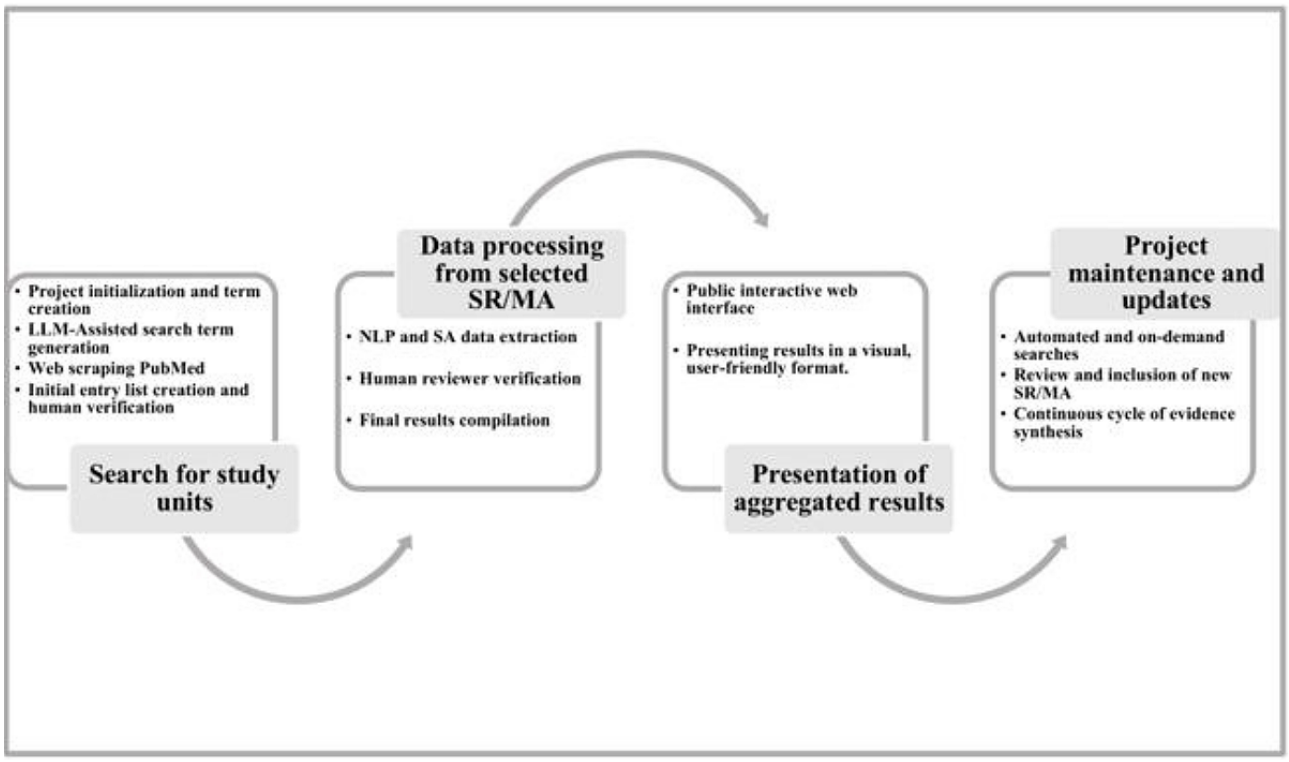
A schematic diagram is provided to clearly illustrate TU's workflow, showing the process from data acquisition to the generation of synthesized results. Abstracts of SR/MA, retrieved from the MEDLINE database via PubMed, form the foundation of the analysis. The decision to use MEDLINE via PubMed as the sole database for literature retrieval in TU is based on its strong coverage of systematic reviews and meta-analyses, as well as the feasibility of leveraging LLMs for search term expansion. Recognizing the potential limitation of relying on a single database, we conducted preliminary assessments to estimate the impact of this decision. Specifically, we evaluated the ability of TU to retrieve references from TURs and analyzed the proportion of systematic review and meta-analysis references found in MEDLINE. Our results showed that TU was able to

retrieve 81.1% (414/511) of TUR references using its AI-assisted search methodology in Medline alone. In addition, an independent assessment of 511 references from 22 TURs found that only 11 references were not indexed in MEDLINE. While some loss of relevant studies is inevitable, these findings suggest that the methodological approach used in TU remains sufficiently comprehensive for tertiary evidence synthesis, balancing feasibility and completeness (unpublished data). The data obtained are processed through a range of techniques, including natural language processing (NLP), sentiment analysis (SA), web scraping (WS), and ML. The expected results comprise synthesized evidence on intervention effectiveness and risk exposures, presented in a graphical and visual format. These results are conveyed in plain language, making them easily understandable by all stakeholders, regardless of their statistical literacy.

The project is continuously updated through automated and on-demand searches, with data from new studies seamlessly integrated into the existing body of evidence. Each inclusion restarts the synthesis process, creating a dynamic, cyclical workflow that ensures the results of the project remain up-to-date (Figure 1).

The implementation of new methodologies in the scientific field requires a comparative validation process with established methods to ensure their reliability and effectiveness. TU, being an innovative methodology still in its theoretical-conceptual stage, must be evaluated against established methodologies. Therefore, the aim of this study is to validate TU by comparing its performance and outcomes with the gold standard, TURs, to establish its credibility and potential superiority.

Figure 1. The Umbrella Collaboration workflow. NLP: natural language processing; LLM: large language models; SA: sentiment analysis; SR/MA: systematic reviews with or without meta-analyses.



Objectives

The primary objective of this study is to assess whether a software-driven AI-assisted system of evidence synthesis, TU, can match the effectiveness of traditional methods of tertiary synthesis, providing a potentially more timely, efficient, and comprehensive approach while remaining open to findings that could demonstrate superior performance. To support the primary objective of evaluating the effectiveness of TU compared to traditional methodologies, this study also aims to assess the accessibility and comprehensibility of TU's outputs as a secondary objective.

Methods

Study Design

Part 1: Quantitative Comparison of Methodologies

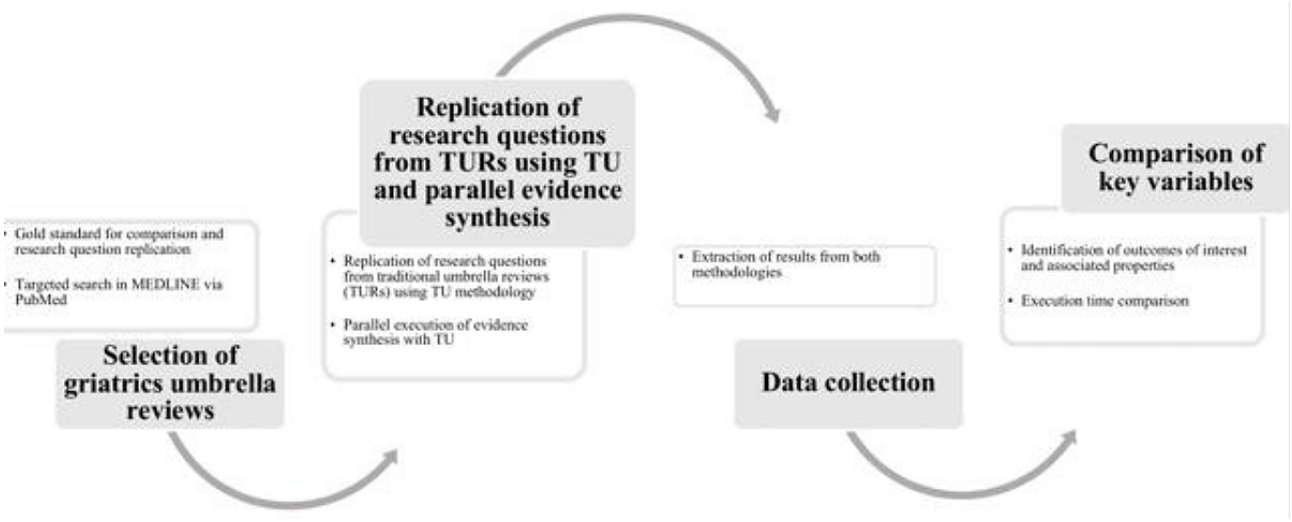
Overview

Figure 2 provides an overview of the study design. The study follows a structured comparative approach in which selected TURs in geriatrics serve as the gold standard for validation. Using the same research questions, projects are conducted in parallel with TU to assess its performance. Data from both methodologies are systematically collected and compared, focusing on key variables such as the identification of outcomes of interest, effect size, effect direction, statistical significance, certainty of evidence, and execution time. The figure illustrates

the step-by-step workflow of the study, from the selection of umbrella reviews in geriatrics as reference models to the comparison of results obtained using TU and TURs.

The first part of this study focuses on a quantitative comparison between the 2 tertiary synthesis methodologies. To facilitate this comparison, a targeted search in PubMed will identify relevant TURs in geriatrics, focusing on representative reviews rather than an exhaustive search. Our approach will involve a focused search in PubMed, using specific terms relevant to geriatrics, to find suitable TURs that serve as a benchmark for this comparative analysis. This targeted search is sufficient for our methodological comparison and does not require the comprehensive search strategy typical of systematic reviews, as our goal is not to cover the entire scope of available literature but to enable a parallel evaluation of synthesis methodologies. Therefore, while the search strategy may appear basic, it is intentionally designed to fulfill the specific needs of our project without aiming for exhaustive literature retrieval, which is beyond the scope of this project.

Figure 2. Study design overview. TU: The Umbrella Collaboration; TUR: Traditional Umbrella Reviews.



Study Variables

In the quantitative comparison, several critical variables will be analyzed. Key among these is the identification and evaluation of outcomes of interest (outcomes). This includes assessing the degree of concordance between the methodologies in identifying outcomes and using a concordance matrix to document and compare the outcomes identified by TU and TURs. In addition, we will analyze the total number of outcomes identified by each methodology, providing a descriptive and statistical comparison. It is essential to define the concept of an "outcome of interest" within the context of tertiary evidence synthesis. An outcome of interest refers to specific aspects identified and evaluated by systematic reviews with meta-analyses that examine the same research question. These outcomes are critical for understanding the overall impact of various interventions on health conditions or the effects of exposure to risks.

A crucial aspect of this analysis involves the comparison of effect sizes for the identified outcomes. TU uses an automated approach for standardizing effect sizes using a custom-designed metric (R_{TU}). This metric transforms all commonly used effect size statistics in evidence synthesis (eg, standardized mean difference [SMD], mean difference [MD], relative risk [RR], odds ratio [OR], hazard ratio [HR], and others) into a single weighted composite measure. The R_{TU} metric enables the aggregation of heterogeneous effect size measures across different systematic reviews supporting a given outcome of interest in tertiary evidence synthesis.

Since this process is fully automated, accuracy is assessed through comparisons with TURs. By replicating research questions from TURs in TU, we compare whether the R_{TU}-derived effect sizes align with those obtained using traditional methodologies. This validation step ensures that the automated transformation process does not introduce systematic distortions and maintains consistency with established effect size estimation methods. Given the diverse metrics used in TURs, such as SMD, MD, RR, OR, and HR, and the unique metric used by TU, we will standardize all effect sizes, used in TURs, to Cohen *d*. This standardization facilitates a direct comparison, ensuring consistency in the interpretation of results.

We will also examine the direction of the effects for each outcome, categorizing them as favorable, unfavorable, or unknown for interventions, and as increasing, decreasing, or unknown for exposures to risks. The statistical significance of the outcomes will be compared by analyzing *P* values and CI, assessing whether the results are statistically significant across both methodologies.

Furthermore, the certainty of the evidence (LoE) associated with each outcome will be evaluated. To assess the LoE within TU, we use sentiment analysis as a NLP technique. This approach allows for the automated classification of certainty indicators extracted from systematic review abstracts. Regarding the concern about the training data for sentiment analysis, at this stage, TU uses a sentiment analysis model initially trained on X (formerly known as Twitter) data. While we acknowledge that this is not highly optimized for medical texts, it provides a cost-effective starting point for sentiment classification without incurring additional expenses. Cloud-based solutions, such as

Azure cognitive services, offer more specialized sentiment analysis models for health care, but these are paid services that exceed our current budget.

We fully recognize the limitations of using general sentiment analysis for LoE, as traditional GRADE (Grading of Recommendations Assessment, Development, and Evaluation)-based approaches consider multiple factors such as study limitations, inconsistency, indirectness, publication bias, and confounders. However, our primary aim is to determine whether a simplified approach, using abstract-level sentiment classification, can yield reasonable agreement with traditional methodologies. TU does not claim to replace the rigor of full-text GRADE assessments but instead seeks to evaluate whether an alternative automated method can provide valuable insights with lower resource demands. We are actively working toward developing our own custom sentiment analysis algorithm tailored to medical literature, trained on validated medical datasets. This will enhance precision and improve TU's ability to evaluate LoE more effectively in the future.

For TURs, this will be done using the GRADE system [23], which categorizes evidence into very low, low, moderate, and high levels. TU applies an SA-based scoring system on a scale from –1 to +1. Both scales will be normalized to a similar quantitative range (0-1) to facilitate comparison. To align the 2 systems, the SA scores are normalized using the following transformation formula: X=(SA score+1)/2. Where X represents the normalized certainty score, ensuring that SA values originally in the range of –1 to 1 are mapped to a 0 to 1 scale. The GRADE ordinal levels are mapped onto the 0-1 scale as follows: very low=0.00-0.25, low=0.26-0.50, moderate=0.51-0.75 and high=0.76-1.00. This process allows TU and TUR certainty ratings to be compared in a standardized manner, enabling statistical concordance analyses between the 2 methodologies.

Finally, the execution time of each methodology will be assessed, with TU providing exact time measurements and TURs relying on an estimated timeframe of 6 to 12 months based on existing literature.

Data Collection and Research Question Replication

Data collection will begin with a targeted search in PubMed to identify TURs in geriatrics, using the search terms "umbrella" AND "geriatric." The identified TURs will serve as benchmarks for our comparative analysis. The research questions from these selected umbrella reviews will be directly replicated in TU without modification, ensuring a precise comparison of outcomes generated by each methodology. TU will be configured to replicate these questions, using automated searches and synthesis through NLP, WS, SA, and ML, with human reviewers verifying and extracting data as necessary. This approach allows us to assess the comparative effectiveness and efficiency of TU relative to traditional methods, particularly in identifying and analyzing outcomes critical to evaluating health interventions and exposure risks. Data from both TURs and TU will be systematically collected and recorded in a database to facilitate precise comparisons of outcomes, effect sizes, and other critical variables, ensuring a thorough evaluation of both methodologies.

The decision to rely solely on abstracts for data extraction in TU was driven by practical and methodological considerations. First, this approach was chosen due to budgetary constraints, as full-text access to all systematic reviews and meta-analyses would require extensive licensing fees or institutional subscriptions, which are beyond the scope of this project. Second, abstracts help mitigate language bias, since all systematic review abstracts indexed in MEDLINE are available in English, regardless of the original language of publication. This ensures a broader and more internationally representative evidence base.

While it is acknowledged that abstracts often contain limited methodological details and may lack comprehensive information on certainty of evidence, outcome effect sizes, or risks of bias, the core objective of TU methodology is to assess whether robust conclusions can still be drawn based on abstracts alone. Recognizing the inherent limitations of abstracts, TU incorporates structured extraction criteria to capture the most relevant information while acknowledging the potential risks of missing key methodological details. The validation process of TU explicitly includes a comparison with full-text TURs to evaluate whether synthesis based on abstracts alone yields comparable conclusions.

Part 2: Evaluation of Ease of Use and Comprehension

Overview

The second part of the study focuses on evaluating and comparing the ease of use and comprehension of the results generated by TU with those from TURs. This evaluation will be conducted through an anonymous and voluntary online survey directed at health professionals, designed to assess their experience with both methodologies.

The survey, developed using Google Surveys for ease of access and data analysis, comprises 16 items. The initial 6 items gather demographic information about the survey respondents, while the subsequent 10 questions directly compare the usefulness and clarity of the results produced by TU and TURs, using a Likert scale ranging from 1 to 5. This scale will measure respondent's perceptions of the clarity, comprehensibility, and ease of use of the results provided by both methodologies (Table 1).

To ensure a thorough evaluation, informational sessions will be held in geriatric departments of university hospitals in Madrid (Spain). During these sessions, the concept of tertiary evidence synthesis and the functionality of TU will be introduced. Health professionals, including those from geriatrics and other rotating specialties, will be given access to the TU platform and guided through its use by an expert. This hands-on experience will be complemented by providing the participants with TUR result tables to facilitate a direct comparison.

Participants will be able to access the survey via a QR code, provided during the sessions, allowing them to complete it either immediately or at their convenience. The survey's responses will be analyzed descriptively, focusing on the overall user experience with TU and its potential advantages in terms of ease of interpretation and presentation compared to traditional methods.

Table 1. Survey questions on the utility of The Umbrella Collaboration.

	Question	Answer Likert scale
1 - 6	Respondent affiliation data	
7	Do you consider that the interactive interface of the "TU"[a] methodology facilitates the understanding of results compared to the static tables of TURs[b]?	• 1: Strongly disagree • 2: • 3: • 4: • 5: Strongly agree
8	Do you believe that the visualization of results using bubble plots in "TU" helps to quickly identify the most relevant outcomes?	• 1: Strongly disagree • 2: • 3: • 4: • 5: Strongly agree
9	Does the graphical representation of the outcomes (illustrated by figures, colors, and sizes) in "TU" enhance your ability to assess the clinical relevance of the results?	• 1: Strongly disagree • 2: • 3: • 4: • 5: Strongly agree
10	Do you find that access to detailed data by clicking on the figures of the outcomes in "TU" interface enhances your evidence analysis experience?	• 1: Strongly disagree • 2: • 3: • 4: • 5: Strongly agree
11	Do you think that "TU" methodology allows for a quicker interpretation of data compared to TUR?	• 1: Strongly disagree • 2: • 3: • 4: • 5: Strongly agree
12	Is the information provided by "TU" useful in your field of work (clinical, research, or educational) for evidence-based decision-making?	• 1: Strongly disagree • 2: • 3: • 4: • 5: Strongly agree
13	Does the ease of use of "TU" interface facilitate greater data exploration compared to traditional methods?	• 1: Strongly disagree • 2: • 3: • 4: • 5: Strongly agree
14	Do you consider the historical evolution of evidence provided by "TU" methodology to be useful?	• 1: Strongly disagree • 2: • 3: • 4: • 5: Strongly agree
15	Does "TU" methodology require less statistical knowledge to interpret the results compared to TUR?	• 1: Strongly disagree • 2: • 3: • 4: • 5: Strongly agree
16	Overall, are you satisfied with "TU" methodology as a tool for tertiary evidence synthesis?	• 1: Strongly disagree • 2: • 3: • 4: • 5: Strongly agree

[a]TU: The Umbrella.

[b]TURs: Traditional Umbrella Reviews.

Statistical Analysis: Data Analysis and Statistical Methods

The quantitative analysis will compare the results obtained by both methodologies. Contingency tables will be constructed to contrast the identification of outcomes, the size effect, the direction of the effect, and the statistical significance, ensuring statistical congruence between the methods. For the evaluation of certainty levels, TU scores will be normalized to a scale comparable to the GRADE levels, which will also be transformed into a numerical scale between 0 and 1.

The chi-square test will be used to determine significant differences between the methodologies. In addition, Pearson and Spearman correlation analyses will be conducted to quantify the relationship between TU certainty levels and GRADE certainty levels of the TURs. Pearson correlation analysis is useful for quantifying the strength and direction of a linear relationship between 2 continuous variables. Moreover, the analysis will be complemented with Spearman correlation analysis due to potential violations of normality assumptions in the data.

Statistical analysis will be performed using IBM SPSS Statistics (version 26), with an alpha level of .05 to determine statistical significance.

Ethical Considerations

This study does not involve human participants, personal data, or animals. All data will be sourced from published materials, and the analyses will be conducted in accordance with established ethical standards for secondary data analysis. In addition, the survey component will be conducted anonymously and on a voluntary basis. Given these considerations, we do not deem it necessary to seek approval from an ethics committee, as the study adheres to standard ethical practices for research of this nature [24].

Results

We will focus on evaluating the effectiveness of the experimental methodology in accurately identifying and analyzing relevant outcomes. Among the results, we will include detailed assessments of effect sizes, the direction of effects, statistical significance, and the certainty of evidence for each outcome. We will compare these findings with those derived from TUR to determine if the experimental approach yields results that are at least equivalent in quality and comprehensiveness.

Finally, the efficiency of the experimental methodology will be evaluated by recording the time taken to complete the synthesis process. While the time required for TUR is estimated to range between 6 and 12 months based on existing literature, we will document the actual time taken by the experimental approach. This will provide a practical measure of the potential time savings offered by the software-driven AI-assisted method, highlighting its feasibility and effectiveness in a real-world context.

To evaluate the ease of use and comprehension of TU within its environment, a detailed survey will be specifically designed. Survey respondents will have access to the TU platform, where they can interact with various interactive screens displaying the results of the synthesis process across different projects completed to date.

Discussion

Principal Findings

The anticipated findings of this study are expected to demonstrate that TU, a semiautomated tertiary evidence synthesis tool, can produce results that are methodologically comparable to TURs while significantly improving efficiency. By leveraging AI-assisted methodologies, TU may streamline the synthesis process, reducing the time and effort required for evidence aggregation. In addition, the study aims to assess whether tertiary evidence synthesis can be effectively conducted using only systematic review abstracts, balancing feasibility with methodological rigor. If successful, these findings could support the broader adoption of AI-driven approaches in tertiary synthesis, potentially transforming the landscape of evidence-based decision-making in health care.

The primary objective of this study is to evaluate whether TU, a software-driven system designed to facilitate tertiary evidence synthesis with AI-assisted methodologies, can match the effectiveness of TURs. TU integrates with its software development advanced technologies such as NLP, SA, WS, and ML to enhance the efficiency of evidence synthesis.

The semiautomated processes implemented by TU could signify a significant advancement in making evidence synthesis more accessible and timely, with the potential for continuous updates as new data becomes available. The study's findings could pave the way for broader adoption of AI-driven methodologies in evidence synthesis, potentially reducing the time and resources needed for comprehensive reviews. TU's integration of software engineering projects and AI with traditional methods could streamline the review process, enabling faster aggregation and interpretation of data across various research domains.

Several software tools assist in systematic and umbrella review processes, such as DistillerSR, Covidence, and Rayyan. These platforms improve efficiency in evidence synthesis by automating tasks such as study screening, data extraction, and literature management. However, they do not offer a fully structured and automated methodology for tertiary evidence synthesis, which remains a predominantly manual process. In contrast, TU is designed to support the entire tertiary synthesis workflow, rather than focusing on isolated stages. TU integrates (1) AI-assisted search term expansion, which enhances literature retrieval by suggesting synonymous terms for human validation; (2) automated data extraction from systematic review abstracts, allowing for a structured and efficient synthesis process; (3) a dedicated framework for tertiary synthesis, unlike other tools that primarily assist in secondary synthesis (systematic reviews); and (4) interactive and visual result presentation, providing stakeholders with an accessible interpretation of findings, rather than traditional tabular outputs.

Ongoing Project Status

Once created, projects in TU remain active indefinitely, preventing obsolescence. This continuous updating of evidence

synthesis is a key feature that differentiates TU from static review methodologies. The system conducts literature searches every 24 hours or on demand by the human reviewer responsible for the project. This allows for real-time incorporation of newly published studies, ensuring that the synthesis remains current and reflective of the latest scientific evidence. While TUR requires manual updates, often years apart, TU transforms the synthesis process into a living evidence system, ensuring that the latest research is incorporated seamlessly. This eliminates the need for reinitiating entire projects and allows researchers to work with continuously updated data.

One similarity between TU and existing platforms is the incorporation of automation to enhance efficiency. However, TU distinguishes itself by providing a fully integrated tertiary synthesis methodology with a self-updating mechanism, ensuring both methodological rigor and computational efficiency in umbrella reviews.

By offering a platform that supports real-time updates and provides accessible synthesis outputs, TU has the potential to enhance the utility of tertiary synthesis for a wide range of stakeholders, including those with limited statistical expertise. However, a key limitation of TU is its reliance on a single database (MEDLINE via PubMed), which might not capture all relevant studies. This study will examine whether this limitation can be mitigated by the system's other capabilities. Ultimately, the timely and comprehensible evidence synthesis provided by TU could facilitate more informed decision-making in clinical settings, particularly in rapidly evolving areas of medical research.

Future research will be essential to further validate and refine TU. Planned next steps include expanding the sample size of included TURs to increase representativeness, conducting blinded validation studies to minimize potential biases, and testing the tool across different reviewer profiles to assess usability beyond expert users. In addition, TU's methodology should be applied to other medical and nonmedical disciplines to evaluate its versatility. A critical aspect of future validation will also involve independent expert review, ensuring that TU's findings align with established methodological standards. Finally, economic feasibility studies comparing TU with traditional synthesis approaches will be necessary to assess its cost-effectiveness and scalability in real-world implementation.

Limitations

The decision to use only one database, MEDLINE via PubMed, in TU is both a recognized limitation and a deliberate choice shaped by resource constraints and technical considerations. While systematic reviews typically require searching multiple databases to capture all relevant literature [25], our approach focuses on testing whether TU can achieve outcomes comparable to TURs despite these limitations. While the pilot study provided preliminary evidence of PubMed's strong coverage, further validation through TU is necessary to confirm its applicability across different domains.

Furthermore, while searching multiple databases is often recommended to avoid language and indexing biases, especially those related to non-English literature [26,27]. TU mitigates some of these biases by focusing on abstracts in English, as all PubMed abstracts are provided in this language regardless of the original publication's language. However, the absence of Chinese databases in our approach is a notable limitation, given that only a small proportion of Chinese journals are indexed in MEDLINE.

The decision to rely exclusively on abstracts rather than full texts in TU is a deliberate methodological choice aligned with the core objective of this study: to evaluate whether tertiary evidence synthesis can be conducted efficiently, with fewer resources, and without requiring extensive methodological expertise from the reviewer, while still producing results comparable to TURs.

We acknowledge that abstracts may lack key methodological details, including certainty of evidence assessments, effect size calculations, and risk of bias evaluations. However, the fundamental hypothesis of TU is that an automated, structured approach to abstract-based synthesis may still yield clinically useful conclusions, particularly when applied under standardized and reproducible conditions. Moreover, relying on abstracts offers two key advantages: (1) minimization of language bias: all systematic review abstracts in MEDLINE are available in English, regardless of the original publication language, which ensures that non-English studies are not automatically excluded due to language barriers, a common issue in traditional systematic reviews; and (2) feasibility and accessibility: full-text access to all systematic reviews requires extensive licensing fees and institutional subscriptions, which may not always be feasible. Abstracts provide a universally accessible data source, allowing for broader implementation of evidence synthesis methodologies.

While TU does not claim to replace the depth of full-text review, this study aims to evaluate whether a structured synthesis based solely on abstracts can yield results that are sufficiently coherent and robust to serve as a complementary or alternative approach. If validated, this methodology could provide an efficient solution for synthesizing evidence in settings where full-text access is restricted or when rapid evidence synthesis is needed.

While we acknowledge the potential benefits of testing TU across multiple medical domains, this study is a pilot study designed to assess the feasibility of our methodology in a single, well-defined field, geriatrics. At this stage, limiting the scope to geriatrics is a strategic choice, ensuring that the study maintains clarity, feasibility, and methodological rigor in its initial validation phase. This focused approach allows for a controlled evaluation of TU against TURs, ensuring that the initial validation is conducted under clearly defined conditions. If the results demonstrate that TU can produce findings comparable to TURs, future studies will expand its application to other medical fields, such as cardiovascular medicine and psychiatry, as well as nonmedical domains, including education, sociology, and other disciplines with abundant systematic reviews. This stepwise approach ensures a methodologically sound progression, allowing TU to be tested and refined incrementally before broader implementation.

In this initial phase of the study, we have prioritized clinical health professionals as the primary participants for the ease of

use and comprehension surveys. This decision is based on the primary objective of TU, which is to facilitate evidence synthesis for clinicians and health care professionals who may not have extensive expertise in systematic review methodologies. Given that TU is designed to enhance the accessibility and usability of tertiary evidence synthesis in clinical practice, it is essential to first evaluate its clinical utility and interpretability among end-users.

We fully acknowledge the importance of a rigorous methodological review by epidemiologists and research methodologists, as well as the need to assess the validity of results produced by TU. However, this will be addressed in a subsequent phase of research, where surveys will be extended to other key stakeholders, including epidemiologists and research methodologists, to evaluate the methodological robustness of TU. Health care policy makers and hospital administrators, assess TU's potential role in decision-making. Patients and caregivers, to explore how synthesized evidence can be communicated effectively to the general population. This stepwise approach ensures that TU is first assessed from a clinical perspective before expanding to other critical stakeholders in future validation studies.

Another limitation of this study is the potential for response bias in the ease-of-use and comprehension survey. Given that most participants will complete the survey immediately after structured demonstrations of TU, their responses could be influenced by the context of the presentation. This could lead to a more favorable assessment of TU than what might be observed in an independent evaluation setting. This halo effect can impact the perceived usability and effectiveness of TU. Future studies should aim to validate these findings through independent assessments in settings where TU is used without direct guidance from the research team.

Conclusion

This study aims to validate TU as a tool for tertiary evidence synthesis in health. If this methodology proves to be as effective as TURs, but more efficient in terms of project execution time and more accessible in terms of ease of use and comprehension, it could significantly enhance the way evidence synthesis is conducted, facilitating informed decision-making, and improving health outcomes. The results of this study may represent a step toward the integration of innovative technologies into the routine practice of evidence synthesis, with the potential to transform the field of health research.

Abstract

Background: Chronic noncancer pain (CNCP) is a frequent reason for counseling in general practice. Current German guidelines emphasize its biopsychosocial etiology and the importance of self-care and nonpharmacological treatment strategies such as education, physical and social activity, and psychological approaches. Comprehensive assessments are necessary to individualize treatment maximally and monitor appropriate use of pain medication. General practitioners face many challenges in implementing holistic pain management, which considers biological, psychological, and social aspects. In project RELIEF (resource-oriented case management to implement recommendations for patients with chronic pain and frequent use of analgesics in general practices), a case management program was developed to facilitate implementation of guideline recommendations on pain management regarding medical assessment and monitoring, patient and practice team education, promotion of self-care strategies, and rational pharmacotherapy.

Objective: We evaluated the feasibility of the intervention and study procedures before applying them in a larger cluster randomized controlled trial. Our secondary objective is to estimate potential effects of the complex intervention.

Methods: A single-arm trial with general practices and patients with CNCP and analgesics use will be conducted, accompanied by a mixed methods process evaluation. The intervention comprises 5 components, including software-supported medical pain history, 3 scheduled structured appointments, e-learning on CNCP for general practitioners and medical assistants, educational material for patients, toolbox with information on (regional) resources for patients and practice teams. Participating practices will be located in the federal state of Baden-Württemberg, Germany, and will recruit eligible patients (adults with CNCP for more than 3 months, with at least moderate pain-related disability, permanent or on-demand use of analgesics or co-analgesics in the previous 4 weeks, and practice team assessed ability to participate actively in the trial). A questionnaire given to the first 150 adult patients entering the practice in February 2025 will help screen eligible patients. The primary objective will be measured

by a set of predefined indicators. The key secondary outcome is pain-related disability measured by the Pain Disability Index German version. All participants will be asked to participate in the process evaluation. Outcome evaluation data will be gathered by paper-based and digitally provided questionnaires to be completed by participants. Process evaluation data will be gathered in surveys and a qualitative study. Descriptive analyses will be performed.

Results: Recruitment occurred between October and December 2024. Targeted sample size was 6 practices and 50 patients. The intervention period will be February-June 2025. It is expected that eligible patients will benefit from the intervention and that improved medication management and intensified use of nonpharmacological treatment strategies will reduce pain-related disabilities and other patient-reported outcomes.

Conclusions: This study will provide valuable information regarding feasibility and potential effects before testing the intervention in a confirmatory cluster randomized controlled trial.

Introduction

Background

About 20% of the patients in German general practices are affected by chronic pain [1], defined as pain that persists for more than 3 months or reoccurs [2]. Classification systems distinguish between chronic primary pain which cannot be explained by a detectable tissue damage (eg, fibromyalgia, unspecific low back, and psychosomatic pain disorders) and chronic secondary pain which is likely to have been caused at least initially by an organ or tissue damage (eg, degenerative or inflammatory diseases of the joints or spine and nerve damages) [2]. While cancer-related pain has characteristics of continuous or intermittent pain [3], chronic noncancer pain (CNCP) comprises any painful condition not associated with malignant disease and persisting for at least 3 months [4]. It interferes with activities of daily life and has a negative impact on quality of life and physical function [5]. CNCP is considered to be a major public health problem and one of the most common reasons why patients seek medical care [6,7]. The understanding of chronic pain pathogenesis has become more differentiated in recent years and there is consensus that chronic pain is always maintained or influenced by an interaction of biological, psychological, and social factors. Furthermore, psychological comorbidities such as depression, anxiety, or posttraumatic stress disorder are frequently associated with chronic pain [8]. Depending on which factors or comorbidities prevail, different treatment strategies are effective. Thus, comprehensive medical pain assessment is necessary in order to individualize treatment as best as possible.

Guidelines emphasize the importance of holistic pain management and nonpharmacological and noninvasive treatment strategies such as education, physical activity, social activity and support, relaxation techniques, or cognitive behavioral therapy. Analgesics should only be used temporarily and supportively until nonmedical treatments show an effect [9]. However, about two thirds of patients with chronic pain take analgesics [10] which may have severe adverse effects. Particularly alarming is the high percentage of patients taking nonsteroidal anti-inflammatory drugs (NSAID) which are also available as over-the-counter drugs. In a large telephone survey, 72% of German respondents with chronic pain stated using nonprescribed NSAID [10]. If taken on a long-term basis, NSAID may lead to renal insufficiency, gastrointestinal damages and cardiovascular events. Furthermore, the rise of opioid prescriptions for CNCP is observed with concern in Germany, even though there are no signs for an opioid epidemic [11]. The majority of opioid prescriptions are issued for CNCP, although it is well known that opioids are frequently not or little effective in this indication and associated with a high risk for adverse events such as obstipation, falls, cognitive impairments, or addiction [12]. If analgesics are applied, it is vital to perform thorough medication management and to adhere to monitoring recommendations. The German guideline for long-term use of opioids in chronic noncancer pain (LONTS) gives clear recommendations for safe opioid management [13]. However, adherence to guidelines might be impacted by factors such as personal attitudes, preferences, and experiences [14] and General practitioners (GP) might be less likely than other specialists to follow a guideline since they favor their own experience [15,16], or might not be aware of guidelines. Suboptimal pain management does not only result in unnecessary suffering of the affected patients but also in high costs for the health care system: patients with pain-related disabilities have a 6-fold higher rate of sick leaves and 4.5-fold higher rate of physician visits [17].

In Germany, patients with CNCP are mainly treated in ambulatory care by GPs and specialists such as orthopedists, neurologists, or rheumatologists. Only 10% have ever seen a pain specialist or received multimodal pain therapy [18]. GPs frequently know their patients and the patient's family for many years. They often act as coordinators of care and are frequently the main prescribers of all medications. Therefore, they play a crucial role in the care of patients with chronic pain. In spite of these good preconditions, it remains challenging for GPs to

implement structured and holistic pain management in their daily practice [9].

Within the project RELIEF (Resource-oriented case management to implement recommendations for patients with chronic pain and frequent use of analgesics in general practices), a case management program was developed to support GP in implementing guideline-based pain management. The program focusses on patients with CNCP and 4 essential areas of pain management: medical assessment and monitoring, practice team and patient education, self-care, and rational pharmacotherapy.

Overall Aim of the Study

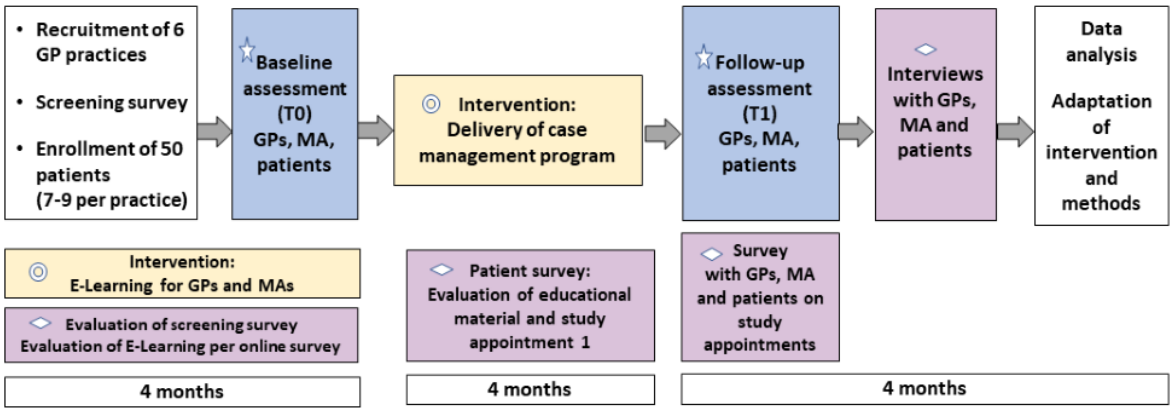
The main objective of this pilot study is to test the developed program in a small number of practices with a small number of patients to assess the feasibility of the developed intervention components (eg, assessment and e-learning) and methods used for recruitment (eg, screening process) and data collection. Thus, a control group (no intervention) will not be involved. The evaluation of the program's potential effectiveness and data generation on the prevalence of the programs' target group in German general practices are secondary objectives. Based on findings of this study, the program and evaluation concept will be adapted where applicable and applied in a subsequent confirmatory cluster randomized controlled trial (not described in this protocol).

Methods

Study Design

A single-arm, exploratory pilot study with accompanying process evaluation will be conducted to pilot the case management program. Conducting a pilot study provides a good opportunity to assess feasibility of a full-scale study and can be considered an essential prerequisite to enhancing likelihood of success of the main study. Pilot studies should be well designed with clear feasibility objectives, and explicit criteria for determining feasibility [19]. Figure 1 details the design for the RELIEF pilot study.

Figure 1. The design of the pilot study in RELIEF. Yellow box (circles): intervention components; blue box (star): outcome evaluation; purple box (diamond): process evaluation. GP: general practitioner; MA: medical assistant; RELIEF: resource-oriented case management to implement recommendations for patients with chronic pain and frequent use of analgesics in general practices.



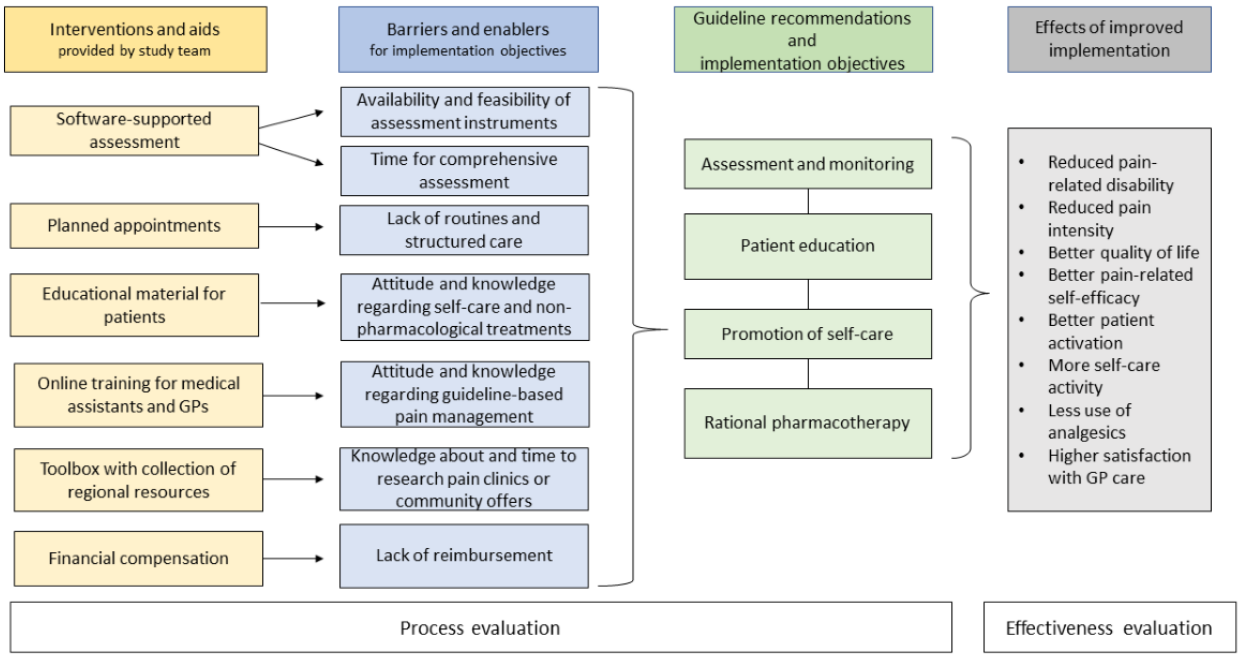
Intervention

The RELIEF intervention consists of five key components: (1) medical pain assessment and monitoring using a module specifically developed for the RELIEF intervention to be applied within an established case management software (CareCockpit) [20], (2) 3 scheduled structured appointments with GPs and medical assistants (MA), (3) e-learning on chronic pain management for GPs and MA, (4) educational video- and paper-based material for patients, and (5) a toolbox with a collection of resources for pain management for patients and practice teams. GP and MA will receive financial compensation for their additional efforts related to participation in the study (€200 [approximately US $216] per GP, €400 [approximately US $432] per MA) and number of included patients (€80 [approximately US $86] per included patient). GPs can apply for a total of 8 continuing medical education points upon completing the e-learning modules.

It is expected that patients participating in the case management program will benefit from the intervention. It is hypothesized that improved medication management and intensified use of nonpharmacological treatment strategies will result in a reduction in pain-intensity and pain-related disabilities, improved patient activation, more self-care activity and less use of analgesics. Figure 2 describes the assumed effect mechanism of the developed intervention.

It is assumed that adherence to guideline recommendations for CNCP by practice teams (green boxes) will improve if the intervention components (yellow boxes) effectively reduce identified barriers or make use of identified enablers respectively (blue boxes). Improved adherence to guideline recommendations will result in improved health outcomes or health behavior, respectively (gray box). Primary and secondary outcomes (gray box) focus on the effects of improved guideline adherence while adherence as well as assumed linkages between interventions and barriers are assessed within the scope of a comprehensive process evaluation.

Figure 2. The assumed effect mechanism of the intervention. GP: general practitioner.



After enrolling in the pilot study, patients will complete a pain assessment through a browser-based proprietary app available to study participants only (TeleVital app linked to CareCockpit) at home on their own digital device (smartphone, tablet, computer, etc). The assessment focusses on various aspects of pain and mental comorbidities. Within 2 weeks, patients will have a scheduled structured appointment (study appointment 1) with their GP during which the patients' specifications in the assessment will be discussed and complemented by an open pain history taking. For this purpose, GPs or medical assistants will perform a manual import of the assessment data into the software CareCockpit, an established case management software currently used by about 800 general practices in Baden-Württemberg, Germany, for the case management program PraCMan [20]. This is a care model for patients with multimorbidity insured by the statutory health insurance AOK Baden-Württemberg. The data import will only be started when the patient is present in the practice to ensure that GPs are able to react immediately on critical information such as severe depression. Practice teams will receive the data in 2 versions: the original version with all items and patients' responses and, in addition, a summary of the assessment with automatically calculated scores.

At the end of study appointment 1, educational material on chronic pain (a booklet and links to educational videos tailored to patient's self-efficacy, to be used as often as patients want, and at their own speed) will be handed out to patients and the date for study appointment 2 will be set for about 2-4 weeks later. During study appointment 2, patients and GPs or patients and medical assistants will reflect on the educational material provided and agree on treatment goals related to daily activities (eg, to be able to do some gardening) and self-care activities (eg, physical activity or relaxation techniques). If necessary, medication is prescribed and therapies outside the general practice are initiated (eg, physiotherapy, multimodal pain therapy, psychotherapy, and rehabilitation), and monitoring activities (diagnostics, amendments to therapy plan, discussion of possible adverse effects, pain management, medication, self-care, etc) are planned. A treatment plan containing all this information will be issued by the responsible GP through the CareCockpit software and the date for study appointment 3 will be set for 4-6 weeks later. During study appointment 3, practice teams will check whether activities could be applied as planned. If necessary, the treatment plan will be adapted. The activities performed during study appointments 1-3 will briefly be documented by the practice teams through a checklist in the CareCockpit module. The intervention period will end with a follow-up assessment 4 weeks after study appointment 3.

A webinar will be offered by the study team to go over study organization and measures with all participating practice teams. Participating GPs and MAs will complete an e-learning on chronic pain management with 4 modules covering the pathogenesis of chronic pain, self-care activities (relaxation technics, physical activity, and topical applications), analgesics and interprofessional and interdisciplinary pain therapy. The e-learning is expected to be completed before the first patient receives study appointment 1. A website with a toolbox containing useful links and information on chronic pain as well as a collection of regional resources (eg, hospitals providing multimodal pain therapy and counseling centers etc.) will be provided by the study team. Table 1 summarizes the planned course of the RELIEF case management program.

Table 1. The course of the case management program in the RELIEF[a] pilot study.

Who	Where	What
Week 0		
MA[b]	Practice	• Enrollment into study
Patient	At home	• Structured pain assessment through TeleVital appT0 baseline assessment through a paper-based questionnaire
Week 2		

GP[c]	Practice	• Study appointment 1:
		  • Discussion of the results of the structured pain assessment
		  • Open pain history taking
		  • Patient receives educational material

Patient	At home	• Reading educational material or watching educational videos, respectively
Week 5 to 6		

• MA
• MA or patient
• GP
	Practice	• Study appointment 2:
		  • Reflection on educational material
		  • Agreement on treatment goals and self-care activities
		  • Treatment plan is issued

Patient	At home	• Applies treatment plan
Weeks 10 to 12		
• MA • GP	Practice	• Study appointment 3: • Monitoring if treatment plan and self-care could be applied as planned; if necessary, adaption of the treatment plan
Patient	At home	• Applies (adapted) treatment plan
Week 16		
Patient	At home	• T1 follow-up assessment; end of pilot study

[a]RELIEF: resource-oriented case management to implement recommendations for patients with chronic pain and frequent use of analgesics in general practices.

[b]MA: medical assistant.

[c]GP: general practitioner.

Recruitment

General practices will be recruited through known contacts such as the established practice network of about 800 practices that use a particular case management system for chronically ill patients (PraCMan) [21] and a network of teaching and research practices affiliated with the Department of Primary care and Health Services Research, University Hospital Heidelberg. The target is to include 6 practices. Based on previous experiences, it can be assumed that about 10% of the practices approached are interested in participating in research projects. Therefore, 60 practices in a predefined region will be randomly drawn and an invitation to participate in the pilot study will be sent to them by postal or electronic mail together with a declaration of interest form. Practices that declare interest in participation will receive written information about study aims and procedures. In case the recruitment target is not met, another random sample will be drawn.

To identify eligible patients and to gather information on the prevalence of the target group in primary care, a screening survey will be conducted (see Data Collection and Outcomes section below). Eligible for participation will be adult patients with CNCP for more than 3 months, with at least moderate pain-related disability (minimum 4 points on a scale from 0-10), permanent or on-demand use of analgesics and co-analgesics in the previous 4 weeks, and practice team assessed ability to participate actively in the pilot study (sufficient cognitive abilities and internet access). Patients with cancer pain or in palliative care will be excluded. Recruitment target for each practice is 7-9 patients. If more than 9 patients agree to participate in the piloting, the practice team will select 7-9 patients who are according to their assessment likely to benefit from the program. Specific reasons for their choices will be explored in the process evaluation.

Data Collection and Outcomes

For the screening survey, each participating practice will hand out a screening questionnaire to the first 150 adult patients entering the practice from a defined date on. The practice team will collect the questionnaires, check eligibility with a provided template and invite all patients meeting the inclusion criteria to participate in the pilot study by handing out the study information material. The practice team will add information regarding reasons for nonparticipation, known CNCP diagnosis, known use of analgesics, and prescription of analgesics during the last month on the screening questionnaires of all patients meeting the inclusion criteria (regardless of whether they agree to participate in the study or not) by checking the patient file. The practice team will deidentify all questionnaires (also of patients without chronic pain) by cutting the lines for name and birthdate and send them to the study center for evaluation purposes regarding prevalence of patients in a primary care setting who meet the inclusion criteria.

Data collection related to medical pain history (used by practice teams only, not by researchers) comprises the following steps: patients receive a weblink from their GP practice leading to a browser-based app called TeleVital and complete the assessment through the app on their own digital device. TeleVital is a proprietary development of the Department of Primary Care and Health Services Research, University Hospital Heidelberg, and facilitates structured data collection in studies which use the CareCockpit. Data generated in the TeleVital app data will be stored on a secure server located at the University Hospital Heidelberg, Germany until it is transferred to the CareCockpit software installed in the GP practice. Data import will be initiated manually by the practice team at the next patient contact. Thus, practice teams will receive the assessment data only when the patient is present in the practice. Practice teams will use the assessment data for the purpose of diagnostics and treatment. It contains information on pain history, pain characteristics, use of analgesics, use on nonpharmacological measures, treatment targets, and items from validated screening questionnaires such as the Pain Detect questionnaire on neuropathic pain [22] and on mental comorbidities such as posttraumatic stress disorder [23].

Data collection for the outcome evaluation comprises the following steps: primary objective of this pilot study is to assess the case management's feasibility, measured by a set of predefined feasibility indicators. Regarding the intervention components, feasibility indicators refer to the software-supported medical pain history, study appointments, educational material for patients, and e-learning for GPs and MA. Feasibility of study procedures will be measured for the patient recruitment and enrollment process, completion of T0 and T1 questionnaires and drop-out rate. To facilitate this assessment, transfer of partial documentation from the CareCockpit to the study center will be used either electronically or paper-based, depending on preference and available resources in the participating practices. Table 2 describes the feasibility indicators in relation to the intervention components, and Table 3 details the feasibility indicators for study procedures.

Table 2. The feasibility indicators for intervention components in the pilot study.

Interventions	Data source	Indicator	Rating
Software-supported medical pain history	CareCockpit data process evaluation	Percentage of patients with pain assessment transferred to practice computer	• ≥80%: feasibility given • <80%, but reasons solvable by modification: feasibility likely • <80% and reasons not solvable by modification: feasibility not given
Planned appointments	CareCockpit data	Percentage of patients who received all 3 study appointments	• ≥80%: feasibility given • <80%, but reasons solvable by modification: feasibility likely • <80% and reasons not solvable by modification: feasibility not given
Educational material for patients	Evaluation questionnaire and patient interviews	Percentage of patients who perceived the provided content relevant and comprehensible	• ≥80%: feasibility given • <80%, but reasons solvable by modification: feasibility likely • 80% and reasons not solvable by modification: feasibility not given
E-Learning for GPs and medical assistants	Evaluation questionnaire and general practitioner and medical assistant interviews	Percentage of health care professional who perceived the e-learning relevant and comprehensible.	• ≥ 80%: feasibility given • <80%, but reasons solvable by modification: feasibility likely • 80% and reasons not solvable by modification: feasibility not given
Toolbox	Survey and general practitioner, medical assistant, and patient interviews	Percentage of participants who perceived the toolbox as relevant	• ≥80%: Feasibility given • <80%, but reasons solvable by modification: feasibility likely • 80% and reasons not solvable by modification: feasibility not given

Table 3. The feasibility indicators for study procedures in the pilot study.

Study procedure and data source	Indicator	Rating
Patient recruitment		
Screening questionnaire	Percentage of patients who agreed to participate in the screening survey	• >80%: feasibility given • <80%, reasons solvable by modification: feasibility likely • <80% and reasons not solvable by modification: feasibility not given
Screening questionnaire	Percentage of patients in screening survey meeting all inclusion criteria	• >10%: feasibility given • <10%, but reasons solvable by modification: feasibility likely • <10% and reasons not solvable by modification: feasibility not given
Screening questionnaire	Percentage of practices that enrolled 7-9 patients	• >80%: feasibility given • <80%, reasons solvable by modification: feasibility likely • <80% and reasons not solvable by modification: feasibility not given
Outcome evaluation		
T0 and T1 questionnaires	Percentage of patients who completed T0 and T1 questionnaires	• >80%: feasibility given • <80%, reasons solvable by modification: feasibility likely • 80% and reasons not solvable by modification: feasibility not given
General practitioner report	Patient drop-out rate	• <20%: feasibility given • >20%, but reasons solvable by modification: feasibility likely • >20% and reasons not solvable by modification: feasibility not given

A range of secondary outcomes will be determined to gather information on potential effects of the program. All secondary outcomes are participant-reported and will be collected before (T0) and after (T1) the intervention by paper-based questionnaires which participants will complete at home and send directly to the study center.

Outcome measures on patient level comprise the German versions of the following validated instruments: Pain Disability Index German version (PDI-G) [24] (key secondary outcome), Patient Activation Measure [25], Short Form 12 Health Survey scale for health related quality of life [26], De-Jong-Gierveld loneliness scale [27], Pain Self-Efficacy Questionnaire German version [28], Avoidance-Endurance Fast Screening instrument [29], Pain-Catastrophising Scale [30], selected items of the European Project on Patient Evaluation of General Practice Care (EUROPEP) questionnaire on evaluation of GP care [31,32], and pain intensity (numeric analogue scale). Further study-specific items will be used to assess the use of self-care such as physical activity (3 items), relaxation techniques (1 item) and use of topical applications (1 item) and patients will be asked to document their pain medication (over-the-counter and prescribed). Secondary outcomes on GP and MA level refer to quality indicators for ambulatory pain management developed in the RELIEF project. Data for the process evaluation will be collected at various points in time as detailed in Figure 1.

During patient recruitment, practice teams will be asked to send the deidentified patient screening questionnaires to the study center for evaluation purposes. The e-learning for GPs and MA will be hosted on the platform Moodle on the server of the aQua Institute, Göttingen. After completion of the e-learning GPs and MA will be asked to fill in a short digitally provided survey to evaluate the training regarding aspects such as subjective knowledge increase, appropriateness of required time, appropriateness of didactical methods, and usability of the platform. The survey will be conducted through the survey tool Lime Survey hosted at a server of the University Hospital Heidelberg. Survey data will be linked through a pseudonym to the following meta-data gathered by the e-learning platform (e-learning completed or not completed, time needed to complete the e-learning (minutes), and number of logins necessary to complete the e-learning).

Patients will complete a paper-based pseudonymized questionnaire focusing on use and perceived usefulness of the provided educational material and experiences with study appointment 1. Patients will complete the questionnaire after going through the content provided and within 4 weeks after study appointment 1. At the end of the intervention period, patients will be asked to fill in a second questionnaire focusing on their experiences with study appointment 2 and 3 as part of the T1 follow-up survey.

All participating GPs and medical assistants will be invited to report their experiences during the pilot in a telephone interview. All patients will be invited to an interview after completing study visit 3. Depending on the response rate, a purposive sample of patients will be drawn. Written informed consent to participate will be obtained using separate information documents and agreement forms. Key questions on the interview guides will refer to intervention feasibility with regards to specified feasibility indicators, usefulness of provided material and tools, perceived effectiveness of the case and care management program, and suggestions for modifications from the perspective of health care providers and patients. Interviews will be recorded and transcribed verbatim. Transcripts will be pseudonymized and stored on secure servers at the Department of Primary Care, University Hospital Heidelberg. All audio files will be deleted after completion of data analysis.

Data Analysis

A plan for the primary analysis will be finalized before data bank closure. All analysis will be performed in R (version 4.2.0 or higher; R Foundation for Statistical Computing) or in SPSS (version 28.0.1.0; IBM Corp) in a validated environment. The final analysis will be done as soon as the database has been declared to be complete and accurate and has been locked. Descriptive statistics will be provided to summarize demographics and baseline characteristics. In general, continuous variables will be described using number of observations, mean, SD, median, Q1, Q3, minimum, maximum, 95% CIs and, if existing, number of missing values at T0, T1 and for T0-T1 if appropriate. For categorical variables, absolute and relative frequencies will be given with missing values being reported as a separate category at T0 and T1. A CONSORT (Consolidated Standards of Reporting Trials) flow diagram will be created to display the progress of all participants through the trial. This includes the number of patients assessed for eligibility and the number of patients excluded because they did not meet inclusion criteria, declined to participate, or any other reason.

Primary Outcome Analysis

For each objective of the intervention components and study procedures, a descriptive analysis will be performed to assess feasibility. For each objective, 95% CIs will be given based on the Wilson Score interval for binary measures [33]. Reasons for not fulfilling an indicator will be categorized and evaluated descriptively.

Secondary Outcomes Analysis

As one of the aims of the study is to estimate the effect size, the 95% CI (2-sided) of the PDI-G percent change from baseline to T1 (T0-T1), which is planned to be the primary outcome in a subsequent cluster randomized trial and therefore of major interest in this pilot study, will be given. Only questionnaires with at least 6 out of 7 answered items will be considered. Missing items will not be imputed. Questionnaires with less than 6 answered items will not be considered.

As a sensitivity analysis, missing values of the PDI-G will be replaced on item level using multiple imputation based on predictive mean matching using the variables age, sex, center, and pain intensity at baseline as potential predictors. Missing scores and differences can then be calculated using the imputed items. Furthermore, a best- and worst-case scenario will be looked at, where missing values will be imputed by the highest and lowest observed value for T0 and T1 in the best case scenario and vice versa in the worst case scenario (lowest and highest observed value for T0 and T1, respectively). As another sensitivity analysis, a mixed linear regression model for the dependent variable PDI-G score at T1 will be performed including age, sex, and PDI-G at T0 as fixed effects and center as random effect. Descriptive analysis at item level and for the total number of pain-related patients at T0 and T1 will be done. Descriptive analysis of the item and score level will be done for all remaining secondary outcomes. For differences in scores between baseline and follow-up, 95% CIs will be reported. Missing values for secondary outcomes will not be imputed.

No sample size calculation was performed, as the main purpose of the pilot study is to investigate feasibility of the applied interventions and study procedures. Considering the exploratory nature of the pilot study, and based on experiences from previously conducted research, a total of 50 patients is considered sufficient to provide an initial estimate of the potential effect of the intervention measured by the PDI-G percent change from baseline to T1 (T0-T1), which is the key secondary endpoint. Assuming a SD of 13.7 and 15.4 score points [34] corresponding to a SD of 19.6% and 22% score points respectively, a sample size of 50 patients and a 2-sided 95% CI would yield the following: assumed SD 19.6: [x-5.6, x+5.6]; assumed SD 22: [x-6.3, x+6.3], where x is the point estimate of the PDI-G percent change from baseline to T1 (T0-T1).

Analysis of Process Evaluation Data

Analysis of the qualitative data collected in the process evaluation will use an inductive approach based on the themes covered in the interview guide (including unintended effects). Data management will be done in MAXQDA (Verbi Software). Written surveys will be conducted digitally through the survey tool Lime Survey hosted on secure servers of the Heidelberg University. All quantitative survey data and data from free text fields will be analyzed descriptively using SPSS and visualized in Excel (Microsoft). In addition, data entered by the practice teams into the CareCockpit software to document activities performed during the study appointments will be transferred to the study center and analyzed within the scope of the process evaluation. All data will be deidentified before analysis. All data generated in the process evaluation will be triangulated for classification of intervention and program feasibility. Final assessment of feasibility will be performed by 2 researchers in a consensus process.

Ethical Considerations

The pilot study in RELIEF received ethics approval from the Ethics Committee of the Medical Faculty at University Heidelberg, Germany (S-329/2024; June 05, 2024) and the state medical association of Baden-Württemberg (B-F-2024-057; July 02, 2024). The study will be conducted in accordance with the Declaration of Helsinki. All participants will give written consent before participation.

Results

The recruitment for this pilot study started in October 2024 and was open until end of December 2024. The targeted sample size was 6 practices and 50 patients. The intervention period began in February 2025 and will run until June 2025. Findings are expected to provide an indication of potential patient benefits as well as feasibility of the interventions and study procedures. First evaluation results regarding potentially necessary adaptations of intervention components and study procedures are expected to be available in July 2025. Publication of findings and necessary adaptations are expected for the second and third quarters in 2025.

Discussion

Principal Findings

Findings in this exploratory pilot study will provide a clear indication regarding intervention feasibility and applied study procedures. It is expected that eligible patients will benefit from the intervention and that improved medication management and intensified use of nonpharmacological treatment strategies will result in a reduction of pain-related disabilities and other patient-reported outcomes. Potentially necessary adaptations of intervention components and study procedures will be finalized before testing the intervention in a randomized controlled trial which is planned to begin late in 2025. The evidence base regarding the chosen combination of intervention measures for patients with CNCP in German primary care is still limited. The expected effects appear to be plausible; however, they are not certain, so this pilot study can provide an important contribution.

The common belief that pain is a normal part of aging may explain why chronic pain is often underestimated and underreported [35]. Studies found that older adults tend to adopt a stoic attitude toward experiencing pain and prefer to use self-reliance–based coping strategies, though these may not always be effective [35,36]. A study in Italy explored coping strategies used by older adults to manage chronic pain and found that frequently coping self-statements, resting, task persistence, and guarding were described, while the least used strategies were relaxation and exercise or stretching [37]. The latter are clearly recommended in German guidelines [9]. Other studies also explored life experiences and needs of older adults with chronic pain and strategies they use to cope with and manage pain [38,39] or aimed to promote effective and tailored pain self-management interventions [36,40]. The RELIEF case management program contains innovative elements: GPs, MAs, and patients may benefit from the more structured care processes and patient activation which in turn can provide room and time for open discussion with patients on their needs. Meticulously obtained pain history for example, provides important information for pain assessment regarding onset and course, pain episodes, quality, intensity, activity impairment, and any stress factors in a patient's personal life [41]. Some elements of the innovative program can be assigned to medical assistants, for example reflecting on the educational material or setting individual treatment targets with patients. Thus, MA will be more involved in CNCP care than usual, which may increase their competences, strengthen their role in the care process, and support sharing of the workload in team-based care [42].

Educational components will be used as an explicit treatment strategy anchored directly in the general practice setting. Care programs for disease management usually offer patient education outside of the GP practice which has the disadvantage of GPs being unfamiliar with the presented content which makes it difficult to refer to and pick it up in the course of treatment [9]. Combining therapies with delivering content remotely through the internet or mobile devices is increasingly used to promote and improve self-management of chronic conditions. And complement face-to-face pain treatments [43]. On the other hand, some elements of the RELIEF program may cause additional burden: patients will be asked to provide detailed information about their pain history, mental condition and personal goals and receive comprehensive information about chronic pain. This may provoke adverse effects such as negative, stressful emotions, yet also has the potential for reflection about perhaps still unused self-care potential and possible behavior adaptation. Participation in the case management program will require additional appointments and therefore be associated with an additional time burden for patients and practice teams alike. This pilot study will assess thoroughly whether the assumed effect mechanisms are plausible and whether the potential benefits outweigh potential harms.

Strengths and Limitations

This study is a single-arm exploratory pilot study which leaves room for bias. Primary and secondary outcomes are based on self-reported data. In the multifaceted program, the potential impact of the various components might be difficult to separate. Strong aspects will be the program's closeness to daily practice and the exploration of implementation outcomes in the accompanying process evaluation which adds value to this study. The analysis of components of the complex implementation program using predefined feasibility indicators contributes to the transparency of the implementation program.

Dissemination Plan

After completing this feasibility study, findings will be disseminated through oral and poster presentations at scientific conferences as well as in a scientific article in a peer-reviewed journal.

Conclusion

This study will provide valuable information regarding potentially necessary adaptations before applying the intervention in a confirmatory cluster randomized controlled trial.

Acknowledgments

Project RELIEF (resource-oriented case management to implement recommendations for patients with chronic pain and frequent use of analgesics in general practices) is exclusively funded by the German Federal Ministry of Education and Research (01GY2106). The funder had no role in design and conception of this study. For the publication fee, the authors acknowledge financial support by Heidelberg University.

Data Availability

In line with the obtained ethics approval, all data sets that will be generated and analyzed during this pilot study and the process evaluation will not be publicly available due to data protection laws. They will be stored on secure servers at the Department of Primary Care and Health Services Research, University Hospital Heidelberg. Deidentified sets of these data can be made available by the corresponding author on reasonable request.

Authors' Contributions

RPD, CS, and SB designed this pilot study and the intervention components and drafted and revised this study protocol. AB provided expertise on statistical analysis and critically revised the manuscript. CS and RPD shared the project management. All authors provided input and critical feedback and approved the final version of the manuscript.

Conflicts of Interest

The principal investigator CS is member of the guideline commission of the German Society of General Practice and Family Medicine (DEGAM). SB is a doctoral candidate in RELIEF. All authors declare no conflict of interest.

Abstract

Background: Integrating digital entrustable professional activities (EPAs) and simulations in medical education represents a substantial shift toward competency-based learning. This approach focuses on developing specific skills through manageable units and enhancing proficiency in high-stakes environments. The technology acceptance model provides a framework to evaluate the adoption of these educational technologies, emphasizing the roles of perceived usefulness and ease of use.

Objective: This cohort study aims to investigate the acceptance of digital EPAs among medical students within simulated training environments. It seeks to understand how perceived usefulness and ease of use influence this acceptance, guided by the principles of the technology acceptance model.

Methods: The cohort study will involve medical students in the clinical phase of their education at Ludwig Maximilians University Munich. The survey, distributed through the Module-6 distributor, will capture their perceptions of digital EPAs. The data will be analyzed using regression analysis.

Results: Data collection is anticipated to be complete by April 2025, with analysis concluded by May 2025. The results will provide insights into students' attitudes toward digital EPAs and their willingness to integrate these tools into their learning.

Conclusions: This study will contribute to the understanding of digital EPAs' role in medical education, potentially guiding future design and implementation of these tools. While highlighting the importance of perceived usefulness and ease of use, the study also acknowledges limitations in sample size and recruitment methodology, indicating the need for further research with more diverse and larger groups. This research is poised to shape future medical training programs, aligning with the evolving landscape of medical education.

KEYWORDS

medical education; entrustable professional activities; EPAs; digital EPAs; technology acceptance model

Introduction

Background

The concept of entrustable professional activities (EPAs) has changed the approach to medical education, shifting the focus toward competency-based learning. They cover core functions like educational theory, curriculum design, and assessment while also addressing emerging areas such as self-development and technology use in health care education [1]. EPAs are designed to break down complex medical skills into manageable units, allowing learners to gain proficiency in specific tasks progressively [1]. This methodology has been instrumental in ensuring that medical trainees are adequately prepared for the responsibilities they will face in their professional lives while empowering teaching staff to maximize the learning outcomes of their students [2].

Complementing EPAs, the use of simulations in medical training has become increasingly important. These simulations provide realistic, interactive environments where students can practice and hone their skills without the risks associated with real-life clinical settings. As highlighted by Chernikova et al [3] and Smetana and Bell [4], computer-based simulations, in particular, offer dynamic representations of real-world medical scenarios. These tools are invaluable for developing both the cognitive decision-making and motor skills essential in the medical field.

However, despite the advancements in and the separate explorations of EPAs and simulations, the combination of these two into a digital format, more specifically digital EPAs, remains largely unexplored. While both EPAs and simulations have been part of extensive research efforts individually, their integration into a digital EPA format offers a new development for these two teaching methods [1,3,4]. Yet digital EPAs and their acceptance among learners and educators remains largely unexamined [5].

In understanding the adoption and effectiveness of these educational technologies, the technology acceptance model (TAM) offers valuable insights. Introduced by Davies [6] and further explored by Marangunić and Granić [5], the TAM posits that perceived ease of use and usefulness are critical factors influencing the acceptance and integration of new technologies in learning environments. This model has been widely applied in various contexts to understand how users come to accept and use technological tools in their work.

The aim of this study is therefore to identify how well students perceive the usefulness of digital EPAs as well as their ease of use. In addition, we will investigate whether this perception influences students' intention of using digital EPAs in their studies.

EPAs in Medical Education

EPAs, as a didactic concept, focus on competency-based curricula to help students acquire specific competencies, potentially contributing to a more flexible duration of training [1]. They are characterized by a gradual reduction of supervision until learners can perform tasks completely independently [7]. This development occurs over five stages, starting with mere presence and observation to the independent guidance of younger learners [1,8]. EPAs represent specific professional activities distinguishing them from conventional learning objectives [2]. A competency-oriented teaching method could reduce the training duration for faster-learning medical students without compromising the quality of education [9]. Such a system could benefit not only medical students but also the teaching staff, program developers, and medical institutions, as well as other employees, by clearly defining which tasks can be performed with what degree of autonomy [1,2,10].

Digital EPAs

Simulations, as interactive representations of real-world scenarios, play a crucial role in the acquisition of complex skills. Simulation-based learning, as demonstrated by Chernikova et al [3] in their 2020 meta-analysis, is a highly effective approach to designing learning environments in higher education and can be beneficial from the beginning of study programs for students at all levels. Simulations provide an effective medium for developing complex skills, such as those required in surgery, combining theoretical knowledge with practical expertise, such as seen in spinal surgery [11]. In combination with the concept of EPAs, as gradually increasing levels of clearly defined competencies, this suggests complementing real-life training with training in simulations. These simulations would need to precede real-life training by allowing students to practice the same competencies (digital EPAs). Systematic use of these digital EPAs could potentially substantially increase the quality of and reduce the time required for real-life training, which is often cost-intensive or requires rare and critical situations (eg, high-stakes operations).

However, such a shift in education would need to be accepted by all stakeholders (ie, medical educators, medical students, and patients).

The TAM

The TAM has significantly influenced the understanding of technology adoption and use [5]. This model's foundation was built on two critical factors: perceived usefulness and perceived ease of use [5]. These factors are pivotal in shaping users' attitudes and intentions toward adopting technology. Davies' [6] original model proposed that users' motivation to use a system is influenced by these two beliefs [5]. Perceived usefulness reflects the degree to which a person believes that using a specific system would enhance their job performance [12]. Perceived ease of use refers to the belief that using a particular system would be effortless [12]. The interaction between these two beliefs plays a critical role in determining the user's attitude toward the system and, consequently, their actual use behavior [6].

The significance of the TAM extends beyond traditional technologies and has proven to be indispensable, especially in designing user-friendly and effective technology-based learning systems. In a world where digital technologies are increasingly coming to the forefront, TAM remains a critical framework for researchers and practitioners to predict and understand user behavior toward new technological advancements.

This Study

In this cohort study, we will focus on medical students, investigating how well they perceive the usefulness of digital EPAs as well as their ease of use in medical education. In addition, we will investigate whether this perception influences students' intention of using digital EPAs in their studies. Since this teaching concept is largely unfamiliar to students, they are first presented with a written EPA, followed by a digital version, which the questionnaire will refer to. The example EPA, as well as the digital EPA, can be accessed via Open Science Framework (OSF) [13].

Methods

Recruitment Plans and Study Population

The study population for this cohort study will consist of medical students in the clinical phase of their studies. This cohort is optimally suited for the application of digital EPAs,

as these are aimed at learning specific skills, which is the core of the clinical phase of medical studies. The plan is to distribute the survey link through the major study distribution lists of Ludwig Maximilians University Munich, such as the Module-6 distributor. This would ensure that only students in the clinical phase participate in the survey. In addition, students would have the flexibility to complete the questionnaire at their convenience.

Inclusion Criteria

Medical students must be at least in their third year of medical training. This ensures that the preclinical foundational subjects, such as macroscopic and microscopic anatomy, physiology, biochemistry, and medical psychology, have already been completed. In addition, they must have passed their first medical state examination.

Exclusion Criteria

Reasonable command of the German language is required to participate in this study.

Data Analysis Plans

A regression analysis will be performed assuming a moderate effect size. Furthermore, an α level, common in social sciences, of .05 was chosen. The statistical power of the study was set standardly at P=.80. To calculate the necessary sample size for these specific parameters, the software G*Power 3.1 [14] was used. This calculation indicated that a sample size of 68 participants is required to meet the above criteria. To provide additional security and account for possible dropouts, a margin of 10% will be added to the calculated sample size. This means that a total of 75 participants should be recruited for the study. Assuming a response rate of approximately 25% (based on previous experiences), we will contact 300 students (about 25% of all viable students at Ludwig Maximilians University Munich) via email.

Questionnaire and Hypotheses

Overview

The basis for the conception of the questionnaire is the research work by Abdul Ghani et al [15], which used the TAM as a foundation for evaluating digital game-based learning. The questionnaire was only adapted to the context of digital EPAs. The entire questionnaire can be found on OSF [13]. Both the German translation shown to the participants and an English version of the questionnaire can be found there. The hypotheses below were formulated based on the TAM and are to be explored through the questionnaire.

Construct: Perceived Usefulness

Operational Definition

Perceived usefulness [6] reflects students' perception of whether the use of digital EPAs in a simulated environment will enhance their performance (independent variable).

Hypothesis

The more useful medical students find digital EPAs in medical simulations, the higher their behavioral intention to use this technology as part of their studies will be.

Construct: Perceived Ease of Use

Operational Definition

Perceived ease of use [6] refers to a student's perception that using digital EPAs for learning skills during their medical studies will require minimal effort (independent variable).

Hypothesis

The easier medical students find the operation of digital EPAs in medical simulations to be, the greater their behavioral intention to use this technology will be.

Construct: Attitude

Operational Definition

Attitude [6] refers to student's judgment on whether the use of digital EPAs is beneficial to them (independent variable).

Hypothesis

The more positive the attitude of medical students toward digital EPAs in medical simulations is, the higher their behavioral intention to use this technology will be.

Construct: Behavioral Intention (Operational Definition)

Behavioral intention [6] refers to a student's intention to theoretically use digital EPAs for their studies during the clinical phase of medical school if they were to be offered.

Due to the construct of the TAM, "Behavioral Intention" is highly influenced by "Perceived Usefulness" and "Perceived Ease of Use," making it the dependent variable.

Digital EPAs

Due to the unfamiliar teaching concept of EPAs for students, as well as the digital EPAs, a formulated EPA and its digital counterpart were created based on a paper by Ten Cate and Taylor [1]. The digital EPA merely represents a theoretical implementation of the previously formulated EPA for students in the future. It cannot yet be tested digitally in this form and can, therefore, only be presented to students conceptually in the form of continuous text. The complete description of the EPA and the digital EPA can be found on OSF [13]. Additionally, there is both a German and an English version for the same reasons as with the above questionnaire.

Ethical Considerations

Ethics approval by the host university is pending. The study will only be conducted once it is granted.

Results

The data collection of this study is expected to be completed by the end of April 2025. Following this, data analysis is to take place, which is to be completed by May 2025, following the reporting standards of the *Journal of Medical Internet Research* for statistics.

All data, in anonymized form, and the code for analysis will be uploaded to the project's OSF repository.

Discussion

This study hypothesized that the higher students' PU and PEU are, the higher their behavioral intention to use will be and that this relationship would lead to higher actual system use [6].

The basis for our study is, on the one hand, the increasing emergence of EPAs in medical curricula as well as in specialist training and continuing education and, on the other hand, the widespread use of digital simulations [1,3,4]. The merging of both concepts remains relatively unexplored and can only be considered a successful development of traditional EPAs if this concept is also accepted by the learners themselves. Using the tried and tested TAM model, a meaningful evaluation of this situation will be made [5]. Since digital EPAs can increasingly contribute to medical training improvement, our findings are to be considered as a starting point for the design and implementation of these didactic tools so that more effective implementation and more engaged use among learners can be promoted in the future.

Nevertheless, our study must be viewed in light of some limitations. The sample size and the methodology of recruitment could limit the generalizability of the results. Future studies should involve larger and more diverse groups of medical students to gain a more comprehensive understanding of acceptance factors. In addition, investigating the long-term effects of digital EPAs on learning outcomes could provide valuable insights.

In summary, this study should serve as a starting point for more extensive research projects so that factors influencing the acceptance of digital teaching technologies in medicine, particularly digital EPAs, can be comprehensively investigated. By emphasizing the importance of usefulness and ease of use for the acceptance and use of digital EPAs, our study opens new perspectives for the design of effective and engaging medical training programs that meet both the needs of the students and the requirements of a constantly changing medical training landscape.

Acknowledgments

MD has received funding during the research for this paper from the "Promotionsstipendium" of the medical faculty of the Ludwig Maximilians University Munich.

Data Availability

All data will be made available in anonymized form on the Open Science Framework repository after completion of the study.

Authors' Contributions

MD was responsible for the visualizations and writing of the initial draft, including substantive translation. CR and MS extensively contributed to the writing process by reviewing and editing the initial draft. Further, MS had the role of supervisor for the project as well as project administration. All authors read and approved the final manuscript.

In preparing this manuscript, a generative artificial intelligence (AI) tool (ChatGPT-4o, version February 2024, OpenAI) was used solely for language enhancement and stylistic refinement. No content generation, data analysis, or research-related functions were performed by AI. The authors retain full responsibility for the originality, accuracy, and integrity of the scientific content presented in this paper. All intellectual contributions and findings are the result of the authors' independent work.

Related Article:

Correction of: https://www.researchprotocols.org/2025/1/e58531

(JMIR Res Protoc 2025;14:e72512) doi:10.2196/72512

The paper "Methodology for the Positive Voices 2022 Survey of People With HIV Accessing Care in England, Wales, and Scotland: Cross-Sectional Questionnaire Study" published in JMIR Res Protoc 2025;14:e58531) had a few errors. Hence, the following edits have been made (changes italicized).

In the **Abstract,** the following subsections had a few sentences modified, as follows:

- Objectives: "This paper aimed to describe the methodology, recruitment strategies, and *key demographic* features of participants…"
- Methods: "…At the start of 2023, due to under-recruitment mainly due to the impact of the monkeypox (Mpox) outbreak, a separate sequential recruitment strategy was initiated in *14 of the largest clinics* to increase participant numbers."
- Results: "…The median age of participants was 52 years, 3428 of participants were men, 2991 were *White*, and 1121 were *Black*."

In the **Introduction** section, the following paragraphs have been revised, as follows:

- "High levels of perceived and internalized stigma associated with *HIV status are experienced* by people with HIV, impacting their mental health…
- PV is a cross-sectional *questionnaire study of people with HIV who receive HIV specialist care in England, Wales, and Scotland, which is carried out every 3-5 years.*…
- Our paper aims to describe the methodology and study design of the second round of the *study: Positive Voices 2022 (PV2022).*"

In **Methods** section, the first column of ***Table 1*** has been edited to improve readability and clarity.

The following incorrect values were updated in ***Table 2***:

- The number of Positive Voices 2022 participants was changed from *4620* to *4622*.
- "Age group (years)" category: The percentage of participants in the 55-64 subcategory was changed from *30.2* to *30.3*.

- "Gender" category: The number and percentage of participants in the "Prefer not to say *and unknown*" subcategory was changed from *34 (0.7)* to *36 (0.8)*.
- "Ethnic group" category: The number and percentage of participants in the "Other (including prefer not to say and unknown)" subcategory was changed from *176 (3.8)* to *178 (3.9)*.
- "Year of diagnosis" category: The number of participants in the "2019-2023" subcategory was changed from *213* to *214*.
- "Year of diagnosis" category: The number of participants in the "2014-2018" subcategory was changed from *800* to *801*.
- Footnote "a" was assigned to the "Age group (years)" category and was updated from *Missing sociodemographic information for 2 participants* to *Age was missing for 2 participants.*

A few abbreviations have been introduced for better readability. These have also been added to the abbreviations list at the end of the article.

A few additional changes have been listed below:

- Under Study Design:
  "The questionnaire data were linked to clinical data on antiretroviral therapy (ART), HIV viral load, and CD4 *lymphocyte* count from the HIV and AIDS reporting system (HARS)…"
- Under Setting:
  "178 HIV clinics in the country, returned an expression of interest, *98* % of whom were in England (99/101)…"
- Under Sample Size:
  "HARS was used as a sampling frame to *provide a representative*, random sample of people with *HIV within each participating clinic, who* could be approached to participate in the PV2022 survey. HARS is a surveillance database held at the UKHSA that consists of pseudonymized data on the demographic, clinical, and *treatment characteristics* of people with HIV that is reported each quarter year by all HIV service providers in England…
  …Therefore, considering this, a sample list of 17,121 patients was created *with the assumption* that approximately 14,400 would be recruitable. …the PV2022 response rate was expected to be between 30% and 50%, resulting in 4320 *to* 7200 participants being recruited. … ±1.4% and ±1.1% *(with 95% confidence)* for the response rates of 30% and 50%, respectively."
- Under Study Management:
  "PV2022 was a collaboration between the University College London (UCL) NICHE *team, the UKHSA HIV national surveillance team, and a NICHE Patient and Public Involvement representative. "A Person-Centered Needs Informed Model of Care for People with HIV" (NICHE)* is a National Institute for Health Research (NIHR) funded program..."
- Under Questionnaire Development:
  "…These included demographic and socioeconomic factors, HIV related factors, comorbidities, met and unmet health, social and welfare *service* needs, quality of life measured by EQ-5D-5L, *height and weight*, smoking and alcohol status *by the Alcohol Use Disorders Identification Test-Consumption (AUDIT-C)*, recreational drug use and general practice (GP), and HIV clinic satisfaction, enabling assessment of trends over time in these factors…
  …New items included in the PV2022 questionnaire included… a modified version of the *Duke-UNC (University of North Carolina)* Functional Social Support Questionnaire…
  Questions on stigma and discrimination were expanded to take account of internalized *and other* stigma and included an adapted validated stigma scale [27]. In addition, participants *who* completed the study online in PV2022 were able to opt-in to complete "Positive Outcomes," an HIV Patient Reported Outcome Measure (PO-PROM), a tool designed for use in clinical settings to assess *the needs and concerns of* people with HIV…"
- Under Study Documents:
  "...a password-protected study log that listed each clinic's sample list of *randomly selected* participants. ... and unique identifier displayed on the outside, as well as the patient information leaflet, *questionnaire*, a freepost..."
- Under Linkage:
  "Data on ART *use*, the most recent CD4 lymphocyte count,..."
- Under Ethical Considerations:
  "All participants received a digital gift voucher for 5 GBP (*equivalent to* US $6.50)..."

In the **Results** section, the following sentences have been edited:

- Under Response Rate:
  "...the original preselected participant recruitment strategy (*49*%, Figure 1). Of the 930 sequentially recruited participants, 906 were able to be matched to HARS: 222 (*25*%) of these had initially been preselected to take part in the survey.
  Men had a higher response rate (60%) (3428 completed out of 5715 accepted or declined) compared with women (1124/2580, 44%) and *White people* had a higher response rate (2991/4724, 63%) compared with *Black African people* (983/2380, 41%) *or those of* other ethnicities (648/1158, 56%)."
- Under Age, Gender, *and Ethnic* Distribution of PV2022 Participants:
  "The median age of PV2022 participants (n=4620) was *52 (IQR 43-60) years, and about* 3 quarters of participants had been diagnosed with HIV more than 10 years ago (Table 2). Nearly a quarter of participants were women (24%) and over a fifth (21%) of participants were *Black African people* (Table 2).
  A total of *67* PV2022 participants identified as transgender or gender diverse...
  Compared with the national population of people accessing HIV care, *Black African individuals were underrepresented in the PV2022 sample (10% lower)*, and *White* participants were overrepresented (13% higher; Figure 2)...

Participants from the sequential recruitment route were younger compared to the preselected random recruitment strategy (median age 49 (IQR 39-57) years versus 53 (IQR 45-60) years, for sequential versus random recruitment respectively), overrepresented men (85% vs 72%) and White people (67% vs 64%) and underrepresented Black African people (14% vs 23%).

A higher proportion of *participants who completed the online questionnaire were White compared to participants who completed the paper questionnaire (67% online vs 63% paper*; Figure 1 and Multimedia Appendix 2)."

In the **Discussion** section, the following edits were made:

- Under Principal Findings:
  "…The pandemic exacerbated inequalities in health and access to health care, particularly amongst those living in economic hardship [38] and for *Black African individuals and those of other* minority ethnic groups [39], and the HIV population consists of a high proportion of these groups.

  Strengths of PV2022 include the large sample size, the inclusion of a broadly representative sample of 1 in 20 people with HIV in *England, Scotland and Wales* (as evidenced by comparison with the national HARS database) and the linkage of participant self-reported questionnaire data to HIV clinical data from HARS.

  ..., whose mental and physical health, and experiences of *health* care, may be different and valuable for informing and improving HIV specialist services.

  Findings from PV2022 informed the development of the intervention for the "Psycho-Social Intervention for People With HIV–Evidence From a Randomised Evaluation" *(SPHERE)* trial, which commenced in United Kingdom HIV clinics in August 2024."

The correction will appear in the online version of the paper on the JMIR Publications website on February 27, 2025, together with the publication of this correction notice. Because this was made after submission to PubMed, PubMed Central, and other full-text repositories, the corrected article has also been resubmitted to those repositories.

Submitted 11.02.25; this is a non–peer-reviewed article;accepted 11.02.25; published 27.02.25.

Abstract

Background: In the intensive care unit (ICU), many patients are unable to communicate their pain through self-reporting or behaviors due to their critical care condition, mechanical ventilation, and medication (eg, heavily sedated or chemically paralyzed). Therefore, alternative pain assessment methods are urgently needed for this vulnerable patient population. The Nociception Level (NOL) index is a multiparameter technology initially developed for the monitoring of nociception and related pain in anesthetized patients, and its use in the ICU is new.

Objective: This study aims to validate the NOL for the assessment of nociception and related pain in critically ill adults in the ICU. Specific objectives are to examine the ability of the NOL to: (1) detect pain using standard criteria (ie, self-report and behavioral measures), (2) discriminate between nociceptive and nonnociceptive procedures, and (3) generate consistent values when patients are at rest.

Methods: The NOL will be monitored in three ICU patient groups: (1) Group A, participants able to self-report their pain (the reference standard criterion using the 0-10 Faces Pain Thermometer) and express behaviors; (2) Group B, participants unable to self-report but able to express behaviors (the alternative standard criterion using the Critical-Care Pain Observation Tool); and (3) Group C, participants unable to self-report and express behaviors. The NOL will be tested before, during, and after two types of standard care procedures: (1) nonnociceptive (eg, cuff inflation to measure blood pressure, soft touch) and (2) nociceptive (eg, tube or drain removal, endotracheal or tracheal suctioning). Receiver operating characteristic curve analysis of the NOL will be performed for Groups A and B using pain standard measures as reference criteria. Mixed linear models for repeated measures

will be used to compare time points, procedures, and their interaction in each group (A, B, and C). Based on power analyses and considering an attrition rate of 25%, a total sample size of 146 patients (68 in Group A, 62 in Group B, and 16 in Group C) is targeted.

Results: This study was funded in April 2020 but could not be launched until 2022 due to the COVID-19 pandemic. Recruitment and data collection began at the primary site in July 2022 and has been implemented at the secondary sites in 2023 and 2024 and is planned to continue until 2026.

Conclusions: The primary strength of this study protocol is that it is based on rigorous validation strategies with the use of pain standard criteria (ie, self-report and behavioral measures). If found to be valid, the NOL could be used as an alternative physiologic measure of pain in critically ill adults for whom no other pain assessment methods are available.

Introduction

Background

Patients in the intensive care unit (ICU) are exposed to many noxious stimuli as part of standard care, which may involve nociception and pain. Although nociception and pain are interrelated, they are distinct concepts. Nociception involves the neural processes of encoding noxious stimuli that lead to autonomic (eg, increased vital signs) and behavioral responses, which may or may not imply the sensation of pain [1,2]. Pain is a personal and multidimensional phenomenon influenced by biological, psychological, and social factors [1-3]. Appropriate detection of nociception and pain is key to providing adequate analgesia during critical illness in order to reduce the risk of adverse outcomes such as prolonged mechanical ventilation, longer ICU stay, and chronic pain development [4,5].

Many ICU patients experience pain at rest, and this pain is significantly increased during nociceptive procedures as part of standard care (eg, drain or tube removal, endotracheal suctioning, line insertion, wound care, and turning) [6-9]. Behavioral responses such as grimacing and muscle rigidity are commonly observed in ICU patients during standard care procedures and have been associated with their self-reported pain [10]. While the patient's self-report (the reference standard) is the preferred method of pain assessment, it is unsuitable for patients unable to rate their pain due to a combination of several factors affecting their capacity to communicate, such as mechanical ventilation (>33% of Canadian ICU patients) [11], sedation, or an altered level of consciousness. In such situations, behavioral assessment tools such as the Behavioral Pain Scale (BPS) [12] and the Critical-Care Pain Observation Tool (CPOT) [13] are alternative standard measures of pain in patients unable to self-report with minimal motor function to exhibit behavioral responses [14]. However, these behavioral assessment tools cannot be used in heavily sedated patients or those receiving neuromuscular blocking agents as they become unresponsive to stimulation [15].

Alternative methods for pain assessment are necessary when none of the pain standard criteria (ie, self-report or behavioral measures) can be used. Although individual vital signs (eg, heart rate, blood pressure) are easily accessible through continuous bedside monitoring, they are not valid for ICU pain assessment due to inconsistent findings across studies and clinically insignificant variation in their values (<20%) [14,16]. However, research in the field of pain and anesthesia has shown that the combination of physiologic parameters is superior to their individual values [17]. Inspired by initial data from healthy subjects exposed to tonic heat stimuli inducing different pain levels [18], the Nociception Level (NOL) index (Medasense Biometrics Ltd) is a multiparameter technology, which was further developed for nociception monitoring and related pain in anesthetized patients [19-21]. In our recent review [22] of 6 studies in anesthetized patients, the NOL index outperformed single physiologic parameters for the detection of nociception during standard care procedures and experimental stimuli [17,20,23-25].

Although the validity of the NOL is supported in anesthesia, its use in the ICU is new. To our knowledge, we are the first research team to have pilot-tested the use of the NOL for nociception and pain assessment in the ICU. We conducted 2 pilot studies in 15 mechanically ventilated [26] and 54 cardiac surgery ICU patients [27] able to self-report their pain. In both studies, discriminative validation of the NOL was supported with higher index values during nociceptive procedures (ie, chest tube removal, endotracheal suctioning) compared with rest and a nonnociceptive procedure (ie, noninvasive blood pressure [NIBP] using cuff inflation). The NOL values were positively associated with self-reported pain and CPOT scores during nociceptive procedures, providing initial evidence of criterion validation with pain standard criteria [26,27]. Also, a NOL cutoff >25 was found to adequately classify patients with moderate to severe self-reported pain intensity (>4/10) [27]. However, these pilot validation studies of the NOL were limited to 2 nociceptive procedures as part of standard care and were solely conducted in ICU patients who were able to self-report. Further validation of the NOL during various standard care procedures in critically ill adults with different levels of consciousness or sedation and in response to analgesic treatment is necessary to confirm its validity for the assessment of nociception and related pain in the ICU.

Study Rationale, Goal, Objectives, and Research Hypotheses

An instrument can only be shown as valid for a specific purpose in a given population and context [28]. The NOL index was initially developed and validated for nociception monitoring and related pain in anesthetized patients [17,19-25]. Therefore, validating its use for nociception (primary purpose) and pain assessment (related purpose) in critically ill adults admitted to the ICU (different population and context of care) is necessary. Inspired by our pilot work, strategies for this larger validation study include: (1) criterion validation (ie, NOL's ability to detect pain according to pain standard criteria) and (2) discriminative validation (ie, NOL's ability to discriminate between nonnociceptive and nociceptive procedures) [28]. Considering that reliability is a necessary condition for validity [28], test-retest reliability of the NOL's ability to generate consistent values in similar conditions (eg, at rest) will also be examined.

Research Question: Is the NOL a valid method for the assessment of nociception and pain in critically ill adults in the ICU context?

In order to answer this research question, specific validation objectives are to examine the NOL's ability to:

1. Detect pain in ICU patients able or not to self-report using appropriate pain standard criteria (ie, criterion validation);
2. Discriminate between nonnociceptive and nociceptive procedures part of standard care as well as before and after the administration of a breakthrough opioid dose (ie, discriminative validation);
3. Generate consistent values in similar conditions (ie, pre- and post-nonnociceptive and nociceptive procedures) when ICU patients are at rest.

Our research hypotheses to be tested include:

H1. The NOL index adequately classifies ICU patients with pain based on either their self-reported pain intensity or CPOT scores.

H2. The NOL index produces higher values during nociceptive procedures compared to nonnociceptive procedures and lower values post- versus preopioid administration.

H3. The NOL index generates consistent values pre- and post-nonnociceptive and nociceptive procedures when ICU patients are at rest.

Methods

Study Design

A prospective observational design was selected as it is appropriate for validation purposes using ICU standard care procedures in critically ill adults. The Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) Statement: Guidelines for Reporting Observational Studies is used for the description and reporting of the study [29].

Settings

This study is conducted in the ICUs of 3 tertiary-level university-affiliated health centers in Montréal, Québec, Canada. These ICUs have a total capacity ranging from 16-59 beds, and each ICU admits, on average, 1000-2750 patients annually.

Participants

A consecutive sampling method is used to approach all eligible patients or their representatives during the study period. This sampling method aims to capture a representative sample of ICU patients able or not to self-report. Eligible ICU patients (Textbox 1) are assigned to one of the following groups:

1. Group A can communicate their self-report of pain and can exhibit behaviors (conscious and alert with Glasgow Coma Scale [GCS] [30] score of 13 to 15 or Richmond Agitation Sedation Scale [RASS] [31] score of 0);
2. Group B cannot communicate their self-report but can exhibit behaviors (altered level of consciousness with GCS score of 6 to 12 with a score ≥4 on the motor subscale or RASS score of –1 to –3); and
3. Group C cannot communicate their self-report or exhibit behaviors (unconscious with GCS score of 3 to 5 with a score ≤3 on the motor subscale or RASS score –4 or –5 or receiving neuromuscular blocking agents).

Exclusion criteria were selected to control for potentially confounding variables that may affect the NOL signal or pain standard measures. Patients assigned to Group A who screen positive for delirium are excluded as this condition is likely to affect the reliability of their self-report of pain [32]. Patients with conditions that may seriously influence perfusion of the hands, heart rate, heart rate variability, blood pressure, repetitive or high movements due to agitation or behavioral responses (eg, agitation, cognitive, or psychiatric conditions) are also excluded, thereby strengthening the internal validity of the study. Finally, patients with *Clostridium difficile* must be excluded because the required disinfection product (ie, sodium hypochlorite 5000-6000 ppm) could damage the NOL device, according to the manufacturer.

Textbox 1. Eligibility criteria of intensive care unit (ICU) patients.

Inclusion criteria:

- Admitted to the ICU >24 hours
- Aged >18 years
- English or French speaking

Exclusion criteria:

- Delirium (Group A only)
- Lack an available finger
- Severe peripheral vascular disease affecting the upper limbs
- Uncontrolled cardiac arrhythmia (eg, atrial fibrillation)
- Pacemaker with paced rhythm
- Severe edema in upper limbs
- Hypoperfusion state or shock and receiving norepinephrine (>14 mcg/min) or equivalent vasopressors to maintain a systolic blood pressure >90 mmHg or a mean arterial pressure >65 mmHg
- Agitated (Richmond Agitation Sedation Scale +1 to +4)
- Psychosis
- Cognitive deficits (eg, Alzheimer)
- Positive for Clostridium difficile
- Pregnancy

Recruitment and Consent Procedures

ICU patients are screened for eligibility by the research staff in collaboration with the medical and nursing team. Potentially eligible ICU patients able to self-report and consent, if they agree to participate, are assigned to Group A. Other potentially eligible ICU patients unable to self-report and consent are assigned to either Group B or C. According to Article 21 of the Quebec Civil Code for minimal risk studies, a significant person qualified to consent to care required by the state of health of the person of full age is asked to provide consent on their behalf for the research study.

Group A: Potentially eligible ICU patients able to self-report are approached for participation by their responsible nurse or physician. If interested, the research staff provides information about the study to the patient and obtain written informed consent.

Group B and Group C: For potentially eligible ICU patients unable to self-report, the person qualified to consent on their behalf is approached by their responsible nurse or physician. If interested, the research staff provides information about the study to the significant person and obtain written informed consent. If a patient participant who was previously unable to consent regains the ability to consent at any time, the research staff provides them with the informed consent form, allowing them to decide on their continued participation in the study. If a patient participant decides to withdraw from the study and requests their research data be removed, all collected information will be deleted.

Study Procedures

Before starting data collection, the group assignment of the participant is confirmed by the research staff. Then, the research staff sets up the NOL device at the bedside, places the finger probe on the participant's finger, and proceeds with calibration (requires less than 5 minutes). The screen of the NOL device is faced away from the patient and family members present in the room to reduce potential bias. Research staff also installs a video camera on a tripod at the foot of the bed to capture the face and the upper body in order to allow for interrater reliability examination of CPOT scores with another trained research staff not present at the bedside.

Participants are assessed at rest before, during, and 15 minutes after nonnociceptive and nociceptive procedures that are part of ICU routine care. Whenever possible, 15 minutes postprocedure are respected to allow for the resolution of the release, reaction, and elimination of stress hormones (ie, epinephrine and norepinephrine) and stress-activated responses that may be present following noxious stimulation [33]. The nonnociceptive procedures are ideally performed prior to nociceptive procedures and include soft touch (ie, research staff touching the patient's arm for 1 minute) and cuff inflation for blood pressure measurement (NIBP), which were empirically shown to be painless in previous studies [34], including our pilot NOL studies [26,27]. In the sequence of nonnociceptive procedures, soft touch is performed first and cuff inflation last. Then, the goal is to observe up to two nociceptive procedures per participant (Textbox 2). Nociceptive procedures are selected according to the standard care required by the patient's condition. These procedures do not involve mobilizing the patient out of bed, as important movements may introduce

artifacts in the NOL data. When possible and as required by the patient's condition, participants are also assessed before and 15 minutes postadministration of a breakthrough dose of an opioid such as fentanyl, morphine, or hydromorphone through a parenteral route (mainly through intravenous or subcutaneous routes) to capture onset or peak of action. The decision to administer an opioid is made as per local practice and based on an assessment performed by the ICU nurse or physician. Within a window of 48 hours after obtaining informed consent, a total of 10 to 12 time points of data collection is completed with each participant during their ICU stay (Table 1).

The NOL index is continuously monitored during the data collection time period, and values are extracted in a standardized manner as done in previous clinical studies for NOL data analysis purposes [24-27]. CPOT assessments (one-minute observation or duration of the procedure) are performed on participants from Groups A and B by research staff, and then conscious patients able to self-report (Group A) are asked to provide their self-report of pain intensity at each time point. Video recording is stopped before participants provide their self-report to avoid possible bias by the research staff, who will view the videos for CPOT scoring at a later time. Finally, demographic and clinical information is extracted from the participants' medical files. At the end of data collection, the study equipment (ie, video camera, tripod, NOL device, and keyboard) is disinfected according to the prevention control infection procedures of each institution before being used for another patient.

Textbox 2. List of nociceptive and nonnociceptive standard care procedures in the intensive care unit.

Nociceptive procedures

- Chest tube removal
- Drain removal
- Mouth, endotracheal, or tracheal suctioning
- Arterial line insertion
- Peripheral intravenous line insertion
- Subcutaneous injection
- Wound care
- Bed turning or repositioning

Nonnociceptive procedures

- Soft touch of the patient's arm
- Noninvasive blood pressure cuff inflation (NIBP)

Table 1. Assessment time points and pain variables to be measured in each group (A, B, and C).

Measure	Nonnociceptive procedures				Nociceptive procedure 1			Nociceptive procedure 2			Analgesic[a]	
	Pre	Soft touch	Cuff inflation	Post	Pre	During	Post	Pre	During	Post	Pre	Post
NOL[b]	A[c], B[d], C[e]	A, B, C	A, B, C	A, B, C	A, B, C	A, B, C	A, B, C	A, B, C	A, B, C	A, B, C	A, B, C	A, B, C
Behaviors	A, B	A, B	A, B	A, B, C	A, B	A, B	A, B	A, B	A, B	A, B	A, B	A, B
Pain level	A	A	A	A	A	A	A	A	A	A	A	A

[a]Administration of an analgesic as required by the patient's condition.

[b]NOL: Nociception Level Index.

[c]Group A: Patients are able to communicate their self-report of pain and can exhibit behaviors.

[d]Group B: Patients are unable to communicate their self-report of pain but can exhibit behaviors.

[e]Group C: Patients who cannot communicate their self-report of pain or exhibit behaviors.

Variables and Measurement Tools

Primary Measure: The Nociception Level (NOL) Index–All Groups (A, B, and C)

The Pain Monitoring Device-200 (PMD-200; Medasense Biometrics Ltd; Figure 1) is used in this study. PMD-200 offers the multiparametric NOL index (0-100) and was approved by Health Canada for clinical use in September 2017. The NOL captures several physiological parameters simultaneously through a finger probe and disposable sensor, which includes 4 small sensors, sampled 50-500 Hz: (1) accelerometer, (2) photoplethysmograph, (3) galvanic skin response, and (4) peripheral temperature. From these 4 sensors, the following physiological parameters are extracted: heart rate, heart rate

variability, photoplethysmography pulse wave amplitude, skin conductance level, number of skin conductance fluctuations, skin temperature, and their time derivatives. All these parameters are integrated and analyzed simultaneously using a Random Forest machine learning model approach to provide the NOL index, which can range from 0 to 100 [17]. A NOL cutoff value >25 for the detection of self-reported pain was found in our pilot study with ICU cardiac surgery patients [27].

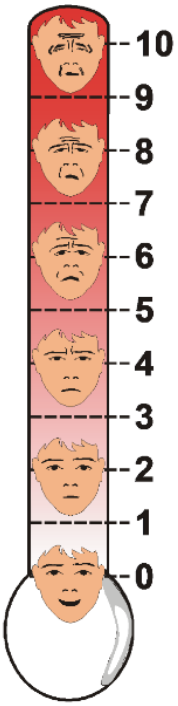
Figure 1. Nociception Level (NOL) index.

The PMD-200 device allows the documentation of each event (ie, beginning and end time of rest and procedure assessment) or any contextual information (eg, interruption during a procedure), which is facilitated with the use of a wireless keypad. All NOL data are electronically collected every 5 seconds by the PMD-200 monitor.

Reference Standard Measure of Pain–Group A

The Faces Pain Thermometer (FPT) was selected to measure pain intensity as it can accommodate adult patients of various ages. It consists of an enlarged visual thermometer including 6 faces with a numeric rating scale scoring from 0="no pain" to 10="worst possible pain" (Figure 2). The validity and reliability (test-retest) of the tool were established in ICU patients [35]. The FPT was used in many previous validation studies led by the primary investigator [13,34,36] and pilot NOL studies [26,27].

Figure 2. The 0-10 Faces Pain Thermometer (FPT)[35].



Alternative Reference Standard Measure of Pain–Groups A and B

The Critical-Care Pain Observation Tool (CPOT) [13] was selected for behavioral pain assessment in critically ill adults. The CPOT was used in our NOL pilot studies [26,27], and it is 1 of the 2 behavioral scales suggested as alternative reference standard measures of pain by the Society of Critical Care Medicine [14] and has been implemented in clinical practice in the 3 study ICUs. The CPOT includes 4 behavioral items: (1) facial expressions, (2) body movements, (3) muscle tension, and (4) compliance with the ventilator (for mechanically ventilated patients) or vocalization (for nonintubated patients). Each item is scored from 0-2, and the total score can range from 0-8. The CPOT has been validated in 47 studies with more than 3900 ICU patients with surgical, trauma, and medical diagnoses from various countries [34]. Consistent findings of good interrater reliability (interclass correlation coefficient [ICC] >0.60 between research staff and ICU nurses) and ability to discriminate between various nociceptive and nonnociceptive procedures were found across studies. Criterion validation of the CPOT was also supported by positive correlations (r>0.40) with ICU patients' self-reported pain intensity [34]. A CPOT score >2 was found to adequately identify patients with self-reported pain (AUC>0.80) [34,36].

The research staff of all sites have been trained to use the CPOT using a standardized training session previously described [37]. Briefly, this 60-minute training session covers the description of the CPOT content and its scoring process. Patient videos are viewed to practice scoring with the tool with the goal of reaching consistent CPOT scores between raters within a total score difference of no more than 1 point.

Demographic and Clinical Information for ICU Patient Participants

Demographic information (eg, age, sex, gender, and ethnicity) is collected from the patient or their representative. Information related to the patient's clinical condition (ie, ICU admission diagnosis, mechanical ventilation, the severity of illness [Acute Physiology and Chronic Health Evaluation; APACHE II] [38], level of consciousness [GCS] [30], sedation level [RASS] [31], delirium screening with the Confusion Assessment Method-ICU [39] or Intensive Care Delirium Screening Checklist [40], according to the respective tool used at each site), as well as medication information (ie, morphine equivalent doses [41] received within 4 hours before and during the entire data collection, sedative agents, vasopressors, and use of opioids before ICU admission) is extracted from the medical records by the research staff. The following clinical information is collected at the time of obtaining consent and performing data collection: mechanical ventilation status, GCS score, RASS score, and delirium screening.

Sample Size Calculation

The primary objective is to validate the NOL using pain standard criteria (ie, self-report and CPOT scores). Therefore, ROC is considered our primary analysis and guides the sample size calculation for Group A and Group B. Power calculations were based on our pilot findings [26,27] and results from previous ICU studies considering a clinically acceptable AUC of 0.75 [42] (using a null hypothesis of AUC=0.50) with a power of 80% and an adjusted α of .025 (2 ROC curves for each procedure in each group). For Group A in whom the self-report of pain is obtained and using a ratio of 2:1 in pain:no pain cases according to self-reported pain intensity scores of <4 and >4, a sample of 54 patients is required. For Group B in whom only the CPOT scores are available and using a ratio of 1.5:1 in pain:no pain cases according to CPOT scores of <2 (no pain) and >2 (pain), a sample of 50 patients is necessary. For Group C (unable to self-report and express behaviors), we will not be able to use any pain standard criterion. Therefore, our main objective is to test whether the NOL can discriminate between a nociceptive procedure and a nonnociceptive procedure. In order to detect a minimal mean increase of 10 in the NOL value during the nociceptive procedure (with a standard deviation of 10 as found in our pilot findings), a minimal sample size of 13 patients is required to run paired t tests with a power of 80% and an α of .01 (to account for multiple test comparisons). Considering an attrition rate of 25% (data collection was completed in 73% of consenting patients in our pilot work), recruitment targets include 68 patients in Group A, 62 patients in Group B, and 16 in Group C for a total of 146 ICU patients. Power calculations were performed by a statistician using Power and Precision 4 (Biostat Inc).

Data Analysis

SPSS software (version 29; IBM) and SAS (version 9.4; SAS Institute) will be used for data analysis. Descriptive statistics will be computed to characterize the study samples and outcomes. The NOL signal quality will be checked for all enrolled patients to ensure the accuracy of the data. As done in previous studies, NOL values will be averaged within 15 seconds before and after the peak value obtained after the start of each nonnociceptive procedure (7 NOL values total around the peak for soft touch and NIBP) and nociceptive procedure. In addition, NOL values will be averaged over a 1-minute period at rest before and after the procedure. CPOT scores will be obtained independently by 2 trained raters, one at the bedside and one who will view the patient videos at a later time. Intraclass correlation coefficients (ICC) will be calculated between the CPOT scores of both raters during procedures. ICC>0.80 will confirm excellent interrater reliability [28].

For objective 1 (criterion validation), the receiver operating characteristic (ROC) curve [43] will be performed to examine the ability of the NOL to adequately classify patients with pain. In patients able to self-report (Group A), an established pain intensity score >4 based on participants' self-reports as the reference standard criterion indicating moderate to severe pain will be used [10,44]. This criterion is also commonly used in practice to support clinical decisions in the administration of opioids. A ROC curve will be obtained for each nociceptive procedure (a total of 2 procedures per patient). In patients unable to self-report but in whom behaviors can be observed (Group B), we will use the determined CPOT score >2 as the alternative reference criterion, which is associated with the presence of moderate to severe pain [44]. Again, for Group B, a ROC curve will be obtained for each nociceptive procedure (total of 2 procedures per patient) [45]. As a supplementary analysis, we

will perform ROC curves for repeated-measures design in each group (A and B) and compare them [46]. In addition, considering that the CPOT will be available in Group A and Group B, ROC curves will be performed in each group separately to compare the AUC of independent curves for each of the 2 procedures [45]. The NOL cutoff value that will optimize both sensitivity and specificity will be determined.

Discriminative validation (objective 2) is our main objective to test in Group C, and paired *t* tests comparing the NOL values of each nociceptive procedure with the nonnociceptive procedure will be obtained. Generalized linear mixed model for repeated measures will allow us to compare the NOL index values across time points (pre, during, and post), procedures (nonnociceptive vs nociceptive), and their interaction in each group (A, B, and C). The generalized linear mixed model technique incorporates the full-information maximum likelihood procedure, which allows parameter estimation for missing data [47]. NOL values are expected to be significantly higher during nociceptive procedures in all 3 groups. Covariates (eg, sex, gender, morphine equivalent doses, opioid use before ICU admission) may be added if appropriate. Finally, NOL data obtained at pre- and postadministration of an opioid dose will be tested separately using paired *t* tests as not all patients will be candidates for these assessments.

For test-retest reliability (objective 3), paired *t* tests will be performed between pre and post-nonnociceptive and nociceptive procedures in all 3 groups. Nonsignificant paired *t* tests are expected to support the stability of NOL values when the patients are at rest.

Ethical Considerations

Ethical approval was submitted in February 2022 and approved by the Medical and Biomedical Research Ethics Committee of the primary site in June 2022 (project # MP-05-2022-2988). A first amendment of the research protocol (version 2) was approved in June 2023 regarding the addition of pacemaker as an exclusion criterion as it affects the generation of the NOL signal. A second amendment of the research protocol (version 3) was approved in September 2024 for the addition of a third study site and revision of the sample size. According to our pilot studies [26,27], participating in this study is not associated with any known risks; however, participants will be informed that if they find the finger probe uncomfortable, they can choose to switch fingers or hands or have it removed to stop data collection. Participation in this research project is completely voluntary. Participants or their representatives have the freedom to decline or withdraw from the study at any time without providing a reason, with no consequences. Opting not to participate or withdrawing will not affect the quality of care and services they are entitled to receive. Participants or their representatives can also choose not to answer specific questions or decline video recording if they prefer.

The confidentiality of collected data, video recordings, and contact information will be maintained. Electronic folders will be saved on the secure server of the institution and their access will be restricted to only the research team members with their own username and password. Mechanisms to ensure confidentiality will include the assignment of numeric codes and the removal of personal identifiers. The code key linking the participants to their research file will be kept in a file protected by a unique password, stored separately from the coded research data, and only accessed by the research team. Informed consent forms will also be stored separately from the coded research data. The REDCap (Research Electronic Data Capture; Vanderbilt University) [48] web application licensed by the primary site will be used to create the data collection forms and to facilitate data storage and management between the study sites.

For monitoring control, safety and security, the research files may be examined by a person mandated by Canadian or international regulatory authorities, such as Health Canada, as well as authorized representatives of the study sponsor (the institution) or the research ethics board. The data will be permanently destroyed after 15 years. All participants have the right to access their study files at any time to verify and correct the information if necessary. They are informed and consented to the fact that summarized deidentified data will be presented in scientific conferences and publications.

Results

This study was funded in April 2020 (see the funding report in Multimedia Appendix 1) but could not be launched until 2022 due to the COVID-19 pandemic. It was registered to ClinicalTrials.gov (NCT05339737) in April 2022. Recruitment and data collection began at the primary site in July 2022 and has been implemented at the secondary sites in 2023 and 2024. Recruitment and data collection will be ongoing until 2026.

Discussion

In alignment with our pilot findings [26,27], we anticipate that the NOL will be able to detect pain according to pain standard criteria and to discriminate between nociceptive and nonnociceptive procedures. The enrollment of critically ill adults with various clinical conditions and the capacity to communicate will allow us to better generalize our validation findings to the ICU population.

Methodological Strengths

The selection of rigorous validation strategies according to methodological guidelines in health measurement is the main strength of this study. With the participation of conscious ICU patients able to self-report, we can use the reference standard of pain, that is, self-reporting, for criterion validation. Furthermore, this validation strategy is reinforced by using the alternative reference standard, that is, the CPOT. Regarding discriminative validation, 2 strategies were selected, that is, discrimination between nonnociceptive and nociceptive procedures as well as before and after opioid administration. Test-retest reliability pre- and post-nonnociceptive and nociceptive procedures will allow us to examine the stability of the NOL values when patients are at rest. Both reliability and validation strategies are necessary to confirm the validity of an instrument [28].

In order to reduce potential bias related to pain scoring, Group A participants who are able to self-report will be blinded to the

NOL values screen during the procedures. CPOT scoring will be completed by research staff before obtaining the patient's self-report (ie, Group A participants) so raters are not influenced by self-reported pain intensity scores. Interrater reliability of CPOT scores will also be examined.

Our study lies in its foundation built upon the robust pilot work of the NOL conducted in the ICU setting. Our previous pilot studies have provided valuable insights and preliminary data to inform and support the research hypotheses and methodological decisions made in this study protocol. By expanding a rigorous validation process of the NOL to patients who are representative of the broader ICU population, the knowledge gained could contribute to identifying an alternative measure of pain in the most vulnerable critically ill adults.

Potential Limitations and Mitigation Strategies

Recruiting ICU patients or obtaining written consent from the persons qualified to consent for them is challenging. This requires daily screening of eligible patients and close follow-up. Support from the nursing staff and physicians is key to identifying eligible patients and approaching those qualified to consent for them. Our research team has developed efficacious recruitment procedures, trained competent research staff, and established close collaboration with ICU care teams in all sites, which facilitate the implementation of this study. The feasibility of recruitment was also demonstrated in our pilot work. A screening log will be completed at each site to compile eligibility criteria and reasons for refusals, losses, or withdrawals. In our pilot studies [26,27], we were unsuccessful in obtaining data from some participants mainly due to missing the procedure, either because temporary fellows forgot to inform the research team or the procedure occurred after ICU discharge. Chest tube removal and endotracheal suctioning were the sole nociceptive procedures included in our pilot studies. Broadening the selection of nociceptive procedures may reduce the number of missed observations of these events. However, we may still miss some procedures due to urgent situations. Also, data collection will be planned as soon as possible after obtaining written consent to minimize losses. In addition, we will document any challenges related to the use of NOL (eg, absence or loss of signal) and troubleshooting strategies. Finally, CPOT raters cannot be blinded to the procedures they will view on the videos. As a result, they may anticipate patients' behavioral responses to the procedure, which may influence their ratings. The examination of interrater reliability of CPOT scores involving trained research staff from different settings and using 2 methods of rating (bedside and video) may help minimize this potential bias.

Conclusion

The validity of the NOL has been supported in anesthetized patients, but its use in the ICU context is still new. Its validation in the ICU is relevant as many critically ill adults may be unable to self-report or express pain behaviors. As part of the validation process, it is key to validate the NOL with patient groups in whom pain standard criteria can be used as well as during nociceptive and nonnociceptive procedures in order to support its validity for both nociception and related pain assessment in the ICU. If found to be valid, the NOL could be used as an alternative measure to detect nociception and pain and to guide pain management decisions in the most vulnerable, critically ill adults.

Acknowledgments

We thank the ICU team and the dedicated research staff for making this study possible. Doctoral support funding to the graduate research trainee (SST) was provided by FRQS (Fonds de Recherche du Québec – Santé), MES-Universités (Ministère de l'Enseignement Supérieur-McGill University), and RRISIQ (Réseau de Recherche en Interventions en Sciences Infirmières du Québec).

This study is primarily funded by the Canadian Institutes of Health Research (CIHR Project Grant #168983) led by CG (principal investigator) and PR (coprincipal investigator) with coinvestigators. SST is a graduate research trainee on this major grant and obtained a research stipend.

Medasense Biometrics Ltd has not been involved in any part of this NOL validation protocol.

Data Availability

The dataset generated during and analyzed during this study is not publicly available due to ethical agreement but may be available from the corresponding author on reasonable request.

Authors' Contributions

CG, PR, SST, DL, MCG, and HTW contributed to conceptualization. CG, PR, SST, DL, MCG, and HTW handled funding acquisition. CG, PR, SST, DL, MCG, HTW, and WO contributed to the methodology. CG and PR performed supervision. CG, SST, and PR contributed to writing the original draft. CG, PR, SST, DL, MCG, HTW, and WO contributed to writing–review and editing.

Conflicts of Interest

None declared.

Abstract

Background: Youth and families play an indispensable role in health research, given their unique lived experiences and expertise. Aligning research with patients' needs, values, and preferences can significantly enhance its relevance and impact; however, recent research has highlighted various challenges and risks associated with youth and family engagement in health research. These challenges encompass the perils of tokenism, power imbalances and dynamics, questioning the motives behind engagement, and limited accessibility to patient-friendly training for patient partners, as well as inadequate training on patient engagement for researchers and the absence of equitable engagement tools. To address these risks and challenges, different patient engagement models, theories, frameworks, and guiding principles have been developed and adopted; to date, however, their transferability to youth- and family-specific engagement in research has been limited.

Objective: The objectives of this project are (1) to determine the extent of the literature on the application of patient engagement models, theories, frameworks, and guiding principles in the context of youth-specific research; and (2) to determine how meaningful the key components and constructs of these models, theories, frameworks, and guiding principles are to youth and their family members.

Methods: This project will use an integrated knowledge translation approach and consists of 2 phases: (1) a scoping review to identify patient engagement models, theories, frameworks and guiding principles in youth research; and (2) a qualitative descriptive study using one-on-one semistructured interviews with youth and family members to understand their conceptualization of meaningful engagement in health research. For phase 1, the following databases were searched: Medline, CINAHL, EMBASE, PsycINFO, and the Cochrane Central Register of Controlled Trials. Literature from 2013 to August 28, 2024, was captured. Primary studies using a patient engagement in research model, theory, or framework, or guiding principles, in youth will be included. The risk of bias of included studies will not be assessed. Extracted data will be quantitatively summarized using numerical counts and qualitatively using content analysis. For phase 2, we will recruit 9 to 17 youth and 9 to 17 family members. Transcripts will be analyzed using an inductive approach outlined by Braun and Clarke.

Results: The project has received funding from the Canadian Institutes of Health Research. A 9-member integrated knowledge translation panel consisting of 6 youth and 3 family members has been established.

Conclusions: The findings from this study will identify what is currently known about the application of patient engagement models, theories, frameworks, and guiding principles in youth-specific research and the important components of these models, theories, frameworks, and guiding principles from the perspective of youth and their families. These findings will be instrumental to developing a youth- and family-specific engagement in research framework called the UNITE framework and subsequently, a validated measure.

Introduction

Background

Patients play an essential role in health research, given their unique lived experiences and expertise, which can significantly enhance the quality, relevance, and impact of research by aligning it with patient needs, values, and preferences [1,2]. The overarching objective of patient engagement in health research is to generate research that contributes to improved health care service delivery, clinical outcomes, and population health [3]. Recent research has highlighted the myriad benefits and positive outcomes associated with patient engagement for patient partners, investigators, and research endeavors [4-8]. For example, engaging patients has influenced initial research priorities, study designs, interpretation of findings, health care interventions, and knowledge mobilization strategies, resulting in outcomes that more closely align with patient perspectives [7,9]. When patient engagement is characterized as meaningful and authentic, it provides a rewarding experience for patients and researchers alike [10].

However, other recent research has highlighted various challenges and risks associated with patient engagement in health research. These challenges, which include tokenism [11-14], power imbalances/dynamics [12,15], limited accessibility to patient-friendly training for patient partners [16], and the absence of equitable engagement tools [17], can have lasting effects on patient partners, including mental and physical exhaustion, deteriorating health, doubts about the value of

engagement, and a sense of having personally failed both the team and the broader patient community [18]. A recent article by patient partners led by Richards et al [18] on how patient engagement can falter highlighted key themes, including "patient partners as a checkmark," "unconscious bias towards patient partners," "lack of support to fully include patient partners," and "lack of recognizing the vulnerability of patient partners" [18].

To address these challenges and risks, various patient engagement models, theories, frameworks, and guiding principles (eg, the strategy for patient-oriented research [SPOR], the patient engagement in research [PEIR] framework, and "ways community members can participate in the stages of research" from the Ontario Brain Institute) have been developed and adopted within the research community [10,19,20]. For example, the PEIR framework [10] includes eight key components, which collectively contribute to meaningful patient engagement in research: (1) procedural requirements, (2) convenience, (3) contributions, (4) support, (5) team interaction, (6) research environment, (7) feeling valued, and (8) benefits. A subsequent measure of meaningful patient engagement in research from the patient perspective has been developed, the Patient Engagement in Research Scale (PEIRS-22) [21,22]. This measure is designed to be completed by adult patients and family caregivers who partner with researchers on projects.

It is important to acknowledge that existing frameworks often predominantly emphasize the benefits of patient partners to the research project and team, sometimes overlooking the reciprocal benefits that may occur between the research team and patient partners, especially youth partners [23]. This skewed approach fails to fully consider the potentially extractive nature of research collaboration, as aptly described by Metz and Damschroder [23], where the research process can unintentionally exploit the knowledge and contributions of youth without adequately reciprocating in terms of personal and professional development opportunities. This issue takes on particular significance when crafting an engagement framework tailored for youth, as research teams have the potential to foster skill development, positively impact their life and career trajectories, and contribute to their holistic growth [23].

Despite the significant contribution of the PEIR framework [10] and the PEIRS-22 [21,22], they lack the incorporation of a comprehensive review of the evidence on existing frameworks, and their development was based on participants with limited diversity in terms of gender, race, education, primary diagnosis (all had arthritis), and age [10,21,22]. These limitations impede the transferability of this framework and measure to youth- and family-specific engagement in health research.

Furthermore, there is a model of engagement specifically designed for use with youth called the McCain model of youth engagement [24]. However, it was developed solely in the context of youth mental health systems research for youth and young adults aged 15 to 29 years [24], limiting transferability (ie, across different contexts and family members) and highlighting the need to develop a broader framework. Accordingly, our research seeks to directly address these specific gaps in existing engagement models, theories, and frameworks by developing a youth and family-specific engagement in research framework, the UNITE framework.

Research Objectives

This proposal has two objectives: (1) to determine the extent of literature on the application of patient engagement models, theories, frameworks, and guiding principles in the context of youth- and family-specific research; and (2) to understand how meaningful the key components and constructs of these models, theories, frameworks, and guiding principles are to youth and their family members. Collectively, these findings will be foundational to the development of the UNITE framework and a subsequent validated measure.

Methods

Study Design

This study will be conducted in 2 phases, with phase 1 consisting of a scoping review and phase 2 consisting of a qualitative descriptive study.

Integrated Knowledge Translation Approach

Integrated knowledge translation (iKT) is defined as a collaborative relationship between researchers and relevant knowledge users as partners that facilitates mutually beneficial decision-making related to a study or research program [25]. Youth aged 10 to 24 years in Canada and their family members who have engaged in health research (ie, as patient partners) in the last 3 years were recruited as iKT panel members via Holland Bloorview Kids Rehabilitation Hospital's Youth Advisory Council and Family Leader Program, professional networks, social media pages, and email lists. A sample of diverse youth advisors who have participated in our previous research on best practices in youth engagement were also approached, including youth with disabilities or developmental differences [26]. A total of 6 youths and 3 family members were recruited to be part of the iKT panels. The lead youth representative will lead the iKT panels. The lead youth representative and research team decided to hold separate iKT panels (ie, having a youth panel and a family panel with the opportunity to mix panels when needed). This approach will ensure that both groups feel comfortable and can freely express their unique perspectives. Activities of the panels have included planning study activities, and may include participant recruitment, data collection and analyses, and knowledge mobilization. Panel discussions will be conducted in a manner that respects diverse perspectives and experiences. A reflective exercise on equity, diversity and inclusion developed by the Strategy for Patient-Oriented Research Evidence Alliance will be conducted with iKT panel members to encourage dialogue and understanding around equity, diversity and inclusion [27].

Phase 1: Scoping Review on Patient Engagement Models, Theories, Frameworks, and Guidance in Youth Health Research

The methodology for the scoping review will follow the methodological frameworks of the Joanna Briggs Institute (JBI) [28] and Khalil et al [29]. The scoping review protocol has been registered on the Open Science Framework Registries [30] and

was guided by and reported according to the Preferred Reporting Items for Systematic Review and Meta-Analysis Protocols (PRISMA-P) [31]. The completed PRISMA-P checklist can be found in Multimedia Appendix 1. The results of the scoping review will be reported using the Preferred Reporting Items for Systematic Reviews and Meta-Analysis extension for Scoping Reviews (PRISMA-ScR) checklist [32].

Stage 1: Developing a Search Strategy

The population, concept, and context (PCC) framework was used to guide the search strategy (population: World Health Organization [WHO] definition of "young people" as those aged 10-24 years [33]; concept: patient engagement in research; context: models, theories, frameworks, and guiding principles). With the assistance of a research librarian, literature search strategies using Medical Subject Headings and text words related to patient engagement and models, theories, frameworks, and guidance or guiding principles were developed. The search strategy combined structured database-specific subject headings (as available) and keywords or synonyms. An information specialist with expertise in conducting searches for systematic and scoping reviews drafted the search strategy using OVID Medline (Multimedia Appendix 2) and worked with the research team to refine and finalize the search. The final search strategy also underwent peer review using the Peer Review of Electronic Search Strategies (PRESS) statement checklist with another librarian/information specialist [34].

The following databases were searched: Medline, CINAHL, EMBASE, PsycINFO and Cochrane Central Register of Controlled Trials. Searches were limited to English. Literature from 2013 to August 28, 2024 was captured, consistent with when the term "patient engagement" became frequently used [35]. We will also search the gray literature in specialized databases like OpenGrey, Grey Literature Report, and GreyNet International, platforms like arXiv, bioRxiv, and SSRN, and databases such as ProQuest Dissertations and Theses.

Stage 2: Evidence Screening and Selection

All primary studies using a model, theory, or framework for patient engagement in research among young people will be eligible for inclusion. Studies with a model, theory, or framework may have also reported on guiding principles. We define young people as those aged 10 to 24 years, consistent with the WHO definition [33]. We define a model as the essential elements or variables of a phenomenon or a specific aspect of a phenomenon; a theory as "a set of analytical principles or statements designed to structure our observation, understanding and explanation of the world"; and a framework as an explanation of a phenomenon by organizing it into a collection of descriptive categories and the relationships between them [36]. Systematic reviews, meta-analyses, editorials, commentaries, and nonspecific conference proceedings will be excluded to focus on including primary results and not preliminary findings or ongoing research; however, the reference lists of such articles will be hand-searched for relevant articles.

Removal of duplicates as well as level 1 and level 2 screening will be managed through Covidence. To increase reliability, the level 1 screening form will be piloted on a random sample of approximately 50 articles. Eligibility criteria descriptions will be revised if deemed necessary by the team, or if low agreement (ie, <70%) [37] is observed, to improve the consistent application of the selection criteria. Agreement will be measured using Cohen κ [38]. A pilot test of the level 2 screening will also be performed on approximately 25% of the articles, similar to the process for level 1 screening. For studies that are excluded at level 2, the reason for exclusion will be recorded. All screening will occur in duplicate and independently. When necessary, another reviewer will be sought to resolve conflicts.

Stage 3: Data Extraction

A standardized data extraction form will be developed by the research team and iKT panels based on the *JBI Manual* data extraction recommendations [28] and those recommended for the extraction, analysis, and presentation of results in scoping reviews [28,39]. Extracted data will include study characteristics (eg, study design, year of publication, geographic location), youth and family participant characteristics (eg, age of the youth), and details of the engagement models, theories, frameworks, and guiding principles (eg, components or values and principles and how they were enabled or enacted in the study), as well as study results. Additional categories for data extraction identified through discussions with the research team and iKT panels will be added to the final data extraction template as applicable. The data extraction template will be piloted for 2 to 3 articles to ensure all relevant results are extracted. All data will then be extracted in duplicate by 2 independent reviewers. Discrepancies in the extracted data will be discussed and resolved by the 2 reviewers. Quality and risk of bias will not be assessed, as this is not required in scoping reviews [32].

Stage 4: Data Analysis

The extracted data will be quantitatively summarized using numerical counts and qualitatively summarized using content analysis [40]. The data will be grouped by the main components of the model, theories, frameworks, guiding principles (and how they were enabled or enacted), study designs, and associated methods (eg, one-on-one interviews). We will also synthesize data on how youth and family members were engaged throughout the research process, the types of outcomes collected, and results. Depending on the available data, subgroup analyses may be conducted by health condition, sex, gender-related variables, and other PROGRESS-Plus characteristics (PROGRESS-Plus is a term meaning "place of residence, race/ethnicity/culture/language, occupation, gender/sex, religion, education, socioeconomic status, social capital") [41]. If feasible, we will contact the study authors of the included studies to confirm that all the data collected were included in the published article (ie, nothing was excluded due to word count limitations of a journal).

Phase 2: Qualitative Study to Understand Key Components and Constructs for Development of a

Framework for Youth- and Family-Specific Engagement in Research

Study Design

Phase 2 will adopt a qualitative descriptive approach [42,43]. Findings from the scoping review will inform the development of the interview guide for phase 2, such as identifying what aspects of the included models, theories, frameworks, and guiding principles resonate with youth and family members and which do not.

Recruitment

We will recruit Canadian youth (aged 10-24 years) and their family members who have had experience in youth engagement in health research (eg, as partners of a research project) within the last 3 years. Participants will be recruited via our professional networks, including those of the iKT panel members (eg, the Kids Brain Health Network, the Bloorview Research Institute Family Engagement Office, and the SickKids Patient and Family Engagement Office), social media pages, and email lists. We will also enlist the help of a diverse group of youth advisors who have participated in our research team's previous research for recruitment [26,44,45]. We aim to recruit 9 to 17 youth and 9 to 17 family members; this is consistent with the sample size in qualitative studies to reach thematic saturation [46].

Data Collection

Youth and family participants will take part in separate, one-on-one, semistructured telephone or online interviews with a member of the research team with expertise in qualitative research methods [47,48]. All interviews will be digitally recorded and transcribed verbatim for data analysis. The interview guides will consist of questions focused on youth and family members' conceptualization of meaningful engagement in health research. The interview guide will be pilot-tested with various members of the research team and iKT panel. We will use probes or recursive questioning during interviews to explore issues in greater depth and verify the interviewer's understanding of the collected information [49,50].

Data Analysis

We will use inductive thematic analysis, as described by Braun and Clarke [51,52], which is consistent with the pragmatic orientation of this research [53]. Codes and themes will be refined through discussion with the larger research team. The software program NVivo (version 14; Lumivero) will be used during the analysis of the transcripts to help organize the codes. Multiple aspects of trustworthiness will be used [54]. For example, we will demonstrate credibility via peer debriefing with various members of the research team and the iKT panels. Transferability will be accomplished by describing the study samples. Independent analysts will review the data and contest the themes to ensure dependability. Finally, confirmability will be accomplished by providing decision trails between data and interpretation [54].

Ethical Considerations

Ethics approval for phase 2 of this project will be obtained from the first author's primary institution (Holland Bloorview Kids Rehabilitation Hospital, Bloorview Research Institute). Informed consent will be obtained from participants prior to the start of the interview. Transcripts from the interviews will be deidentified to ensure privacy prior to data analysis. Participants will be compensated for their time in the form of gift cards. The amount compensated will be consistent with the Canadian Institutes of Health Research (CIHR) Patient Partner Compensation Guidelines (CAD $50 [US $34.96] per participant) [55].

Results

This work is supported by a CIHR Healthy Youth Catalyst Grant received in March 2024 (HEY- 192883; Multimedia Appendix 3). A 9-member iKT panel consisting of 6 youth and 3 family members has been established and has been actively involved in the study. We anticipate that phase 1 of the study will be completed in March 2025. Ethics approval for phase 1 was not required as it did not involve collecting or using data from participants. Ethics approval for phase 2 of the study will be applied for in winter 2025. Phase 2 of the project is anticipated to be completed in August 2025. A detailed timeline of the project can be found in Multimedia Appendix 4.

Discussion

Anticipated Findings

The findings from this study will allow us to identify what is currently known about the application of patient engagement models, theories, frameworks, and guiding principles, which are often designed for adults, in the context of youth-specific research, and to understand the importance of the components that make up these models, theories, and frameworks from the perspective of youth and their families.

Dissemination Plans

We will use a variety of passive and active end-of-grant knowledge mobilization approaches to disseminate our findings, which will be codeveloped with our iKT panels. We will ensure youth and family voices are heard to develop flexible communication plans that will suit diverse needs. Traditional knowledge translation will include dissemination through meetings locally, nationally, and internationally (eg, PxP and For Patients, By Patients) and publications in peer-reviewed journals. Members of the research team are affiliated with and situated within pediatric institutions where the UNITE framework will be disseminated and implemented. We will codevelop plain language summaries with youth and family partners with clear, simple, and individualized messages for patients and family and community service organizations to augment the accessibility of the information. Finally, members of the research team will also discuss and distribute the UNITE framework within their expansive training curriculum and a planned youth-focused engagement in research course.

Future Directions

This project lays the foundational work for developing a patient engagement framework called the UNITE framework, which will include equity, diversity, and inclusion considerations, and

the subsequent development and validation of an associated measure of engagement. Future research will involve the implementation of the UNITE framework and a subsequent measure in a learning health system context within pediatric institutions that our research teams are associated with. The UNITE framework and associated measure will contribute to meaningful and sustained engagement of youth and their families in health research by addressing gaps in current patient engagement frameworks.

Strengths and Limitations

A strength of this study is the inclusion of gray literature (eg, reports and policy literature) for phase 1 (the scoping review). This will provide a more comprehensive understanding of the concept (patient engagement in research) and context (models, theories, frameworks, and guiding principles) that we are interested in, as well as mitigate publication bias [56]. In addition, the search strategy for phase 1 has been reviewed by the iKT panel and undergone peer review using the PRESS statement checklist [34], which further strengthens the relevance, comprehensiveness, and quality of the search strategy. One limitation of this project is the potential for selection bias (specifically for phase 2), where individuals who had either very positive or very negative experiences with patient engagement in research may be more likely to participate in the study, which may limit the applicability of the study's findings. However, the adoption of the iKT approach and having the iKT panels (consisting of youth and their families) assist in the recruitment for phase 2 of the study should result in the recruitment of a variety of individuals with diverse interests.

Conclusions

The current proposal will lead to the development of a youth- and family-specific engagement in research framework, UNITE, with future research focused on the development of an associated validated measure. The UNITE framework and measure will lay the foundation for meaningful and sustained engagement in health research by youth and their families, ultimately contributing to enhanced health care service delivery, improved clinical outcomes, and increased overall well-being and quality of life for youth and their families [1-3].

Data Availability

The data collected during this study are available from the corresponding author upon reasonable request.

Authors' Contributions

SEPM, AT, and CJ conceptualized the overall study design and methods, wrote the manuscript, and approved the final manuscript as submitted. CJ, SEPM, and AT informed the design of the study engagement approach and coordinated the knowledge user engagement. SEPM, CJ, and AT contributed to the design of the study knowledge mobilization strategies. All authors provided input and guidance on the study design and approved the final manuscript as submitted.

Abstract

Background: The Canadian long-term care (LTC) workforce cares for increasingly complex residents. With greater care needs come greater demands. Despite this, LTC staffing and resources are largely unchanged and underresearched over the last decade. The Atlantic provinces are home to the oldest population in Canada, indicating a high need for LTC. The health and well-being of the LTC workforce are critical components of care quality, yet only in Western Canada are such data routinely and systematically collected. Translating Research in Elder Care is a 2-decade research program studying the LTC work environment and has found strong links between the working conditions of LTC staff and resident outcomes. We draw upon their success to generate the evidence needed to understand, support, and manage the LTC workforce in Canada's four Atlantic provinces.

Objective: This study aims (1) to assess the quality of work life among staff in LTC homes in Atlantic Canada; (2) to examine the effects of the work environment on the quality of work life; and (3) to build capacity for research in the LTC sector in Atlantic Canada among knowledge users, researchers, and trainees. The objective of this paper is to describe the approach needed to examine the quality of work life and health of care staff in LTC homes.

Methods: Stratified random sampling will be used to recruit homes in Atlantic Canada. The sampling frame was designed to recruit 25% of the LTC homes in each of the 4 provinces with proportional representation by size; ownership model; and, if applicable, region or language. Key outcome variables include measures of mental health and well-being, quality of work life, intention to leave, workplace context, and missed or rushed care. Primary data will be obtained through structured interviews with care aides and web-based surveys from registered nurses, licensed practical nurses, managers, and allied health providers. Eligible participants were from an LTC home with at least 25 residents, 90% of whom were aged 65 years or older, and had worked in the home for at least 3 months. Multivariate analyses include regression analysis for explaining predictors of quality of work-life outcomes and multilevel modeling for more complex relationships of staff outcomes by provinces and LTC home characteristics.

Results: Data collection and cleaning are complete as of October 2024 (N=2305). Care aides (n=1338), nurses (n=724), allied health providers (n=154), and managers (n=89) from 53 homes make up the sample. Data analysis is ongoing. Initially, individual reports will present descriptive data for each participating LTC home. Concurrent analysis is planned for publication in peer-reviewed journals.

Conclusions: This peer-reviewed research protocol lays the foundation for a comprehensive analysis of the effects of the work environment on the quality of work life of LTC staff in Atlantic Canada.

Introduction

Background

This protocol is for a collaborative investigation that aims to address profound deficiencies in data to understand, support, and manage the long-term care (LTC) workforce in Canada's 4 Atlantic provinces. In Canada, LTC homes are funded by provincial governments and provide a range of health and personal care services to predominantly older adults who require 24-hour nursing, personal, and support care [1]. Residents of LTC have higher levels of acuity and have more complex care needs than in the past decade as a result of increased life expectancy and delayed entry due to an increased emphasis on home care [2]. Approximately 81% of residents in Canadian LTC homes live with mild to severe cognitive impairment, 27.1% have seven or more chronic conditions, and 51.5% have extensive limitations in activities of daily living [3]. As the care needs of residents become greater, so do the demands placed on the LTC workforce. Despite this, LTC staffing and resources have remained largely unchanged and underresearched over the last decade [4,5].

The LTC workforce cares for residents with complex needs, but their work environments are strained by heavy workloads, inadequate resources, and critical staffing shortages [4,5]. The health and well-being of the LTC workforce are critical components of care quality [5], and yet only in the Western Canadian provinces of British Columbia, Alberta, and Manitoba are such data routinely and systematically collected [6]. In Atlantic Canada, no data are available on workforce characteristics or the work experiences of LTC care providers (ie, indicators of health, well-being, or burnout). LTC in Canada is provincially regulated, meaning policies, regulations, and practices differ among provinces; fundamental differences in how LTC is organized between Western provinces and Atlantic Canada influence how staff work and care for residents, including staffing models and ratios, and education and training requirements of staff. While many other Canadian provinces have continuously relied on internationally trained care workers to supplement the domestic workforce, this is a relatively new phenomenon in the Atlantic Canadian provinces of Nova Scotia, Prince Edward Island, Newfoundland and Labrador, and New Brunswick. Chamberlain et al [7] reported in 2018 that only 35% of care aides working in Alberta LTC homes spoke English as a first language in comparison to 95% of LTC care staff in a Nova Scotian 2021 pilot study [8]. Additionally, according to the 2021 census, between 96% to 99% of the population in Nova Scotia, Prince Edward Island, Newfoundland and Labrador spoke English as a first language, and as a bilingual province, nearly 70% of the New Brunswick population spoke English as a first language while the remaining 30% spoke French [9]. While recent efforts from governments in Atlantic Canada to bring internationally educated workers into LTC have been largely deemed successful from a recruitment perspective [10-12], little is known about how the changing composition of the workforce impacts the LTC environment. More specifically, it is unknown if, and to what degree, domestic and international staff feel supported as they adjust to a more diverse workplace. Further, the combined population of all 4 Atlantic provinces is fewer than 2.5 million [13] and far fewer staff are trained internationally. These differences limit the ability to generalize workforce data from the Western provinces to Atlantic Canada.

Given the relationship between work and care conditions [14,15], data on the LTC workforce are important as they allow policy makers to identify and address workforce issues that compromise resident care and the health and well-being of care staff. Understanding the work environment will assist in future workforce planning and the strategies designed to improve work conditions and ultimately care conditions.

Translating Research in Elder Care

Translating Research in Elder Care (TREC) is a program of research spearheaded by Carole Estabrooks and a group of researchers from Alberta Canada who have been studying the LTC work environment in the Western Canadian provinces for nearly 2 decades [6]. TREC has analyzed the impact of the LTC work environment on staff quality of work life, mental health, and well-being outcomes in 7 waves of data collection [5,7,16-18]. These data enable in-depth longitudinal analysis that demonstrates the impacts of policy changes, interventions, and events such as COVID-19 [19-21]. The TREC research program also links the staff survey data within a clinical microsystem to resident outcomes using data from the Resident Assessment Instrument for LTC [22]. Evidence of strong links between the working conditions of LTC staff and resident outcomes is reported. For example, significant relationships were found between the use of best practices and care staff's social capital and organizational slack (time and staffing) [23]. In examining the demographic profile of the LTC workforce, staff who provide the majority of direct resident care had little formalized training, were racially diverse, and had high rates of English as a second language [7]. More recently, TREC has designed and delivered interventions to enhance the work environment in LTC, such as Safer Care for Older Persons in (residential) Environments [21] and Improving Nursing Home care through Feedback on Performance [24], and a coherent breathing intervention to decrease stress, insomnia, and anxiety [25].

The TREC measurement system, including the care aide structured interview and the regulated staff web-based survey, were consistent with the instruments used in this study in Atlantic Canada. The minor exceptions were because of localized staff job titles and translation of survey instruments to enable staff in designated French LTC homes in New Brunswick to participate in their French language. The goal of our team is to build upon the work of TREC and to use their comprehensive data collection tools to build an Atlantic Research Collaboration (ARC) and to generate the evidence needed to understand, support, and manage the LTC workforce in Canada's 4 Atlantic provinces. Ultimately, we will identify work environment areas that are amendable to intervention so that targeted interventions can be designed and delivered at the regional, provincial, institutional, and unit levels to enhance the quality of the LTC work environment.

Study Purpose and Objectives

This ARC on LTC (ARC LTC) involved researchers and collaborators form 4 provinces to describe and examine the relationship between the health and quality of work life of LTC staff and their work environment (organizational context). The research aims are as follows.

- To assess the quality of work life among staff in LTC homes in Nova Scotia, Prince Edward Island, Newfoundland and Labrador, and New Brunswick.
- To examine the effects of the work environment on quality of work life.
- To build capacity for research in the LTC sector in Atlantic Canada among knowledge users, early career researchers, and trainees.

Methods

Study Design

This is a cross-sectional, multilevel survey study with an integrated knowledge translation approach with knowledge users (ie, representatives from LTC homes, health authorities, provincial ministries, and key sector organizations) embedded throughout the project. We use the Checklist for Reporting Results of Internet E-Surveys (CHERRIES) reporting guidelines for web-based or internet surveys as a framework for our approach [26]. A detailed description using the CHERRIES checklist is present in Multimedia Appendix 1. Our methods are consistent with the established recruitment and data collection protocols used by TREC [23,27] and will enable comparison of data not only across the Atlantic Canadian provinces but also with the Western Canadian provinces.

Study Context

The LTC sectors in Atlantic Canada are diverse with variations in names assigned to LTC homes, regulatory oversight, ownership models, and titles given to unregulated care staff (Table 1). The study's design is sensitive to these differences with some modifications made to the sampling frame to reflect the uniqueness of individual provinces. In this protocol, we use the terms LTC home and care aide to describe the facility where care staff work or residents live, and the unregulated staff, respectively.

Table 1. Characteristics of homes by province in 2023.

Characteristics	Nova Scotia	New Brunswick	Newfoundland and Labrador	Prince Edward Island
Name of LTC[a] homes	Nursing home	Nursing home	LTC homes	Manors or nursing homes
Government responsible	Department of Seniors and LTC	Department of Social Development	Department of Health and Community Services	Department of Health
Legislative framework	Homes for Special Care Act	Nursing Home Act	Health and Community Care Services Act	Community Care Facilities and Nursing Homes Act
Ownership model	Public, private for-profit, and not-for-profit	Private corporations run by boards of directors	Public	Public, private for-profit, and not-for-profit
Title for unregulated care staff or care Aides	Continuing care assistant	Resident aide	Personal care attendant	Resident care worker
Regulated nursing staff	Registered nurses and licensed practical nurses	Registered nurses and licensed practical nurses	Registered nurses and licensed practical nurses	Registered nurses and licensed practical nurses
Allied health providers presence of these providers varies by province and LTC home	Recreation therapist, aide social worker, dietitian physiotherapist, aide occupational therapist, and aide	Recreation therapist, aide social worker, dietitian physiotherapist, aide occupational therapist, and aide	Recreation therapist, aide social worker, dietitian physiotherapist, aide occupational therapist, and aide	Recreation therapist, aide social worker, dietitian physiotherapist, aide occupational therapist, and aide

[a]LTC: long-term care.

Theoretical Framing

The critical socioecological framework [28] is used to guide this research. This framework depicts how behaviors are influenced by characteristics of, and interactions between, the individual and immediate social network (microsystem), local environment or community (mesosystem), and the larger system (macrosystem). The ecological framework supports the bidirectionality of this influence (eg, the work environment may affect individual staff feelings of well-being and vice versa). The framework highlights the complexity of staff's experiences

and agency within the LTC environment and their ability to engage in change to enhance resident care. It acknowledges how the work environment is shaped and buffered by factors in the micro, macro, and meso levels. Embedding our research in the critical socioecological framework will enable us to examine the inter-relationships among individual experiences, the work environment, and the larger provincial and regional LTC policy context.

We will examine LTC at the macro, meso, and micro levels (see Multimedia Appendix 2 [29-39] for how the survey content is organized at the meso and micro levels). At the macro level, all 4 Atlantic provinces provide public funding to LTC. Although regulations, guidelines, and staffing ratios differ by province, individual homes vary in how they operationalize them internally. At the meso level, institutional practices, policies, and work culture, along with heavy workloads associated with complex LTC residents have a major impact on staff. About 80% of resident care in Canada is provided by unregulated care aides who have little, if any, formal education [7]. Despite their pivotal role in LTC, care aides may not receive the recognition they deserve, nor do they always feel like valued members of care teams [23]. Contextual factors in work environments such as leadership, culture, and social capital, influence individual staff at the micro level and account for greater job satisfaction, empowerment, and autonomy [40,41]. The critical socioecological framework can facilitate our understanding of the multilayered influencers on LTC staff's quality of work life, and ultimately, resident care and quality of life in LTC homes in Atlantic Canada.

The dynamic nature of the LTC environment including things such as changes in the complexity of resident care needs and the increasing number of staff who speak English as a second language, could prompt changes in workplace policies and culture. Changes in both policies and culture can impact how staff work at the micro level as well as how organizations operate at the meso level. The nature of these bidirectional relationships affects how staff work, how they experience their work, and their perceived ability to support the changes needed in the work environment.

Sampling

Facility Sampling and Eligibility

A stratified random sampling technique will be used to recruit homes from each of the 4 provinces. The sampling frame was designed to recruit 25% of the LTC homes in each province (Table 2) with proportional representation by size (large: >120 beds; medium: 70-119 beds; and small: 25-69 beds); ownership model (eg, public, not-for-profit, and private for-profit); and, if applicable, region or language. These strata have been previously associated with residents' quality of care [42,43]. Oversampling will be done in Newfoundland and Labrador and Prince Edward Island to ensure a minimum of 8 homes in these provinces and a sufficient sample to enable cross-tabulation. Because Prince Edward Island only has 1 health region, and New Brunswick is a bilingual province with designated English and French homes, the region strata will not be used in Prince Edward Island, and linguistic designation will be used in New Brunswick.

To be eligible to participate, homes need to provide 24-hour, on-site housing and health care services for older adults by professional (nursing) staff, be stand-alone facilities (ie, not attached to an acute care hospital), and have a minimum of 25 LTC beds with at least 90% of the resident population aged 65 years or older. Homes will be ineligible if they are hybrid care homes integrated with an acute care facility or hospital, or share central services (eg, human resources and laundry) with an acute care facility or hospital.

Table 2. Number of LTC[a] homes included in the sample and strata by province (2023 estimates).

Characteristics	Nova Scotia	New Brunswick	Newfoundland and Labrador	Prince Edward Island	Total
Total number of LTC homes, n	92	73	43	19	227
Eligible homes, n (% of total)	81 (88%)	71 (97.3%)	27 (62.8%)	15 (78.9%)	194 (85.5%)
Sample (25% of eligible), n	20	18	8[b]	8[b]	54
Strata	Region ownership size	Language size	Region size	Ownership size	—[c]

[a]LTC: long-term care.

[b]Newfoundland and Labrador and Prince Edward Island were oversampled.

[c]Not applicable.

Staff Sample and Eligibility

Our sample will include senior administrators, managers, regulated nursing staff, unregulated care staff, and allied health providers (Table 3). All staff must have worked at the LTC home for 3 months or longer. In addition to the 3-month criteria, managers must work a minimum of 50% of the time at the LTC home, nurses must work a minimum of 6 shifts a month at the LTC home, care aides must be able to identify a unit they work on more than 50% of the time and work a minimum of 6 shifts a month on that unit, and allied health must provide at least one-third of their services that equals 6 days a month at the LTC home. Senior administrators who hold executive positions in LTC, such as chief executive and operation officers, will be required to provide the standardized facility (eg, physical design) and unit-level data (eg, staffing models).

Table 3. Estimated number of care staff in LTC[a]—both regulated and unregulated by province.

Characteristics	Nova Scotia	New Brunswick	Newfoundland and Labrador	Prince Edward Island	Total by staff group
All registered nurses or licensed practical nurses in LTC, n	1611	2625	1278	299	5813
Sample pool from LTC homes (25%), n	322	656	320	150[b]	1448
Desired sample (60% of eligible staff), n	193	394	192	90	869
All care aides, n	3866	4875	962	710	10,413
Sample pool from LTC homes (25%), n	773	1219	241	355[b]	2588
Desired sample (60% of eligible staff), n	464	731	144	213	1553
Desired care staff (registered nurses, licensed practical nurses, or care aides) sample total, n	__[c]	—	—	—	2422

[a]LTC: long-term care.

[b]Prince Edward Island was oversampled (50%).

[c]Not applicable.

Sampling Procedures

With the exception of Prince Edward Island, each province will have a team of staff responsible for recruitment and data collection. Due to the size and resources in Prince Edward Island, recruitment and data collection will be assigned to the Nova Scotia team. Each provincial research team will create a database of their LTC homes that includes information on each stratum, along with the name and contact information of facility administrators. The stratified proportional random sampling procedure will be performed centrally by a project manager who will then inform provincial teams of the randomly selected LTC homes to recruit. Homes identified in the randomization procedure will be emailed a letter of invitation from the province's lead investigator and if necessary, a follow-up phone call from a member of the research team. Meetings via Microsoft Teams will be held with homes who express interest in the study. During these meetings, the nature and purpose of the study will be explained along with details of what participation entails. Homes that agree to enroll in the study will be asked to sign a facility agreement form that outlines the expectations of participation. If approval of an operator is required for facility participation the operator is asked to sign an operational approval form prior to the home signing a facility agreement.

Once a home agrees to participate, research staff will conduct orientation meetings (one in-person visit and MS Team or telephone meetings as needed) with administrators and site liaisons to (1) verify the eligible participant pool for completing staff surveys; (2) identify the number and types of care units, staff assignment, and shifts; and (3) discuss the logistics of data collection (eg, dates for data collection, promotion and recruitment strategies, interview flow and schedule, contact information for a site liaison).

Measures

Data will be collected using TREC's suite of survey instruments. TREC data collection tools have been administered in Western Canada at several points in time [5,7,18,23] and in Nova Scotia in 2021 with 10 LTC homes [8]. A key component of the surveys is the Alberta Context Tool (ACT), which was developed to measure 10 dimensions of the organization context within health care settings (eg, leadership, culture, feedback, staffing). The ACT contains slight variations for each category of staff and was developed and refined for use in LTC [44]. In addition to the ACT, other surveys will be used to collect data on staff demographics, their perceptions of physical and mental health, well-being, burnout, job satisfaction, as well as missed and rushed care. Permission to access and use these tools has been obtained. Minor revisions to the survey instruments have been made with permission to reflect Atlantic Canada–specific context (eg, provincial term used for care aides). Details of these tools, including their psychometric properties, are outlined in Multimedia Appendix 2 [29-39].

Translation

Many of TREC's suite of tools are only available in English, which means they have to be translated to French to accommodate the New Brunswick French LTC homes. The quality of these translations is critical in maintaining the integrity of the data collected, and the comparability of data across provinces. The TREC research team has a preexisting rigorous translation protocol that was modified by Hoben et al [45] and is based on international best practices [46]. The first step in the process is to identify the proprietary rights of each survey and to establish which tools are available in French. Of the tools in the suite, 6 tools have existing French versions, and 2 of these cannot be altered. We will obtain permission to translate the remaining 6 tools from English to French (Multimedia Appendix 2).

Translation of these 6 tools and the full TREC survey will involve a rigorous systematic process of forward translation from English to French, back translation from French to English, and cognitive debriefing. Once the forward and back translation processes are completed, additional reviewers will examine the changes for accuracy and precision and, if necessary, make recommendations for the final translation.

We will recruit 4 LTC staff members to complete the translated surveys to verify the understanding, clarity, and appropriateness

of the items. This step is for language, comprehension, and cultural issues only; these pilot data will not be included in the study's sample.

Additional translations will also be required for other research materials, such as demographic questionnaires, consent forms, standardized instructions, and explanations of items within individual surveys.

Data Collection Procedures

Based on TREC's experience, data to determine care home units for the study and the number of eligible staff will be collected during the initial in-person meeting between a member of the research team and an LTC care home administrator. Data collection for staff will not begin until these data are obtained. Meetings will take approximately 1 hour and will include a tour of the LTC facility and will allow research staff to build a relationship with care home administration.

A staff member at each care home will be designated as the site liaison by the LTC administrator. The site liaison will work with research staff on promotion, participant recruitment, and scheduling of data collection. An individualized data collection schedule will be cocreated for each home that allows for maximum access to eligible staff and minimum disruptions to the home. Data collection will take place during days, evenings, nights, and weekends. Data collection will be scheduled over a 1-week period, but, if necessary, more time will be provided.

Informed consent will be obtained from all staff prior to data collection. Staff survey data will be collected through a self-administered web-based survey or during a structured interview using Microsoft Teams. Regulated staff will be provided with a link to the closed web-based survey and instructed to complete it voluntarily and independently on the web using the Nooro research platform, on which the survey was thoroughly tested by project staff prior to data collection. Codes given to staff can be used to leave and reenter the survey without losing progress; once the survey is submitted, the code can no longer be used to access the survey thus preventing duplicate entries.

Care aides (unregulated staff) will be scheduled to meet in a private and quiet space with a trained data collector via Microsoft Teams. The data collector will administer the surveys using Computer Assisted Personal Interviewing (CAPI) techniques; survey questions will be read to the participant in a structured interview format using standardized language, and the data collector will enter responses directly into the Nooro research platform. In the event of a staff member becoming upset during data collection, interviews will be paused, and a support protocol will be initiated, including the provision of a list of local mental health resources. The variation in data collection procedures between regulated staff and care aides is based on previous feasibility testing conducted by the TREC team which determined structured interviews are more effective than self-administered web-based surveys for care aides and can be conducted in less time [27].

Facility- and Unit-Level Data

One facility profile survey will be completed for each participating LTC home, and unit profile surveys will be completed for each unit in the LTC home. These surveys collect data such as the size, ownership model, unit information (ie, number and size of resident care units), types of units (eg, dementia and psychiatric), human resources (eg, physicians and nurse practitioners), care staff complement (eg, type and number of staff on each unit on a given shift), quality improvement activities, and access to programs and services. These surveys will be completed by research staff with LTC administrators or their designate (eg, a director of care or unit manager) through Microsoft Teams during or shortly after the staff data collection period.

Staff Data

Surveys or interviews can be completed during work time and will take approximately 35 minutes. Multimedia Appendix 2 details the measures that will be collected. Survey item totals varied by staff survey type: care aide surveys have 154-169 items depending on responses to adaptive questions and are answered continuously in the interview format; nurse surveys have 207-219 items across 50 pages; allied health surveys have 138-149 items across 37 pages; and manager surveys have 209-229 items across 53 pages. Items or scales were not randomly ordered. Regulated staff completing the web-based survey could review and change their answers if desired before submission. There are no automatic completion checks alerting participants if their web-based survey contains missed items. Data collectors administering the care aide survey are to check for completion, however, it is not obligatory for care aides to answer missing items.

Data Collector Training

Training will be in accordance with TREC's training program for quality assurance purposes and to ensure consistency. Data collectors will receive in-depth standardized CAPI and survey interview training, which will be done in collaboration with TREC's field coordinator and the ARC LTC staff who have experience with implementing the TREC Survey.

Data collectors will participate in 3 training sessions followed by a quality assurance test. The 3 sessions will be 2-3 hours long and delivered in-person or using Microsoft Teams meetings. These web-based sessions will be recorded for onboarding additional staff at later points in time. The sessions will include didactic teaching, group discussion, and survey practice with peers. Topics will include project background, survey overview, CAPI administration, accessing the survey platform, consent process, shift schedules and resources, and strategies for challenging interviews (eg, technology issues, managing participant distress, keeping participants on track). In addition to survey practice during the 3 sessions, data collectors will be instructed to practice on their own or with friends and family.

During the quality assurance testing, each data collector will complete a minimum of 2 surveys. Data collectors must meet all criteria (eg, obtaining proper consent, reading questions verbatim, appropriate use of scales, proper flow, correctly

inputting responses, acting professional, answering or navigating participant questions, managing technology issues, managing participant distress, keeping participants on track). If necessary, additional training will be provided to data collectors on an individual basis to ensure they are able to conduct quality interviews meeting all quality assurance criteria.

Upon completion of training, each data collector will complete at least 1 practice interview with an ARC LTC staff member. Data collectors must receive approval from the ARC LTC staff before being cleared to conduct interviews. Ongoing quality assessment will continue throughout the data collection phase to ensure proficiency in administering surveys using CAPI, consistency between data collectors, and consistency across time ensuring high-quality data.

Ethical Considerations

Ethical approval for this protocol was obtained from the research ethics boards of the academic institutions of each of the investigators. The study was first reviewed and approved by the Research Ethics Board at Mount Saint Vincent University, Nova Scotia (2023-039), and then subsequently reviewed and approved by ethics boards at Dalhousie University, Nova Scotia (2023-6887); University of New Brunswick (2023-133); Memorial University of Newfoundland (2023.212 or 2024.1112); and Health Prince Edward Island (2023-10-19 or 2024-02-12). Care staff participation will be voluntary, and the information collected will be completely confidential. Data collection with care staff will be held in a private location and no names will be stored with study data. Potential participants will be sent a copy of the consent form prior to the interview, and it will be reviewed just prior to initiating an interview. Informed consent including the purpose of the study, approximate length of completion, data storage and privacy, research team, and ability to opt-out at any time prior to survey completion will be obtained prior to starting the survey. After each care aide survey, the data collector will complete an interview checklist which will capture feedback on the interview and rate its quality. Biweekly data quality reports will be compiled and the number of interviews completed and in progress, time to complete interviews, and occurrence and nature of missing data or extreme scores will be reviewed by investigators and staff. Any unexpected issues will be reviewed with data collectors on a regular basis. Data collectors may be observed conducting interviews for ongoing quality assurance purposes. Data are anonymized upon survey entry, and as such, there is no way to identify or remove participants' responses once the survey has been submitted. Study reports at the unit level will only be available if more than 8 staff from the care unit participate; in cases where fewer than 8 staff from 1 care unit participate, reports will only be available at the facility level to protect participants from being identified. No data will be presented unless the cell size is 5 or more. The identities of the LTC homes that participate will also be held in confidence; sites will only be described by their province, size, region, and language. All the data and the results will be kept indefinitely on a secure server in the Health Research Data Repository that resides in the Faculty of Nursing, University of Alberta. The nominated principal investigator JMK is the data custodian for these data. Contingent on subsequent ethics reviews, its access will be highly restricted. The Health Research Data Repository will support storage, data analysis, and access control for all ARC LTC team members and trainees. Research team members may access the data remotely using unique usernames and strong passwords. Users are unable to download any data or access the internet while logged into the repository. Identifiable data and personal information will be stored separately from their deidentified counterparts to ensure participant confidentiality. Any print documents will be stored securely in locked file cabinets by the project lead in each of the provinces. All staff who participate in the study will receive a CAD $10 (US $7.55) coffee gift card as a token of appreciation. These cards will be supplied to the facility liaison who will hand out cards to staff who agree to participate on survey completion. In addition, LTC homes that participate will be provided with a small stipend at the completion of the study to compensate for any work associated with their participation; the stipend will be based on the size of the home (ie, small, medium, or large). All staff will be given an opportunity to obtain a copy of the study's findings.

Knowledge Translation

As part of the feedback process, tailored reports will be generated for each individual care home. These care home reports will be shared with the home administrator. Staff participants will be given the opportunity to receive a generalized report on the study's findings. If they wish to receive results, they will be asked at the end of the survey to provide an email address. Email addresses for feedback purposes will not be linked to any data provided by participants.

Data Analysis Plan

To assess the quality of work life among staff working in LTC homes in Atlantic Canada, data will be analyzed by home, by province, and in combination to identify and assess associations, interactions, and predictors of health and work-life outcomes. No correction methods will be calculated. Regression analysis and statistical modeling techniques will be used to explain how work environments within LTC homes are impacting the quality of work life and health of staff. For example, is the work environment (an independent variable) correlated with job satisfaction and burnout? In what way do demographic variables, such as age, or English as a second language mediate the effect of work environment on quality of work life and intention to leave? Multimedia Appendix 3 shows the proposed statistical approaches. Multilevel modeling will be conducted to explore the complex interplay among characteristics at the micro (eg, LTC staff), meso (eg, unit and facility), and macro (eg, province) levels and their effects on indicators of quality of work life and health. Early careers researchers, trainees, and knowledge users will be involved in all aspects of data analysis to help build capacity for research in the LTC sector in Atlantic Canada.

Results

Data collection occurred between November 2023 and June 2024 and is complete. Between July 2024 and September 2024, data were cleaned and organized for analysis. Data analysis is underway. Initially, individual reports will present descriptive data for each participating LTC home comparing their staff responses to mental health and well-being by occupational group

with those of staff from all other facilities participating in their province. A series of three reports are proposed: (1) demographics and perceptions of work life (eg, burnout, job satisfaction, and intention to leave); (2) personal health and well-being (eg, general anxiety, posttraumatic stress disorder, and insomnia); and (3) organizational context (including the 10 dimensions of the ACT [44]; eg, leadership, culture, feedback, and staffing). Concurrent with this descriptive analysis, analytical analysis is planned for publication in peer-reviewed journals.

Discussion

Overview

This study aligns with Canadian and global priorities related to creating a sustainable health workforce and improving service delivery for those residing in LTC [47]. Specifically, our study builds on the influential research of the TREC group in Western Canada who developed and refined a comprehensive methodology for understanding the context of LTC and more notably, identifying solutions for enhancing the work environment and improving the quality of resident care [15,20]. Such work has been proven effective in enriching the work life of staff and improving system efficiency [15,16]. To date, a key finding of TREC's work is the importance of organizational context to support the implementation of interventions to improve staff outcomes. Given the difference in the organization and delivery of LTC services across Canadian provinces [4], this study will generate much-needed data for enhanced and targeted planning and decision-making in the Atlantic LTC sector. Findings from this study will support a greater understanding of our LTC work environment and workforce, and to use these regional data to determine where knowledge users can introduce interventions to improve staff quality of work life.

Expected Findings

Concerns about the LTC workforce have existed for some time, but these have heightened since the COVID-19 pandemic [41]. The pandemic brought unprecedented challenges to LTC and staff were forced to navigate these stressors while maintaining the highest standards of care under difficult and often unsafe conditions. We expect to verify the extent to which these conditions continue to impact staff's health and well-being, including stress, anxiety, and quality of work life, and assess whether care aides continue to report a poorer quality of work life than other LTC staff as reported in a Nova Scotian study in 2021 [48]. This Nova Scotian study's finding is significant as it underscores the distinct struggles care aides face in LTC. These struggles may stem from providing direct care to increasingly complex residents or they may be associated with undervaluing of their work within an LTC work environment (eg, low pay, limited education), or both.

Should our research findings, across LTC settings and geographical locations, be consistent with those of the study by Keefe et al [48], it will provide further evidence to advocate for tailored supportive interventions specifically designed for care aides. For instance, our findings could inform policies related to the minimum educational requirements of care aides, which are currently lacking in some Atlantic Canadian provinces. Research findings could also support the need for job redesign, particularly efforts to provide care aides with more formal interaction within the workplace. Enhancing care aides' inclusion into decision-making processes, providing mentorship programs, or enriching team-based care in a way that acknowledges and values the perspective that care aides bring will enable greater connection to their workplace [16,49,50]. Such approaches could recognize the vital contributions of care aides, affirming their roles as essential members of care teams, and enhancing their status within the workplace.

We are confident that our study will provide data to assess recent policy initiatives within Atlantic Canada regarding the recruitment of internationally educated nurses to address the staffing shortage in LTC. These efforts include targeted recruitment campaigns, streamlined credentialing processes, and both professional and personal support programs. In the short term, these efforts appear to be successful as evidenced by the increasing number of nurses who have migrated to the region from targeted countries. However, despite these short-term successes, little is known about the long-term sustainability and effectiveness of these recruitment strategies, especially in terms of retention and overall job satisfaction. This gap is important because the long-term success of these initiatives is crucial for ensuring that Atlantic Canada can maintain a stable and skilled health care workforce in the face of ongoing human resource challenges. Our data will offer valuable insights not only into the work patterns of these migrant workers but also into their work integration experiences, including job satisfaction, relationships with colleagues, and their intentions to leave their current roles. Such information will be crucial for understanding the true impact of international recruitment efforts and for identifying areas where improvements can be made to enhance retention and overall workforce stability in our region.

It is also expected that our findings will be able to provide recommendations for how to address the deficits in the LTC system that have been exposed during the COVID-19 pandemic [51]. As the Atlantic provinces are home to the oldest population in Canada, policy makers require region-specific data to ensure sustainable and quality LTC is available for those who need it. Efforts to provide quality LTC must recognize that work conditions are care conditions, and consider the context where care takes place. The results of this study will support workforce planning and provide much-needed data on the LTC sector's current and future capacity. Study findings promise to identify elements in the work environment that are amendable to change and enable policy makers to develop strategic responses needed to support care staff, enhance worker health and well-being, and ultimately create the conditions that maximize staff's ability to provide quality care.

Limitations

The study has a number of limitations. While it is anticipated that there will be great interest among the LTC sector to participate in this research, it is possible that some homes may still be recovering from the pandemic or have human resources challenges that preclude them from participating in the study.

We are using a stratified random sample to ensure provincial representation but the strata used in the sampling frame need to be adapted to reflect the uniqueness of each province. For example, language (French and English) is a stratum used only in the sample of LTC homes in New Brunswick, and the ownership model (ie, public, private for-profit, and not-for-profit) is only being used with the LTC homes in Prince Edward Island and Nova Scotia. While the decision to modify these strata was made to ensure adequate representation of subgroups within each province, we recognize the need for our data analysis procedures to account for these differences. We will perform rigorous comparisons between provincial data to identify and account for differences in strata. If necessary, we will use statistical techniques such as multilevel modeling to account for differences across provinces. We will also acknowledge any potential threats to external validity that may arise as a result of our sampling plan during our dissemination activities.

Acknowledgments

The authors have received funding from the Canadian Institute of Health Research (FRN 186055), Research Nova Scotia (RNS 2022-2407), Newfoundland and Labrador Centre for Health Research, Nova Scotia Health, Health Prince Edward Island, and Research New Brunswick.

Data Availability

The datasets generated or analyzed during this study are not publicly available due to limited access to the University of Alberta Health Research Data Repository where they are housed. Data are available from the corresponding author on reasonable request.

Authors' Contributions

JMK is the lead researcher and nominated principal investigator who received Canadian Institute of Health Research, Research Nova Scotia, and Health Prince Edward Island funding. CAE is the principal investigator of the Translating Research in Elder Care research program whose surveys are used in the study. CAE and RM are co–principal investigators and RM received funding from Research New Brunswick. LEW, CM, AM, and MJH are coinvestigators on the research proposal. RM and JMK drafted the manuscript. MJH and CAE provided input into the statistical analysis for the study. All authors contributed to the manuscript and approved the submitted version.

Abstract

Background: Transgender and nonbinary individuals have received increasing attention within HIV research, with studies documenting the pervasive role stigma plays in creating and sustaining health inequities. However, the proliferation of HIV stigma research with this population has also raised concerns about research practices that may unintentionally stigmatize or retraumatize the very communities they are designed to benefit. Conducting stigma research is critical for generating accurate information about HIV epidemiology, risk and protective factors, and intervention strategies for transgender and nonbinary individuals. Yet, little research has directly examined the experiences of transgender and nonbinary individuals when participating in these studies or identified specific research practices (eg, recruitment materials or study framing, choice of specific survey measures, data collection protocols, and researcher behaviors) that may influence study participation, retention, and data quality. Equally important, research has not adequately examined the potential for unintended harm due to emotional distress experienced by participating in such research and what specific strategies might mitigate against potential distressful research experiences.

Objective: This study aimed to develop a set of empirically based trauma-informed guidelines for conducting HIV-related stigma research with transgender and nonbinary individuals to increase researchers' capacity to recruit and retain transgender and nonbinary individuals in HIV-related stigma research, enhance the quality of data collected, and reduce unintentional harm in stigma research methodology.

Methods: The study will engage in primary data collection using both qualitative and quantitative methodology. First, we will use in-depth qualitative interviews with 60 participants representing 3 participant groups: researchers, mental health clinicians, and transgender and nonbinary individuals who have participated in HIV-related and sexual health research. Second, the qualitative findings will be used to develop an initial set of survey items representing a preliminary set of guidelines. Third, we will engage 75 participants in a 3-round modified Delphi method, to refine the guidelines and promote their acceptability among key stakeholders.

Results: The study is funded by the National Institute of Mental Health starting in July 2022 and data collection began January 2023. The study's findings underscore the critical importance of adopting a trauma-informed approach to HIV stigma research with transgender and nonbinary individuals.

Conclusions: To make meaningful strides in stigma research, it is imperative to examine experiences of stigma that may happen within the research context and identify strategies for improving data quality and reducing unintentional harm in study recruitment, methodology, implementation, and dissemination.

Introduction

Background

Over the past 2 decades, transgender individuals, particularly Black and Latina transgender women, have received increasing attention within HIV research [1-9]. Such research has consistently documented the pervasive role stigma plays in creating and sustaining health inequities among this population. However, this research proliferation has also raised questions about practices that may unintentionally stigmatize or retraumatize the very communities they are designed to benefit [4,10-15]. One area of particular concern is the measurement of stigma as part of HIV-related research with transgender and nonbinary individuals. First, there is concern that specific items within commonly used measures may unintentionally recreate or activate stigma. For example, many stigma and minority stress scales [16-19] include items that may be experienced as stigmatizing (eg, "Being transgender is disgusting to me") [19] or ask participants to recount and relive traumatic experiences (eg, history of physical and sexual violence, family rejection, and experiences of discrimination and harassment) to document their association with negative affect or health behavior [2]. There has been considerable debate within the larger field of trauma-related research as to whether recalling and answering questions about past trauma has negative or positive consequences for study participants [20-29]. However, there is surprisingly limited research within HIV science on the potential emotional impacts of participating in stigma research. Second, there are no evidence-based guidelines for person-centered, trauma-informed, and actively destigmatizing implementation of HIV stigma research. Conducting stigma research is critical for generating accurate information about HIV epidemiology, risk and protective factors, and intervention strategies for transgender and nonbinary individuals. Yet little research has directly examined the experiences of transgender and nonbinary individuals when participating in these studies, or identified specific research practices (eg, recruitment materials or study framing, choice of specific survey measures, data collection protocols, and researcher behaviors) that may influence study participation, retention, and data quality [30]. Equally important, research has not adequately examined the potential for unintended harm due to emotional distress experienced by participating in such research and what specific strategies might mitigate against potential distressful research experiences.

Impact of Stigma on HIV-Related Outcomes

Research documenting multiple and intersecting structural factors, including racism, sexism, transphobia, homophobia, and other systems of stigmatization, oppression, and traumatic victimization that contribute to the disproportionately high rates of HIV infection and HIV-related morbidity in this population [2-4,6,7,14,31-35]. One of the strengths of HIV research in this area has been its intersectional focus, [36] as well as the acknowledgement that stigma operates at individual, interpersonal, and structural levels. Intersectional approaches demonstrate the ways in which HIV-stigma and other sources of stigma occur simultaneously and interact to impact transgender and nonbinary individual's daily experience, health outcomes, and engagement with care. Research suggests that transgender and nonbinary individuals may experience this impact as traumatic, and support trauma-informed approaches that seek to mitigate retraumatization within the provision of care [37-43]. Transgender and nonbinary individuals health disparities have been directly linked to intersectional and multidimensional stigma processes [37,41,44,45], underscoring the extent to which this approach is essential for advancements in transgender and nonbinary individual–specific stigma frameworks, measurement, and intervention development.

Potential for Unintentional Harm

Within the fields of clinical psychology and neuroscience, there has been intense debate about the impact of research about traumatic experiences on study participants [20-29]. Some evidence suggests that such research might lead to traumatization or cause further harm to those with previous exposure to violence or abuse. One meta-analysis of studies about traumatic events found that approximately 25% (IQR 4.3%-50%) of adult participants reported distressing impacts (ie, unexpected upset, negative emotions, unwanted thoughts, or distress) as a result of research participation. Although, most people find that participating in trauma research is distressing, they also report that they find it worthwhile and meaningful [28]. Neuroscience research on memory reconsolidation suggests that the context and content of memory reactivation may determine its harmful or therapeutic impact. Data indicate that research participants anticipate or attribute negative impacts to study participation; in 1 large-scale study of traumatic experience, 94% of participants rated their participation as more than minimal risk, with participants that had greater previous exposure to trauma reporting higher levels of distress [46]. However, limited research within the field of HIV has directly examined the potential impact of stigma research itself on transgender and nonbinary participants.

Impact on Engagement in HIV Prevention and Care

Growing recognition of the importance of community partnership for HIV research with transgender and nonbinary individuals has led to a rise of studies that rely on community health centers or other service agencies for research recruitment and implementation [47-50]. It is well established that experiences of stigma within these settings may negatively impact transgender and nonbinary individual's willingness to receive needed health care, including HIV testing, treatment, or pre-exposure prophylaxis [37-39,51,52]. If stigmatizing or harmful research is conducted within these settings, there is the potential to reduce transgender and nonbinary individual's trust in the very organizations upon which they depend to access life-saving services. As such, it is essential to understand

whether and under what conditions HIV stigma research may result in unintentional harm or stigmatization of transgender and nonbinary individuals, and how harmful impacts can be reduced.

Impact on Recruitment, Engagement, and Data Quality

Evidence indicates that mistrust of research projects, study teams, or settings leads to difficulties with recruitment and retention of study participants and may be associated with false or misleading responses to study measures. Studies indicate that research mistrust is particularly strong among transgender and nonbinary participants, who may report feeling used or mistreated within HIV research contexts [53-55]. In 1 study, transgender women reported that research scripts and procedures can be experienced as microaggressions [55]. Critical HIV-related stigma research is likely to underperform and fail to provide much needed data on stigma processes if participants are discouraged from participating or alienated from the research enterprise by perceptions that stigma research is itself stigmatizing [56].

Need for Empirically Grounded Research Guidelines

Many HIV stigma studies report incorporating intentionally affirming components into their research practice, such as measures of self-esteem, community-connectedness, or other resilience factors [57,58]. However, there has been no systematic compilation of these strategies, or analysis of their potential use in reducing stigma experiences. This research gap results in a lack of consensus of what is meant by trauma-informed HIV stigma research, as well as gaps in how to best implement and evaluate stigma-reducing measures in HIV research practice. Outside of HIV research, there are models for patient-centered, trauma-informed health research [59] that could be adapted to better inform implementation strategies, but such adaptation needs to be grounded in empirical data from participants, researchers, and practitioners with direct experience in the field.

Theoretical Frameworks

This study is based on an interdisciplinary integration of minority-stress and trauma-informed theoretical frameworks to explain health inequity. Minority stress theory [60] is a strong epidemiological framework for explaining disparity but is less precise in specifying mechanisms of an individual stigmatized person's behavior, feelings, or experience. To complement this theory, we incorporate a conceptual framework developed specifically to support the mental health of TGNB individuals [61], which combines 2 trauma-informed care models to guide our research questions and analysis. The first, developed by Fallot & Harris [62,63], emphasizes five principles of interaction: safety, trustworthiness, collaboration, choice, and empowerment. The second, guiding principles of trauma-informed care created by the Substance Abuse and Mental Health Services Administration within the US Department of Health and Human Services, focuses on attention to cultural, historical, and gender issues that impact power relationships, privilege, and oppression [64]. This trauma-informed theoretical approach attends to the potential presence of trauma-related symptoms on the thoughts, feelings, needs, and reactions of TGNB research participants, and aims to actively disrupt retraumatization through the creation of interpersonal processes and settings that emphasize safety, trust, collaboration, empowerment, and choice. Rather than focusing on isolating and describing stigmatizing internal and external experiences that happen to a marginalized person, a trauma-informed approach to stigma research centers how those marginalizing experiences thwart a survivor's wellness, healing, and resilience [65]. Trauma-informed approaches are, therefore, inherently person-centered, and strengths-based in that they entail recognition of the signs and symptoms of trauma in an individual's behavior and guide clinical responses to minimize negative impact on the survivor's natural recovery process [64]. These characteristics are likely to support greater engagement, quality, and benefit of HIV research among transgender and nonbinary individuals [55].

Study Aims

The primary aim of this study is to develop empirically informed, trauma-informed guidelines for conducting HIV-related stigma research with transgender and nonbinary individuals. This work seeks to address critical gaps in the field by improving recruitment, retention, and data quality while reducing the potential for harm during research participation. Specifically, the study focuses on the following aims. First, this study aims at understanding participant experiences by conducting in-depth interviews with transgender and nonbinary participants who have engaged in HIV or sexual health-related research to explore their experiences, including factors that contribute to or mitigate distress, stigma, and harm. This aim seeks to uncover the nuanced challenges and opportunities for designing research that supports participant well-being. Second, this study aims to gather stakeholder perspectives by conducting in-depth interviews with researchers and mental health clinicians to identify current practices, challenges, and strategies for implementing trauma-informed and person-centered approaches in HIV stigma research. This aim emphasizes understanding the perspectives of professionals who interact with transgender and nonbinary populations in research and clinical settings. Third, this study aims to develop and refine trauma-informed guidelines by using findings from the first and second aims to create a preliminary set of trauma-informed research guidelines. These guidelines will be refined through a modified Delphi process involving transgender and nonbinary individuals, researchers, and mental health professionals to ensure their relevance, acceptability, and applicability across diverse research contexts.

By integrating qualitative interviews with a structured consensus-building approach, this study aims to establish actionable and evidence-based recommendations. These guidelines will enhance the ethical rigor and methodological quality of HIV stigma research, contributing to improved health equity and reducing unintentional harm in research practices.

Methods

Study Objectives

Our study is designed to address a critical gap in existing HIV stigma research with transgender and nonbinary individuals by examining experiences of stigma within the research context

and identifying strategies for improving data quality and reducing unintentional harm in study recruitment, methodology, implementation, and dissemination. This study will engage in primary data collection using both qualitative and quantitative data collection methodology. To accomplish the study aims we will first, conduct in-depth interviews with transgender and nonbinary individuals (n=30) to better understand how they understand and experience participation in HIV-related stigma research, including willingness to respond to questions about stigma and factors that may contribute to or mitigate potential distressing or stigmatizing experiences within the research context. Second we will conduct in-depth interviews with 2 groups: investigators who conduct HIV-related stigma research with transgender and nonbinary individuals, to better understand perceptions of and experiences with conducting stigma research with transgender and nonbinary individuals and compile existing strategies for mitigating harm (n=15) and mental health professionals (n=15) who provide care to transgender and nonbinary individuals to better understand ways in which experiences of stigma can be measured and studies can be conducted in a manner that is person-centered, trauma-informed, and actively destigmatizing. Third, we will develop a set of empirically informed guidelines for conducting HIV stigma research with transgender and nonbinary individuals. We will use a modified Delphi technique to engage a panel of transgender and nonbinary individuals, mental health providers, and researchers in a consensus building process to identify practical recommendations for person-centered, trauma-informed recruitment, measurement, and conduct of HIV-related stigma research with transgender and nonbinary individuals.

The sample sizes for this study were designed to ensure robust data collection and meaningful analysis across all phases. For aims 1 and 2, the sample size was chosen based on recommendations for similar qualitative inquires to ensure thematic saturation and demographic diversity [66-69]. In aim 3 the Delphi panel will consist of 75 participants (25 transgender and nonbinary individuals, 25 researchers, and 25 clinicians), aligning with best practices for achieving reliable consensus and providing robustness against attrition [68,70,71]. These sample sizes ensured methodological rigor, demographic representativeness, and the capacity to develop empirically informed, trauma-informed research guidelines.

Qualitative Interviews

Aim 1: Semistructured Qualitative Interviews With Transgender and Nonbinary Individuals

Overview

In aim 1, we will conduct a series of in-depth semistructured qualitative interviews with 30 transgender and nonbinary individuals.

Participants

Our sample will be stratified by gender identity and HIV status. We will ensure that >40% of participants will be aged 18-29 years and at least 70% people of color, due to the disproportionately high HIV infection rates among these populations and lack of access to HIV prevention and treatment services. Eligible participants will be aged >18 years; identify as transgender, nonbinary, or gender diverse; and have participated in an HIV prevention or treatment related research study.

Recruitment

Participants will be recruited through existing research panels, transgender health-related social media and listservs, and word of mouth. Interested participants will fill out an eligibility screener survey. For those who are deemed eligible, they will be provided a link to the study website [72] to schedule their interview at a day and time of their choice, with the study team member of their choice. Participants will be provided with a link to an electronic consent form on the study website, as well as the interview guide before the interview. The interviewer will review the consent form with the participant and obtain verbal consent before conducting the interview.

Interview Procedures

Interviews will be designed to last no longer than an hour and a half, and participants will be compensated US $80 for their time. All interviews will contain a core set of questions to assess how transgender and nonbinary individuals understand and experience participation in HIV-related stigma research, including decision-making processes around participation, perceptions of study purpose, risks and benefits, participants' willingness to respond to questions on stigma, factors that may contribute to or mitigate potential distressful or stigmatizing experiences within the research context, and opinions of the research after participation. Participants will also be asked to identify specific strategies to enhance researcher's capacity to design and implement stigma research that is person-centered, trauma-informed, and actively destigmatizing.

Aim 2: Semistructured Qualitative Interviews With Researchers and Mental Health Professionals

Overview

In aim 2, we will conduct a series of in-depth semistructured qualitative interviews with 2 groups, investigators who conduct HIV-related stigma research with transgender and nonbinary individuals (n=15) and mental health providers who provide care to transgender and nonbinary adults (n=15).

Participants

Investigators (n=15) will be stratified by career stage: early (n=5), middle (n=5), or late (n=5) stage investigators to represent a range of perspectives and experiences with conducting stigma research with transgender and nonbinary individuals. Our sample of mental health professionals (n=15) will include mental health clinicians with a master's degree in either social work, marriage and family therapy, or mental health counseling or a doctoral degree in clinical psychology (PhD or PsyD) who provide individual or group therapy to transgender and nonbinary adults (aged 18 years or older) and have training in providing trauma-specific or trauma-informed clinical practice.

Recruitment

Early, middle, or late-stage investigators with existing HIV-related transgender health research will be identified by Google Scholar and the National Institutes of Health (NIH) RePORTER. Investigators will be contacted by a study team

member by email and invited to participate in our study. Mental health professionals will be recruited through professional networks and word of mouth. Interested participants will fill out an eligibility screener survey. For those who are deemed eligible, they will be contacted by a study team member to schedule their interview. Participants will be provided with a copy of the study consent form. The interviewer will review the consent form with the participant and obtain verbal consent before conducting the interview.

Interview Procedures

Aim 2 will consist of 30 semistructured interviews with 2 groups, investigators who conduct HIV-related stigma research with transgender and nonbinary and mental health clinicians who provide counseling to transgender and nonbinary adults (aged 18 years or older). Interviews are designed to last no more than an hour and a half, and participants will be compensated US $50 for their time. *Interviews with investigators* will assess understanding experiences of conducting HIV-related stigma research with transgender and nonbinary individuals, including perceptions of study purpose, risks and benefits, question and measurement selection and creation, and factors that may have contributed to or mitigated against distressful or stigmatizing experiences within the research context. *Interviews with mental health professionals* will focus on identifying ways in which experiences of stigma can be measured in a manner that is person-centered, trauma-informed, and actively destigmatizing, including suggestions for using person-centered, trauma-informed language when developing questions or measures, and strategies to assist researchers around developing protocols and procedures to assess for and address potential distressful situations within the research context.

Development of Interview Guide (Aims 1 and 2)

The interview guide was developed through a collaborative, trauma-informed approach to ensure that all protocols and procedures reflected the study's goals and minimized potential harm to participants. This process involved a 3-step methodology with the transgender-identified research team. First, the team conducted an in-depth review of existing trauma-informed care models and adopted the framework developed by The Institute on Trauma and Trauma-Informed Care (ITTC) at the University of Buffalo, which emphasizes the principles of safety, choice, empowerment, collaboration, and trustworthiness. Second, components from ITTC's Trauma-Informed Organizational Change Manual [73] were adapted and integrated into the research procedures, including participant recruitment, consent, interview data collection, and analysis, to align all research activities with a trauma-informed approach. Third, the interview questions, prompts, and scripts were mapped to the ITTC framework to minimize risks of retraumatization and ensure a supportive environment for participants. Interview questions were refined to align with the study's 4 overarching research questions and tailored to the perspectives of the 3 participant groups, researchers, community stakeholders, and mental health clinicians, ensuring comparability and analytic integrity across the study phases (Multimedia Appendix 1).

Qualitative Analysis Plan (Aims 1 and 2)

Data collected in aims 1 and 2 will be analyzed using rapid qualitative analytic methods, [74-77] to identify key themes that best reflect the research decision-making process, perceptions and experiences of transgender and nonbinary individuals. We will assign four trained team members to summarize a subset of the interview transcripts independently, extracting key data into a summary template based on our framework and interview guide; triangulate key themes in the transcript through documenting observations, quotations, and reflections into the summary template; meet to compare and combine templates for each interview; and create a comprehensive matrix identifying common themes and contrasts across and within stakeholder groups.

Application of Knowledge Gained in Aims 1 and 2 to Aim 3

In preparation for aim 3, we will use the themes that were identified in the qualitative interviews to develop a preliminary list of survey items for use in the first stage of the modified Delphi process (aim 3) [78]. The use of qualitative interviews in a pre-Delphi phase [78-80] allows for all relevant stakeholder groups to guide the Delphi process by contributing to the development of the first round Delphi survey. To ensure that the Delphi survey items describe and capture the perceptions and experiences of all the stakeholder groups participating in aim 3, we will develop items using the language and narratives participants use during their interviews [78,80,81]. For example, the language used to describe and the meaning behind core concepts within stigma research may differ distinctly between stakeholder groups and could contribute to inaccurate measurement and interpretation of research findings. By integrating language from each stakeholder group into the Delphi survey we hope to better reflect the experiences of all relevant stakeholders involved in this process [79,82,83]. We will then compare the themes and associations derived from Aims 1 and 2 to better understand areas of concordance and discordance between stakeholder groups [78-81,84]. For example, it is possible that interview findings highlight similar domains across participant groups that are key to understanding and improving stigma research procedures, yet what is important to address within these domains may differ by stakeholder group. The use of qualitative interview findings will help further parse out and include survey items that address this complexity.

Aim 3: Development of Empirically Informed Guidelines for Conducting Stigma Research With Transgender and Nonbinary Individuals

Overview

To accomplish aim 3 we will use a 3-round modified Delphi method [85] to develop a set of empirically informed guidelines for conducting HIV-related stigma research with transgender and nonbinary individuals. The modified Delphi method will include 4 structured steps: panel formation, quantitative survey development, data collection and analysis, and guideline development [68,69,85,86].

Panel Formation

We will recruit 75 participants from the following 3 stakeholder groups, transgender and nonbinary individuals (n=25), researchers (n=25), and mental health professionals (n=25). Our sample size is based on previous studies which demonstrate that this sample size provides stable results robust to participant attrition or inconsistent responding [68,70,71]. Individuals who participated in aims 1 and 2 will be recruited to participate in aim 3.

Survey Development

Survey development will occur in 3 steps. First, the transcripts and codes from aims 1 and 2 will be reviewed to draft the initial survey items based on the most salient themes and domains pertinent to all aspects of the research process, including recruitment, measurement, retention, and dissemination. Each survey item will be designed to capture a single idea and be easily understood by participants. Second, we will develop a rating scale for the Delphi survey items that best capture the original content from aims 1 and 2. Third, we will finalize the items and organize the survey into the following 3 sections, Trauma-Informed Principles for Research Practice, Trauma-Informed Research Standards, and Trauma-Informed Research Competencies.

Quantitative Data Collection and Analysis

A survey will be administered online by REDCap (Research Electronic Data Capture) [87,88] at 3 time points (rounds 1-3). Participants will be compensated US $40 for their time after the completion of each survey. In each round, participants will be asked to rate each item on a 5-point scale indicating whether the item should be included in the research guidelines. Survey items will be categorized according to the decision matrix in Textbox 1, which has been widely used in previous studies [85,86]. In round 1, all items created by our study team will be included in the survey. At the end of each survey section in round 1, participants will be encouraged to provide feedback on items (ie, how to improve wording or messaging) and suggest novel items to include [68,85,86]. After round 1, we will analyze survey responses, including participant comments, and edit existing or draft new items to be included in the round 2 survey based on participant suggestions. In the second-round survey, participants will rerate items that receive a near miss in the first round and rate new items the research team crafted based on suggestions from participants in round 1. At the end of rounds 1 and 2, participants will be sent a report outlining survey results. Statements to be rerated will be displayed with the overall percentages for each rating and then by stakeholder group so participants can compare their response with others' responses. The report will allow participants to consider whether to retain or change their ratings in the next round. Finally, in round 3, only items rated for the first time in round 2 or received a near miss rating will be included in the final survey (Textbox 1).

Textbox 1. Decision matrix for developing expert consensus.

Endorsed

- If between 80%-100% of participants of each group rate a statement as either essential or important, it will be endorsed as a guideline.

Re-rated (near miss)

- If between 80%-100% of participants of each group rate a statement as either essential or important, it will be endorsed as a guideline.

Rejected

- If none of the above conditions are met, a statement will be rejected for inclusion as a guideline.

Guideline Development

At the end of round 3, the research team will create a document comprised of the endorsed items to be widely disseminated. Once the document is completed, participants will be invited to attend a 1-day virtual convening where we will present and discuss the final guidelines document as well as the goals and next steps for dissemination and implementation.

Ethical Considerations

Ethics Approval

The study received expedited approval from the City University of New York Human Research Protection Program (#2022-0280-Hunter).

Informed Consent

Participants were electronically sent a consent form and interview guide in advance to review at their own pace once their interview was scheduled. Before the start of each interview a trained study team member reviewed the consent form with participants and obtained verbal consent to participate. Before completing the Delphi survey participants affirmed that the agreed to participate.

Privacy and Confidentiality

All data were anonymized to protect participant identities.

Compensation

Participants were compensated US $40- US $80, depending on the study phase, to ensure fairness.

Results

The study was funded by the National Institute of Mental Health from July 1, 2022, to June 30, 2024. The study successfully achieved its specific aims. We successfully completed data collection and analysis for aims 1 and 2 recruiting 30

transgender and nonbinary participants (aim 1) and a total of 34 participants in aim 2 (17 researchers and 17 clinicians). As outlined above, we directly applied the knowledge gained to the development of the preliminary set of guidelines voted on in aim 3. The Delphi process for aim 3 is entering its final survey round, and we are actively preparing the finalized guidelines for dissemination (Table 1).

Table 1. Study timeline and progress by aims.

Phase	Planned timeline	Current progress
Aim 1: interviews	January 2023-June 2023	Completed (30 participants)
Aim 2: interviews	July 2023-December 2023	Completed (34 participants)
Application of knowledge gained from aims 1 and 2	January 2024-March 2024	Completed
Aim 3: Delphi survey	March 2024-June 2024	Ongoing (final survey round)

Discussion

Principal Findings

This study addresses a critical gap in HIV-related stigma research by developing trauma-informed guidelines to improve the quality of research involving transgender and nonbinary individuals. HIV stigma research has historically documented the pervasive role of stigma in shaping health inequities but has largely overlooked the unintended harms participants may experience within the research process itself. By using an interdisciplinary, trauma-informed approach grounded in qualitative data collection and a modified Delphi method, this study emphasizes principles of safety, trustworthiness, collaboration, empowerment, and cultural sensitivity. The findings aim to enhance participant engagement, reduce emotional distress, and improve data quality, thereby advancing ethical and effective research practices. Through active collaboration with community members, researchers, and clinicians, this project provides a model for addressing stigma while centering participant well-being and resilience.

The study's findings underscore the critical importance of adopting a trauma-informed approach to HIV stigma research with transgender and nonbinary individuals. Interviews with community members, researchers, and clinicians revealed the significant benefits of trauma-informed principles for enhancing participant trust, retention, and engagement while also improving the quality of collected data. Key findings include the following.

Higher Data Quality and Participant Engagement

Stakeholders across all groups emphasized that trauma-informed practices create safer and more supportive environments for participants, leading to more honest and comprehensive data. For instance, researchers noted that flexible interview formats and clear communication protocols increased participant willingness to share sensitive information.

Improved Team Dynamics and Research Outcomes

Researchers and clinicians reported that adopting trauma-informed principles, such as trustworthiness and collaboration, not only benefits participants but also enhances team cohesion and efficiency in implementing study protocols.

Ethical and Methodological Standards

The findings contributed to the development of trauma-informed research standards, including guidelines for ethical recruitment, harm minimization, and culturally sensitive data collection protocols. These standards prioritize participant autonomy and recognize the compounded effects of intersecting identities, such as race, gender, and sexual orientation.

Institutional Support Needs

Participants consistently highlighted the necessity of institutional support for implementing trauma-informed practices. Recommendations include increased funding, researcher training, and revisions to institutional review board protocols to ensure systemic integration of these practices into research frameworks.

Guidelines for Trauma-Informed Research

Preliminary guidelines developed through this study emphasize the integration of trauma-informed principles into every aspect of the research process. These include ensuring safety and dignity, using affirming language, and providing participants with opportunities for feedback and choice throughout their involvement in studies.

The findings collectively highlight the transformative potential of trauma-informed approaches for improving HIV stigma research practices. By addressing participant needs and mitigating harm, these practices ensure ethical rigor and enhance the impact of research on health equity for transgender and nonbinary populations.

Comparison to Previous Work

Previous research on HIV stigma has predominantly focused on documenting stigma and its health impacts without critically examining research practices themselves. Our study extends the NIH's Stigma and Discrimination Toolkit [89] by addressing the need for guidelines to reduce stigma within the research context. This complements existing frameworks and fills a critical gap. By focusing on the process rather than outcomes alone, this research provides a novel contribution to the field.

Strengths and Limitations

The study's strengths include a diverse, multidisciplinary research team with significant community representation, innovative use of the Delphi method, and the integration of trauma-informed principles. Limitations include the absence of a bioethicist on the team and potential challenges in generalizing findings to other populations beyond transgender and nonbinary individuals. Future research could explore the applicability of these guidelines in other contexts and populations.

Future Directions

Key next steps include developing researcher training modules and advocating for institutional review board and institutional policies that mandate trauma-informed practices. These guidelines could extend to other areas of health inequities research.

Dissemination Plan

This study prioritizes transparency and community engagement in disseminating findings. The dissemination plan aligns with trauma-informed principles by emphasizing accessibility, mutuality, and collaboration with the community and stakeholders.

Community-Focused Dissemination

A dedicated study website was created to provide participants and stakeholders with clear and accessible information about the study aims, process, and team. This platform has been instrumental in sharing updates, progress, and findings during the study period.

Two newsletters were distributed to participants and posted on the website to update stakeholders about study progress and preliminary findings. These newsletters ensured continuous engagement with the community and maintained trust.

Final study findings will be summarized in community-friendly formats, such as infographics and plain-language reports, and shared through newsletters and the website. This ensures that findings are accessible to diverse audiences, including those with varying levels of education and technical expertise.

Academic and Professional Dissemination

Findings have been shared at national and international conferences, ensuring visibility within academic and professional circles. Future presentations will focus on engaging institutional review boards, research institutions, and policy makers.

The trauma-informed research guidelines will be published in academic journals and policy briefs, targeting audiences involved in HIV research, social work, and public health.

Workshops and webinars will be conducted for researchers and community health organizations to facilitate the implementation of the guidelines. These sessions will provide practical strategies for adopting trauma-informed practices.

Collaborative Dissemination

The final guidelines will be shared during virtual or in-person gatherings with study participants and community members. These sessions will include opportunities for participants to provide feedback and discuss the next steps for implementation.

Findings will be disseminated through partnerships with community-based organizations and health centers. This approach ensures that the guidelines reach the people and institutions directly involved in HIV stigma research and care.

Sustainability and Long-Term Impact

Recommendations for integrating trauma-informed practices into institutional review board review processes, funding applications, and researcher training will be disseminated to key institutions. This will include targeted briefings and resource-sharing with institutional review boards and funders to encourage systemic change.

Training materials, including video tutorials and toolkits, will be developed to help researchers and institutions adopt the guidelines. These materials will be shared through academic and community networks. By using these dissemination strategies, this study aims to ensure that its findings are accessible, actionable, and impactful across diverse audiences, including researchers, policy makers, and the communities at the center of the research.

Conclusion

To make meaningful strides in stigma research, it is imperative to examine experiences of stigma within the research context and identify strategies to improve data quality while reducing unintentional harm in study recruitment, methodology, implementation, and dissemination. This study addresses these critical needs by developing empirically informed trauma-informed guidelines for conducting HIV-related stigma research with transgender and nonbinary individuals.

Grounded in interdisciplinary theoretical frameworks and extensive collaboration with transgender and nonbinary participants, researchers, and clinicians, this study highlights the transformative potential of trauma-informed approaches. These guidelines emphasize the principles of safety, trustworthiness, collaboration, empowerment, and cultural sensitivity, demonstrating their capacity to enhance participant engagement, foster trust, and mitigate risks of retraumatization. Findings further underscore the importance of systemic institutional support, including training programs, funding mechanisms, and policy revisions at the institutional level, to ensure the widespread adoption of these practices.

The study achieved its goals by developing and refining these guidelines through rigorous qualitative analyses and a modified Delphi process. By embedding trauma-informed principles into research methodologies, this work sets a new standard for ethical and effective research practices. These guidelines have the potential to increase researchers' capacity to recruit and retain transgender and nonbinary participants in stigma research, improve the quality of collected data, and reduce the unintended harms of research participation.

Next steps include broad dissemination of the guidelines through community-friendly formats, workshops, and academic publications. These efforts will ensure that the findings are accessible to a diverse range of stakeholders, including researchers, clinicians, policy makers, and community organizations. By reshaping HIV stigma research methodologies, this work contributes to advancing health equity and ethical research practices, with implications for other high-priority populations and fields of health disparity research.

Acknowledgments

The authors wish to thank Alexander Harris, Amiyah Guerra, Lila Starbuck, and Ash Smith for their assistance with study administration and data collection. This study is funded by the National Institute of Mental Health (R21MH131477). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Data Availability

The datasets generated during and analyzed during this study are not publicly available to protect the identity of the participants, as some of the details mentioned in the qualitative interviews include information that could help identify the individual. Data are available from the corresponding author on reasonable request.

Authors' Contributions

AK contributed to conceptualization, methodology, writing original draft, writing review and editing, supervision, and funding acquisition. SAG managed methodology, writing review and editing, supervision, and funding acquisition. DB handled methodology and writing review and editing. ERC contributed to writing review and editing, project administration.

Abstract

Background: Wheelchair users live predominantly sedentary lifestyles and have a substantially higher risk for cardiometabolic disease and mortality compared to people without disabilities. Exercise training has been found to be effective in improving cardiometabolic health (CMH) outcomes among people without disabilities, but research on wheelchair users is limited and of poor quality.

Objective: The primary aim of this study is to examine the immediate and sustained effects of a 24-week, telehealth, movement-to-music cardiovascular (M2M-C) exercise program on core indicators of CMH among adult wheelchair users compared to an active control group. The secondary aim is to explore the beneficial effects of M2M-C exercises on cardiovascular capacity, physical activity, and quality of life. Intervention components include tailored exercises and remote performance monitoring, delivered via live videoconference training by a telecoach and asynchronous videos.

Methods: This study's design is a parallel-arm randomized controlled trial enrolling 132 physically inactive adult wheelchair users with poor cardiometabolic profiles. The M2M-C intervention group involves 24 weeks of virtual live and monitored home exercise training (3×/wk, 15-40 min/session), followed by a 12-week maintenance period where participants have access to an online media library of exercise videos. The control group involves 36 weeks of self-guided exercise through access to a media library of exercise videos, including videos for range of motion, muscle strength, and balance. The primary outcomes are cardiometabolic indicators of health, and assessors are blinded.

Results: Recruitment procedures started in January 2024 with the first participant enrolled on March 18, 2024. All data are anticipated to be collected by November 2027, and the main results of the trial are anticipated to be published by February 2028. Secondary analyses of data will be subsequently published. A total of 16 participants have been recruited as of paper submission.

Conclusions: The knowledge obtained from this trial will provide evidence to inform exercise prescriptions aimed at improving CMH among adult wheelchair users.

Introduction

Background

People with physical disabilities have higher risks of cardiometabolic disease than the general population. For example, studies have reported that as many as one-third of people with spinal cord injury (SCI) may be diagnosed with cardiometabolic disease (ranging from n=41, 29% to n=222, 34.1%), which is nearly twice as prevalent as reported in people without SCI [1-3]. Another study found that adults living with cerebral palsy or spina bifida are 52% more likely to experience any type of cardiometabolic morbidity than adults without cerebral palsy or spina bifida (n=15,302) [4]. Meta-analyses have demonstrated that conventional aerobic exercise, such as running, walking, and cycling at a moderate-to-vigorous intensity, are effective in managing indicators of cardiometabolic health (CMH) in the general population [5-9]. However, people with physical disabilities, particularly wheelchair users, are typically unable to engage in conventional modalities of exercise long enough to obtain CMH benefits. Wheelchair users include users of any wheeled devices for their primary means of mobility, such as manual and powered wheelchairs or motorized scooters, and may include individuals in a variety of disability groups, including those with SCI, cerebral palsy, spina bifida, multiple sclerosis, or limb loss. A total of roughly 5.5 million wheelchair users in the United States would benefit from an accessible aerobic exercise program to reduce their cardiometabolic disease risk [10].

However, there is limited evidence that aerobic exercise improves CMH among wheelchair users. Most evidence is observational and nearly all randomized controlled trials (RCTs) have small sample sizes limited to a single population (eg, those with SCI). There are no large confirmatory RCTs that demonstrate that aerobic exercise improves CMH in adult wheelchair users. A recent meta-analysis of 3 RCTs, with samples of 15-21 adults with SCI, determined that 6-weeks of aerobic exercise improved CMH among adults with SCI (ie, decreased fasting glucose and insulin and increased fasting high-density lipoprotein cholesterol fraction) [11]. Another meta-analysis of 16 pre-post and controlled trials with sample sizes of 5-20 adults with SCI determined that vigorous exercise training improved cardiorespiratory fitness in adults with SCI [12] (ie, increased peak power output, muscular strength, and time to fatigue) but did not improve CMH risk factors, such as blood pressure (BP), cholesterol, and insulin sensitivity. Noted limitations of these studies included small sample sizes, inclusion of participants already within healthy ranges for CMH at baseline, lack of a control group, use of laboratory-based training, and inclusion of a single population (those with SCI). Therefore, the finding that CMH measures did not improve must be interpreted with caution.

Interventions that have sought to improve physical activity levels have also failed to improve CMH among wheelchair users. The largest physical activity trial among wheelchair users (n=128), Workout on Wheels, increased self-reported physical activity by 17 min/wk, with no significant between-group differences in cardiorespiratory fitness or CMH measures [13]. Other recent lifestyle interventions (eg, behavioral coaching) have similarly failed to elicit significant CMH benefits among people with disabilities, even while achieving large sample sizes [14]. Thus, the exercise doses or intensity studied may be suboptimal for improving CMH among people with physical disabilities. Despite failures to improve CMH, many of these physical activity trials have informed the creation of the most recent guideline related to CMH for people with SCI [15,16]. Collectively, there is an urgent need for well-designed interventions that can provide an effective exercise dose for people with disabilities, including wheelchair users, while obtaining evidence for improving CMH through physical activity.

Rationale for Telehealth Exercise Program

A telehealth exercise program was developed to overcome the barriers of participation in exercise requiring individuals to leave their homes and use expensive equipment. This study uses an exercise program that includes various movement patterns that are coupled with elements of music and imagery, referred to as movement to music (M2M) [17]. The M2M program uses a range of different muscle groups allowing for a safer form of exercise than arm ergometry. Moreover, M2M incorporates a theory-driven telehealth delivery protocol that removes the most common barriers to participation in community and clinical exercise training studies (ie, cost, transportation, and time) [18,19]. The design of the movement-to-music cardiovascular (M2M-C) intervention is based on four key elements of social cognitive theory: self-efficacy, self-regulation, outcome expectations, and social support. These components are essential for promoting positive health behavior change. To effectively integrate these principles, the M2M-C program provides a structured, individualized, and progressively challenging exercise routine. Participants receive regular feedback and personalized guidance from M2M-C instructors and telecoaches, which helps build confidence and maintain motivation. In addition, the incorporation of music enhances movement quality and motor coordination [20] while serving as a powerful motivational tool [21]. By increasing enjoyment and improving mood, music makes exercise more appealing and engaging. This approach is consistent with the broader goal of promoting sustained physical activity among wheelchair users by addressing both psychological and physical barriers to exercise adherence.

To test whether the M2M program can improve CMH outcomes among wheelchair users, this study uses a parallel-group RCT with blinded assessors. The intervention group will use the M2M program, composed primarily of cardiovascular exercises (M2M-C), which will be compared to an active control condition using prerecorded non-M2M exercise videos. The M2M-C exercises were informed by disability exercise guidelines and reviews of relevant studies [22]. This study is referred to as the Cardiometabolic Health Intervention Using Music and Exercise

(CHIME) study. The primary aim is to examine the effects of a 24-week, synchronous M2M-C program on core indicators of CMH in adult wheelchair users with ≥2 cardiometabolic risk factors. The secondary aim will explore the beneficial effects of M2M-C exercises on cardiovascular capacity, physical activity, and quality of life. We hypothesize the M2M-C intervention will yield both immediate and sustained CMH outcomes among adult wheelchair users with poor cardiometabolic profiles.

Methods

Study Design

This study's protocol follows the SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) guidelines [23,24].

Aims and Design of this Study

This study's design includes three aims. The primary aim examines the immediate effect of a 24-week, synchronous M2M-C training protocol compared to a 24-week, asynchronous activity control on core indicators of CMH among 132 adult wheelchair users with ≥2 cardiometabolic risk factors. The secondary aim examines the immediate effect of M2M-C training compared to the active control condition on cardiovascular capacity, physical activity, and quality of life. The first tertiary aim evaluates the sustained effects of M2M-C training (24 to 36 wk) on physical activity participation. A second tertiary aim evaluates the potential response heterogeneity in CMH, cardiovascular capacity, and physical activity outcomes using prespecified moderator variables (eg, age, sex, body composition, diet, or ethnicity) to understand for whom the intervention is most effective.

This study's aims will be tested using a parallel-group, assessor-blinded RCT design. For primary and secondary aims, we hypothesize that a telehealth M2M-C program will lead to significantly greater improvements in CMH outcomes, peak oxygen consumption (VO_{2peak}), physical activity level, and quality of life from baseline to 24 weeks compared to controls. For the tertiary aim 1, we hypothesize that M2M-C participants will maintain physical activity levels from week 24 to week 36.

Participants

Recruitment

We are recruiting participants who receive health care from a large medical center residing in the southern United States through direct referrals from health care professionals (eg, physicians or therapists) and distribution of study materials (eg, flyers, newsletters, or advertisements) to various clinics, hospitals, and medical rehabilitation service providers.

Eligibility Criteria

Adult wheelchair users who do not participate in health-enhancing volumes of exercise [16] and have ≥2 cardiometabolic risk factors are recruited for this study. Potential participants are prescreened for the eligibility criteria via telephone screening, medication list review, and physical screening. The onsite, physical screening to confirm eligibility occurs in the baseline visit.

Textbox 1 lists the specific participant eligibility criteria. Participants undergo a 2-stage screening process. The first stage, eligibility screening, is undertaken during a scripted phone screening by the project coordinator. The presence of CMH risk factors [25] is initially screened based on the self-reported height and weight to estimate the BMI and waist circumference, as well as the physician-prescribed medications that are relevant to CMH risk factors (eg, are you taking any medications related to increased BP? Has your doctor ever expressed concerns about your cholesterol level?).

Textbox 1. Inclusion and exclusion criteria.

Inclusion criteria

- Full-time or part-time use of a wheelchair device (manual wheelchair, power wheelchair, or electric scooter) self-reported as the primary means of mobility
- Aged ≥18 years
- Able to use arms to exercise
- Obtaining <90 minutes of moderate-to-vigorous intensity exercise per week in the last month
- ≥2 cardiometabolic risk factors:
  - Elevated waist circumference: ≥102 cm in men and ≥88 cm in women
  - Elevated triglycerides: ≥150 mg/dL
  - Reduced high-density lipoprotein cholesterol fraction: <40 mg/dL in men, <50 mg/dL in women
  - Elevated blood pressure (BP): ≥130 mm Hg systolic BP or ≥85 mm Hg diastolic BP
  - Elevated fasting glucose: ≥100 mg/dL
- No contraindication to participate in moderate-to-vigorous intensity exercise as informed by physician's medical clearance for exercise
- Not currently participating in a structured exercise program
- Able to converse and read in English

Exclusion criteria

- Medically unstable to perform the prescribed home exercise as determined by their physician
- High-level tetraplegia and unable to use arms to exercise
- No internet access was determined via self-report and internet speed test
- Positive pregnancy test
- Other physical conditions that can potentially prevent them from participating in an exercise routine (eg, pressure sore and open wound)

Justification for exclusion criteria

- Exclusion of pregnant individuals: The use of dual-energy x-ray absorptiometry for body composition analysis involves minimal radiation exposure. However, to eliminate any potential risk to the fetus, pregnant individuals will be excluded.
- Exclusion of individuals with medical instability: To minimize the risk of adverse events during the intervention, participants must be medically stable and have clearance from a health care provider to engage in moderate-to-vigorous intensity exercise.
- Internet access requirement: As the intervention is delivered via a tele-exercise platform, participants must have reliable internet access to ensure they can fully engage in the program, participate in live sessions, and receive remote monitoring and feedback.

The second screening stage involves a review of participation medications (self-reported) and a physical examination by laboratory staff. The medication list is obtained before the baseline visit using a secure electronic survey, and this study's staff reviews and verbally confirms them during the baseline visit. If the potential participants currently take ≥2 medications related to CMH risk factors, then they can proceed to the baseline physical examinations. Otherwise, they proceed to physical screening in the following order: manual BP, tape-measured waist circumference, and fingerstick blood sampling for triglycerides, high-density lipoprotein cholesterol fraction, and glucose using the lipid analyzer (Cholestech LDX, Abbott). If the potential participants meet the eligibility criteria with BP and waist circumference, fingerstick blood sampling is omitted.

Ethical Considerations

Ethical approval for this study was obtained from the University of Alabama at Birmingham Institutional Review Board on December 22, 2022 (IRB-300009718). This study's protocol adheres to all relevant ethical guidelines for research involving human participants, including medical records and patient information.

Informed consent will be obtained from all participants before the baseline visit or during the baseline visit. During the consent process, participants will receive detailed instructions about this study, including its objectives, procedures, potential benefits, and any associated risks or discomforts. They are also informed of their rights, including the ability to withdraw from this study at any time, to ensure that their participation is completely voluntary. This comprehensive approach is designed to ensure that all participants fully understand this study before providing their consent.

To protect participants' privacy, all data collected will be anonymized by assigning each participant with a study number to ensure that no personally identifiable information is directly linked to the data. Demographic, personal, and exercise test

data will be securely stored in REDCap (Research Electronic Data Capture; Vanderbilt University) and Box (Box, Inc), which are secure, password-protected databases. Access to these data will be limited to authorized research personnel, and all information obtained during this study will be used for research purposes only.

Participants will receive up to US $830 for their participation in this study. Compensation will be provided in stages, with participants receiving US $150 at the baseline assessment, US $200 at the 12-week assessment, US $250 at the 24-week assessment, and US $150 at the 36-week assessment. In addition, participants will receive US $40 for each of the two interview sessions to ensure fairness and transparency in recognition of their time and effort.

Power Analysis and Sample Size

We plan to recruit 132 participants into this study (66 per treatment group), with the expectation that at least 100 (50 per group) will complete this study. We anticipate an attrition rate of 23% based on the average attrition rate between the largest home-based behavioral interventions among wheelchair users (33%) [13] and our scoping review of exercise trials for people with various disabilities (13%) [14]. Due to the nature of the proposed exercise training involving one-on-one training and supervision, we believe that the role of exercise training coaches in this study will lead to lower attrition rates as it has in our past studies [26].

Power calculations were performed using nQuery (version 8.5; Statsols). For the primary outcome of CMH, we obtained SDs of biomarkers of this outcome from our pilot study among individuals with SCI (6-wk arm crank exercise training), including SDs of 43 mg/dL for total cholesterol, 4.3% for body fat, and 22.4 mg/dL for triglycerides [27]. Assuming a final sample size of 50 participants per group, a 2-sided 2-group *t* test (2-tailed), and a significance level of .05, we will have at least 80% power to detect differences of 24.4 mg/dL for total cholesterol, 2.5% for body fat, and 12.7 mg/dL for triglycerides (and greater) between the intervention and control groups as being statistically significant. This is equivalent to detecting an effect size (Cohen *d*) of 0.566 (a moderate effect size) as statistically significant between the two groups.

Outcomes

Outcomes are assessed at baseline, midintervention (12 wk), postintervention (24 wk), and follow-up (36 wk) time points. Physiological outcomes are assessed by anonymous-to-treatment assessors. The assessors are not involved in random assignment or the intervention delivery and do not directly communicate with the M2M instructors and assistant health coaches about participants. Data collection with physiological outcomes is conducted at a local research facility affiliated with a major medical center. Self-reported outcomes are administrated via a secure electronic database, referred to as REDCap. Online platform analytics are used to assess heart rate (HR) and video minutes viewed and stored in the cloud. Figure 1 shows the schedule of assessments.

Primary Outcome Measures

CMH outcomes are assessed via venipuncture blood specimen, brachial cuff BP, and body composition.

- High sensitivity C-reactive protein (hsCRP; mg/L): hsCRP is a critical marker of inflammation that contributes to proinflammatory and prothrombotic elements of cardiovascular risk. A single hsCRP measure is a strong predictor of myocardial infarction or coronary heart disease mortality and several other diseases of the circulatory system in people without a history of such conditions [28]. Changes in hsCRP may occur from as early as 8 weeks of exercise [29].
- Hemoglobin A1c (HbA1c, mmol/mol): HbA1c is a measure of red blood cell mean hemoglobin glycation over the previous 3 months. Exercise interventions without a dietary

component should yield a small to moderate effect on HbA1c after a month of training [30].

- Fasting insulin (μIU/mL): A high fasting insulin level indicates the presence of insulin resistance and whether an individual shows glucose intolerance. Exercise interventions without a dietary component should yield a small beneficial change in fasting insulin levels after a month of training [30].
- Fasting glucose (mmol/L) and homeostatic model assessment of insulin resistance: This is calculated as [fasting insulin (μU/mL) × fasting glucose (mmol/L)]/22.5 [31].
- Fasting triglycerides (mg/dL): A triglyceride level >150 mg/dL, is largely supported as an indicator of cardiovascular risk [32,33]. Exercise interventions without a dietary component should yield a small beneficial change in triglyceride levels after a month of training [30], even among people with normal triglyceride levels [34].
- Fasting cholesterol (mg/dL): Abnormalities in the lipid profile, including elevated total and LDL cholesterol as well as decreased HDL cholesterol, are predictors of future cardiovascular disease among young and middle-aged people [35,36]. Exercise interventions without a dietary component should yield a small effect after 1 month [30].
- BP (mmHg): Moderate-intensity exercise has been shown to reduce BP [37].
- Waist circumference (cm): The waist circumference is measured at the level of the superior border of the iliac crest, above the umbilical level, and at the midline level [38] using a Gulick tape.
- BMI (kg/m^2): Dual-energy x-ray absorptiometry (DXA) scan is used to measure weight-adjusted BMI, in addition to total mass, lean mass, and fat mass. It is evident that people with SCI often have elevated waist circumference (≥94 cm), but their BMI is less than 30 kg/m
  2
  [39].

Secondary Outcome Measures

Secondary outcomes include cardiovascular capacity, pulmonary function, grip strength, and self-reported physical and psychosocial health outcomes.

- VO_{2peak} (ml/kg/min): VO_{2peak} is measured during a graded exercise test as an indicator of cardiovascular capacity using an arm ergometer (Lode) and open circuit spirometry with a metabolic cart (TruOne, ParvoMedics). Arm ergometers are considered the gold standard modality for exercise testing among people with disabilities who use wheelchairs or cannot run or cycle for prolonged periods [40,41]. Before starting the test, participants rest for 3-5 minutes. They are then instructed to maintain a pace between 55 to 65 revolutions per minute throughout the testing period. The participant starts their test with 2 minutes of warm-up without any resistance, and then the resistance is increased every minute by 10 watts until the participant reaches volitional fatigue or subjective discomfort (eg, shortness of breath and chest pain) or achieves 2 or more of the following termination criteria: age-predicted maximum HR of more than 85%; rate of perceived exertion (RPE) of 8 or more on a 0-10 scale; respiratory energy exchange ratio of 1.1 or higher; or plateau in oxygen consumption [42]. HR and oxygen consumption is measured continuously.
- FEV1 (forced expiratory volume over 1 second) and FVC (forced vital capacity; liters): Pulmonary function is measured by (1) how much air the participant exhales quickly, and (2) how much air can be expelled after taking a full breath via a portable spirometer (MIR Spirobank). These will be measured 3 times, with a 1-minute resting period between each trial during the testing session.
- Grip strength (kg): Grip strength is measured using a hand-held dynamometer (Jamar Hydraulic Hand Dynamometer, Lafayette Instruments) for both hands, with 3 trials conducted for each hand and a 1-minute resting period between each trial.
- Self-reported physical activity (min/wk): The volume of physical activity is measured using the Leisure-Time Physical Activity Questionnaire for SCI [43].
- Self-reported physical and psychosocial health: Various aspects of physical and psychosocial health are measured using standardized questionnaires by the National Institutes of Health PROMIS (Patient-Reported Outcomes Measurement Information Systems) [44]. This includes Pain Intensity, Pain Interference, Fatigue, Sleep Disturbance, Global Health, Ability to Participate in Social Roles and Activities, Depression, Anxiety, and Physical Function.

Moderating Outcome Measures

The moderating outcome measures are as follows:

- Demographics and clinical characteristics of participants (eg, age, sex, ethnicity, diagnosis, or medications)
- Exercise behavior measured by Exercise Self-efficacy Scale [45,46], and Exercise Goal Setting and Planning Scale [47] based on Social Cognitive Theory constructs
- Self-reported diet using the Rapid Eating Assessment for Participants Shortened Version [48,49]
- Exercise enjoyment using the Physical Activity Enjoyment Scale [50] and satisfaction via qualitative, semistructured one-on-one interview
- Exercise session duration based on attendance rate and video minutes viewed via online platform analytics
- Exercise intensity based on minutes exercised at moderate-to-vigorous intensity using an optical HR monitor (Polar Verity Sense, Polar) and RPE scale 0-10: The RPE is periodically asked during the exercise session to adjust the intensity and at the end of the exercise session to obtain the overall exertion level. The talk test is used as a secondary measure, primarily to ensure that participants stay in the moderate-to-vigorous intensity training zone and that RPE is related to aerobic strain as opposed to anaerobic. Additionally, this is an important indicator of exercise intensity, especially for individuals with a blunted exercise HR response.

Random Assignment

After participants are determined eligible and all baseline assessments are complete, they are randomized into 1 of the 2

groups, M2M-C or control (n=66 per group), with a 1:1 allocation ratio. The randomization sequence is generated and only known by the project statistician using a computer-generated random schedule in permuted block (SAS; version 9.4; SAS Institute Inc). The block size is unknown to intervention staff.

Intervention Arm—Home-Based, Synchronous Aerobic Exercise Training Using M2M

The prescriptive exercise guideline in this proposed study was generated through a critical review of the relevant literature. To determine an appropriate exercise dose, we used data from 16 studies of moderate-intensity aerobic exercise included in a recent meta-analysis on CMH effects of exercise training in the general population [22]. Specifically, we calculated the total prescription (average prescription per week × intervention duration) for each study and the overall average. We determined that an aerobic exercise training dose of approximately 2400 minutes (40 h) over 6 months would be necessary for CMH benefits. We then spread the minutes across a 24-week intervention period for this trial with wheelchair users to ensure adequate time to safely and progressively reach the prescribed dose. The session structure and exercise minutes for each week are presented in Table 1, and the intervention components are summarized in Table 2.

Table 1. Movement-to-music cardiovascular session structure and exercise in minutes for each week.

Week	1	2	3	4	5	6	7	8	9	10	11-24
Checking in	5	5	3	3	3	3	3	3	2	2	2
Range of motion	5	5	5	5	5	5	5	5	5	5	5
Aerobic	15	15	20	20	25	25	30	30	35	35	40
Cool down	5	5	5	5	5	5	5	5	5	5	5
End discussion	5	5	5	5	5	5	5	5	3	3	3
Exercise min/session	25	25	30	30	35	35	40	40	45	45	50
Total min/session	40	40	45	45	50	50	55	55	60	60	60

Table 2. Summary of movement-to-music cardiovascular program features.

Feature	Description
Prescription	• 2400 minutes of exercise across 24 weeks • Progressive • Individualized
Frequency	• 3 times per week
Session duration	• 25 to 50 minutes
Intensity	• Moderate-to-vigorous • Maximum heart rate at or above 70% • Rate of perceived exertion between 3 and 7
Intervention length	• 24 weeks
Setting	• Home
Exercise mode	• Aerobic using M2M[a]
Supervision	
Who	• M2M instructors • Assistant telecoaches
Mode	• Remote telecoaching
Oversight	• Zoom (Zoom Communications, Qumu Corporation) and TeleRehab app (JNP Enterprises LLC) • Live, instruction sessions with M2M instructors • Monitoring sessions with assistant health coaches using recorded live session videos
Meeting with the instructor or coach	
Weeks 1-8	• 1× M2M instructors • 2× assistant telecoaches
Weeks 9-16	• 1× M2M instructors • 1× assistant telecoaches • 1× self-guided with no supervision
Weeks 17-24	• 1× assistant telecoaches • 2× self-guided with no supervision
Equipment provided	• Computer tablets • Tablet stand • Polar heart rate monitor
Intervention safety	• Zoom oversight • Adverse event or serious adverse event reporting

[a]M2M: movement to music.

During the 24-week training phase, the M2M-C group receives 1:1 synchronous training from M2M-trained exercise instructors and assistant health coaches within a remotely coached, home-based setting using telehealth monitoring platforms (ie, Zoom, TeleRehab app). The intervention is administered 3 times per week, starting at 25 minutes per session and increasing by 5 minutes every 2 weeks to a maximum of 50 minutes. The exercise program focuses on improving cardiorespiratory fitness using a series of movement patterns accompanied by music. The program is tailored to an individual's functional abilities (eg, use lower limb if able, slow vs fast tempo, level of trunk control) and preference of musical themes, including classical, country, decades (oldies), international, jazz or blues, and pop.

For the first 8 weeks of the training phase, participants attend 1 instructional session with an M2M instructor per week, and the live session is video-recorded via Zoom. Participants attend 2 monitoring sessions in the same week to repeat the exercise using the prerecorded video of the week with assistant telecoaches. For the second 8 weeks (wk 9-16), participants continue to attend 1 instructional session with an M2M instructor per week, and the live sessions are video recorded. Participants attend 1 monitoring session with assistant telecoaches and 1

self-guided session without any supervision. For the third 8 weeks (wk 17-24), participants no longer meet with M2M instructors. Using the recorded videos between weeks 11 and 16 (ie, 40 minutes per video; archived with no instructions), participants attend 1 monitoring session per week with assistant telecoaches and 2 self-guided sessions in the same week.

Telehealth Monitoring Platform

The exercise intensity is prescribed at a moderate-to-vigorous intensity level, which is monitored through a web-based platform with physiologic devices to support remote telehealth supervision of the intervention. The platform, referred to as TeleRehab, includes an Android (Google LLC) app that is installed on a computer tablet with Bluetooth capability (Samsung FE S7, Samsung USA), which sends data and allows 2-way communications to a secure web server. HR data are recorded and transmitted for real-time viewing by both the user and research staff using an optic HR sensor (Polar Verity Sense, Polar). The device instructions from the manufacturer state that the sensor can be worn on the head, forearm, or upper arm. For the M2M-C exercise intervention, the HR sensor is placed on a thin, elastic sports headband and worn on the temple of the head. Based on internal testing among research staff (nonpublished findings), the head placement resulted in more accurate readings during intervention exercise than when the device was worn on the forearm or upper arm. The head placement avoided signal disruption caused by the rapid and consistent arm movements required for the exercise intervention. At the end of each session, the platform provides the summary of exercise minutes (ie, light or moderate-to-vigorous) based on the predetermined HR zone. For participants with blunted HR, RPE is used. The TeleRehab app was an upgraded version of one used previously in a tele-monitored feasibility exercise study among people with SCI [51].

Control Arm—Home-Based, Asynchronous Standard Exercise Training

For ethical and engagement purposes, the control group receives access to a YouTube playlist of standard exercise training (SET) videos adapted for people with physical disabilities. They are advised a similar prescription as the intervention group of 3 exercise sessions per week. The SET program is based on the National Center on Health, Physical Activity, and Disability 14-Weeks to a Healthier You program launched in 2008. It involves various exercises that are performed in both standing and seated positions, including the upper and lower extremity range of motion (2 videos, 5 min each), muscle strength (3 videos, 5 min each), aerobic fitness (1 video, 5 min; 2 videos, 10 min each), balance (1 video, 2 min; 2 videos, 5 min each), and a cool down (1 video, 5 min) [52].

Procedure

This study's procedure is administered by a project coordinator with oversight by the principal investigator (PI) and coinvestigators and monitored through a fidelity monitoring plan. Our intervention fidelity plan is based on the best practices and recommendations from the Behavior Change Consortium [26]. These recommendations are intended to link theory and application across 5 primary study phases, including study design, provider training, monitoring and improving the delivery of the intervention, and monitoring and improving the enactment of intervention skills.

The project coordinator, who is specific to participant engagement, contacts interested participants via telephone, describes this study and its requirements, and conducts the screening based on this study's inclusion and exclusion criteria. For eligible individuals, the project coordinator then obtains physician approval. Upon approval by the physician, the project coordinator then distributes the informed consent document electronically as a final step in enrollment. After completing the informed consent, a baseline self-report questionnaire packet and a current medication list form are sent electronically. The project coordinator follows up with a telephone call to schedule a baseline data collection visit and provide verbal and written instructions regarding the baseline testing procedure, completion of the questionnaire packet and medication list, and directions with parking information. The project coordinator contacts the participant by telephone 24 hours before the appointment as a reminder. Upon arrival at the adaptive human performance laboratory, the project coordinator reviews this study's procedures with the participant and then initiates the baseline data collection. The baseline data collection is undertaken by treatment-anonymous research staff who will administer the second level of eligibility screening based on CMH indicators. The eligible participant then undertakes a series of physiological tests, and the composition of those measures takes approximately 2 hours.

Once the baseline assessment is completed, participants are randomly assigned to either the intervention or control conditions using a random numbers sequence with concealed allocation. The project coordinator unfolds the allocation information via this study's database, communicates the condition of assignment with the participant and, if allocated to the M2M-C intervention, prepares the necessary equipment for program participation. The participant will also meet with instructors and assistant telecoaches. If allocated to the control condition (SET), the project coordinator prepares the tablet with access to the SET videos. Lastly, the project coordinator will schedule a goal-setting session to be completed within 2 weeks between the participant and PI. This is carried out for both groups.

Participants in both intervention and control groups receive a 15-minute, individual goal-setting session at each time point from the PI, who is trained in physical activity counseling. They discuss participant's outcome expectations from the program and review the goal of the program based on the given exercise prescription. The participants are prompted to share any foreseen barriers to complying with the program and guided to develop a relapse prevention plan (eg, identifying activities and social support to reactivate participation; outlining consequences for continuing and discontinuing the program). Additionally, the participants are prompted to share additional health goals and receive guidance on making them specific, measurable, attainable, relevant, and time-bound.

The intervention and control participants complete the same measurement procedures at the 12-week (midintervention) and

the 24-week (postintervention) time points. There is no physiological data collection at the 36-week follow-up, as the aim to be addressed is sustaining physical activity behavior.

Participants receive up to US $830 for completing the measures per assessment period, including baseline as well as 12-, 24-, and 36-week assessments, and 12- and 24-week interviews. Semistructured exit interviews are conducted at the 24-week assessment for the first 30 participants to identify opportunities for intervention improvement and refinement.

Data Analyses

All data will be exported into and analyzed using SAS software (version 9.4 or later). Statistical tests will be 2-sided and will be performed using a significance level of 5%. Data analyses will follow intent-to-treat principles. Data will be initially examined for variations, outliers, errors, and patterns of missing values. Missing data will be inputted using multiple imputation techniques where necessary based on the assumption that the missingness mechanism is at random. Descriptive statistics, such as means, SDs, frequencies, and proportions, will be obtained for this study's variables.

Primary and Secondary Aims

We will analyze between-group differences (differences between the intervention and control groups) and within-group changes from preintervention to the 12-week midintervention (immediate effects of the intervention) time point. "Clinically significant improvement" was defined for each risk factor based on the minimum change deemed clinically important; for our purposes, "clinically significant improvement" equates to the following: approximately 10% decrease in total cholesterol, 30% reduction in triglycerides, and 5% reduction in body fat from the beginning of care to the most recent measure.

Tertiary Aims

Our analyses will focus on only the within-group changes from the preintervention to the 12-week midintervention to the 24-week postintervention (sustained effects of the intervention) time point. For all 3 aims, comparisons of cardiometabolic indicators, measures of fitness, and scores of self-reported questionnaires between and within the 2 groups will be performed using generalized linear mixed model techniques, including mixed models repeated measures analyses. The specific covariance matrix, such as the unstructured covariance matrix, will be selected based on the final data. The Tukey-Kramer multiple comparisons test will be used as the post hoc test for pairwise comparisons of means. These models will allow us to assess the between-group effect, the within-group effect, and the group-by-time interaction. Covariates of scientific interest such as wheelchair use status (full-time vs part-time), medication use (use vs nonuse), and participant characteristics (eg, age, sex, race, and severity of disease) may be included in some of these models. Pearson (or Spearman, if needed) correlation analyses will be performed between pairs of study variables. Analyses of categorical variables will be performed using the Pearson chi-square test (or Fisher exact test, if needed). Baseline characteristics will be evaluated using the 2-group *t* test for continuous variables or the chi-square test for categorical variables. For all aims, missing data that is not rectified through ongoing review of source documents may be managed with multiple imputation, and the influence of the missing data assessed with sensitivity analysis. Continuous variables will be examined for normality of distribution using graphical techniques and tests of normality. Transformations will be performed for continuous variables that are not normally distributed, or nonparametric methods will be used for these variables.

Adherence and compliance data are logged onto the online training platform. Adherence and compliance rates will be assessed as proportions and their corresponding exact 95% CIs will be obtained. These rates will be obtained overall and separately by age, sex, body composition, and ethnicity. These rates will be compared separately for age group, sex, body composition, and ethnicity using the chi-square test or Fisher exact test if the assumptions for the chi-square test are not met.

We will consider the suggested outcomes as potential moderators and test effect modification by including appropriate interaction terms in our repeated measure of mixed models, including the severity of motor impairment (ie, PROMIS Physical Function 12a), clinical diagnosis (eg, SCI vs multiple sclerosis vs stroke), psychosocial metrics specific to readiness to change (eg, self-efficacy and goal setting skills), and other factors, such as wheelchair use status (full-time vs part-time), medication (use vs nonuse), and diet quality (healthy diet vs less healthy diet).

Results

Recruitment procedures started in January 2024 with the first participant enrolled on March 18, 2024. All data are anticipated to be collected by November 2027, and the main results of the trial are anticipated to be published by February 2028. Secondary analyses of data will be subsequently published. A total of 16 participants have been recruited as of August 20, 2024.

Discussion

Principal Findings

The CHIME study proposes a parallel-group RCT for examining the 24-week effects of an evidence-based M2M program compared with a control condition for yielding immediate and sustained CMH outcomes among adult wheelchair users with poor cardiometabolic profiles. This study anticipates that after 24 weeks, participants in the M2M-C intervention group will show significant improvements in key cardiometabolic risk factors, such as reduced HbA_{1c} levels; lower fasting glucose and triglycerides; and decreased BP, waist circumference, and body fat percentage, compared to the control group. Furthermore, the M2M-C intervention is expected to improve health-related physical fitness, including measurements such as VO_{2peak}, FEV1, FVC, and grip strength, in line with self-reported psychosocial health outcomes. In addition to the improvements in CMH and physical fitness, we anticipate that these benefits will be sustained during the maintenance phase (up to 36 wk). This suggests that wheelchair users may be able to adhere to telehealth-based exercise programs over the long

term. If successful, this study will be the largest and sufficiently powered confirmatory RCT trial targeting CMH outcomes in this population. The prescribed exercise dose was informed by the review of the relevant literature [22]. If successful, this study will establish an evidence-based recommendation of adequate exercise dosing for adult wheelchair users with poor CMH profiles.

Strength and Limitations

This study uses an evidence-based M2M program with modifications to focus on aerobic training and telehealth delivery [53,54]. The M2M program has been specifically designed and tested for safety and effectiveness for balance, walking endurance, and volume of physical activity among people with various disabilities (eg, multiple sclerosis, stroke, and SCI) [17,55,56]. Studies involving fitness training and traditional modes of exercise, such as riding a stationary bike and lifting weights, often result in low adherence rates for many people due to a lack of enjoyment or social interaction [57,58]. Several studies have reported that adding music improves exercise adherence [59] and enjoyment [60,61]. The enjoyment was a highlighted component of the M2M program in addition to its safety and effectiveness, and it has the potential to improve aerobic fitness and CMH when the exercise intensity is regulated by trained instructors.

This study has been designed to deliver quality exercise interventions in the convenience of the participant's home with minimal exercise equipment. However, many exercise interventions often fail to be made available after research trials due to a lack of resources and support. To support the sustained exercise behaviors and gains, postintervention resources will be provided to study participants for their maintenance period (wk 25-36) and can be used after that time. The M2M-C intervention participants will have access to an online library of exercise videos, including their 24-week M2M-C videos, and the control participants will have access to the SET exercise videos. In addition, all participants will be introduced to the National Center on Health, Physical Activity and Disability (to receive continuous support through various health-related programs that are specifically designed for people with disabilities. Participants will be given the center's website and email addresses, in addition to their toll-free hotline.

Limitations

One of the major limitations of this study is that it relies on self-reported data for certain outcomes, such as physical activity, exercise behavior, and diet. Self-reported data can sometimes overestimate or underestimate actual behavior and can be affected by recall bias, where participants may not accurately recall their physical activity or exercise habits [62]. In addition, the time frame for these questionnaires is limited to a 1-week period, which may not fully capture participants' typical physical activity and exercise patterns over time. To address these limitations, future studies could incorporate objective measures, such as wearable devices and activity trackers, to supplement self-reported data. These tools would provide a more comprehensive and accurate understanding of physical activity patterns and engagement, helping to mitigate the biases associated with self-reported data. An additional limitation of the trial is that participants are not blinded to treatment due to the nature of the intervention being an online exercise program.

We may experience problems with the participants adhering to this study's protocol due to the requirement of onsite physiological data collection. Transportation is a well-documented barrier for people with disabilities, especially our target population who may require assistance with transferring in and out of a vehicle or obtaining accessible public transportation. To overcome this barrier, we have arranged a ride service that contains accessible vehicles. In addition, there may be some attrition during the maintenance period (wk 25-36) wherein there is no planned coaching and contact. Potential attrition is expected from this study but we have developed a plan to minimize it using the taper-down approach of coaching and contact during the 24-week training period.

Lastly, the current design of the trial involves intensive supervision of training by the M2M instructors and assistant health coaches, which is approximately 43 hours per participant over the 24-week training period (ie, 19, 16, and 8 hours for each 8-wk phase). The high volume of staff time to implement this study may hinder the scalability of the program in its current form.

Clinical and Practical Implications

The M2M-C intervention has potential clinical and practical implications if proven successful. First, the M2M-C program would demonstrate the feasibility of delivering a structured, individualized tele-exercise platform. This approach effectively addresses common barriers faced by wheelchair users, such as transportation challenges, limited access to fitness facilities, and a lack of tailored exercise programs. The M2M-C program offers a convenient and accessible solution for engaging in physical activity from the comfort of one's own home. Its adaptability makes it suitable for various settings, including rural or underserved areas where traditional exercise programs may not be available. The use of telecoaching also allows for regular interaction and personalized support, which are essential for maintaining motivation and long-term adherence. Moreover, if the M2M-C intervention proves successful, there is the potential for it to be expanded to serve a broader range of clinical populations. The program's emphasis on individualization—adjusting exercises to align with each participant's physical capabilities and fitness level—makes it adaptable. With appropriate modifications, the M2M-C program could be extended to other groups, including individuals with different types of mobility impairments and older adults with physical disabilities. This flexibility highlights the M2M-C intervention as a versatile tool for promoting physical activity on a larger scale, potentially reaching diverse populations in need of accessible exercise solutions.

Abstract

Background: Although substantial progress has been made in establishing evidence-based psychosocial clinical interventions and implementation strategies for mental health, translating research into practice—particularly in more accessible, community settings—has been slow.

Objective: This protocol outlines the renewal of the National Institute of Mental Health–funded University of Washington Advanced Laboratories for Accelerating the Reach and Impact of Treatments for Youth and Adults with Mental Illness Center, which draws from human-centered design (HCD) and implementation science to improve clinical interventions and implementation strategies. The Center's second round of funding (2023-2028) focuses on using the Discover, Design and Build, and Test (DDBT) framework to address 3 priority clinical intervention and implementation strategy mechanisms (ie, usability, engagement, and

appropriateness), which we identified as challenges to implementation and scalability during the first iteration of the center. Local redesign teams work collaboratively and share decision-making to carry out DDBT.

Methods: All 4 core studies received institutional review board approval by June 2024, and each pilot project will pursue institutional review board approval when awarded. We will provide research infrastructure to 1 large effectiveness study and 3 exploratory pilot studies as part of the center grant. At least 4 additional small pilot studies will be solicited and funded by the center. All studies will explore the use of DDBT for clinical interventions and implementation strategies to identify modification targets to improve usability, engagement, and appropriateness in accessible nonspecialty settings (Discover phase); develop redesign solutions with local teams to address modification targets (Design and Build phase); and determine if redesign improves usability, engagement, and appropriateness (Test phase), as well as implementation outcomes. Center staff will collaborate with local redesign teams to develop and test clinical interventions and implementation strategies for community settings. We will collaborate with teams to use methods and centerwide measures that facilitate cross-project analysis of the effects of DDBT-driven redesign on outcomes of interest.

Results: As of January 2025, three of the 4 core studies are underway. We will generate additional evidence on the robustness of DDBT and whether combining HCD and implementation science is an asset for improving clinical interventions and implementation strategies.

Conclusions: During the first round of the center, we established that DDBT is a useful approach to systematically identify and address chronic challenges of implementing clinical interventions and implementation strategies. In this subsequent grant, we expect to increase evidence of DDBT's impact on clinical interventions and implementation strategies by expanding a list of common challenges that could benefit from modification, a list of exemplary solutions to address these challenges, and guidance on using the DDBT framework. These resources will contribute to broader discourse on how to enhance implementation of clinical interventions and implementation strategies that integrate HCD and implementation science.

implementation science; human-centered design; evidence-based psychosocial interventions; mental health

Introduction

Background

Psychosocial clinical interventions such as psychotherapy, counseling, and case management are a preferred mode of treatment by most people seeking care for mental health problems [1-5]. Access to evidence-based clinical interventions remains variable among diverse groups, leading to mental health disparities across racial and ethnic, geographic, and socioeconomic status [6-16]. Furthermore, implementing clinical interventions in nontraditional and integrated settings (eg, primary care, telehealth platforms, and schools) has shown mixed success. These settings can serve as a *safety net* for accessing mental health treatment when traditional options are inaccessible [17-20]. Addressing barriers to implementing clinical interventions in these settings is vital to promote more equitable access to mental health services for all.

Poor availability of clinical interventions is often due to intervention complexity and suboptimal fit with many settings where clinical interventions are deployed [21]. Implementation strategies—"systematic intervention process(es) to promote the uptake of evidence-based health innovations into usual care"—have often taken the form of complex tools and processes (eg, train the trainer, booster training, incentive models, and decision supports) [22,23]. However, these often fall short because they can be excessively costly and cumbersome [22,24]. Different needs of recipients and settings can lead to high rates of reactive adaptations of clinical interventions and implementation strategies by their intended users in many settings where they are deployed. Reactive adaptations are unplanned or improvised changes during an implementation process in response to unanticipated challenges [25]. While reactive adaptations can compromise clinical potency, those that are proactively tailored to different care settings can improve sustainability and impact [26-29]. A systematic review of cultural adaptations to health and mental health services highlighted how adaptations motivated by cultural sensitivity are not guaranteed to demonstrate increased efficacy [30]. Instead, patient-centered approaches that account for individualized needs and barriers to service are recommended to guide adaptations [30,31].

Human-Centered Design and Implementation Science

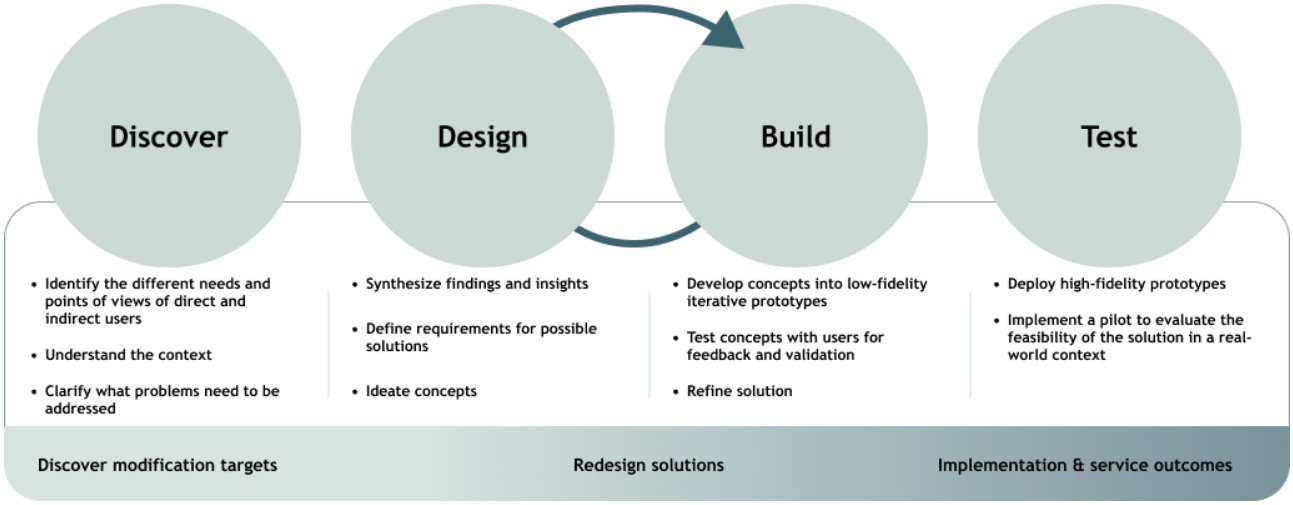
Human-centered design (HCD) and the closely related discipline user-centered design offer a suite of methods to develop useful, compelling, intuitive, and enjoyable products, services, and tools based on people's needs [32,33]. HCD relates to the evolution of human-computer interaction (HCI), a multidisciplinary field that incorporates computer science, cognitive science, and human factors engineering as a response to personal computing, collaborative work, and interconnected technologies in everyday life [34]. While HCD's origins are rooted in technology, it has been used beyond the context of digital technologies to address therapeutic elements and implementation supports [35]. HCD has been applied to improve usability, reduce burden, and increase the contextual appropriateness of clinical interventions and implementation strategies [36-40].

The fields of HCD and implementation science share common objectives and offer complementary methods that can support clinical interventions and implementation strategies innovation and redesign [41-44]. HCD techniques are particularly well positioned to help with redesign, which we define as adaptations to clinical interventions and implementation strategies while preserving effective components (ie, fidelity-consistent adaptation) [45]. HCD's traditions of situating problem discovery and solutions in user needs, usability, engagement, innovation, and rapid exploration are core strengths that align with implementation science's goal of improved adoption, fidelity, reach, and adaptation of clinical interventions and implementation strategies [41]. Combining HCD and implementation science traditions for clinical intervention and implementation strategy redesign grounds novelty in empirical evidence.

Integrating HCD and Implementation Science Through the Discover, Design and Build, and Test Framework

The University of Washington Advanced Laboratories for Accelerating the Reach and Impact of Treatments for Youth and Adults with Mental Illness Center (UWAC), which is funded by a grant from the National Institute of Mental Health (NIMH), is a multidisciplinary team of experts from the fields of mental health, implementation science, and HCD focused on improving usability, engagement, and appropriateness of clinical interventions and implementation strategies in diverse and nonspecialty settings (eg, rural, urban, low-income, primary care, and schools). Drawing on strengths from different disciplines, UWAC developed the Discover, Design and Build, and Test (DDBT) framework (Figure 1) at the start of the center (ie, "UWAC 1.0"). The current DDBT framework guides teams in redesigning clinical interventions and implementation strategies to improve usability, engagement, appropriateness, and implementation outcomes while preserving clinical interventions' core components [46]. Key principles underlying this model include the following: (1) not all clinical interventions and implementation strategies are designed for all settings; (2) "there is no implementation without adaptation" [47]; (3) unchecked, reactive adaptations have the potential to exclude essential active ingredients [48,49]; and (4) reactively adapted clinical interventions and implementation strategies can negatively impact implementation and clinical outcomes.

Figure 1. Discover, Design and Build, and Test (DDBT) redesign framework.

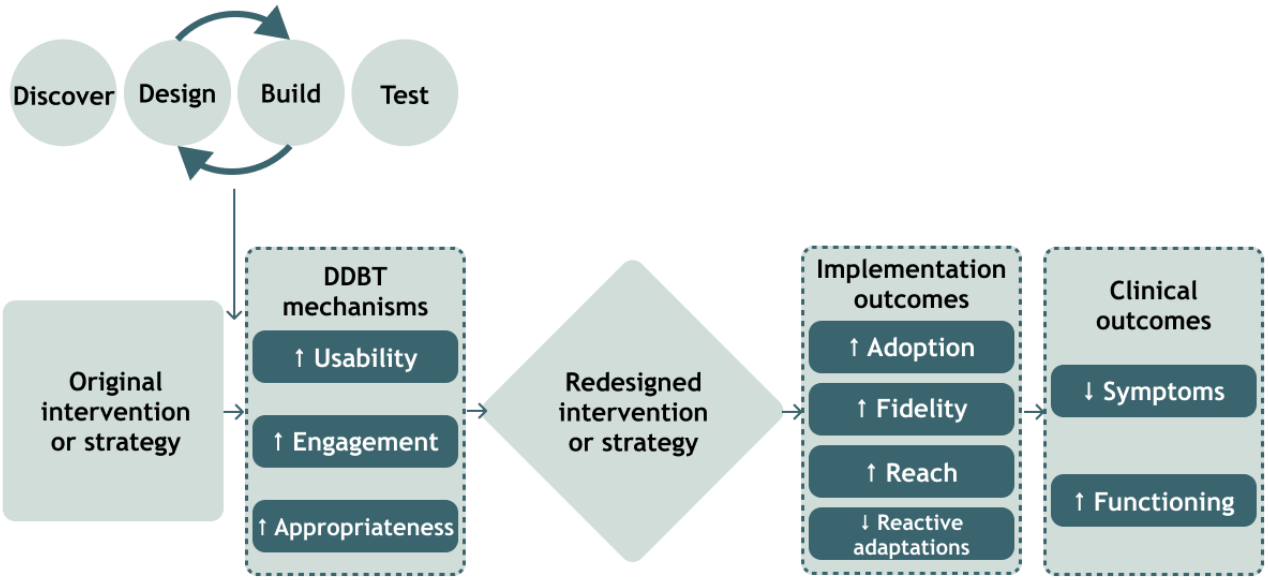


The DDBT framework is modeled after existing HCD frameworks [50] and is an iterative stepped approach to systematically (1) understand usability constraints of existing clinical interventions and implementation strategies, (2) iteratively design solutions for usability challenges with redesign teams of direct and indirect users, and (3) test and refine prototypes. We define direct users (also known as "primary users") as people who directly interact with the clinical intervention and implementation strategy and indirect users (also known as "secondary users") as people affected by the clinical intervention and implementation strategy. HCD places a strong emphasis on explicitly identifying relevant community collaborators and users to ensure that new products effectively meet their needs [51,52]. DDBT starts by identifying multilevel factors that drive clinical intervention and implementation strategy usability problems, engagement challenges, and problems with contextual appropriateness (Discover phase). Once problems and challenges are identified, modifications are iteratively created between the design team and practitioners and clients, until a new version of the clinical interventions and implementation strategies is developed to address crucial issues and enhance usability, engagement, and appropriateness (Figure 2; Design and Build phase). Early prototypes of clinical interventions and implementation strategies are assessed with small samples (eg, 5-25 participants) to answer design questions using paper or other "low-fidelity" (ie, sufficient to communicate a concept but potentially lacking functionality, some content, and look and feel of final materials) versions of modifications, which reduces waste of unnecessary investment in programming and development until as late in the process as possible. Findings from the Design and Build phase are incorporated to develop high-fidelity prototypes, which are tested against the unadapted version to ascertain if the modified clinical interventions and implementation strategies result in improved implementation (eg, increased adoption, fidelity, reach, and reduced reactive adaptations) and equivalent or better mental and behavioral health outcomes because of the changes to usability, engagement, and appropriateness (Test phase). Additional details

on the DDBT framework are outlined in our UWAC 1.0 protocol paper [46].

All UWAC research uses the DDBT framework, which is applied flexibly based on project needs and allows us to evaluate the extent to which incorporating HCD and implementation science methods impacts clinical interventions and implementation strategies. Since 2018, DDBT has been used in >18 UWAC studies and 16 National Institutes of Health (NIH)–funded awards external to UWAC. During UWAC 1.0, we originally assessed impact of DDBT on 3 mechanisms: learnability (ie, extent to which users can understand or facilitate use) [46], usability (ie, extent to which users can achieve specified goals of effectiveness, efficiency, and satisfaction) [50], and sustained quality of care (ie, extent of treatment fidelity and impact on target outcomes) [46]. Analysis of UWAC 1.0 projects resulted in (1) identification of common usability issues in clinical interventions and implementation strategies that could benefit from modification (ie, "typology of modification targets") and corresponding heuristics to guide their design [53], (2) reflections on potential exemplary solutions to these challenges (ie, library of clinical interventions and implementation strategies redesign solutions), and (3) guidelines for using the DDBT framework [46].

Figure 2. University of Washington Advanced Laboratories for Accelerating the Reach and Impact of Treatments for Youth and Adults with Mental Illness Center (UWAC) theory of change for clinical intervention and implementation strategy redesign. DDBT: Discover, Design and Build, and Test.



UWAC Theory of Change for Clinical Intervention and Implementation Strategy Redesign

Our UWAC 1.0 findings and the implementation literature [21] outline how limited availability and the use of clinical interventions and implementation strategies are persistently attributable to organizational and system characteristics (eg, readiness to adopt, resources and culture, and leadership), clinician and adopter characteristics (eg, appropriateness and perceived efficacy of clinical interventions and implementation strategies for patients) [28,54,55], and incentives to engage in clinical interventions and implementation strategies [29,56].

As a result, we updated DDBT's underlying theory of change to highlight how adoption of clinical interventions and implementation strategies are largely due to usability (eg, extent to which clinical interventions and implementation strategies can be used to achieve specified goals with effectiveness, efficiency, and satisfaction) [53]; engagement (eg, degree of user participation and enthusiasm for the aspects of clinical interventions and implementation strategies that require user involvement) [57]; and appropriateness (eg, perceived fit, relevance, or compatibility of clinical interventions and implementation strategies for a given practice setting, practitioner, or consumer) [58] (Figure 2). These mechanisms are direct targets of DDBT-driven redesign and the focus of the new iteration of funding between 2023 and 2028 (ie, "UWAC 2.0"). We ultimately expect DDBT to result in changes to proximal implementation outcomes (adoption, fidelity, reach, and reactive adaptation) and clinical outcomes.

DDBT Mechanisms

Usability

Usability is an underlying outcome at all stages of the HCD process. Understanding the extent to which designs are unusable and opportunities to increase an existing solution's usability can inspire innovation and adoption [53]. Deployment of clinical interventions and implementation strategies will continue to be subpar unless usability can be addressed, the historically unidirectional relationship between developers and users can be overcome, and insufficient incorporation of user perspectives can be remedied [59]. Usability is assessed through usability evaluations and usability testing, where prototypes are evaluated using established heuristics [60] and observing users complete critical tasks [61]. Usability assessment methods stem from evaluating technologies; however, these techniques have been used to improve usability, decrease burden, and increase contextual appropriateness of nontechnological mental health clinical interventions and implementation strategies [5,36,39,53].

Approaches to assessing usability frequently couple interview-type questions with surveys and observation [62]. As a form of usability evaluation, metrics such as the System Usability Scale (SUS) [63] are questionnaires that assess perceived usability. The SUS is a widely used instrument to measure usability of technologies by industry. Task-based usability testing involves asking participants to complete tasks while using a prototype or product. This method can be used to gather baseline usability data for an existing clinical intervention and implementation strategy and assess usability of clinical intervention and implementation strategy prototypes [53]. The think-aloud protocol (TAP) involves participants verbalizing thought processes as they use clinical interventions and implementation strategies [39] to complete assigned tasks, including actions they consider taking and reactions to materials as they encounter them. Similarly, the Cognitive Walkthrough for Implementation Strategies (CWIS) is a 6-step method for evaluating clinical interventions and implementation strategies usability, which can include interviews as part of task-based usability testing [39].

UWAC 1.0 projects assessed usability through usability questionnaires, CWIS [39], and TAP [64,65]. We developed the Intervention Usability Scale (IUS) [37] and Implementation Strategy Usability Scale (ISUS) [39] to better measure clinical intervention and implementation strategy usability; these scales are closely aligned with SUS. SUS scores of ≥70 out of 100 are considered adequate usability, and we anticipate a similar threshold for IUS and ISUS. Cross-project usability data informed the typology of modification targets: 12 unique categories of clinical intervention and implementation strategy usability issues of varying severity. These categories help researchers understand common barriers to clinical intervention and implementation strategy use that can be prevented and addressed during clinical intervention and implementation strategy redesign [53].

Engagement

Engagement, and adaptations to improve engagement, relates to clinical interventions fidelity and clinical outcomes [66-69] and is a defining feature of quality of care [70-72]. Engagement describes user connection to clinical interventions and implementation strategies and their capacity to sustain a connection [57]. Engagement is distinct from common health concepts of compliance, adherence, and coverage because it incorporates a dimension of quality and welcomes the possibility that different people may engage differently with different parts of clinical interventions and implementation strategies based on varying needs. Typical users include the practitioners who deliver them (eg, clinicians, implementation practitioners, and intermediaries) and the individuals who receive them (eg, clients, practitioners, and service system administrators). Our work has found that engagement can be negatively impacted by insufficient buy-in, components that are inaccessible to different users, little support for communication or rapport building, and requirements or constraints that inadvertently shift one user's responsibilities to another (eg, practitioners completing client tasks) [53].

Engagement is a common focus in HCI literature [57,73-75], where there is an active conversation around how to best assess the quality of interactions rather than quantity of interactions. Multidisciplinary UWAC project teams present an opportunity to incorporate different approaches to improving engagement in translational research [76-78]. We conceptualize engagement as a multifaceted construct focused on interaction quality (ie, participation and enthusiasm) that is enhanced by clinical interventions and implementation strategies that are well designed and result in improved adoption, fidelity, reach, and adaptations. There are subjectivity-oriented and objectivity-oriented approaches to measuring engagement [57]. Subjectivity-oriented measures are self-reported and include questionnaires, observation, perceived task outcomes, and interviews. Objectivity-oriented measures minimize researcher involvement and can include behavior logging, psychophysiological measurements, or telemetry. Within HCI, objectivity-oriented measures such as user data—logs, time, number of interactions, and frequency of log-ins—are commonly used.

Appropriateness

Appropriateness captures perceived fit between clinical interventions and implementation strategies and the settings to which they are deployed [58]. Client needs and therapeutic style drive how mental health practitioners modify clinical interventions and implementation strategies in practice [26]. During UWAC 1.0, we observed how practitioners and recipients felt that exciting innovations can be inappropriate for specific contexts (eg, schools) or for users facing challenges with identifying and selecting goals or implementation plans. Challenges included clinical interventions and implementation strategies' excessive time demands in their delivery, incompatibility with existing workflows or roles, unavailable system infrastructure requirements, overreliance on digital technology, and, importantly, practitioner perceptions of the fit of the clinical interventions and implementation strategies to specific client problem types. These issues are well documented as multifaceted factors that influence clinical intervention and implementation strategy adaptations [29,45]. During UWAC 1.0, we used the Intervention Appropriateness Measure (IAM) [79] across projects to assess appropriateness.

Study Purpose

Center Aims and Structure

Our goal is to overcome obstacles that prevent quality mental health interventions from reaching historically marginalized groups through addressing critical clinical intervention and implementation strategy problems with the DDBT framework. Building on learnings during the first iteration of the center, UWAC 2.0 focuses on addressing longstanding problems with *usability*, *engagement*, and *appropriateness* of clinical interventions and implementation strategies that result in high rates of reactive adaptations in settings where they are deployed. Within UWAC, the Methods Core team provides methodological and technical support to all projects and maintains cross-cutting project data on UWAC outcomes to determine the impact of DDBT on clinical interventions and implementation strategies. These data will be used to refine and expand UWAC's typology

of modification targets and library of redesign solutions. This iteration of the center emphasizes increased leadership and application of DDBT methods by local project redesign teams (eg, administrators or champions) that receive methodological training and supports from the Methods Core team to work alongside investigators, increasing their decision-making at all stages of the design process. This is a shift from the previous centralized model, where projects engaged users, but project principal investigators (PIs) and UWAC Methods Core team members often led the design process. The Methods Core team will address the subsequent aims during UWAC 2.0.

Aim 1: Identify Clinical Intervention and Implementation Strategy Modification Targets to Improve Usability, Engagement, and Appropriateness in Accessible Nonspecialty Settings (Discover Phase)

Known determinants of successful clinical intervention and implementation strategy use exist at several levels, including clinical interventions (eg, complexity); practitioner and client (eg, training, attitudes, and intention to use); and organizational (eg, climate, leadership, resources, and supervision). Historically, adaptations of clinical interventions and implementation strategies have been driven by academics rather than the lived experiences of recipients. Using the Consolidated Framework for Implementation Research (CFIR) [80] as our guide in the Discover phase of each UWAC project, we support project redesign teams to use HCD methods to identify targets within our typology of modification targets [53]. Qualitative analyses will allow us to compare targets identified via local DDBT, characterized by user involvement in redesign teams and shared decision-making about target prioritization and solutions, with those derived from our original, centralized application of DDBT [46]. Aim 1 outcomes will inform typology revisions and allow for comparisons between the original, centralized DDBT and the local DDBT. An updated typology will be broadly disseminated to inform future research.

Aim 2: Develop Redesign Solutions With Local Teams to Address Clinical Intervention and Implementation Strategy Modification Targets (Design and Build Phase)

Using rapid, iterative design principles, we are supporting research project teams in redesigning clinical interventions and implementation strategies to enhance usability, engagement, and appropriateness. We will systematically catalog these design solutions using the Framework for Modifications and Adaptations of Evidence-Based Interventions (FRAME) or FRAME for Implementation Strategies (FRAME-IS) [26,29,45]. We will examine solutions and the populations, organization types or structures, practitioner types, and clinical interventions and implementation strategies in which they work, identifying solutions that transfer across different contexts or are uniquely suited to specific contexts. Aim 2 outcomes will be compared with centralized DDBT outputs, resulting in an updated library of redesign solutions organized by target and redesign method (ie, localized vs centralized), and shared with the interested community.

Aim 3: Determine If Redesign Affects Changes in Usability, Engagement, and Appropriateness (Test Phase)

Each project conducting a Test phase will include a hybrid effectiveness-implementation trial [81,82] with a primary comparison between the original clinical intervention and implementation strategy and the DDBT-adapted version on theorized mechanisms (usability, engagement, and appropriateness), implementation outcomes (adoption, fidelity, reach, and adaptations), and client outcomes. Projects will apply FRAME or FRAME-IS [29,45] to examine the extent to which DDBT decreases reactive adaptations to the clinical intervention and implementation strategy (ie, unplanned or due to unanticipated obstacles) during implementation. We hypothesize that DDBT-informed, prospective, and planned adaptations will reduce the number and extent of reactive adaptations. The Methods Core team will systematically integrate new data from the UWAC projects with existing data in an integrated cross-project analysis of how redesign affects theorized mechanisms, implementation outcomes, and patient outcomes. Aim 3 outcomes will be disseminated to the field and inform new projects designed to test which redesign strategies best improve DDBT mechanisms and outcomes.

Methods

Overview

Composed of an interdisciplinary team and advisory board with experience in HCD, implementation science, psychosocial clinical interventions, and research methods and data, the Methods Core team supports one large hybrid effectiveness-implementation study (NIH R01), 3 exploratory pilot studies (NIH R34s; Multimedia Appendix 1), and at least 4 pilot projects (NIH R03s) during UWAC 2.0. These projects aim to improve clinical intervention and implementation strategy access and scale in diverse settings. The R01 Problem Solving Treatment-Aid (PST-Aid; NCT06494384; PIs: IB, PR, and SAM) will test a DDBT-designed decision support tool for Problem Solving Treatment (PST) in a large network of primary care clinics. R34 Research Units on Behavioral Intervention in Educational Settings (RUBIES; NCT06508515; PIs: KB and JL) will create a novel implementation strategy to support the delivery of evidence-based classroom supports for students with autism. R34 Trauma-Focused Cognitive Behavioral Therapy (TF-CBT; PIs: ARL and DW) will redesign and test an evidence-based clinical intervention for youth trauma for use in education settings. R34 Brief Intervention for School Clinicians (BRISC; PIs: EB, JVD, and Elizabeth McCauley) will adapt an existing set of effective implementation strategies to enhance delivery of a school-based engagement, assessment, brief mental health intervention, and triage strategy. Funding for all core projects began in 2023. Multimedia Appendix 2 outlines key details (eg, study design and sample) of each study. PST-Aid and RUBIES were part of UWAC 1.0 as R34 and R03 projects, respectively, highlighting how UWAC 2.0 activities build on previous accomplishments. UWAC funds pilot projects through a competitive solicitation process, with a particular focus on supporting and mentoring investigators from

historically marginalized groups. All projects use the DDBT framework to address clinical intervention and implementation strategy usability, engagement, and appropriateness in partnership with local community collaborators. UWAC provides projects direct support for integrating methods and measurement approaches and professional development that centers diversity, equity, and inclusion (DEI) values.

DDBT Constructs

Projects collect common data on DDBT mechanisms and constructs to determine the impact of modifying clinical intervention and implementation strategy targets. The Methods Core team maintains a list of recommended and required measures for projects to gather at each DDBT phase ("Center Measures and Guidance"; Multimedia Appendix 2). We developed Center Measures and Guidance to facilitate DDBT hypothesis testing and data management across UWAC, help teams select methods based on project design objectives, and satisfy NIMH reporting requirements. Center Measures and Guidance include 15 constructs with 26 quantitative and qualitative measures across DDBT phases. The Methods Core team provides project teams support with integrating and adapting these measures for projects through a consultation model. This is a shift from our approach in UWAC 1.0, where the Methods Core team provided more personalized measurement support to project teams. Multimedia Appendix 3 [83] outlines each construct with a description of related measures and activities, and relevance to each DDBT phase. The Methods Core team provides data management for all projects, maintains survey instruments in REDCap (Research Electronic Data Capture; Vanderbilt University), and conducts cross-project analyses. Each project is responsible for conducting its own analyses. The Methods Core team provides guidance on ensuring recruitment, data analysis, and dissemination practices incorporate diverse perspectives and accurately represent the lived experiences of participants to inform clinical intervention and implementation strategy redesign.

DDBT Theory of Change Mechanisms

Usability

All projects are expected to report usability issues on existing or redesigned clinical interventions and implementation strategies and standardized usability metrics to the Methods Core team. Because interviews alone can be limiting for identifying usability issues because of issues with recall or challenges with describing behavior, UWAC projects are encouraged to combine interviews with other methods such as CWIS and TAP. This helps projects learn what a participant is considering doing next and why, better understand their in-the-moment goals, and identify misconceptions. For example, R34 BRISC will use TAP and a cognitive walk-through methodology with users to identify opportunities for redesign and improve implementation based on user needs [39]. The Methods Core team supports projects with adapting surveys (eg, SUS, IUS, and SUS) and implementing cognitive walkthroughs and usability testing for projects.

Engagement

We expect all projects to assess engagement quantitatively using the User Responsiveness Scale and qualitatively (ie, thematic findings from observation or other chosen methods) during the Discover and Test phases of existing and redesigned clinical intervention and implementation strategy. The Methods Core team developed the User Responsiveness Scale based on the Patient Responsiveness Scale [66]. The User Responsiveness Scale has 10 statements that cover participation and enthusiasm for a clinical intervention and implementation strategy that participants rate on a Likert scale. The original Patient Responsiveness Scale has demonstrated strong internal consistency (Cronbach α=0.86) and construct validity.

Appropriateness

R01 and R34s are expected to administer the IAM [79] or revised goodness-of-fit interview [84] during the Discover and Test phases of existing and redesigned clinical interventions and implementation strategies to probe areas of alignment and misalignment on goals and expectations, roles, etc. IAM is a 4-item survey and the leading instrument for measuring clinical intervention and implementation strategy contextual fit with good internal consistency (Cronbach α=0.87) and adequate test-retest reliability (r=0.73). The goodness-of-fit interview is particularly well-suited to probe on clinical intervention and implementation strategy appropriateness issues identified through IAM. We will use content analysis to analyze goodness-of-fit interview data. For example, R34 RUBIES will conduct goodness-of-fit interviews to explore the appropriateness of the RUBIES implementation strategy ("RUBIES-Team") for the school environment using the CFIR domains to drive questioning.

Proximal Implementation Outcomes

Adoption and Reach

Adoption and reach are implementation outcomes specified in the CFIR [58] and Reach, Effectiveness, Adoption, Implementation, and Maintenance [85] frameworks. We expect projects to report on adoption and reach as part of the Design (if feasible) and Test phases. All projects will report adoption and reach of the intervention. For redesigned implementation strategies, the approach to measuring adoption and reach depends on the project. For example, R34 RUBIES defines adoption as educators' first use of the RUBIES-Team at any point during the study and will measure reach for both RUBIES-Individual (ie, an original implementation strategy) or RUBIES-Team in three ways: (1) the number of other educators with whom trained educators share RUBIES strategies; (2) the number of other students with whom trained educators share RUBIES strategies; and (3) the number of other contexts and settings in which they applied RUBIES strategies.

Intervention and Implementation Strategy Fidelity

Fidelity is a core implementation outcome [58]. We expect projects to report on fidelity as part of the Design (for existing clinical interventions and implementation strategies) and Test phases. Teams choose an approach to measuring fidelity based on redesign goals. For example, R34 RUBIES rates paraeducator fidelity to treatment (eg, weekly ratings of the paraeducator's

homework completion and behavior support plan implementation). R34 TF-CBT will code session recordings using the Therapy Process Observational Coding Scale [86] and the Therapy Process Observational Coding Scale–Self-Reported Therapist Intervention Fidelity for Youth [87] at baseline, 3 months, and 6 months. Finally, R01 PST-Aid will measure initial and sustained fidelity using a PST Fidelity Scale. Initial fidelity will be measured as the number of sessions it takes providers to get certified; providers must have 2 sessions rated as "satisfactory" on the PST Fidelity Scale to receive certification. Sustained fidelity will be measured as the number of "satisfactory" sessions during the 6 months after certification, as measured by the PST Fidelity Scale.

Planned Adaptations

Characterizing adaptations, or redesign solutions, is key to all 3 Methods Core team aims to better understand and address challenges to clinical interventions and implementation strategies. We expect projects to characterize adaptations with FRAME or FRAME-IS [29] as part of the Design and Build phase, where planned and proactive changes will be made as a part of the redesign process. For example, R34 BRISC will analyze recorded intervention sessions using FRAME or FRAME-IS. The R01 PST-Aid will code randomly selected session audio recordings per client for fidelity and adaptations using FRAME or FRAME-IS. Projects will share adaptations made with the Methods Core team and describe whether these adaptions were made proactively (eg, as part of the redesign process in the design and build phases) or reactively (eg, unplanned or due to unanticipated obstacles in the test phase). Across projects, the Methods Core team will systematically categorize adaptations to examine solutions and the populations, organization types or structures, practitioner types, and clinical interventions and implementation strategies in which they work. Our objective is to identify transferable and unique solutions to different contexts and clinical interventions and implementation strategies. This information will ultimately inform an updated version of the library of redesign solutions.

Unplanned or Reactive Modifications

Reactive or unplanned modifications during the Test phase will be measured using a 17-item Center-developed measure based on the FRAME or FRAME-IS to assess the nature of modifications. Providers will self-report any changes they made while they administer the intervention.

Distal Service Recipient Outcomes

During the Test phase, projects are expected to collect clinical and functional outcomes. Teams will administer standardized assessments (eg, Patient Health Questionnaire [88], Quality of Life in Neurological Disorders [Neuro-QOL] [89], Satisfaction with Social Roles for adults [90], and the Neuro-QOL Social Relations Scale for youth [91]). The Neuro-QOL measures are widely used to assess functioning in usual social roles, activities, and responsibilities. The scales have been evaluated with thousands of participants from the general population of the United States and in clinical inpatient and outpatient settings who have a wide variety of presenting problems [89-91]. All projects will also use idiographic (ie, individualized) client outcome monitoring based on the Top Problems Assessment [92], an approach informed by goal attainment scaling [93,94] that has been found to be highly sensitive for monitoring clinical intervention outcomes and thus is preferred over standardized or nomothetic assessments by both practitioners and clients [95].

Demographic and Process Measures

Demographics

All projects are expected to collect participant demographic data mandated by the NIMH at all phases. Teams collect additional demographic data on the basis of the project needs. For example, the R34 RUBIES collects required educator and student demographics (eg, age, gender, and race) and additional data on school characteristics (eg, school size, percentage eligible for free or reduced lunch, racial and ethnic composition, percentage of English language learners, percentage in special education, annual funding for external resources, and per capita number of community-based organizations). Data will be tabulated to satisfy federal demographic and data reporting requirements as well as cross-project meta-analyses and comparisons.

User Needs and Experience

All projects are expected to clearly identify direct and indirect users and incorporate methods that address user needs. Explicit user identification produces more usable products and ensures that the design team does not underestimate user diversity [96] or create designs based on the team's own needs [36,97,98]. clinical intervention and implementation strategy users should include the deliverers (eg, providers of clinical interventions) and recipients (eg, clients and implementation strategy targets such as administrators or clinicians). Identification of users for a clinical intervention and implementation strategy includes (1) generating a preliminary user list, (2) articulating the most relevant characteristics that reflect anticipated users, (3) describing and prioritizing main user groups, and (4) selecting typical and representative users [96]. For example, in R34 TF-CBT, direct users are school counselors and social workers who provide mental health services, as well as public school students with histories of traumatic stress. Potential indirect users in this project include caregivers of students. We included users who are diverse with respect to characteristics such as age (eg, students), race and ethnicity (eg, students and practitioners), culture (eg, students and practitioners), and clinical domain experience (eg, practitioners), which are features known to impact experiences of usability, engagement, or appropriateness [53,99-101].

Projects will use interviews to identify key challenges that users might face when applying clinical interventions and implementation strategies. Interviews consist of questions derived from HCD principles such as organizational and community culture, values, and challenges in applying clinical interventions and implementation strategies. For example, in R34 RUBIES, the team will interview educators about their existing opportunities to learn behavioral management strategies for students with autism who exhibit challenging behavior. Interviews will identify promising professional development approaches and areas to improve the existing RUBIES

multifaceted implementation strategy. Additional interviews with school administrators or lead special educators are likely to surface critical organizational factors that can serve as design constraints for any subsequent redesign solution [102,103].

As described earlier, interviews can be supplemented through observation methods to better understand interactions in real-world settings. Projects can use an adapted form of TAP, where participants (eg, clinicians or clients) and researchers watch recordings of sessions while the participant explains what they were thinking in the moment. This approach can offer additional suggestions for improvement on the design of a clinical intervention or offer ideas for tools that could support the clinician during implementation. Interviews can also supplement comparative testing (eg, A/B testing) to explore and evaluate a broader landscape of design options and reach more robust solutions. A/B testing is an evaluation method in which ≥2 versions of a prototype are compared sequentially or in parallel to determine which version is easier to use and better meets user needs [104]. For example, R34 BRISC will build prototypes of digital asynchronous learning modules for novel users as well as posttraining support tools; initial prototypes will undergo comparative testing to finalize solutions to be evaluated in the Test phase. The pragmatic applicability and match of potential designs to the targeted service environments and resource constraints will be systematically addressed.

Participant Research Burden, Incentive Appropriateness, and Research Satisfaction

At the end of the Test phase, projects are expected to measure the burden of participation in the study. This instrument includes 6 questions to understand participants' perceived burden of participating in the study, appropriateness of the level of compensation offered, and overall satisfaction with the study experience. This information will be used to help improve future protocols. Response frequencies will be tabulated for the 4 close-ended responses and themes will be summarized from open-ended responses.

Adherence to DDBT Process (DDBT Fidelity and Cost Measure)

All projects are expected to complete a Fidelity and Cost survey in REDCap about their application of HCD techniques at the end of each DDBT phase. We are developing the survey to systematically collect data on how the DDBT framework guides clinical intervention and implementation strategy redesign and link design activities with project goals. To facilitate teams in drawing on a range of methods, the Fidelity and Cost survey focuses on understanding which goals of each DDBT process teams completed (Figure 1) and the methods they used to support each goal. We will conduct descriptive statistical analyses and content analysis of data to understand the frequency of goals completed and HCD strategies used, links between strategies and goals, and modifications made to strategies during their use.

We will measure the costs of applying DDBT to help understand the resource requirements involved in its use, which can be a major challenge of HCD and coproduction methods [105]. Projects are expected to report total costs of redesign, reported through a Fidelity and Cost Survey in REDCap at the end of each phase (this is optional for R03 projects). We will aggregate activity-based costs (eg, time to create, complete, and analyze each activity; participant payments or time) across individuals, use budgets or other institutional records to assign hourly costs by role, and then add in any fixed costs (eg, materials and activity-specific software). We will calculate total DDBT costs, as well as phase-specific and activity-specific DDBT costs. Analyses will follow best practices by placing all US dollar values onto the same metric, including an index year to account for inflation; local or national average cost-of-living values to account for geographic variation in prices; and discounting of costs from different years due to preferences for delayed over immediate costs. We will conduct sensitivity analyses to examine the robustness of our cost estimates [106,107] by identifying areas of uncertainty in measuring units and prices for our ingredients, and then calculating costs across a range of plausible values (eg, we can substitute limits of 95% CIs for uncertain prices).

Team Collaboration, Trust, and Respect

At the end of each DDBT phase, R01 and R34s team members are expected to complete a survey that assesses satisfaction with the collaboration, impact of collaboration, trust, and respect. This survey is modeled after the Transdisciplinary Tobacco Use Research Center's measure of Team Collaboration and Transdisciplinary Integration, which assesses satisfaction with the collaboration, impact of collaboration, trust, and respect [108]. Continuous review of outcomes will allow for critical assessment and course correction as needed and recommended by these bodies. Participation is confidential, and teams will receive an aggregate report of the number of team member participants and average scores for each item. Any free-response comments are additionally summarized. We will encourage teams to discuss results to improve their projects.

Community Participation in Research

The collaboration survey questions described earlier will be administered with additional questions to characterize the extent to which redesign teams engage users in a localized DDBT process. This instrument is based on an existing measure of community participation in research [109,110], which has been modified to target the design of clinical interventions and implementation strategies across 6 dimensions: identification of design issues, design activities, use of resources, design methods, indicators of success, and sustainability. Redesign teams will complete the measure at or near the end of each DDBT phase and then discuss ratings in an interview.

Investigator Satisfaction With the Support They Receive From the Center

At the conclusion of projects, we will ask investigators to share their level of satisfaction with support from UWAC through a 5-item Likert survey adapted from a survey used by the University of Washington IMPACT Center [111]. We intend to use these data to improve how the Methods Core team provides projects technical support.

Data Analysis

The Methods Core team provides data management and guidance on all DDBT constructs. For Aim 3, fundamental

comparisons are the differences in DDBT mechanisms (usability, engagement, and appropriateness) and implementation outcomes (adoption, reach, adaptation, and fidelity [and sustainment for the R01 PST]) for the original (unadapted) clinical intervention and implementation strategy versus the DDBT-informed (localized) clinical intervention and implementation strategy. We will conduct a (1) qualitative multiple case study analysis and (2) quantitative meta-analysis across projects. Case studies will examine each project's context, implementation, mechanisms, and outcomes.

For each project, we will also develop analytical summaries to facilitate between-project comparisons. Using the constant comparative method [112], we will compare projects to group common and divergent themes. The meta-analytic synthesis will increase our inferential ability by combining results from the underpowered R34s. For the meta-analysis, each project's mechanism and outcome will be summarized as a Cohen *d* effect size comparing localized DDBT with original clinical intervention and implementation strategy and corresponding 95% CI, using random effects weighting by the inverse of the within- and between-studies variance. Standard data screening and adjustments will be made to the data (eg, to limit the effect of outliers, they will be winsorized). Each project will be additionally advised on how to address possible confounders in analysis and reporting. For instance, projects will be encouraged to use naive participants in the Design and Build and Test phases, recognizing that adaptations of smaller elements of complex clinical interventions may require the participation of experienced participants during the Design and Build phase. In addition, randomization will occur at appropriate levels to avoid contamination by intralevel communication. Nonmonotonic missing data will be addressed via inverse probability weighting or multiple imputation, as appropriate [113]. The Methods Core will aggregate these data across projects into a series of working meta-analyses of the effectiveness of DDBT on each mechanism and outcome.

Finally, determining whether a DDBT-modified clinical intervention and implementation strategy leads to better implementation and clinical outcomes is ultimately a question of mediation. Although the initial R34 and R03 studies are not likely to yield large sufficient sample sizes to meaningfully test such an implementation mechanism question, the R01 PST will provide a direct test of the DDBT theory of change (Figure 2). Aggregating project data over time will allow us to eventually test a range of mediation-focused hypotheses via multivariate network meta-analyses.

Incorporating DEI

During UWAC 2.0, we are improving the integration of DEI initiatives throughout Center activities. Projects selected for UWAC 2.0 and pilots must demonstrate potential substantial impact on clinical or public health outcomes, especially for historically marginalized communities. The Methods Core team provides mentorship on incorporating and adapting methods so that teams are positioned to conduct research that respects diverse populations and maximizes community benefits. Project teams will be provided training and consultation on the Adapting strategies to promote implementation reach and equity method, a 3-step process for adapting implementation science to promote equity, and expertise in methods for explicitly incorporating equity into the measurement of implementation outcomes [114]. We will also collaborate with projects to ensure diverse representation and decision-making during the DDBT phases, crucial stages where diverse viewpoints and demographically representative samples are essential. To facilitate diverse engagement, we will offer resources on building equitable research-practice partnerships, contextualizing implementation science to specific communities, and enhancing community collaborator capacities for community-engaged research. Consultation on quantitative critical research [115] will be provided to examine the treatment of race within quantitative methods and support equity testing through disaggregation, moderator exploration, and mixed methods triangulation.

UWAC additionally supports faculty and staff as part of its DEI work. The center team engages with historically marginalized investigators in planning and conducting center activities so that DEI efforts are integrated throughout center mentoring, pilot funding, methods support, and support for investigators planning future proposals. These measures include enhancing communication strategies based on team science [77] and avoiding a "minority tax," which refers to assigning additional responsibilities to marginalized or underrepresented team members to promote diversity [116,117]. The Methods Core team also advises investigators on using patient-centered and nonstigmatizing language when reporting findings.

Ethical Considerations

The University of Washington Institutional Review Board (IRB) approved materials and procedures for all 4 core projects and deemed projects minimal risk by June 2024 (PST-Aid: STUDY00017272; RUBIES: STUDY00017261; TF-CBT: STUDY00017262 and STUDY00019451; and BRISC: STUDY00017263 and STUDY00019682). All studies follow best practices across studies: review and collect informed consent and Health Insurance Portability and Accountability Act authorizations (when not waived) from participants; collect parental assent for individuals <18 years of age; compensate participants financially for their time and, when appropriate, with continuing education credits; and ensure participants are aware that they may opt out or leave the study at any time. When personal health information (eg, name, date of birth, and contact information) is collected, we preserve participant privacy and confidentiality by storing those identifiers separately from the study data and only linking them to study data via a code. The Methods Core team will provide support to pilot project teams on institutional review board applications after studies are funded.

Results

Overview

UWAC 2.0, including the 4 core projects detailed in Multimedia Appendix 3, received funding in June 2023. We provide a brief synopsis of each study's progress as of January 2025 in the subsequent sections. Across studies, as well as the to-be-funded R03 pilots, we anticipate DDBT will result in changes to the clinical intervention and implementation strategy mechanisms,

proximal implementation outcomes (ie, adoption, fidelity, reach, and adaptation), and clinical outcomes.

R01 PST-Aid

This study began in the Design and Build phase, as the Discover phase was completed during an R34 in UWAC 1.0. For the Discover phase, the study team has completed a codesign workshop and user testing with patients and providers from a nonprofit, health informatics network with independent community-based health centers. The study is beginning the Test phase, and the team is recruiting the first cohort of providers. Providers will be randomized to receive training in either PST implementation as usual (ie, training and sessions supported by paper worksheets for practitioners and clients to use as they complete PST) or PST-Aid (ie, a web-based app that promotes practitioner-client collaboration in the use of PST for goal setting and action planning).

R34 TF-CBT

At the time of submission, the study team has completed a task analysis of unadapted TF-CBT to prioritize components to develop scenarios for testing with students and school-based mental health practitioners. The study has finalized TF-CBT user-testing scenarios and are actively recruiting students and practitioners to begin the first of 3 waves of testing for the study. These data will then inform the redesign of TF-CBT, which aims to be more usable in school settings.

R34 RUBIES

Discover and Design and Build phase study activities, including focus groups, cognitive walkthroughs, and user testing with paraeducators and other school personnel (eg, principals and teachers), are complete. These data are being used to inform the Test phase where the study team is recruiting paraeducators and students and their caregivers to begin RUBIES training. Once recruited, this Test phase will include a 2-year randomized controlled trial enrolling paraeducators and students who will then be randomized to 1 of 2 implementation strategies: RUBIES-Individual or RUBIES-Team.

R34 BRISC

This study is scheduled to begin in April 2025, and the study team has received institutional review board approval.

Discussion

Charting New Research Directions

Our vision is to address persistent issues with usability, engagement, and appropriateness that are barriers to clinical intervention and implementation strategy use by drawing from the fields of HCD and implementation science. The first iteration of the center advanced our understanding of how DDBT can guide clinical intervention and implementation strategy adaptations for uptake in historically marginalized communities. During UWAC 2.0, we aim to continue serving as a multidisciplinary incubator to find viable solutions for improving implementation of clinical interventions and implementation strategies using DDBT through the R01, R34s, and pilot projects. Table 1 summarizes potential outputs and future directions by aim. Focusing on usability, engagement, and appropriateness and providing and testing ways to measure engagement in a clinical intervention and implementation strategy context is particularly novel. UWAC 2.0 will further test the robustness of the DDBT theory of change, expand the potential evidence base for its utility in combining HCD and implementation science for clinical intervention and implementation strategy redesign, and add to the field's understanding of how to apply DDBT to a variety of clinical intervention and implementation strategies and contexts.

Our experiences underscore a benefit of developing additional resources for DDBT, HCD, and implementation science. UWAC 1.0 outputs contributed to foundational conversations on the intersection of HCD and implementation science and produced potential pathways to address conceptual overlap and distinctions [43] and terminology [42]. We additionally developed resources such as CWIS [39], IUS [37], the ISUS [39], and a typology of modification targets and usability issues [53]. We have accumulated substantial experience adapting common HCD methods for different contexts and communities, and we hope these adaptations can support future teams in their use these methods. We plan to build on these methodological advancements, which have been used beyond the UWAC team by a broader research community interested in HCD and implementation science methods and measurement. As we learn with UWAC 2.0 project teams, we will continue to identify and develop additional resources for UWAC project teams and the broader research community on specific methods, team science, equity-oriented design practices, and grant writing. Developing additional resources aligns with the Methods Core team shifting to a consultation model on using the DDBT framework during UWAC 2.0. UWAC projects receive technical support from the Methods Core team with greater emphasis on building local capacity to apply DDBT rather than having the Methods Core team members conduct some of the DDBT activities.

Table 1. Expected center-level outputs and future directions by aim.

Aim	Expected outputs	Potential future work
Aim 1: identify clinical intervention and implementation strategy modification targets to improve usability, engagement, and appropriateness in accessible nonspecialty settings (Discover phase)	• Updated Typology of Modification Targets that expands the previously identified usability issue categories [53] • New insights on engagement and appropriateness issues in clinical intervention and implementation strategy redesign	• Incorporate additional findings from non–UWAC[a]-funded projects that have used the typology of modification targets
Aim 2: develop redesign solutions with local teams to address clinical intervention and implementation strategy modification targets (Design and Build phase)	• Updated Library of Redesign Solutions	• Recommendations on how to approach measuring engagement and appropriateness with a focus on clinical intervention and implementation strategy redesign
Aim 3: determine if redesign affects changes in usability, engagement, and appropriateness (Test phase)	• Integrated cross-project analyses to demonstrate the impact of DDBT[b]-informed redesign	• Further expansion of DDBT and associated methods to new domains in health and social services

Limitations

UWAC 2.0 and the DDBT framework represent a robust effort to integrate HCD with implementation science, although several methodological limitations merit consideration. The standardized measures we are using to assess usability, appropriateness, and engagement have evidence of psychometric soundness, but these measures have not yet been evaluated in all the contexts in which they will be applied. Redesign solutions developed by local teams may rely primarily on context-specific adaptations, which may not generalize to other settings and may not address systemic barriers that impact usability or accessibility. Therefore, reactive modifications (ie, primary outcome) needed to address additional barriers may not be reduced. In this work, there is a tension between our desire to standardize DDBT phases and measures, to facilitate center-wide learning, with promoting the adaptability and flexibility to adapt to specific goals, contexts, and populations that is necessary for good design projects. This, combined with the variability of research project contexts, the small sample sizes of redesign teams and subjective nature of the proposed mechanisms may impede our ability to make inferences across projects.

Conclusions and Impact

There is a pressing need to ensure that clinical interventions and implementation strategies are easily implementable and meet the needs of the communities they aim to help. Integrating HCD and implementation science offers promising approaches to tackle this challenge. UWAC 2.0 expands and strengthens our efforts to ensure that accessible community service settings and marginalized communities see the benefit of decades of research on effective clinical interventions and implementation strategies.

Acknowledgments

This project is funded by the National Institute of Mental Health (2 P50MH115837; principal investigators: ARL and SAM). The funding body had no role in the study design, writing of the manuscript, or decision to submit the paper for publication.

Data Availability

Clinical outcome data for the R01s and R34s will be made publicly available through the National Institute of Mental Health National Data Archive. The quantitative datasets generated and analyzed during this study are available from the corresponding author on reasonable request.

Authors' Contributions

All authors contributed to conceptualizing the study. ARL, SAM, and MDP led funding acquisition and created the protocol with support from the team on methodology. MDP led plans for data curation and formal analysis. ARL, SAM, BM, and TA wrote the original draft with review and editing support from all authors. BM and KPO oversaw project administration.

Abstract

Background: Electronic health records (EHRs) have been associated with information overload, causing providers to miss critical information, make errors, and delay care. Information overload can be especially prevalent in medical intensive care units (ICUs) where patients are often critically ill and their charts contain large amounts of data points such as vitals, test and laboratory results, medications, and notes.

Objective: We propose to study the relationship between information overload and EHR use among medical ICU providers in 4 major United States medical centers. In this study, we examined 2 prominent EHR systems in the United States to generate reproducible and generalizable findings.

Methods: Our study collected physiological and objective data through the use of a screen-mounted eye-tracker. We aim to characterize information overload in the EHR by examining ICU providers' decision-making and EHR usability. We also surveyed providers on their institution's EHR to better understand how they rate the system's task load and usability using the NASA (National Aeronautics and Space Administration) Task Load Index and Computer System Usability Questionnaire. Primary outcomes include the number of eye fixations during each case, the number of correct decisions, the time to complete each case, and number of screens visited. Secondary outcomes include case complexity performance, frequency of mouse clicks, and EHR task load and usability using provided surveys.

Results: This EHR usability study was funded in 2021. The study was initiated in 2022 with a completion date of 2025. Data collection for this study was completed in December 2023 and data analysis is ongoing with a total of 81 provider sessions recorded.

Conclusions: Our study aims to characterize information overload in the EHR among medical ICU providers. By conducting a multisite, cross-sectional usability assessment of information overload in 2 leading EHRs, we hope to reveal mechanisms that explain information overload. The insights gained from this study may lead to potential improvements in EHR usability and interface design, which could improve health care delivery and patient safety.

KEYWORDS

electronic health records; information overload; eye-tracking; EHR usability; EHR interface

Introduction

Electronic health records (EHRs) can be a source of information overload for providers; however, the mechanisms that explain overload and their link to patient safety are not understood. Information overload in the EHR is associated with missing critical information that affects the decision-making process [1-3]. Studies have relied on secondary data analysis or subjective measures to assess the effect of information overload on decision-making processes; however, the use of physiological and objective data to study information overload has shown great potential in other domains [4]. We propose using eye-tracking approaches coupled with objective patient safety measures to investigate current EHR design flaws [5-9]. These methods reveal mechanisms that explain overload, such as fatigue and degradation in performance. Furthermore, poor EHR interface design contributes to inefficiencies [10], frustration [11], and medication errors [12].

Although advantageous over paper-based documentation, EHR use is associated with new physician-related challenges that may increase medical errors [13]. EHR interface design can lead 50% of providers to make an error when ordering medication tapering [12]. In addition, too much information contributes to patient safety risks, such as 30% of providers missing test results in the EHR, leading to care delays [2,14]. Information overload increases cognitive load and error rates among physicians during clinical simulations. Common issues contributing to information overload included an overabundance of clinically irrelevant information, poor data presentation, and excessive alert notifications [15]. However, we have limited knowledge of the relationship between information overload and EHR usability.

Our study uses objective eye-tracking data along with self-reported task load and usability surveys to better understand the challenges Intensive care unit (ICU) providers face in using EHRs to provide patient care. By measuring providers' performance, information seeking load, and information processing load, we aim to characterize information overload in the EHR by examining decision-making and usability outcomes.

Methods

We conducted a multisite, cross-sectional usability assessment of information overload in 2 leading EHRs among medical ICU providers in 4 US medical centers. Between the 4 sites, 2 leading EHR systems are used. The ICUs at the medical centers vary in terms of the catchment area; however, all 4 medical centers in the study are considered level I trauma centers, each with level 3 ICU support. The number of ICU beds between the 4 medical centers ranges from approximately 74 to 200 ICU beds each.

Providers will be recruited by the individual study site teams at each medical system using emails, flyers, and word of mouth. Interested providers will be asked to complete an initial screening survey before scheduling a session to ensure that they are an ICU provider or, if they are a resident, that they have completed at least one ICU rotation.

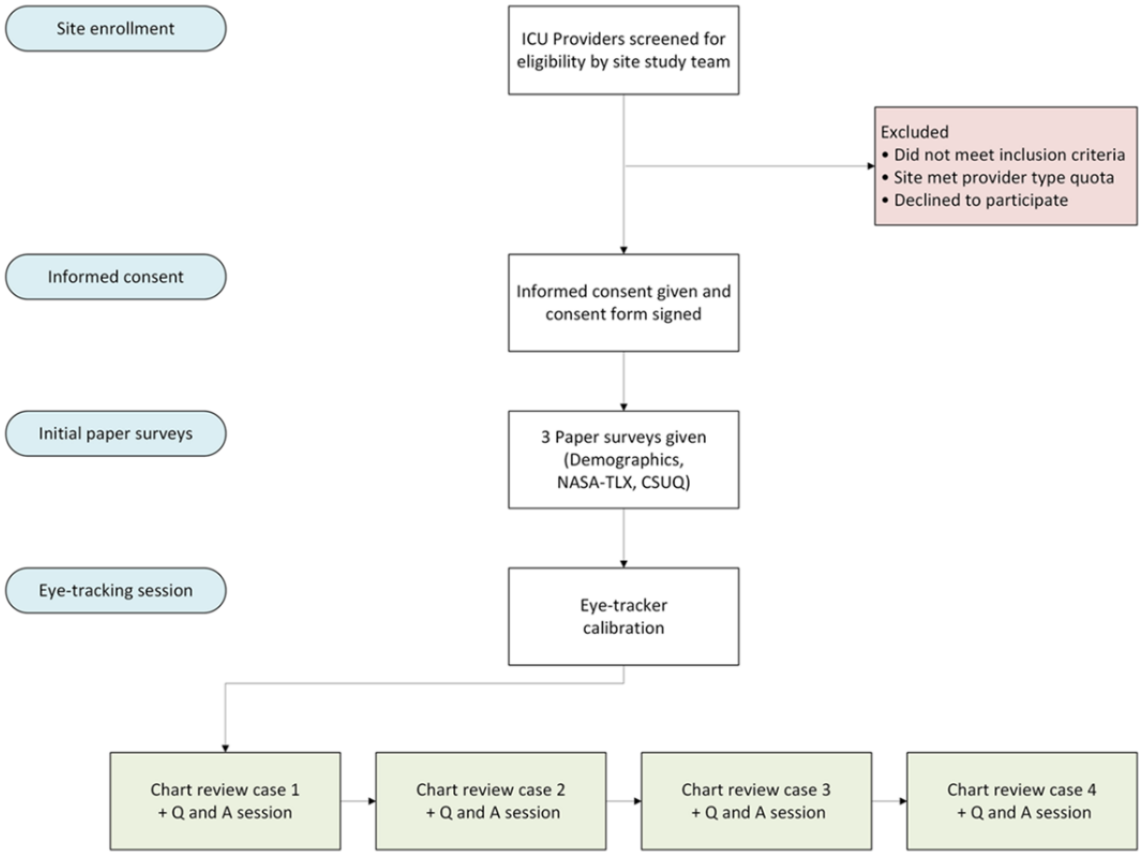
The sessions will occur in a simulation laboratory or private space that mimics the ergonomics of natural inpatient settings. Our team used the standard computer screen in each practice setting, with ICU-like ergonomic placement, ambient lighting, and seating. To ensure standardization among the cases, the lead investigators at each site met via Zoom (Zoom Video Communications) to determine a rubric for patient records to be included in the study. The study team created 4 ICU patient cases for inclusion, based on reviews of our 2 domain experts. Next, the domain experts created a set of universal experimental questions and tasks for providers to complete for each patient.

Before each session, the usability specialist explained the study and consent forms to providers, assuring them that the goal is to assess EHR usability rather than clinical knowledge. Participants are informed that their participation is voluntary and that they can decline to participate at any time. After the informed consent has been obtained, each provider will be asked to complete 3 pages of paper surveys.

We then ask providers to complete a basic calibration exercise while looking at the monitor which allows the eye-tracking software to be calibrated to each provider's eye shape and eye size. We record pupil diameter and fixation points on the screen continuously during the study session. All sessions used the same screen-based eye tracker.

Each provider was then logged in to their institution's EHR environment, where 4 simulated ICU patient records are presented in random order to eliminate selection bias. Providers reviewed 1 patient case at a time and were encouraged to review the patient chart as if they were prerounding on this patient, using their typical workflow. The provider then indicated to the research assistant (RA) when they completed their chart review and were ready to begin a series of question-and-answer activities about that specific patient. The RA asked the provider a series of questions in which the provider responded verbally, and the RA recorded the answers using both audio and written recordings. Providers were allowed to navigate through the EHR to answer these questions. After completion of question-and-answer activities, the provider then reviewed the next patient record. A process map detailing the study procedure from enrollment to usability session can be seen in Figure 1.

Figure 1. Process map illustrating the various study steps from recruitment to completion of the usability session. CSUQ: Computer System Usability Questionnaire; ICU: intensive care unit; NASA-TLX: National Aeronautics and Space Administration–Task Load Index; Q and A: question and answer.



Patient Cases

A team of critical care physicians created 4 patient cases. Each patient was representative of a patient that could be hospitalized in an ICU setting. Of the 4 patients, 2 were considered basic or "standard" ICU patients while 2 were considered to be complex patients. The 2 basic patients were less critically ill, not currently ventilated, on fewer medications, and had fewer abnormal laboratory values. The 2 complex patients were critically ill with many abnormal laboratory values, on the ventilator with poor oxygenation, and on complicated medication regimens.

The nurse informatician on the study team worked with the primary investigator and each site's study team to build the patient cases in their institution's EHR test environment. The same 4 cases were used at all study sites, and the nurse informatician monitored case builds to ensure consistency and accuracy across study sites.

Case Questions

Providers were asked 5 questions for each patient following their preliminary chart review. These questions were created by a critical care physician (TB) and reviewed by a critical care physician team before data collection. Questions were written to ensure the answer is present within the EHR and that providers at different levels of experience can realistically locate the answer. While some questions were considered more basic and only needed 1 EHR screen or data point to answer, other questions were more complex and required synthesizing multiple data points or locating information not frequently accessed. This approach allows us to analyze the time it takes to answer these questions and how many EHR screens and mouse clicks each provider uses before answering a question. Questions were scored as either correct, partially correct, or incorrect by the team nurse informatician. Alternate answers will be reviewed by a critical care physician (SC) for scoring.

Sample

Our initial goal was to recruit 80 ICU providers, 20 at each site, with the following distribution: 15 physicians and 5 advance practice providers (APPs). The physician group will be divided into 3 subgroups: 5 attending physicians, 5 fellow physicians, 5 resident physicians, and 5 APPs including nurse practitioners and physician assistants. Our actual recruitment was 81 ICU providers, comprised of 53 physicians and 28 APPs. Each study team's local RAs circulated departmental emails and flyers at each site. They provided interested individuals with a link to an online calendar showing available time slots to facilitate appointment scheduling. Once an appointment was scheduled, the RA emailed each participant their appointment time and location with a map, as well as a contact number for same-day inquiries or cancellations. Inclusion criteria: ICU physicians and APPs on active full-time ICU service OR Residents who have completed at least 1 ICU rotation, use an institutional EHR, and speak English.

Statistical Power

The design effect arising from the clustering within-person inherent to the study's design is estimated using the following formula: $D_{eff}=1+(m-1)$, where m=average cluster size (4 cases)

and *P*=intraclass correlation coefficient (ICC). Assuming an ICC of .6 (a common ICC for similar intensive repeated measures designs), the application of this equation results in D_{eff} of 1.09, for an effective sample size of 294 (320/2.8). In a multivariable linear regression context assuming N=114, 5 person-level effects, 3 case level effects, a 2-tailed critical *P*=.05, and 80% power, the minimum detectable effect size is represented by a Cohen f^2 of 0.10, which is considered a small effect. In a multiple logistic regression with 2 tailed critical *P*=.05 and 80% power, the minimum detectable odds ratio is 3.23, which is considered a medium-sized effect.

Materials and Software

To measure the extent and effect of EHR information overload, we used several tools during the 1-hour sessions.

Providers were asked to complete 3 paper surveys before the eye-tracking session. The first survey asked basic demographic questions, including age, gender, years since graduation (medical school or APP schooling), years of experience with their institution's EHR, and the estimated number of hours they use their institution's EHR each week. We also asked the providers if they are on service that day (pre- or post-usability session) and to rate their level of sleepiness and stress on a Likert scale. The second paper survey used was the NASA (National Aeronautics and Space Administration) Task Load Index (NASA-TLX) which asked providers to rate the task load of their institution's EHR, including how mentally and physically demanding it is to use and their level of satisfaction and confidence with using the EHR [16]. The third and final paper survey was the Computer System Usability Questionnaire (CSUQ) which asked providers to rate their satisfaction with their institution's EHR system including questions about usability, ease of use, the system interface, and overall functionality [17].

Our study used a noninvasive screen-based eye tracker to provide further insights into a provider's cognitive processing during the sessions. The Tobii Pro Fusion is an advanced eye-tracking system with 2 eye-tracking cameras taking up to 250 images per second to ensure accuracy. The Pro Fusion mounts onto the bottom of any monitor, allowing us to record eye-tracking data seamlessly. The Tobii eye-tracker was used with Tobii Pro Lab software to create a seamless recording that includes eye-tracking data and screen recording. Used by renowned researchers in medicine and psychology [18,19], the Tobii eye-tracker and software will provide us with fixation points, gaze areas, and eye movement type. These measures will provide us with insight regarding providers' information processing behaviors, in particular, the relationship between fixation points (a measure of concentration) and the outcome variable (decision-making accuracy). We have expertise in analyzing large and complex data sets from Tobii, considered the most accurate eye-tracking device manufacturer in the world.

Outcomes

Primary outcomes are cognitive overload (ie, fixation points), usability (clicks and completion time), and performance score. Secondary outcomes are the provider reported EHR workload and usability using the NASA-TLX and computer system usability questionnaire surveys.

To characterize information overload, we will explore under what conditions providers experience EHR information overload. We will accomplish this by determining which patient cases create the highest level of information overload, indicated by the least number of eye fixations, meaning a loss of concentration. We also want to understand the consequences of a lack of concentration as it relates to decision accuracy and time. Understanding the underlying factors and the consequences of information overload will fill a significant gap in the literature.

Analytical Plan

Each participant will receive a single score for each question determined by the domain expert (0: incorrect, 0.5: partial, and 1: correct). Correct decisions are the aggregate of the correct answers, and errors are the aggregate of the incorrect answers. For each participant, we will compute a score for each patient case and a total score for all the patient cases. Case scores will depend on the number of questions asked, such that if a case has 5 questions to be answered, the total score of this case will be equivalent to the highest possible points (5).

Our past work will inform ways to compute case scores [10,12]. Responses and scores will be assigned by 2 domain experts (the site-Principal Investigator and a senior ICU provider).

Eye-tracking data gives the frequency and duration of fixations for each participant. We will calculate participants' fixation points based on (1) total fixations for the study, (2) total fixations per patient case, and (3) total fixations per EHR screen visited.

We will compute descriptive statistics for patient and case characteristics, employing chi-square tests, *t* tests, and ANOVAs to examine between-group differences, where appropriate. We will examine differences between provider types (physicians and APPs), as well as between sites. Given the nested nature of the data (ie, repeated case assessments nested within providers), we will use multilevel modeling as the primary analytic approach. Each patient case will be coded based on the days of ICU stay and the presence or absence of key characteristics such as vent settings and intake and output, to determine the level of complexity. Case variables will be entered into the model as case-level (Level 1) predictors. Models will also account for person-level (Level 2) factors such as participant gender, age, clinical role, site, and years of EHR experience. We will use SAS (version 9.4; IBM Corp) using PROC MIXED for continuous outcomes and SAS PROC GLIMMIX for binary and count outcomes.

Ethical Considerations

Recruitment and site testing occurred sequentially, such that the study was implemented at one site at a time, allowing the study team to be present on site to add organization to the data collection process. Each participant was required to read and sign a consent form specific to their medical center, witnessed by a representative of that medical center. Participants were allowed to opt out of the study at any time. We used one

screen-based eye-tracker device for data collection at each site. We recruited through flyers and departmental email communications at each site. Participants were compensated with a US $100 gift card for their participation. All data collected were deidentified and study participants and their data were assigned a unique identification number. Study data entry and management systems are secured and password protected to ensure participant privacy and confidentiality. The University of North Carolina at Chapel Hill's institutional review board (IRB) approved this study (IRB #20-3384).

Results

This EHR usability study was funded in 2021. The study was initiated in 2022 with a completion date of 2025. Data collection was completed in December 2023 with a total of 81 provider sessions recorded. The primary analysis is ongoing and expected to be published in early 2025.

Discussion

Study Significance and Strengths

This study aims to characterize information overload in the EHR and uncover possible improvements to EHR interfaces and user skills. We will deploy a mixed methods approach to better study providers' reactions to information overload in the EHR. We will use usability evaluation metrics, eye-tracking, and surveys to assess the aforementioned relationship. The use of physiologic data, namely eye-tracking, will produce new knowledge about providers' cognitive performance during EHR interaction. Eye-tracking will allow us to quantify fixation points, a measurement of cognitive overload, as providers interact with basic and complex ICU patient cases. In this study, we examine the 2 most prominent EHR systems in the US, which will generate reproducible and generalizable findings that can be applied to clinical settings using an EHR system. Another strength of this study is the inclusion of different professional roles, including residents, APPs, fellows, and attending. This diverse sample will enable subgroup analysis to test if information overload has similar effects on different professional roles.

Examining information overload within EHRs will demonstrate the critical impact of EHR usability on clinical decision-making, especially in high-pressure environments like ICUs. By measuring and assessing information overload, we can identify design opportunities in EHRs that may improve providers' ability to access and process vital information. This knowledge enables health systems to enhance patient safety and the quality of care by tailoring training and support systems that address specific challenges faced by providers. Future research needs to involve longitudinal studies to evaluate the long-term effects of information overload on clinical performance and patient outcomes. Incorporating qualitative methods, such as interviews with providers, will complement our quantitative findings to create a comprehensive understanding of EHR interactions. Potential interventions may include the implementation of information visualization within EHRs to facilitate information processing, implementing tailored training programs for providers, and developing integrated decision support tools. These research goals aim to enhance EHR usability, reduce the cognitive burden on health care professionals, and promote a safer and more efficient health care delivery system.

Limitations

Although we proposed adequate recruitment numbers, we understood that recruiting the exact number of participants in each professional role may be challenging. Alternatively, we expanded recruitment to include medical ICUs in other affiliated hospitals within the same health care system. All study sites include multiple hospitals to enable expanding recruitment within the same system and under the same IRB. Potential bias may occur from recruiting participants who are technology enthusiasts. We attempted to mitigate this bias by predefining a quota for every professional role to ensure we have representation from junior and senior providers. This mix of roles was done to include persons with varying degrees of technological astuteness.

Variations in EHR design and performance may affect the study findings. We account for this limitation by including the 2 most prominent EHR systems and 4 different medical centers, leading to more generalizable findings. The study protocol was not published earlier to keep the study design and the components of the patient cases undisclosed to avoid introducing bias to potential participants.

Future Directions

We will use our findings from this study to guide future research on information overload in the EHR. Observations of the current opinions and functionality of each of the 2 institutional EHRs will be used to prepare for a randomized controlled trial using the same 4 US medical centers. This randomized controlled trial will compare the current institutional EHR's interface with a visualization dashboard, examining the differences in provider efficiency and fatigue.

Conclusions

Our study aims to characterize information overload in the EHR by examining decision-making and usability outcomes among medical ICU providers. By conducting a multisite, cross-sectional usability assessment of information overload in leading EHRs, we hope to reveal mechanisms that explain overload, such as fatigue and degradation in performance. Through the use of eye-tracking approaches coupled with objective patient safety measures, we aim to investigate current EHR design flaws and their impact on decision-making processes. The insights gained from this study will contribute to a better understanding of the relationship between information overload, EHR usability, and patient safety, ultimately leading to potential improvements in EHR interface design and health care delivery.

Acknowledgments

We sincerely thank the study site teams at Mayo Clinic, Medstar, and UPMC for their collaboration on this important work.

Abstract

Background: Teens with socially complex needs—those who face multiple and potentially overlapping adversities—are disproportionately affected by several barriers to mental health screening and treatment. Pediatric primary care (PPC) is a typically low-stigmatized setting for teens that is visited at least annually. As such, implementing digital mental health tools (DMH), as low-intensity treatments in PPCs may increase the reach of such tools for teens with socially complex needs.

Objective: This study aimed to evaluate the Teen Assess, Check, and Heal (TeACH) System in comparison to a control condition while integrated into PPCs at 2 Medical Centers serving teen patients in Chicago, Illinois. Through collaboration with key players throughout the design and implementation planning phases, the TeACH System is hypothesized to increase teen patient self-reported engagement with DMH and address specific individual-level barriers to mental health care, compared with a digital psychoeducation control condition.

Methods: Eligible participants will be recruited through PPC clinics housed within the University of Illinois Chicago (UIC) and Rush University Medical Center (RUSH). Recruitment involves invitations from research staff members and primary care clinicians and staff members, as well as posting flyers with QR codes at the specified clinics. All participants complete a brief demographic survey, baseline survey, and Kiddie-Computerized Adaptive Tests Anxiety Module. Participants are randomized to receive either the control condition (digital evidence-based workbook) or the intervention (TeACH System Feedback and Resources). All randomized participants will then be invited to complete an immediate and 1-week follow-up survey. The primary outcomes assess changes in engagement with DMH (ie, likelihood to use DMH for anxiety and actual DMH use) and individual-level barriers to mental health care (ie, symptom understanding and confidence to act). Descriptive analyses will be conducted to characterize the sample and usability ratings of the TeACH System. Linear or generalized linear mixed effects regression models will examine differences in primary outcomes over time.

Results: Recruitment began in July 2024 and data collection is expected to be completed by August 2025. To date, 122 teens have assented to complete study activities, 80 have been randomized (an additional 24 teens have had subthreshold anxiety symptoms and were therefore not randomized), and 42 teens have completed the 1-week follow-up assessment.

Conclusions: This study will provide preliminary feasibility data that may inform how the TeACH System and other DMH low-intensity treatments might better engage and support teens with socially complex needs.

Introduction

Background

Even before the multiple endemics occurring since 2020, pediatric mental health disorders and symptoms were the leading causes of disability and negative sequelae for youth [1]. For some time, mental health disorders have been the most common disease of childhood in the United States, surpassing the *combined* rates of multiple pediatric conditions (eg, cancer and diabetes) [2-4]. Despite the tremendous impact of mental health disorders on teens, millions do not receive mental health care [2]. Anxiety is particularly untreated, as up to 80% of youth with a diagnosable anxiety disorder do not receive mental health care [2,3,5]. Most exposed to this failure of mental health care are teens with socially complex needs, those who face multiple and potentially overlapping adversities, such as (1) enduring adverse childhood experiences, (2) residing in a systemically excluded community that experiences disproportionate disparities in health outcomes and health care access, or (3) being minoritized due to socioeconomic status as well as racial, ethnic, gender, or sexual identity or identities [1,6-8]. Teens with socially complex needs have multiple barriers placed between them and mental health care, which the current system is failing to address [9-15]. As such, traditional methods for reaching such teens are not working, resulting in life-long health disparities and a significant public health impact [2,6,7,16,17].

Digital Tools Implemented in Primary Care to Extend Care Capacity

Pediatric primary care (PPC) is one setting with strong potential as an environment to engage and screen teens with socially complex needs. Indeed, nearly all youth visit a PPC office annually for well-child visits as well as illnesses or injuries that necessitate care (eg, ear infection) [18]. As such, PPC is a centralized and typically low-stigmatized setting for teens of all backgrounds. Mental health care is increasingly warranted in PPC, with the American Academy of Pediatrics recommending universal anxiety screening for all children and adolescents, aged 8-18 years, during PPC visits [19]. However, PPC providers report variable administration of standardized assessment measures [20] and multiple barriers to mental health screening, broadly [20-22]. Further, when mental health needs, such as anxiety, are screened or arise in PPC, pediatricians report multiple barriers to assessing mental health needs and connecting patients to therapy [23,24], adding to the obstacles to care noted above. Even in the case of using a collaborative care model for depression in primary care [25], a pragmatic approach for anxiety that embraces the logistical realities that providers face in delivering mental health screening and ensuing recommendations is lacking [26,27]. A potential solution to these barriers is to incorporate digital mental health tools (DMH) as a low-intensity treatment (LIT) into PPCs. LITs are patient-facing tools that may provide screening, psychoeducation, resources, or combinations of these items. Given the long-standing efficacy of LITs in digital and other delivery mechanisms for mild to moderate symptom presentations (eg, self-help books) [28], DMH LITs have been proposed as a scalable and strategic first-line model of care in PPC and similar care environments [29].

Integrating DMH LITs into spaces that teens already visit, such as PPC, has the potential to increase mental health care reach. However, uptake and subsequent clinical outcomes will not be impacted if teens do not engage with DMH in their daily lives [30]. One problem is a lack of implementation planning early on in the design processes for DMH [31,32]. Also implicated in poor engagement is a failure to address the range of multilevel implementation barriers, spanning from individual-level barriers (eg, problem recognition, stigma, and confidence to act), intervention barriers (eg, usability and relevance), and systemic barriers (eg, accessibility and cost) [24-27,33]. Interventions such as incorporating motivational interviewing [34] and usage incentivizes [35-37] have improved DMH engagement, but diminish scalability [38]. As such, means to target barriers must be identified and harnessed to address poor engagement, the perennial failure of DMH deployment to date.

Objectives

In this study, human-centered design methodologies and an implementation science framework [39-41] were used to guide the development and implementation of the Teen Assess, Check, and Heal (TeACH System). Through the use of these methodologies and frameworks, the TeACH System was designed to target individual-level barriers to care (eg, feedback to directly respond to problem recognition, stigma, and confidence to act on symptoms), DMH intervention barriers (eg, human-centered design methodologies to optimize usability and relevance), and systemic barriers to care (eg, increase accessibility by integrating in a space already visited by teens, remove cost barrier by providing a freely accessible service and resources) [24-27,33]. Our primary aim was to increase DMH

engagement for teens with socially complex needs through: (1) engaging teens and caregivers from the systemically-excluded and underserved communities of Chicago, Illinois, to refine the TeACH System to be engaging, appropriate, and in line with cultural and user needs; and (2) integrating the TeACH System into PPCs serving teens on the West Side of Chicago. The West Side of Chicago was selected for initial implementation planning and integration evaluations as part of a larger body of research focusing on adapting DMH LITs for and with teens living in communities disproportionately inflicted with health disparities, violence exposure, and higher economic hardship (eg, [42]). Through collaboration with key players throughout the design and implementation planning phases, the TeACH System was hypothesized to increase teen patient self-reported engagement with DMH and address specific individual-level barriers to mental health care, compared with a digital psychoeducation control condition. This hypothesis is being evaluated through a pilot feasibility randomized controlled trial in Chicago PPCs, comparing engagement outcomes for teens with anxiety randomized to use the full TeACH System to those who are provided access to a publicly available, digital evidence-based workbook for teens (psychoeducation control) [43,44].

Methods

Positionality

Positionality influences all aspects of a research study and is connected to the researchers' personal and philosophical views [45]. In recognition of this influence, the positionality of the lead author of this study has been reported elsewhere [23] and is similarly described: (1) author CSS is a lifelong Chicagoan, (2) trained social worker, and (3) a pediatric psychologist who believes that engaging youth with DMH and in health environments they already frequent maybe 1 path to get more resources directly to youth to use as they need and want, but that DMH will not become a panacea to disparities. As a monolingual, White woman trained in health care settings, she has biases and experiences that may impact her interpretation of findings (eg, she is comfortable in health settings; DMH has primarily been tested with individuals who have overlapping identities with her [eg, college-educated and White women] [46]). To minimize bias, author CSS partnered with key players, by establishing interdisciplinary mentor and peer collaborator teams, to learn with teens, caregivers, and providers about their wants and needs for DMH in health care settings.

Procedures

Study Design

The study design is a pilot feasibility randomized controlled trial. The participant focus is teen patients in PPCs with anxiety. While universal anxiety screening is recommended [19], pediatric anxiety has a long-standing history of being underrecognized and often untreated [47-49]. Participants first answer initial screening eligibility questions (ie, age, clinic location, and ability to complete and read surveys in English), followed by completing a digital assent. While a waiver of guardian consent was obtained from the institutional review board, participants are able to "opt in" to have a guardian provide consent in English or Spanish, should they elect to do so. Following assent and optional guardian permission, participants complete a brief demographic survey, indicate their preference for future contact (ie, text message or email), and complete a brief assessment of the primary outcomes (Measures section). All participants then complete the Kiddie-Computerized Adaptive Tests (K-CAT) Anxiety Module [50] to ensure eligibility (ie, a score >29 and indicating mild or greater anxiety symptoms). Participants who do not meet these criteria are excluded and offered access to a publicly available, digital evidence-based workbook for teens [43,44]. Participants who do meet the criteria for mild or greater symptoms of anxiety are randomized into either the control arm (digital evidence-based workbook [43,44]) or the Intervention Arm (TeACH System Feedback and Resources). Randomization is automated through the Research Electronic Data Capture (REDCap, Vanderbilt University) platform, and study staff members are blind to allocation. Following a review of these resources, all participants are invited to complete an immediate follow-up survey. One week following this interaction, participants are invited to complete the same follow-up survey. Figures 1 and 2 display the study design flow.

Figure 1. Participant flow through TeACH system trial in pediatric primary care K-CAT: Kiddie-Computerized Adaptive Tests.

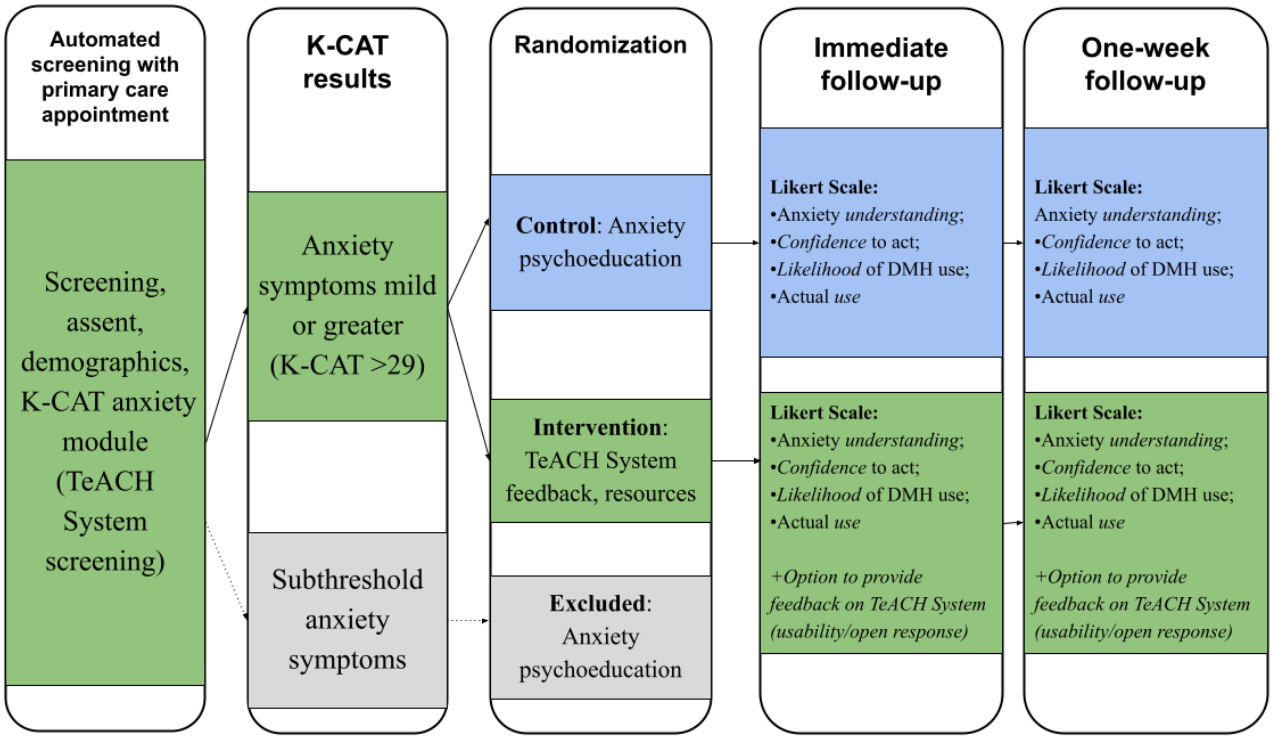

Figure 2. Study flow diagram.

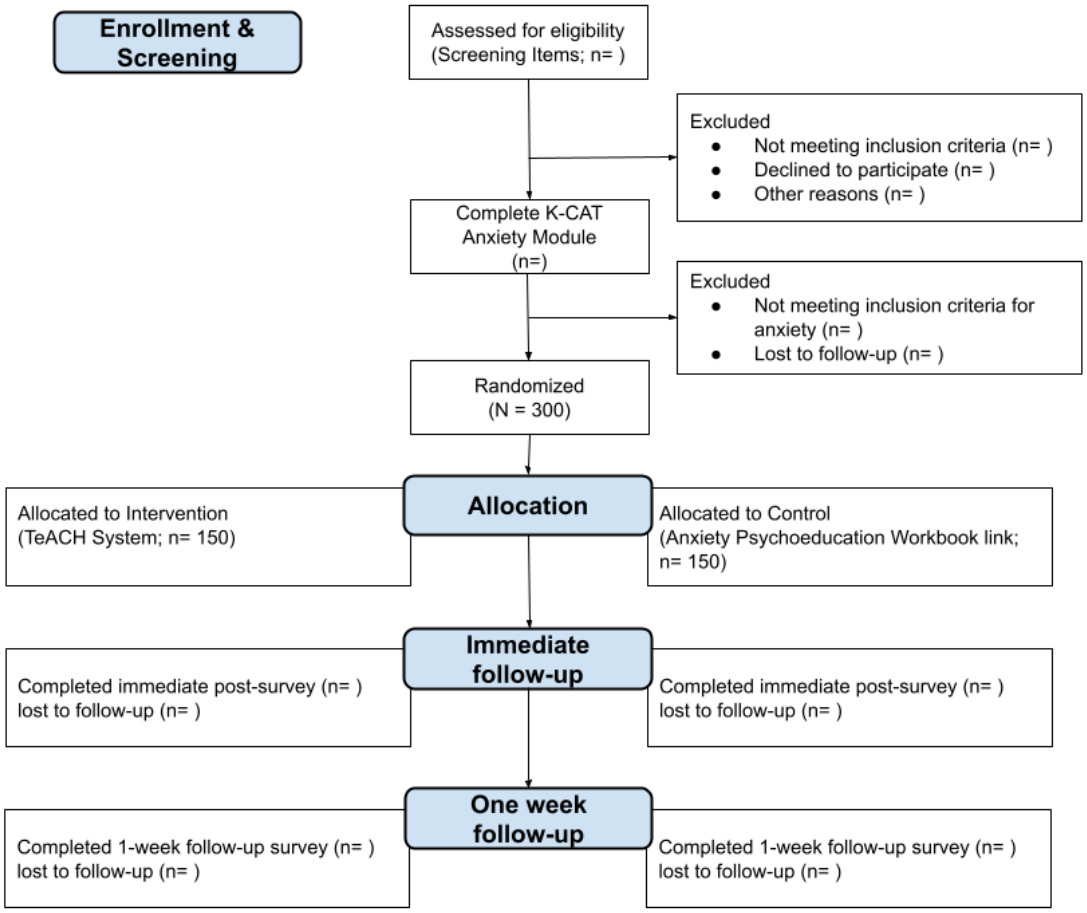


Setting and Recruitment

Eligible participants are being recruited through PPC clinics housed within the University of Illinois Chicago (UIC) and Rush University Medical Center (RUSH). Both hospital systems' primary campuses are situated on the West Side of Chicago and serve diverse patient populations [51,52]. Eligible participants are being recruited in clinics through (1) QR codes on displayed and circulated flyers, including sharing of the flyer by PPC pediatricians, trainees, and staff; and (2) invitation from research staff (ie, offered tablet in the clinic waiting room or while waiting in an exam room) or PPC clinicians and staff members.

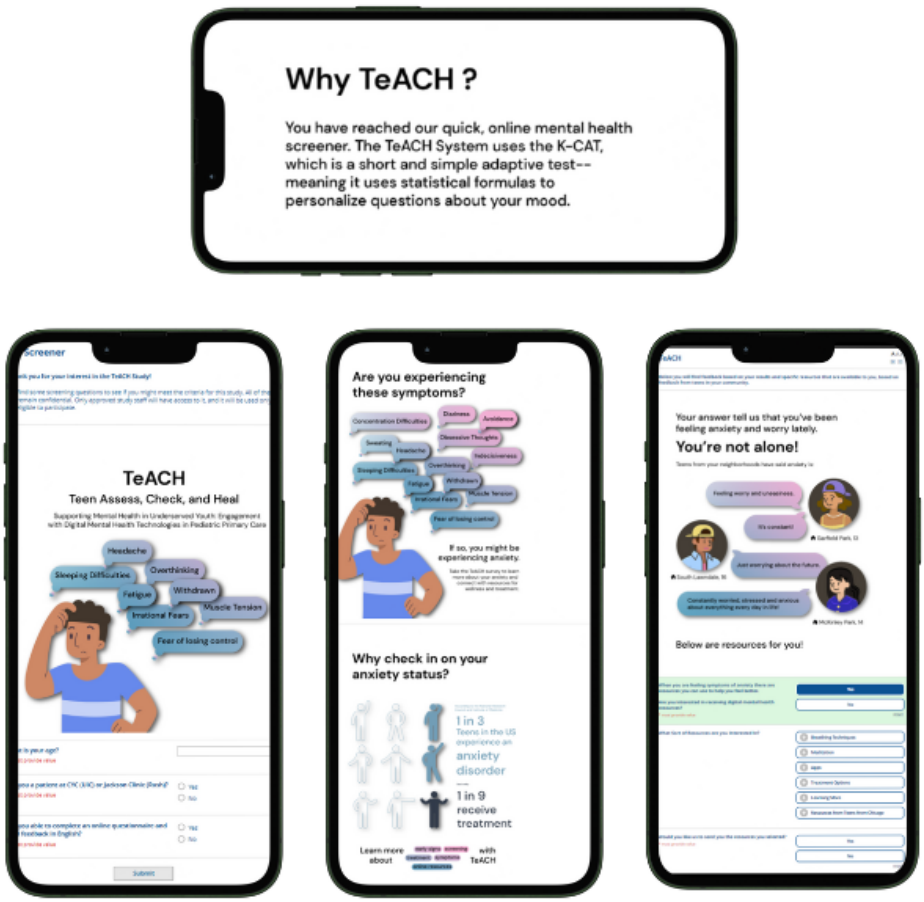
Inclusion and Exclusion Criteria

For study inclusion, participants must be (1) receiving care at the specified clinics at UIC or RUSH; (2) between 13 and 17 years of age; and (3) able to speak and read in English. These inclusion criteria are determined by teen self-report (ie, answering 3 screening questions based on these criteria). Following assent and completion of a demographics and engagement survey (Measures section), final inclusion criteria are assessed based on responses to the K-CAT Anxiety Module. Namely, to be randomized, participants must also meet criteria for mild or greater symptoms of anxiety (ie, K-CAT Anxiety Module score >29) [50]. There are no assessments for comorbidities, nor any exclusion criteria beyond not meeting the inclusion criteria noted above.

TeACH System

The TeACH System is a DMH LIT that includes teen patient-facing brief assessment, feedback, and resources for symptoms of anxiety (sample screenshots displayed in Figure 3. Increasing DMH engagement for teens with socially complex needs is the primary aim of the current iteration of the TeACH System. The mechanism to achieve this outcome includes the use of key player involvement throughout the design and implementation planning processes. Consistent with a broad spectrum of community-engaged research practices [53], involvement of teens and caregivers from the West and South Side Communities of Chicago have ranged from 1-time interviews and focus groups to co-design activities, with plans to form a community advisory board for the broader line of research led by this team [42,54,55]. Most relevant to the design of the current iteration of the TeACH System (eg, direct quotes described below), formative usability testing sessions were completed remotely with 10 teens (mean age 15.9, SD 0.99 years; female: n=8, 80.0%; Hispanic or Latino: n=6, 60.0%; Middle Eastern of North African: n=1, 14.3%; White: n=6, 60.0%) and 7 parents of teens (mean age 41.86, SD 8.7 years; female: n=5, 71.4%; Hispanic or Latiné: n=1, 14.3%; Middle Eastern or North African: n=1, 14.3%; Black or African American: n=4, 57.1%) from the West and South Side Communities of Chicago.

Figure 3. Sample screenshots of the TeACH system.



TeACH System Assessment

The TeACH System uses the Kiddie-Computerized Adaptive Tests (K-CAT) Anxiety Module to assess teen patient anxiety symptoms [50]. The K-CAT Anxiety Module (youth report; ages 7 to 17 years) uses an item bank of more than 200 items, typically offering 10 questions to a teen user to predict the likelihood of a diagnosis of generalized anxiety disorder (area under the receiver operating characteristic curve=0.83). However, the module is not limited to generalized anxiety disorder and may also be used for general anxiety screening in youth [50]. Future iterations of the TeACH System may use the full K-CAT (ie, assessing anxiety, depression, substance misuse, oppositional defiant disorder, attention-deficit/hyperactivity disorder, mania, conduct disorder, and suicidality), but the current version of the TeACH System is solely assessing anxiety. This decision was driven by input from PPC clinicians and staff members who expressed concern about follow-up mental health care, safety, and workflow disruptions around more expansive digital mental health assessments [23]. Participants in the current study are eligible for randomization with a score greater than 29 on the K-CAT Anxiety Module, indicating mild, or higher anxiety symptoms [50].

TeACH System Feedback

Following the completion of the K-CAT, the TeACH System informs users that they will be provided feedback and specific resources that were informed by feedback from "teens in your community." The feedback provides an infographic that starts by stating: "Your answer tells us that you've been feeling anxiety and worry lately," followed by the validation that "You're not alone!" Following this, 4 quotes from Chicago teens describe anxiety as: "feeling worry and uneasiness"; "It's constant!"; "Just worrying about the future"; and "Constantly worried, stressed, and anxious about every day in life!" before proceeding to viewing resources, users are prompted that "When you are feeling symptoms of anxiety, there are resources you can use to help you feel better." In sum, the feedback section aims to briefly address multiple individual barriers to care, including problem recognition (ie, "Your answers tell us that you've been feeling anxiety and worry lately."), stigma (ie, "You're not alone!" and quotes from "Teens from your neighborhoods"), and confidence to act (ie, "When you are feeling symptoms of anxiety, there are resources you can use to help you feel better") [24-26].

TeACH System Resources

Following the feedback, users are asked if they would like to receive DMH resources. The resources are all freely accessible online and are presented to participants through both sample screenshots and links to their direct sources (eg, App Store, YouTube, and TikTok). All resources are grounded in evidence-based skills (eg, progressive muscle relaxation and diaphragmatic breathing) and psychoeducation (including brief videos from teens and young adults with lived experience with anxiety). If participants indicate that they do not wish to receive DMH resources, they are asked to provide a reason as to why. If they would like to receive DMH resources, they are asked what types of resources they would prefer (eg, "Breathing Techniques," "Apps," and "Learning More"). This checkbox selection allows teens to view the content they wish, as opposed to getting all options at once, which can be overwhelming. Users may also opt to have the resources sent to them at their preferred method of contact (ie, email or text message).

TeACH System Platform

The TeACH System is intended to be adaptable and scalable. As such, using a simple but secure platform that may be easily edited at minimal cost was ideal. UIC's instance of REDCap was therefore selected as the platform to build and manage the TeACH System [56]. REDCap is housed and managed by the University, as is common across multiple university and health care systems. To enhance the aesthetic appeal and engagement of the TeACH System for teen users, the UIC Innovation Center collaborated on its development within REDCap. An interdisciplinary team of researchers applied human-centered design techniques and analysis frameworks to effectively present the survey and maintain participant interaction throughout. They used user journey maps and extensive user testing to ensure a smooth and intuitive survey flow. The team also crafted a distinct visual language for the TeACH System, incorporating contemporary graphic elements inspired by popular social media platforms, calming color choices, and clear, simple language to appeal to the teen audience and put users at ease.

Control Condition

Following screening, assent, demographic characteristic assessment, and completion of the K-CAT Anxiety Module, participants randomized to the control condition receive different feedback and resources than those allocated to interact with the full TeACH System. The control condition includes immediate feedback about anxiety symptoms (ie, "Your answers tell us that you've been feeling anxiety and worry lately."). Following this, participants are queried whether they would like access to a digital resource. If they respond negatively, they are prompted to provide their reasoning. If they respond positively, they are provided with a direct link to a free download of an evidence-based workbook for teens with anxiety [43,44].

Measures

Demographics

Following assent, teens are asked to report the following demographic information: name, age, ethnicity (Hispanic or Latiné and Middle Eastern or North African), race, pronouns, gender, preferred language, the reason for visiting primary care, and preferred method for contact (ie, email or text message).

Primary Outcomes

The primary outcomes are administered within REDCap and are assessed at 3 time points for all participants: (1) baseline: following assent and before administration of the K-CAT; (2) post interaction: immediately after receiving the allocated feedback and resources; and (3) maintenance: 1 week following the interaction. The primary outcomes are discrete variables focusing on individual-level barriers to mental health care (ie, symptom understanding, confidence to act [24-26]) and engagement with DMH (ie, likelihood to use DMH for anxiety, actual DMH use). Namely, through a questionnaire created for this study, participants rate on a Likert scale (1=not at all to

5=completely): (1) anxiety *understanding* (ie, "I understand what anxiety is."); (2) *confidence to act* (ie, "I feel confident I can do something if I feel anxiety."); and (3) *likelihood* to use digital tools for anxiety (ie, "If I feel anxiety, I would use a digital tool to help (app, website, and reel or video)."). Following this, participants indicate whether they have used a digital tool for their anxiety before (ie, yes, no, and unsure).

Usability

Usability of the TeACH System and its control arm are assessed post interaction (ie, immediately after receiving the allocated feedback and resources) and 1 week after the interaction through the After Scenario Questionnaire, a 3-item measure of usability [57].

Data Analyses

Overview

Descriptive analyses will be conducted to characterize the sample, primary outcomes, and usability ratings of the TeACH System. To assess changes in the engagement outcomes over time and account for missing data, linear or generalized linear mixed effects regression models will examine differences in responses to the baseline, postinteraction, and maintenance questionnaires. Demographic variables and existing DMH use, as well as their interactions with time, will be examined as covariates to assess differential engagement outcomes based on these variables.

Sample Size and Power

Power and sample size computations were based on previously published work [58,59]. Conservative estimates of sample sizes were estimated (ie, anticipating a 15% attrition rate on the follow-up survey), which indicated that 300 patients were deemed appropriate to examine the initial TeACH System use (ie, K-CAT Anxiety module, feedback, and resources) after being invited during their PPC appointment. With an expected 15% attrition rate for the follow-up questionnaire 1 week later, we would be adequately powered for within-subjects (pre vs post using the main effect of time) and between groups comparisons (TeACH System vs Control condition using treatment by time interaction). For within-subjects comparison, our proposed sample size is overpowered such that we should exceed 90% power to detect differences generally considered to be moderate in size (d=0.5) with a sample size exceeding approximately 70 participants. To detect within-subjects differences from baseline to endpoint equivalent to d=0.34 for the engagement outcomes, we would require a sample size of approximately 136 for 95% power. As such, our proposed sample is more than adequate for the planned within-subjects comparisons. For between-group comparisons with the anticipated 15% attrition rate, we should have 95% power to detect differences generally considered moderate in size (d=0.5) with 240 participants. With our proposed sample size of 300 participants, we will have 80% power to detect smaller differences equivalent to d=0.34.

Ethical Considerations

All procedures were approved by the institutional review boards of the University of Illinois Chicago (2024-0252) and Rush University Medical Center (20051313). Further, ongoing study monitoring is being overseen by an independent Data Safety and Monitoring Board. All participants complete a digital assent and are compensated for completing a follow-up assessment with a US $15 Amazon e-gift code (see the section Study Design below).

Results

This study received funding from the National Institute of Mental Health on September 13, 2021 (K08 MH125069), and began recruiting at UIC in July 2024 and at Rush in August 2024. Earlier funded activities informed the design and implementation planning for the current trial [23,32,42,54]. To date, 122 teens have assented to complete study activities, 80 have been randomized (an additional 24 teens have had subthreshold anxiety symptoms and were therefore not randomized), and 42 teens have completed the one-week follow-up assessment. We expect data collection to be completed by August 2025.

Discussion

Overview

The current feasibility study aims to evaluate the TeACH System in terms of (1) increasing engagement with DMH and (2) addressing individual-level barriers to mental health care. These outcomes are being examined in the context of integration in urban PPC clinics and in comparison to a control condition (ie, access to a digital workbook). The design and implementation plan for the TeACH System involved collaborative input from key players (ie, teens, caregivers, and PPC staff and clinicians) to increase the likelihood of teen engagement and acceptability in a dynamic health care setting [23,42,54].

The TeACH System stands as one of a growing number of DMH LITs being evaluated and implemented in care settings (eg, [60,61]). DMH LITs have demonstrated promise in increasing engagement for minoritized teens, compared with more intensive digital and traditional care models [37]. Amid this landscape, some unique aspects of the TeACH System situate it to adapt and scale well based on user and setting needs. First, the TeACH System is housed on a secure, stable, and editable platform (ie, REDCap [56]) and may therefore be adapted across iterations and for differing populations and settings. For example, screening may be expanded from self-reported anxiety only (current version) to up to 8 diagnostic categories assessed through the K-CAT (ie, anxiety, attention-deficit/hyperactivity disorder, conduct disorder, depression, mania, oppositional defiant disorder, substance use disorder, and suicidality [50]). Second, infographics and other design features may be changed to reflect the language and design preferences of different target groups. Similarly, resources may be edited or changed based on availability (eg, open access removal of a video), population preferences, and platform safety and availability (eg, if a "TikTok ban" results in higher teen use of a different platform). Finally, the TeACH System–and any future iterations are grounded in human-centered design with input from key players to target DMH engagement. Such targeting is hypothesized to serve as a mechanism of DMH to ultimately impact clinical

outcomes [62]. In sum, the TeACH System has been designed for teens with both anxiety and socially complex needs while visiting primary care. However, future iterations may be easily adapted at any level for integration in settings youth visit regularly and trust.

Future Directions

The scope of this study is associated with specific limitations and caveats, all of which inform future research directions. First, the current iteration of the TeACH System focuses solely on anxiety. While originally aimed to include the full K-CAT assessment, the scope was limited to anxiety to meet the implementation needs of PPC clinicians and staff members [23]. Anxiety was also selected to establish proof of concept for this first iteration, as anxiety is highly prevalent and socially minimized by clinicians and the public, making it less likely to be effectively screened and treated. Once the TeACH System establishes initial feasibility, it can be broadened to address multiple disorders through a larger study. Second, the K-CAT demonstrates the strongest accuracy when the parent proxy report and child self-report are integrated [50]. While the current iteration of the TeACH System is solely teen-facing, there is the potential for the TeACH System to have both caregiver and teen-facing elements in the future. Alternatively, summative feedback from this study may indicate that teens or families prefer for this to be a teen-facing tool, but with the option to inform trusted adults in their life about the indication of anxiety from the K-CAT. Further, the K-CAT is available and validated in both English and Spanish. As such, future iterations may also include cultural and linguistic adaptations to serve teens and caregivers who speak Spanish. Finally, while PPC is typically visited annually by most teens, integration in this care setting does not ensure that all teens will be reached. PPC was selected to establish feasibility for reasons detailed above, but future iterations may be adapted and integrated in other community spaces in which teens and families spend their time (eg, schools, parks, libraries, and churches).

Conclusions

LITs have a long-standing history of benefiting individuals with mild to moderate mental health symptoms [28], implicating DMH LITs as a promising first-line approach in care settings [29]. The TeACH System represents 1 possible DMH LIT that may provide brief assessment, feedback, and resources for teen patients without unduly burdening a busy health care environment nor requiring the approval of a guardian to use. This study will provide preliminary feasibility data that may inform how the TeACH System and other DMH LITs might better engage and support teens with socially complex needs.

Acknowledgments

The team wishes to thank the clinicians, staff members, and patients at the Child and Youth Center at the University of Illinois Chicago and the Pediatric Primary Care clinics of Rush University Medical Center.

Authors' Contributions

CST led all aspects of this work, including conceptualization, funding acquisition, methodology, and writing the original draft of the manuscript. GB, KR, and ML conducted project administration and supervision. DLS led formal analysis. CF, CA, GD, RMC, NM, GM, AT, and KMW completed visualization and design activities. ELG, WAJ, and NSK provided additional supervision.

Conflicts of Interest

None declared.

Abstract

Background: Mobile health (mHealth) interventions that leverage social support (SS) can improve partner involvement and pregnancy experiences and promote antenatal care (ANC) attendance and skilled births. In our previous studies, we used behavioral frameworks to develop a user-centered mHealth-based, audio SMS text messaging app to support pregnant individuals to use maternity care services in rural Uganda (Support-Moms app). In our pilot study, we observed high intervention uptake, acceptability, and feasibility, as well as increased ANC attendance and skilled births.

Objective: With the promising pilot data, we propose a type 1 hybrid implementation-effectiveness trial to test if this novel patient-centered automated and customized mHealth-based SS intervention is effective and cost-effective enough to warrant future large-scale implementation into Uganda's routine maternity care.

Methods: We will physically recruit 824 pregnant women at <20 weeks of gestation living in Mbarara and Mitooma districts, southwestern Uganda, and randomize them (1:1) to receive standard of care or the Support-Moms app, with at least 2 of their identified social supporters. Our primary outcome will be the proportion of skilled births. Secondary outcomes will include number of ANC visits, institution-based delivery, mode of infant delivery, preterm birth, birth weight, SS, obstetric complications, and deaths (maternal, fetal, and newborn). We will assess other implementation, service, and client outcomes through study records, the mHealth platform, and questionnaires with all women in the intervention, their social supporters, health care providers (HCPs), and managers from participating facilities. We will conduct face-to-face in-depth exit interviews with 30 purposively selected intervention participants and 15 facility HCPs and managers to explore implementation strategies for scale-up. Annual maternity resource allocations, costs, number of ANC visits, and deliveries will be assessed from facility records up to 36 months after implementation. We will estimate incremental cost-effectiveness ratios concerning cost per additional HCP-led delivery, per death averted, and per quality-adjusted life year gained as cost-effectiveness measures.

Results: This study was funded in September 2023. Ethics approval was obtained in February 2024, and actual data collection started in March 2024. As of January 2025, 75% (618/824) of all projected study participants provided consent and were recruited into the study. Participants are expected to be followed up until delivery, and 15% (124/824) have so far exited. Data analysis for the trial is expected to start as soon as the last participant exits from the study. The qualitative interviews will start in April 2025, and data will be analyzed and published as soon as data collection is done, which is expected in March 2027.

Conclusions: We are testing the feasibility, acceptability, and cost-effectiveness of implementing Support-Moms into routine maternity care from individual and facility perspectives. We hypothesize that Support-Moms will be an effective and cost-effective strategy to improve maternity service use for women in rural Uganda and similar settings.

Introduction

Background

While maternal mortality has fallen over the last 20 years, an estimated 300,000 women die each year from preventable causes related to pregnancy and childbirth, and 99% of the deaths occur in low- and middle-income countries (LMICs) [1]. Over 99% of infant deaths also occur in LMICs [2,3]. Persistently high maternal mortality ratios (MMRs) in LMICs are partly attributed to challenges accessing care, with undiagnosed or poorly managed pregnancy-related complications from direct or indirect causes [1]. Recurrence risks of fatal episodes increase exponentially among women who survive previous fatal episodes unless preventive measures for early detection and monitoring throughout the perinatal period are adopted [2,4-6]. Antenatal care (ANC) prevents perinatal and maternal morbidity and mortality by early detection and treatment of prenatal complications and identifying women at high risk to ensure delivery in skilled settings [7-11]. ANC supports women, their families, and communities to navigate challenges at a critical time during pregnancy; debunks misconceptions; increases information transfer; and can motivate women to seek facility delivery and care [9]. The World Health Organization (WHO) and other authorities have called for urgent evaluation of adaptable and context-specific health solutions to promote ANC uptake and maternity services to reduce maternal and early childhood mortality and morbidity [9,11-14]. Identifying and scaling up interventions that improve access to and the use of available health care in pregnancy and childbirth has the potential to prevent 823,000 stillbirths, 1,145,000 neonatal deaths, and 166,000 maternal deaths annually in the 75 highest-burden countries [2,4-6].

Despite expanded capacity to increase the number of skilled birth attendants at community facilities, Ugandan women still have low rates of ANC use and skilled births, resulting in one of the highest MMR (189/100,000) and perinatal mortality rates (34 deaths/1000 births) in the world [15]. Women's lack of information, social support (SS), financial independence for emotional and economic provisions, decision-making autonomy regarding childbirth, birth preparedness, and perceived need for maternity care services are important challenges to using available maternity services in these settings [1,16-19]. One analysis showed that women at risk of unskilled home births needed relevant and context-specific strategies to encourage ANC attendance and skilled delivery [20]. The high cost of MMR highlights the need for adaptable interventions that boost ANC and maternity services use to reduce MMR and early childhood deaths [12].

SS is an important pillar of health promotion that has been directly linked to health care–seeking behavior, infant care practices among mothers, and HIV care in sub-Saharan Africa (SSA) [21-25]. SS can mitigate structural and physical barriers to health care access at individual and societal levels, including facilitating self-efficacy to complete positive health behaviors [26-28]. Spouses, relatives, and friends have been the sources of SS among individuals living with HIV in SSA [23-25]. Community health workers (CHWs) can provide or promote additional SS during pregnancy, leading to better health outcomes [29,30]. Village health teams (VHTs), which comprise community members identified by their community who are trained on major health programs, improve timely care seeking for facility delivery [31-35]. VHTs have historically focused on the treatment of infectious diseases, such as malaria, pneumonia, and tuberculosis [35]. Their role as an additional resource for peripartum women has not been harnessed. Therefore, social network involvement not only addresses individual but also family- and societal- or community-level barriers to care in a setting with modest availability of health centers (HCs) providing needed services [17,25,36-38].

Mobile health (mHealth) interventions can be practical, effective, and scalable tools to improve maternal health care delivery and outcomes. Many SMS text messaging and other mHealth interventions can help individuals internalize risks and potential impact of various medical conditions as well as the needs and benefits of health services [11,13]. mHealth approaches can empower individuals to seek help, address specific health concerns, strengthen informed decision-making, and improve outcomes in the perinatal period [14,39]. Scheduled SMS reminders and telephone voice messaging approaches can enable people to increase control over their health by improving knowledge transfer, learning, and comprehension. These gains may improve the perceived need to use available services, especially when interventions are well directed and executed to provide accurate and relevant information on the promoted behavior [11,13,14,25,39-42]. Several studies have found that mobile phone–based messages can be motivational as a source of individual or family SS [43], cues to action [44], or to challenge societal negative beliefs [45]. Mobile phone interventions have also been shown to increase ANC attendance [46,47], institutional delivery [48,49] and vaccination rates (such as tetanus toxoid) [11,49].

mHealth interventions that specifically bolster SS can improve pregnancy experiences by decreasing anxiety and depression [50-53] and increasing perinatal bonding [52] and communication within social networks [53]. These benefits are mediated by promoting existing family structure and social networks, which in turn foster financial and emotional coping mechanisms to enable women to overcome socioeconomic and

physical barriers to care, such as food insecurity, transportation, and provision of delegated service to overcome competing priorities [25,53-55]. Community and social network engagements toward mobilization of resources to enable health care access are practical, scalable, and sustainable approaches toward participatory health care financing and use [56]**.** Although SMS alone is a convenient and lower cost approach to support health care interventions with higher delivery success, the provision of multiple messaging options, such as voice messages and social networks involvement, has been crucial to extend reach beyond the individual literate personal phone owners in SSA [57,58].

Health awareness and motivating health care use are key elements of developing effective behavior change interventions [59]. However, mHealth interventions are not always effective in improving health care and use. Whereas the failure of impact has been attributed to a mismatch between the function, adaptability, and need for mHealth interventions in some settings [11,14], end-user designs that use iterative approaches in app development can improve health care service use [60]. In a formative study, we observed that knowledge gaps influenced women's past and future decisions to not attend ANC and pursue unskilled home births [17,20]. Women were also largely dependent on their significant others for economic provisions, which, together with the existing gender and traditional norms, limited women's ability and freedom to make family or health decisions to seek skilled care. Therefore, we developed an mHealth-based SS intervention (the Support-Moms intervention) using the health care use model by Andersen [61] that incorporates predisposing-, enabling-, and need-based factors to improve intervention uptake and service use. We then considered the framework by Bendixen et al [62] to personalize the information and tailor the system for our targeted end users. Our novel mHealth app was developed as part of a career development award (NIH-K43TW011004). This app or intervention was compatible with local regular mobile phone types, providing varying text and audio delivery mediums for individuals who were literate and who were not. In a randomized 3-arm pilot study (N=120) pregnant women who had not presented for ANC by their second trimester were equally randomized to receive (1) standard of care, which is the routine ANC information given at the maternity centers (control); (2) scheduled SMS audio messages from the final messaging prototype (scheduled messaging [SM]); and (3) SM, plus social supporter engagement through SMS (SS) [63].

We observed high intervention acceptability and feasibility, with >80% of women receiving ≥85% of intended messages within 1 hour. Over 95% of women found the app easy to use and compatible with their existing messaging programs; they also reported that the messages were useful and engaging and would strongly recommend the intervention to others. Nearly all women in the SS arm (39/40, 98%) had a skilled delivery compared to 78% (31/40) and 70% (28/40) of the women in the SM and control groups, respectively. All women whose social supporters were engaged on the app (SS arm: 40/40, 100%) attended ≥4 ANC visits, compared to 83% (33/40) and 50% (20/40) of the women in the SM and control groups, respectively. Fewer women (8/40, 20%) in the SS arm missed any visits due to the lack of transportation compared to 58% (23/40) and 68% (27/40) of the women in the SM and control groups, respectively. In addition, fewer maternal or fetal complications (3/40, 8%) were reported in the SS arm compared to 13% (5/40) and 25% (10/40) complications in the SM and control groups, respectively. Using the Duke-University of North Carolina (UNC) Functional Social Support scale [64], women in the SS arm reported improved SS (median 3.4, IQR 2.8-3.6) compared to 2.8 (IQR 2.6-3.2) and 2.4 (IQR 2.2-2.8) in the SM and control arms, respectively (score ranges from 1 to 4, and 4 indicates high levels of SS). In qualitative interviews, all women described the intervention as useful, actionable, and easy to use; tailored health information helped them to learn, internalize, and comprehend ANC and skilled delivery benefits, strengthening their informed decision-making as they were reportedly able to easily share and discuss information with their significant others, who in turn committed to providing them the needed support to prepare and seek help. Women also expressed that the involvement of their significant others within a friendly, trusted, and familiar environment helped them to mobilize needed support during pregnancy. Involving both health care providers (HCPs) and end users in characterizing, developing, and formulating the mHealth intervention allowed its tailoring to their preferences. Given the success in our pilot work where 78% (93/120) of the women used feature phones and promising preliminary efficacy data presented earlier [36,63], the next logical step was to assess the effectiveness, implementation, and scalability of such multiple messaging strategies to improve care access in SSA, where the contextual factors that drive successful interventions differ, but the public health impact of such interventions is likely to be the greatest [65].

Objectives

We now propose a type 1 hybrid implementation-effectiveness trial to evaluate and implement this intervention into routine care. We will test the effectiveness of the intervention in a randomized controlled trial (aim 1). We will apply the implementation outcomes framework by Proctor et al [66] to evaluate implementation, service, and client outcomes and conduct in-depth interviews with users and key stakeholders to contextualize or clarify these outcomes as well as explore implementation strategies for future scale-up using the Consolidated Framework for Implementation Research (CFIR; aim 2). We will then assess the costs and cost-effectiveness of implementing the Support-Moms intervention into routine care (aim 3). We hypothesize that implementing Support-Moms will be an effective and cost-effective strategy to improve maternity service use.

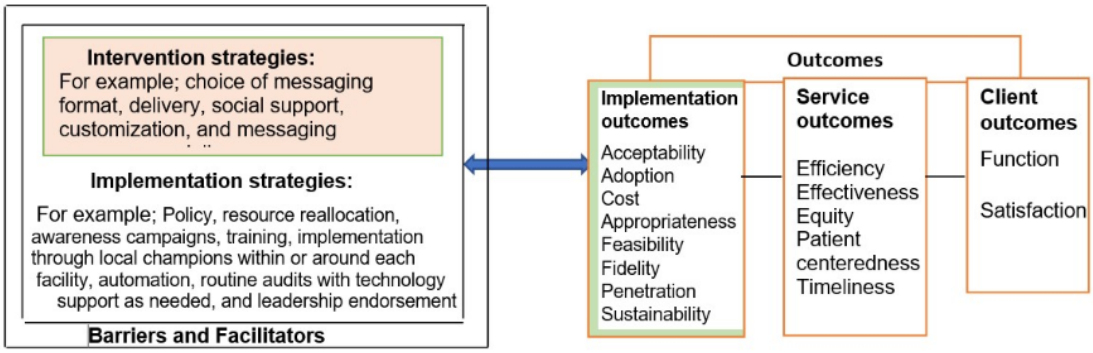
Methods

Study Overview

We propose to evaluate the effectiveness and implementation of the Support-Moms app into routine care. We hypothesize that Support-Moms will improve maternity service use and reduce the MMR when integrated into routine care. We will test the effectiveness of the Support-Moms intervention in a randomized controlled design (aim 1); evaluate intervention

implementation using the implementation outcomes framework by Proctor et al [66], as outlined in Figure 1 (aim 2); and then refine implementation strategies for future scale-up using the CFIR, as outlined in subsequent sections [67]. We will assess the cost and cost-effectiveness of implementing this intervention into routine care and its implication for sustainability (aim 3). These outcomes will serve as indicators of implementation success or necessary preconditions for attaining desired service outcomes for women in rural, resource-limited settings. This will enable us to identify practical, context-specific, and actionable strategies for achieving optimal implementation effectiveness at a low cost. The intervention strategies were developed in our pilot work together with facility HCPs. In the cost-effectiveness analysis, if Support-Moms and standard of care are found to have equivalent effectiveness, we will conduct a cost-minimization analysis where only the cost of Support-Moms per participant will be estimated and reported (no incremental cost-effectiveness ratios [ICERs] will be calculated). This alternative approach would remain informative to the policy makers and stakeholders in maternity service use. Notably, simultaneous assessment is warranted given the (1) strong preliminary evidence, (2) relatively low investment needed for costing, and (3) overall efficiency of our proposed type 1 hybrid effectiveness-implementation trial approach.

Figure 1. Modified conceptual framework by Proctor et al [66] for implementation and evaluation.



Study Setting

Uganda's public health system is organized into 7 tiers with national and regional referral hospitals, general district hospitals, and 4 levels of community HCs. Staffing and available services vary across the 4 levels; HC3 carry out vaginal deliveries, whereas HC1 and HC2 serve as low-resource referral units. HC4s and hospitals conduct normal and cesarean deliveries and have ambulances and blood transfusion services [68]. Private HCPs operate in parallel to the public health system to provide maternal health care. Mbarara District is located approximately 270 km southwest of the capital, Kampala [69]. Mbarara District hosts a regional referral hospital that serves the southwestern region (Mitooma district inclusive); most deliveries are high risk [70]. Mitooma District borders Congo and is situated approximately 370 km southwest of the capital [71]. These 2 sites were selected for this research based on their geographic, sociocultural, and institutional diversity and high maternal mortality and morbidity data (Table 1 presents more details). Both districts have publicly funded and operated facilities with an active maternity care unit. Participants may be seen at any of the maternity sites in these 2 districts or other neighboring districts (Table 1), with recruitment and follow-up organized through CHWs. This consideration, plus the diversity of the settings and the study population, has potential for generalizability to similar settings. The local economy of these 2 districts is also largely based on subsistence agriculture, with both food and water insecurity being common [72,73]; ANC attendance of ≥4 visits is still at 58%, and the skilled facility delivery rate is approximately 70%. Maternity services, including delivery, are largely provided free of charge through public HCs.

Table 1. Mbarara and Mitooma district statistics 2019.

Characteristics	Mbarara, n	Mitooma, n
Total population	Approximately 250,000	Approximately 185,000
Annual registered ANC[a] visits	31,200	18,350
Annual public facility deliveries	14,800	4450
MMR[b] per 100,000 live births	328	412
Hospital availability	5 (4 are private)	0
Publicly funded HC4s[c]	2	1
Publicly funded HC3s	10	6
VHTs[d]	246	143
Other private facilities providing maternity services	34	12
Total HCPs[e]	253	104

[a]ANC: antenatal care.

[b]MMR: maternal mortality ratio.

[c]HC: health center.

[d]VHT: village health team.

[e]HCP: health care provider.

Aim 1: Testing the Effectiveness of the Novel Support-Moms Intervention in a Randomized Controlled Trial

We will enroll a cohort of 824 adult pregnant individuals with gestational ages ≤20 weeks at enrollment (determined by last normal menstrual period or ultrasound scan where available). Consenting participants will be randomized 1:1 at enrollment to standard of care (Ministry of Health [MOH] guidelines–based routine care and information giving, n=412, 50%) versus the Support-Moms (intervention) group (n=412, 50%). We will identify, screen, and enroll people through the existing CHWs or VHT structure from areas within a 10 km radius of all publicly funded maternity centers across Mbarara and Mitooma districts, who have not yet presented for ANC by the beginning of their second trimester. We will power the study to test the superiority of the Support-Moms intervention for our primary effectiveness outcome: HCP-led skilled birth delivery. Secondary outcomes will include (1) number of ANC visits, (2) institution-based delivery, (3) SS, (4) mode of infant delivery, (5) all deaths (maternal, fetal, and newborn), (6) preterm birth, (7) birth weight, (8) breastfeeding, (9) completion of postnatal care, and (10) complications of pregnancy and childbirth (eg, obstructed labor, ruptured uterus, need for neonatal or maternal resuscitation or assisted ventilation, severe preeclampsia or eclampsia, postpartum hemorrhage, maternal or newborn sepsis, and other infections).

Recruitment and Enrollment of Study Participants

We will include individuals who (1) are in the first trimester of pregnancy and have not yet presented for ANC, (2) reside in the catchment area of a study HC, (3) are emancipated minors and adults aged ≥18 years, (4) report access to a cell phone with reception in their home, (5) are able to identify at least 2 social supporters living within the study districts, and (6) are able to provide consent. Notably in our pilot study, >95% of screened individuals had access to a cell phone, and all were able to identify at least 2 social supporters living within their communities [63]. We will track the exclusion rates to inform generalizability. CHWs will notify study research assistants (RAs) about potentially eligible participants, who will then contact and seek written informed consent and assent for emancipated minors (ie, those aged <18 years and pregnant) before enrollment into the study. Participants will be asked to identify 2 individuals from their existing SS network with whom they have had stable, long-term relationships and believe they would be available to help them during the pregnancy and study follow-up period. Eligible social supporters will include spouses, relatives, CHWs, and friends [23-25] aged ≥18 years; who are aware that the study participant is pregnant; and who own a cell phone for personal use with reported reliable reception. Potential social supporters will be excluded from the study if they are unable to use SMS or are unwilling to receive SMS notifications, as this was identified as a barrier in the pilot study. In the pilot study, one of the eligible social supporters identified by women included a spouse (75%), friend (38%), sibling (10%), parent (53%), and a CHW (25%), and we expect a similar distribution in the trial. There will be no gender exclusion criteria for social supporters. We will emphasize the selection of an existing partner, who is aware of the pregnancy, as one of the social supporters. This was not a problem in our pilot study, as most women were able to suggest a partner as a potential social supporter, alongside a friend, sibling, parent, or CHW. A few partners were excluded because they did not own a cell phone for personal use (5/40, 13%) or were not aware of the pregnancy (5/40, 13%). All other eligible social supporters that were identified by participants in the social supporter arm (80/80, 100%) were successfully enrolled and completed study procedures. RAs will contact social supporters from the intervention arm within 2 weeks of the enrollment of pregnant women to confirm an active relationship at the time of their

enrollment. Eligible social supporters will be offered an explanation of the study procedures and an opportunity to participate in informed consent. The study nurse will inform consenting social supporters about the objectives of ANC and skilled delivery as well as danger signs during pregnancy using standard MOH and WHO guidelines [9,74].

Randomization

Before the study initiation, the study statistician will generate a randomization table, inaccessible by other study team members, and lock it and store it in the REDCap (Research Electronic Data Capture; Vanderbilt University) study database. Participants will be stratified according to district and HC level and randomly assigned to either intervention or control arms in a ratio of 1:1 in blocks of 10. RAs will be informed of the arm assignment by the REDCap module after consent and at the time of enrollment. Study participants in the control group will receive MOH guidelines–based routine care and information giving. The intervention group will receive the intervention described in the next section.

Intervention Delivery and Components

The final messaging prototype that includes tailored SMS and audio health information (described earlier) will be delivered by the Support-Moms app developed through a partnership with iStreams-Uganda, an app development company based in Mbarara that developed the app, and with an existing mHealth platform [75]. The unique multimedia design allows women to be registered on the platform and be tracked throughout pregnancy and the postpartum period. Enrolled women receive automated and scheduled SMS text messages, reminders, and notifications about upcoming appointments as well as informational voice messages in their preferred language. The app includes a data collection platform and stores information submitted in real time directly from the participant's phone, thus allowing managers to access up-to-date data on process measures (eg, automated SMS text messages sent and accessed) as well as intervention delivery and health outcomes. Fixed SMS data are stored in a secure cloud, which is Health Insurance Portability and Accountability Act (HIPAA) compliant. iStreams-Uganda works in partnership with Africa's Talking, a platform that facilitates access to a telco infrastructure that uses automated SMS, voice, airtime, and other application programming interfaces—mechanisms tested and successfully used during our pilot study. This automated technology for SMS [23,25] and calls [36,63] has also been used for other studies in Uganda.

Both SMS and audio messages will be delivered at participants' preferred time and day of the week for free to optimize intervention delivery. A weekly SMS reminder on the impending ANC appointment and expected date of delivery at their preferred time and day of the week, plus a day before the scheduled ANC visit, will be sent to study participants. Social supporters will receive weekly SMS notifications to motivate the pregnant women participants to be present for scheduled ANC visits during the pregnancy as well as for delivery. Notifications to the 2 preidentified social supporters will provide information about the upcoming ANC visits and delivery due date during the study follow-up period. ANC appointment dates will automatically be generated based on the provided LNMP and MOH guidelines [74] at enrollment. Social supporters will be able to personalize the SMS content at enrollment (the default message will be "This is your reminder to assist your friend [XXX] attend her upcoming ANC visit due soon"). They will also be advised to assist study participants with problems that may affect ANC attendance or facility delivery. The intervention is designed to build on existing supportive relationships of study participants within their communities. All women and their social supporters will receive all accredited messages included in this app for at least 4 months, including the standard routine care provided at the community maternity centers.

Data Collection

Baseline participant characteristics will be collected from study participants from both arms as well as among the social supporters in the intervention arm physically (Table 2). Data collected through participant questionnaires will be conducted in the local languages, Runyankole and Rukiga. We will collect outcome data in two ways: (1) through medical record review of the routinely provided ANC cards, postnatal discharge forms (where available), and records at the relevant HCs and (2) through participant exit interviews 2 to 4 weeks following delivery to enhance data completion, particularly for people who did not deliver at a facility.

Table 2. Baseline questionnaire items for study participants and social supporters.

Topic	Details of measure
Individual level	
Individual characteristics	Age, education, employment, socioeconomic status, marital status, religion, and self-efficacy[a]
General and mental health[a]	We will assess psychological symptoms using validated Hopkins Symptoms Checklist for depression and anxiety [76,77].
Alcohol or substance use	We will assess alcohol use using the 3-item consumption subset of the AUDIT-C[b] [78,79] due to its association with adherence and health outcomes.
Reproductive history	Gravidity, parity, gestational age, prenatal and antepartum high-risk morbidities, and NCDs[c]
Pregnancy and childbirth perceptions	Health beliefs, knowledge and risk awareness, need for skilled delivery, and childbirth practices
Relationship level	
Reproductive goals and motivation	We will adopt the 6 items used in Uganda to assess personal and partner pregnancy desires [80-82], In total, 18 questions or statements reflect 6 parenthood motives [83].
Relationship power and gender-based violence[a]	We will assess gender-based violence [84] and relationship power [85-87] given its relationship with home births in Uganda [17].
Social support[a]	We will adopt and measure social support using a version of the Duke-UNC[d] Functional Social Support Scale [26], a tool that has been widely used in Uganda [64].
Community level	
Service availability[a]	Distance to the nearest health facility, availability of midwives, history of home or facility birth, community support for alternative birthing choices, and relationships with HCPs[e]
Societal level	
General health and food insecurity[a]	We will assess the general health of women, including diagnosed NCDs, and measure food insecurity using the HFIAS[f] [88]
Societal norms[a]	Beliefs about pregnancy, childbirth, birth order, twin delivery, facility delivery, and fatality
Quality of life[a]	Improved Short Form-6 Dimension version 2 survey by Brazier et al [89] to assess the quality of life

[a]Collected at exit interviews.

[b]AUDIT-C: Alcohol Use Disorders Identification Test-Consumption.

[c]NCD: noncommunicable disease.

[d]UNC: University of North Carolina.

[e]HCP: health care provider.

[f]HFIAS: Household Food Insecurity Access Scale.

To additionally reduce the risk of missing data, for participants who cannot be contacted, we will conduct home visits and interview the next of kin for those who are lost from observation or who die during the study period. These survey data will include the date and location of the birth; whether there was a skilled birth attendant present; mode of delivery (ie, vaginal vs cesarean delivery); birth outcome, including preterm birth, maternal, fetal, and newborn deaths, and any other complications of the birth (eg, obstructed labor, ruptured uterus, need for neonatal or maternal resuscitation, severe preeclampsia or eclampsia, postpartum hemorrhage, maternal or newborn sepsis, and other infections); weight and height of the newborn; number of ANC visits completed; use of breastfeeding; and attendance at postnatal care. Finally, we will administer the Duke-UNC Functional Social Support Questionnaire to measure reported SS received by women during pregnancy and childbirth.

Aim 1: Analysis Plan and Sample Size Calculations

We will first summarize health-related and sociodemographic data between arms. For our primary effectiveness outcome, HCP-led skilled birth delivery, we will fit a multivariable logistic regression model, with study arm as the predictor of interest, and age, high-risk pregnancy, and health facility at enrollment as a priori additional variables in the model, due to their strong association with the selected outcome [70,90,91]. In our primary intention-to-treat model, we will consider women with missing outcome data, after home visits and next of kin interviews, as presumed to have not received skilled birth (ie, there will be no missing outcome data in our primary analysis). In sensitivity analyses, we will (1) repeat the analysis after excluding women with missing outcome data and (2) include additional potential confounders in the model that may have persisted despite individual randomization (eg, number of previous deliveries at a facility, socioeconomic status, distance to facility, history of facility delivery, food insecurity, alcohol

use, and depression). Although not designed to detect a difference, we will also explore additional secondary outcomes, including (1) number of ANC visits completed, (2) mode of infant delivery, (3) institution-based delivery, (4) presence of one or more birth complications, (5) child mortality, (6) maternal mortality, (7) preterm birth, (8) birth weight, (9) completion of postnatal care, (10) SS, and (11) initiation of breastfeeding. Both our pilot data and other similar studies estimate that 70% of the women in Uganda deliver with a skilled attendant [15,48,49]. Finally, we will explore the role of SS as a moderating effect of the intervention through a prespecified stratified analysis among women in the upper versus lower half of SS in the cohort, as measured by the Duke-UNC Functional Social Support Scale [64]. To test our primary effectiveness hypothesis, allowing for a 2-sided type I error of 5%, 90% power, and assuming a 5% loss to follow-up, we will require 824 participants to detect a 10% difference in HCP-led skilled birth delivery between arms. Data analysis will be conducted using Stata (version 17; StataCorp LLC). The findings will be presented as descriptive statistics, scatter plots, and graphs; statistical significance will be considered at $P \leq .05$. While we will ensure completed data are collected through timely cleaning and REDCap prompts, we will still be able to detect the same effect in the primary outcome with the power of 85% in the unlikely event that we lost up to 18% of the records due to missing data.

Aim 2: Evaluating Intervention Implementation

We will evaluate intervention implementation using the framework by Proctor et al [66] (Figure 1) and plan for future scale-up per the CFIR [67] (Table 3). While the effect of the Support-Moms intervention on HCP-led skilled birth delivery, ANC attendance, and other secondary outcomes in aim 1 is critical, the translation of its potential benefit into routine care impact requires understanding the implementation process. We chose the evaluative framework by Proctor et al [66] because it consists of essential implementation science outcomes with attention to both services and clients, which will be critical for uptake and long-term use of Support-Moms in routine care (Figure 1 and Table 4). Then, we will consider and refine implementation strategies for future scale-up using the CFIR as a determinant implementation science framework (Table 3) [67].

Table 3. Consolidated Framework for Implementation Research (CFIR) constructs that will guide data collection on intervention challenges, facilitators, and potential strategies by care users, health care providers (HCPs), and payers and managers.

CFIR construct	Interview topic	Possible questions to elicit implementation strategies from users and implementers
Intervention characteristics	Intervention-setting fitness, automation, and auditing	On the basis of the reported or presented acceptability, effectiveness, patient centeredness, satisfaction, and function outcomes, how can the intervention be improved for increased implementation?
Outer setting	Existing policy, resources, and MOH[a] willingness and capacity to support increased demand for services and adopt the intervention	On the basis of the presented adoption, penetration, and other outcomes, as well as existing policies and resource commitments, what rollout strategies will be most effective in overseeing intervention implementation?
Inner setting	Facility adaptive reserve, leadership endorsement, and resource reallocation	On the basis of the identified cost-effectiveness, how can existing resources be reallocated to promote intervention uptake?
Individual characteristics	Patient centeredness, support, and community referrals	On the basis of acceptability, satisfaction, and function, what potential support will be needed for individuals using Support-Moms to improve uptake, enthusiasm, and retention?
Implementation process	Experience of HCPs on app enrollment, patient interaction, and increased demand and implementer's intention to "try," budgeting, sustainability, timing, execution, and scale-up	Explore implementers' support and satisfaction of the app to improve service use; approaches to publicizing and dissemination; engaging CHWs[b], focal HCPs, and social supporters as champions; long-term funding, potential impact; and "leading" or "lagging" indicators of the implementation success

[a]MOH: Ministry of Health.

[b]CHW: community health worker.

Table 4. Application of the framework by Proctor et al [66] to evaluate implementation, service, and client outcomes.

Outcomes and domain	Specific intervention measures	Data source
Implementation outcomes		
Acceptability	• Reported ease of use and performance expectancy, effort expectancy, social influence, facilitating conditions, self-efficacy, and behavioral intention to use the app in the future • Overall user acceptability per the tool by Weiner et al [92] • Qualitative: For example, participants: How was it for you to use these SMS, messaging, or calls? and HCP[a]: How was it for you using the messaging app?	• Exit interviews • Exit questionnaire
Adoption	• Initiation and use of the app over time • Percentage of eligible and participating social supporters	• mHealth[b] platform • Study records
Appropriateness	• Relevance (for setting) and compatibility • Overall appropriateness with the tool by Weiner et al [92] for both HCPs and end users • Qualitative: For example, participants: What happened when you received SMS or voice calls? and HCP: What happened or what did you observe when you enrolled people on the app?	• Exit interviews • Exit questionnaire
Cost	• Refer to aim 3: Evaluating the Cost and Cost-Effectiveness of Implementing the Support-Moms Intervention Into Routine Care and Its Implication for Sustainability section	• Refer to aim 3
Feasibility	• Percentage of users willing to participate; percentage of women, spouses, and social supporters meeting eligibility criteria; recruitment or participating rates, and reason for not participating. • We will use the tool by Weiner et al [92] to measure feasibility for both HCPs and end users.	• mHealth platform • Study records • Exit questionnaire
Fidelity	• Percentage of HCs[c] with capacity and integrity to deliver intended service (ANC[d], skilled deliveries, and admissions), percentage of accessible cell phones, and percentage of messages automatically sent out • Percentage of SMS or voice calls received by the participant over anticipated per protocol • Percentage of network, dead battery, phone losses, and phone functionality issues encountered	• Study records • mHealth platform • Facility audits
Penetration	• Number and type of HCs and HCPs engaging with the app • Percentage of eligible participants and social supporters enrolled	• Facility audits • Study records
Sustainability	• Use of the app over time, social supporter engagement over time, and user retention • Percentage of participants lost to follow-up and percentage of additional staff needed • Qualitative: All, for example, what challenges did you experience or face while using this app?	• Facility audits • Study records • Exit interviews
Service outcomes		
Efficiency	• Time spent on enrolling participants on the app, time spent on deliveries, timely delivery of needed supplementary or reference information, cost of delivery • Qualitative: All, for example, what do you think about this intervention?	• mHealth platform • Exit interviews
Effectiveness	• Refer to aim 1	• Refer to aim 1
Equity	• App use by facility type, participant type, and demographics	• Study records
Patient centeredness: accomplished during the formative and pilot work [36,60]		
Timeliness	• Perceived impact on ANC attendance and skilled deliveries • Qualitative: How was your experience attending ANC and preparing for birth and delivery?	• Exit interviews
Client outcomes		
Function	• Perceived quality, impact on maternity care, use, and life (survey by Brazier et al [89]) • Qualitative: How did this intervention help you in your pregnancy or work as an HCP?	• Exit questionnaire • Exit interviews

Outcomes and domain	Specific intervention measures	Data source
Satisfaction	• Satisfaction with intervention content, delivery, and credibility (Client Satisfaction Questionnaire) [93] for both HCPs and end users • Qualitative: What concerns do you have about using this technology to support you?	• Exit questionnaire • Exit interview

[a]HCP: health care provider.

[b]mHealth: mobile health.

[c]HC: health center.

[d]ANC: antenatal care.

Data Collection

Implementation Metrics

A trained RA will administer interviewer-led questionnaires at the trial exit (Table 4 presents outcomes and data sources) to (1) all intervention arm postpartum women, (2) all intervention arm social supporters, (3) all HCPs from participating facilities who enroll and deliver participants within the study sites, and (4) MOH key stakeholders and managers expected to inform rollout and adoption by the MOH. We will use a standardized checklist to conduct facility audits during implementation to document ANC visits and deliveries registered; maternity admission data; maternal mortality; disease cases managed; prescription data; laboratory data; and resource allocations at baseline, 12, 24, and 36 months following the implementation of the intervention for all study sites. A facility inventory will be done to inform our understanding of baseline conditions and set up for maternity and reproductive health services at the hospital and HC4 and HC3 public maternity centers.

We will use quantitative data on reported acceptability, appropriateness, effectiveness, function, and satisfaction to purposively select a subset of up to 15 postpartum individuals for exit in-depth interviews (or until saturation is met [94]), 15 social supporters, and up to 10 HCPs (approximately 2 for each facility level or district; refer to Table 1) involved in participant app enrollment and facility deliveries to clarify or contextualize observed outcomes based on the framework by Proctor et al [66] as outlined in Table 4. We will ask participants to describe actual events and experiences wherever possible (eg, for postpartum individuals, what worked well or poorly with receiving the messages and the challenges experienced during the study) to not only ensure coverage of specific areas but also allow unanticipated themes to emerge. We will further explore the feasibility, appropriateness, acceptability, patient centeredness, and sustainability of involving social networks in this intervention, as well as relationship dynamics, which have been shown to influence social supporter interventions [23-25] (eg, the social supporter's specific role, their relationship throughout pregnancy, routine communication, the type of voluntary and requested SS given or received during pregnancy toward improving her experience, ANC visits, birth preparedness, childbirth, and the app-related challenges and opportunities). We will schedule these interviews between 4 and 6 weeks post partum. HCPs will also be interviewed at the end of the study to clarify potential opportunities and problems that were experienced with the intervention and its delivery. These will facilitate appropriate conclusions about effectiveness and implementation success.

Implementation Strategy Development

Using CFIR, we will develop guides to further interview these postpartum individuals, social supporters, and HCPs on the intervention, individual, and inner settings to inform our implementation strategies and optimize intervention delivery (Table 3). We will develop some initial implementation strategies based on these findings and the literature (eg, awareness campaigns in the community and dissemination or publicizing the app, implementation in facilities through local champions within or around each facility to maintain enrollments, training, choice of messaging format, automation, and routine audits with technical support as needed). At the end of the implementation period, we will present data on outcomes and cost-effectiveness of the framework by Proctor et al [66] (refer to aim 3), along with the preliminary implementation strategies to the facility, district, and national MOH managers and stakeholders who have key roles in budgeting and policy or service implementation and are expected to evaluate or endorse the app. Using CFIR-informed interview guides (Table 3), we will interview 5 to 10 of these key MOH managers and stakeholders for feedback and refine our initial implementation strategies for testing in a subsequent study. All qualitative interviews will be audiotaped with the participant's permission and transcribed verbatim. RAs will be trained on the interview guides. All HCP and MOH interview guides will be piloted with 3 staff managers at Mbarara Hospital to ensure optimization, comprehension, and appropriateness.

Intervention Fidelity

Intervention fidelity plays a key role in assessing intervention effectiveness [95,96]. An RA will ensure participants know how to use the phone to retrieve information. CHWs and HCPs from the targeted public HCs will be trained to enroll participants onto the app, with technical support from the study research teams, led by ECA and GRM. We will measure the 3 elements of implementation fidelity as outlined in Table 4. Notably, 13% of the women enrolled in our pilot study missed some app messages because of lost phones or phone functionality issues. To minimize dead battery and charging issues, solar chargers will be given to study participants to charge their phones as needed during enrollment. These chargers are readily available and inexpensive, and we will be tracking their cost. Phone losses will be assessed on a case-by-case basis, replaced sparingly, and costs will be determined accordingly. Outgoing SMS and voice messages will be monitored daily by the data management team. The times and lengths of individual outgoing calls and engagements will be recorded and transmitted to the server. Message deliveries during periods of inadequate cellular reception will be stored for later transmission. Although

2-way messaging has been found to be useful in other settings [11,14], our key factors in this proposal are to provide scheduled, targeted information and catalyze SS for women seeking maternity care, a mechanism that showed promising results in our pilot preliminary data. Moreover, 2-way messaging creates a burden on the health system that may not be sustainable. However, we will assess the need for this type of feature in the exit interviews for further exploration. In addition, contact numbers of the VHT and CHWs attached to the neighboring public HC will be provided to address any questions, referrals, or emergencies that may arise. SMS and voice call delivery or reception will be considered as proxies for accessing information to alter existing predisposing factors (such as negative health beliefs and low awareness) that could enable and improve perceived need to seek care with the help of available social networks, factors that will be assessed during exit interviews (Table 2 presents more details).

All quantitative data will be collected using a web-based database that will be developed in REDCap to improve data completeness, management, and quality control monitoring. Errors or out-of-range entries are reported immediately on the website so the original interviewer can reconcile the problem in a timely manner. Data entry verification will include algorithms that automatically check completed forms for missing, out-of-range, or inconsistent values before a form can be saved on the website.

Aim 2: Quantitative Analysis Plan

We will summarize implementation outcomes for Support-Moms users and implementers using descriptive statistics. Success in the implementation survey data will be identified qualitatively and by the top tertile of relevant scales (eg, acceptability, feasibility, satisfaction, and appropriateness). We will explore similarities and differences across HCs and districts over time as well as potential associations between implementation outcomes and effectiveness at HCs and district levels. We will summarize all findings and present them through a Delphi process or technique [97], with a final meeting involving key MOH managers and stakeholders. We will describe the ranked implementation strategies selected by app users and key MOH managers and stakeholders after the dissemination process.

Aim 2: Qualitative Analysis Plan

In-depth interviews will be digitally recorded and transcribed. The first set of exit interviews will be conducted to understand participants' or stakeholders' experiences and perspectives of the Support-Moms intervention and clarify the implementation, service, and client outcomes outlined in Table 4. The goal of the CFIR-informed interviews will be to refine and inform implementation strategies for integrating the Support-Moms intervention into routine maternity care. Qualitative analysis will be inductive [98], and categories will be derived from the different study textile participants, HCPs, and MOH manager and stakeholder interviews. These responses will be transcribed into English, if needed, and coded using NVivo (version 13; Lumivero). Data analysis will be jointly performed. The study coordinator and research fellow will double code 5 sampled transcripts from each category and, together with the principal investigator, resolve any coding disagreements to ensure consistency in the codebook. Dyadic analysis will also be performed between pregnant individuals and their social supporters. Categories will then be developed and presented with illustrative quotes from data to explain experiences, challenges with the intervention, and recommendations to improve its implementation into routine maternity care.

Aim 3: Evaluating the Cost and Cost-Effectiveness of Implementing the Support-Moms Intervention Into Routine Care and Its Implication for Sustainability

The incremental cost and the cost-effectiveness of the Support-Moms intervention or program will be estimated from HCP and health system and societal perspectives to guide the decision makers on continuation, incorporation, integration, sustained use, and routinization—a method that has previously been used in a Ugandan context [99]. We will measure and record the cost of developing and implementing the intervention (program costs), the cost to HCPs from increasing demand for or use of services, and costs to users (intervention participants and their social supporters). The cost of developing and delivering the intervention will be estimated in consultation with the app developers, data from the pilot study, the maintenance team, time and motion studies conducted at representative sites over a 2-week period, as well as administrative records during implementation. The costs of maternity service use to access care will be collected from all aim 1 participants and HCPs at exit; all intervention users and HCPs will provide the cost of care seeking and intervention involvement. We will identify comprehensive tasks required by both users (eg, time used to seek care) and HCPs (eg, training and staff time) and quantify public-sector resource use during the use and provision of the HCP-led service during the 3 years of implementation. Routine and additional public-sector unit costs will be collected from the health management information system [100] and administrative records at the facility and district levels, MOH, and other safe motherhood implementing partners. Direct and indirect costs to intervention users and HCPs because of involvement in the intervention (such as trainings, time used to seek care, and time used by HCPs to enroll users on the app) will be collected from participant exit interviews and administration records. The costs of providing user phones and solar chargers will be explored.

Cost-Effectiveness Analysis

Cost analysis will include estimating program costs, costs to HCPs, and costs to users as described above. We will also develop a decision tree model to assess the potential impact of economic, clinical, or health outcomes of the Support-Moms intervention against routine care [101,102]. The model will incorporate cost items, relevant clinical probabilities, and case outcomes, allowing a cost-effectiveness evaluation. We will combine the costs and outcomes for each branch of the tree using branch possibilities to simulate the expected costs and outcomes of the intervention and routine care. We will hypothesize service users using routine maternity services or enrolled on the Support-Moms app (per trial arm) as they pass through different health states over time and within acute and chronic health states of 3 key maternal morbidities of sepsis,

postpartum hemorrhage, and hypertensive disorders [70,103-105]. Our cost-effectiveness evaluation will account for the outcomes for both the mother and the infant throughout their lifetime at the annual discounting rate of 3% [106]. The clinical and cost outcomes for the infant (eg, low birth weight and stillbirth or intrauterine fetal deaths) will be incorporated in the decision tree. We will use 1-way and probabilistic sensitivity analyses to quantify the confidence level or robustness in this model analysis output in relation to the outputs and the payer's willingness to pay thresholds [101,107]. We will estimate ICERs in terms of cost per additional HCP-led skilled birth delivery and per death averted. In addition, we will estimate ICERs per disability-adjusted life years averted and quality-adjusted life years (QALYs) gained (QALYs derived from the collected SF-6Dv2 data) as the main summary measures of cost-effectiveness [108] in line with the country's gross domestic product per capita (GDPpc) [109], to assess the value for money of adopting or providing the Support-Moms app long-term compared to routine care. If ICERs per QALY or per disability-adjusted life years <300% of GDPpc, Support-Moms will be deemed cost-effective, highly cost-effective for ICERs <100% of GDPpc, and not cost-effective otherwise. The decision tree and cost-effectiveness analyses will be programmed in TreeAge (TreeAge Software, LLC).

Ethical Considerations

The ethics approval was obtained from the Mbarara University of Science and Technology Research Ethics Committee (MUST-2022-631) and Uganda National Council for Science and Technology (HS3366ES). Study site administrative permission was obtained from the Mbarara district health officer, Mbarara City Health Officer, Mitoma District health officer, and the director of clinical services at the MOH. We are continually seeking and obtaining written informed consent from all study participants before enrolling in the study. The participants can withdraw from the study at any time. Participant data are anonymized at all times. The study was registered at ClinicalTrials.gov (NTC05940831). The research outcomes from this study will be published in international peer-reviewed journals and presented to the Ugandan MOH as policy briefs and at selected national and international conferences.

We are making firm attempts to adequately explain study purpose, schedule, expectations at the time of enrollment, and data collection and continually updating residence and phone details at each visit to minimize loss to follow-up. We are using appropriate means of contact based on participant preference and information on the best telephone network for the time of the day to telephone or send text messages, with emphasis that participation in this study is voluntary. However, reasons for decline or withdrawal from the study are being sought and documented. Participants are reimbursed for their study visits; a small compensation for their transport worth approximately UGX 20,000 (US $5.50) altogether is given at the end of each of the 2 planned baseline and exit interviews. Participating HCPs are reimbursed with US $5 as compensation for their time after every interview. The estimated time needed for interviews and other study procedures per visit is approximately 1.5 hours.

Results

This study was funded in September 2023. Ethics approval was obtained in February 2024, and actual data collection started in March 2024. As of January 2025, 75% (618/824) of all projected study participants have consented and been recruited into the study. Participants are expected to be followed up until delivery, and 15% (124/824) of the participants have exited to date. Data analysis for the trial is expected to start as soon as the last participant exits (expected in March 2026). The qualitative interviews will start in April 2025, and data will be analyzed and published as soon as data collection is done. Data collection is expected to be completed by March 2027.

We are currently recruiting at least 60 women or individuals and their social supporters per month. We have registered no loss to follow-up so far.

Discussion

We are targeting to recruit 824 pregnant women or individuals who have not yet presented for ANC by their second trimester, residing in Mitooma and Mbarara districts, with self-reported access to a cell phone with reception in their home for personal use, and are able to identify at least 2 social supporters living within the study districts. Uganda has approximately 30 million people who access mobile phones (most adult Ugandans), and 71% of users are connected using a basic feature phone [110]. Women or individuals are being identified by CHWs and VHTs, who then notify the study RAs to contact and seek written informed consent before enrollment into the study. Eligible social supporters who own a cell phone for personal use with reliable reception and know the study participant is pregnant be asked to provide consent and will be recruited within the first 2 weeks preceding enrollment of the pregnant women or individuals to ensure an ongoing relationship at the time of their enrollment. Adult HCPs who conduct deliveries within the study sites and MOH facility managers and stakeholders who participate in budgeting, procurements, or funding for facilities are being identified and offered enrollment into the study.

We developed an intervention aimed at improving communication of targeted, health-related information, motivating and mobilizing SS for pregnant women to use maternity services in rural southwestern Uganda (Support-Moms) [36]. Through an iterative approach, we (1) identified preferred key ANC topics from stakeholder interviews with 30 women and 5 HCPs and characterized a preferred messaging intervention; (2) developed content for SMS text and audio messages with 4 medical experts based on identified topics; (3) designed an app prototype through partnership with an mHealth development company (iStreams); and (4) pilot-tested the prototype and sought user experiences and feedback to refine the intervention through 3 different sets of 10 iterative exit interviews, 2 focus group discussions, and 5 cognitive interviews.

We are currently conducting a type 1 hybrid effectiveness-implementation trial [111] to test if this novel patient-centered mHealth-based SS intervention is effective and

cost-effective if implemented into routine care from individual and facility perspectives. We will simultaneously assess other implementation, service, and client outcomes per the framework by Proctor et al [66] and refine implementation strategies for future scale-up using the CFIR (individuals, intervention, inner and outer settings, and process). We hypothesize that this intervention will be an effective and cost-effective strategy to improve maternity service use for women in rural Uganda and similar settings. Data collection is underway. Our results will present the functionality of our mHealth intervention, its ability to stimulate and encourage routine health care use, and improve maternal-fetal health outcomes among all rural women, including those with limited education. The results of our work will be usable for other groups designing similar interventions to promote perinatal health in resource-poor settings. Results of this study will also provide requisite data for maternal health policy change and lay the groundwork for evaluation for a regional implementation of the intervention.

Notably, our study will have some strengths. Unlike in many studies, we used conceptual frameworks to characterize and develop patient-centered content and design aimed at making findings more relevant and generalizable to rural communities where the impact of such interventions is likely to be the greatest. This approach is often lacking in mHealth development, most of which is often led by developers and investigators, with limited input from end users [11,14,112]. While many mHealth interventions have been developed in Uganda [113-115], very few have been in the reproductive health field [114,116], and fewer have been evaluated at scale in the public sector [115,117]. Therefore, our study will be among the first ones to test mobile maternal health apps in a randomized controlled trial in Uganda, concurrently assessing effectiveness and other implementation metrics, information that is critical for guiding ultimate use and integration of this intervention in routine care. In this study, we are studying a high-risk population, in which <70% of women deliver with a skilled attendant [15], <58% attend at least 4 ANC visits (of the 8 recommended by the WHO), and thus are likely to benefit from this intervention. We believe that our grounded approach, using appropriate implementation science models and partnering with key regional stakeholders to evaluate an intervention in a rural low-resource setting, will enhance the likelihood of uptake, adoption, and integration into routine care.

We are leveraging existing CHWs, social networks, and resources to encourage uptake, retention, and adoption within a community that largely depends on family and community networks to thrive [42]. This approach is hypothesized to improve pregnancy experiences, partner involvement, support, communication, and mental health during and after pregnancy, ultimately offsetting the downstream cost of avoidable maternal morbidity and mortality [50-53]. We are also building on our pilot, promising preliminary data, and it will provide vital evidence about effectiveness, uptake, and sustained use of this tailored mHealth approach designed to address common individual, family, and community or societal barriers to health care use in Uganda.

We are building on our experience from our previous work done within a typical public health facility setting to recruit and follow up participants. Many people in Uganda move frequently in search of stable work or new settlements, including pregnant individuals [25]. In addition, some change or lose their mobile phones or phones could be inaccessible at times due to network issues. We are using our previous clinical research experience in conducting similar trials to maximize the feasibility of our mHealth intervention and retention in care. SMS distribution is controlled, and women are routinely scheduled for ANC randomly and independently. Consequently, the risk of contamination (eg, discussing and sharing information) at the facility level is minimized. To minimize potential contamination in the community, we are making an effort to clearly explain the study procedures to CHWs or HCPs and intervention women who may learn about different arm allocations through casual conversations, an approach that worked well during our pilot. We have developed and administered a quality control checklist for a few randomly selected control participants so far to assess contamination between arms every 3 months.

Acknowledgments

The authors acknowledge all the research assistants currently collecting data and all the women who have graciously accepted to participate in this study. They acknowledge the facility managers and district health officials for supporting this work. This work was funded by the National Institutes of Health-Eunice Kennedy Shriver National Institute of Child Health and Human Development (grant 1R01HD111692-01).

Data Availability

The datasets generated or analyzed during this study will also be available from the corresponding author on reasonable request.

Authors' Contributions

All authors conceptualized the project and participated in the research protocol writing. ECA wrote the first draft. All authors reviewed the manuscript and approved it for submission.

Conflicts of Interest

None declared.

Abstract

Background: Misuse of prescription opioids remains a public health problem. Appropriate short-term use of these medications in opioid-naive patients is indicated in selected settings but can result in unintended prolonged opioid use (UPOU), defined as the continuation of opioid therapy beyond the period by which acute pain would have been expected to resolve. Clinical strategies aimed at preventing UPOU are lacking due to the absence of information about how this poorly understood clinical phenomenon actually develops.

Objective: In this research project, 3 Clinical and Translational Science Awards (CTSA) programs (Mayo Clinic, University of Michigan, and Yale University) leveraged the conceptual framework for UPOU to investigate how patient characteristics, practice environment characteristics, and opioid prescriber characteristics facilitate or impede UPOU. All data management and analyses were conducted at a fourth CTSA program (University of Minnesota). This work was accomplished by pursuing 3 specific aims.

Methods: In aim 1, opioid-naive adults receiving an initial opioid prescription were recruited for study participation. Opioid prescriptions were identified longitudinally, and patterns of use were categorized as short-term, episodic, or long-term use using established criteria. Using a prospective case-control design, patients progressing to UPOU were matched 1:1 with patients who did not develop UPOU, and differences in patient characteristics were assessed. In aim 2, clinicians who prescribed opioids to patients in aim 1 were identified and recruited for prospective assessments. Institutional and individual practice environments were assessed using a validated self-report survey. In aim 3, structural equation modeling was used to evaluate data collected in aims 1 and 2, and identified interactions were further evaluated in a large national administrative claims database.

Results: Patient recruitment began on August 1, 2019. However, due to the COVID-19 pandemic, patient recruitment was slowed and intermittently interrupted over the ensuing 3-year period. As a result of regional variations in the impact of the COVID-19 pandemic on research activities, the majority of patient and clinician recruitment occurred at the Mayo Clinic site.

Conclusions: Following complete data analyses, it is anticipated that electronic health record systems will be leveraged to help clinicians identify at risk patients and to develop direct-to-patient educational materials to raise awareness of the risk factors for developing UPOU.

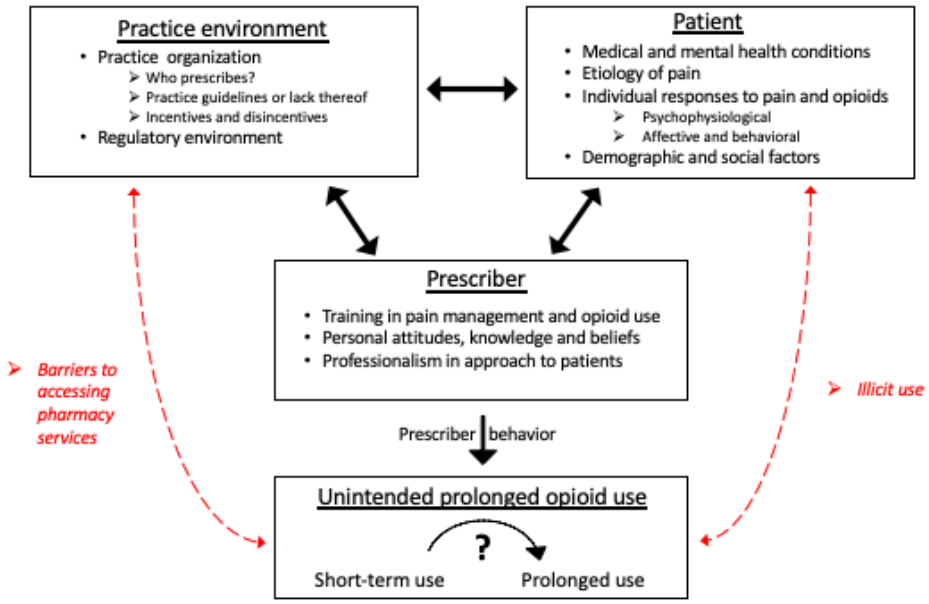
Introduction

Background

Misuse of prescription opioids remains a public health problem [1]. Appropriate short-term use of these medications in opioid-naive patients is indicated in selected settings but can result in a previously underrecognized segue to unintended prolonged opioid use (UPOU), defined as the continuation of opioid therapy beyond the period by which acute pain would have been expected to resolve [2,3]. Clinical strategies aimed at preventing UPOU are lacking due to the absence of information about how this poorly understood clinical phenomenon actually develops.

Investigators at Mayo Clinic previously organized a group of thought leaders to develop a conceptual framework for understanding the broad array of factors potentially contributing to UPOU [4]. A conceptual framework is essential both to guide the study of this clinical problem and to identify potential targets for interventions aimed at mitigating the development of UPOU. The framework is comprised of 3 domains, including patient characteristics, practice environment characteristics, and opioid prescriber characteristics that interact to either facilitate or impede UPOU (Figure 1) [4].

Figure 1. The conceptual framework for unintended prolonged opioid use.



Within each domain, potential factors, drawn from the relevant literature, moderate or mediate the influence of each domain. However, the necessary evidence within each of these domains is frequently lacking. This is critically important because 25% of patients in a population who received an initial opioid prescription proceeded to UPOU [3]. This work relied on a medical records linkage system unique to the geographically defined region, limiting the ability to perform larger studies across different patient populations. It also did not perform prospective assessment of several factors important to evaluate the proposed conceptual framework.

Study Objectives

In this research project, 3 Clinical and Translational Science Awards (CTSA) programs (Mayo Clinic, University of Michigan, and Yale University) leveraged the conceptual framework for UPOU to investigate how the patient characteristics, practice environment characteristics, and opioid prescriber characteristics facilitate or impede UPOU. All data management and analyses were conducted at a fourth CTSA program (University of Minnesota). This work was accomplished by pursuing three specific aims.

Specific Aim 1

The first aim was to identify incident cases of UPOU and prospectively assess their characteristics in comparison to new opioid users who did not progress to UPOU. At each site, opioid-naive adults receiving opioid prescriptions were enrolled. Opioid prescriptions and self-reported opioid use were followed, and patients progressing to UPOU were identified in real time. A matched sample of patients who did not develop UPOU were recruited for assessment of framework elements, including biochemical confirmation of opioid use, pain-related measures of physical and emotional functioning, and medical and social histories.

Specific Aim 2

The second aim was to assess clinicians prescribing opioids to incident cases of UPOU and new opioid users who did not progress to UPOU. Clinicians treating patients recruited in aim 1 were recruited for prospective assessment of prescriber characteristics including questions about past training in pain management, and attitudes and beliefs about pain and opioid use. The practice environment was assessed including practice organization, practice size, and estimated proportion of patients receiving pain management services.

Specific Aim 3

The third aim was to evaluate the conceptual framework. Using the information gathered in aims 1 and 2, structural equation modeling (SEM) was used to evaluate the associations between framework elements in each domain. Identified interactions were further evaluated in a large nationally representative administrative claims database.

Methods

Study Settings and Participants

Overview

In specific aim 1, opioid-naive adults receiving an opioid prescription (n=780 at each site) were identified at each clinical site (Mayo Clinic, University Michigan, Yale University) and recruited for study participation. A research coordinator assisted in activating a mobile platform on each patient's personal smartphone for purposes of providing informed consent and completion of study outcome measures. Opioid prescriptions were identified longitudinally by review of each patient's electronic health record (EHR). Patients progressing to UPOU were identified in real time, and patterns of opioid use were categorized as short-term, episodic, or long-term use using the Consortium to Study Opioid Risks and Trends (CONSORT) criteria [5]. Patients meeting criteria for episodic or long-term use were considered to have progressed to UPOU. Characteristics associated with UPOU were used to assess framework elements, including biochemical confirmation of opioid use; pain-related measures of physical and emotional functioning; and medical, surgical, psychiatric, and social histories.

In specific aim 2, clinicians who prescribed opioids to patients in aim 1 were identified and recruited for prospective assessments. Institutional and individual practice environments were assessed using a self-report survey validated in a national sample of physicians [6].

In specific aim 3, SEM was used to evaluate data collected in aims 1 and 2 to identify the associations between framework elements in each domain. Identified interactions were further evaluated in a large national administrative claims database (OptumLabs Data Warehouse [OLDW]).

Study Settings

Each CTSA clinical site leveraged established resources and clinical infrastructure.

Mayo Clinic

Olmsted County residents who previously consented to have their medical records used for research purposes were identified using the Rochester Epidemiology Project (REP) medical records linkage system [7,8]. The REP provides access to all medical records for Olmsted County residents. The indications for opioid use in these patients were both surgical and nonsurgical pain. Patients recruited from this site reflected the characteristics of UPOU as it developed in a geographically defined population.

University of Michigan

The surgical specialty clinics at the University of Michigan were used to identify opioid-naive patients receiving an initial opioid prescription following common surgical procedures, including knee and hip arthroplasty, inguinal hernia repair, intra-abdominal procedures, and thoracic and breast procedures [9]. The indication for opioid use in these patients was acute surgical pain. Patients recruited from this site reflected the characteristics of UPOU as it developed in a surgical setting.

Yale University

Yale New Haven Health is a large health care delivery system that provides services to individuals residing in the greater New Haven, Connecticut area. The EHR was leveraged to identify opioid-naive adults receiving an initial opioid prescription. These individuals were contacted using the patient communication portal of the EHR to assess their interest in participating in the research project. The indication for opioid use among these patients was surgical and nonsurgical pain. Patients recruited from this site reflected the characteristics of UPOU as it developed in a large health care delivery system.

Study Participants

A total of 780 patients were approached for recruitment at each site (N=2340), and eligibility criteria for study participation are outlined in Textbox 1. Patients meeting these eligibility criteria were further categorized based on CONSORT criteria [5]. Criteria for the long-term CONSORT category included episodes of opioid prescribing lasting longer than 90 days and including 120 or more total days of supply or 10 or more prescriptions [5]. Criteria for the episodic CONSORT category included episodes lasting 90 days or longer, with total days of supply being fewer than 120 and the total number of prescriptions filled being fewer than 10. Criteria for the short-term CONSORT category included episodes of opioid prescribing lasting 90 days or fewer [5]. Although study participation was limited to adults who own a smartphone, recent data from January 2018 demonstrated 77% of US residents own a smartphone [10].

Textbox 1. Eligibility criteria.

Inclusion criteria:

- Age ≥18 years
- No use of opioids for 6 months before the issuance of the initial opioid prescription as confirmed by review of the electronic health record and patient self-report
- Willingness to participate in all aspects of the study including use of the mobile platform on their personal smartphone

Exclusion criteria:

- Cancer-associated pain
- Concurrent treatment for cancer (eg, chemotherapy and radiation therapy)
- Residence in an extended care facility
- Any surgery or hospitalization within the past 6 months
- Mental health disorders that could impede functioning in an ambulatory care setting (eg, schizophrenia and dementia)
- Non–English-speaking individuals
- No smartphone; although study participation was limited to adults who own a smartphone, recent data from January 2018 demonstrated that 77% of US residents own a smartphone [10]

Specific Aim 1

Overview

At each of the 3 sites, a total of 780 opioid-naive adults receiving an initial opioid prescription were approached for enrollment. Subsequently issued opioid prescriptions were monitored by reviewing the EHR, and patients progressing to UPOU were identified in real time. Time-matched samples of patients who did and did not develop UPOU were recruited for assessment of outcome measures.

Participant Recruitment

Participant recruitment was site specific. For example, the Mayo Clinic site leveraged the resources of the REP to identify a population-based cohort of potential patients who had previously provided informed consent for the use of their medical records for research purposes. Since 2002, Mayo Clinic and Olmsted Medical Center have used a proprietary software system to document and manage all prescriptions including prescriptions for opioids [11]. These two institutions provide a vast majority of medical care for Olmsted County residents [7,8,12,13]. The electronic prescription system was used to identify previously opioid-naive Olmsted County residents receiving an initial opioid prescription as previously described [3]. These individuals were contacted by telephone and invited to participate in the study. The Michigan site used resources associated with the University of Michigan Analgesic Outcomes Study (AOS) [9]. The AOS is a prospective, observational cohort registry of postsurgical acute and chronic pain outcomes. Previously opioid-naive patients in the AOS registry were invited to participate in study. The Yale University site used the EHR to identify previously opioid-naive patients receiving an initial opioid prescription. More specifically, the EHR was screened by study personnel for the issuance of any opioid prescription, and previously opioid-naive patients were contacted using the EHR patient portal system and invited to participate in the study.

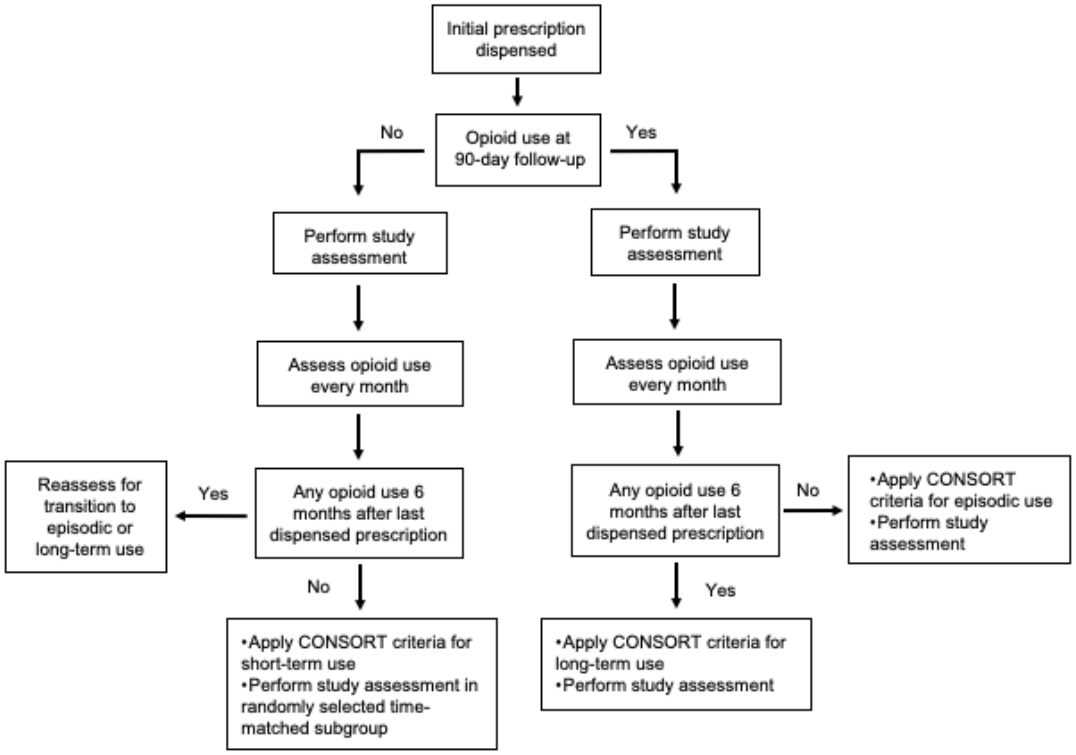
Mobile Smartphone Platform

All study participants were assisted by study personnel in downloading the smartphone platform (CareEvolution). The smartphone platform complied with the security and privacy controls defined by the National Institute of Standards and Technology SP 800 53 Rev 5 as designated by the Federal Information Security Modernization Act. The platform was granted authorization to operate by the National Institutes of Health and is Health Insurance Portability and Accountability Act compliant [14]. The smartphone platform was used to obtain informed consent and to collect all outcome measures.

Timeline for Establishing Consortium to Study Opioid Risks and Trends Criteria for Opioid Use

The timeline of the study was governed, in part, by the temporal requirements for applying CONSORT criteria (Figure 2). The beginning date of an episode of opioid use was defined as the date that the initial prescription was issued, with no previous opioid prescriptions issued for the preceding 6-month time period. The end date of an episode was the date that the last dispensed medication supply was exhausted, based on the days of supply as documented in the prescription instructions with no opioid dispensing in the ensuing 6 months. Patients who continued to use opioids on day 90 following issuance of the initial opioid prescription were invited to participate in the study assessment. Although it was not possible to accurately apply CONSORT criteria for episodic or long-term use on day 90, the study assessment was performed at this time point to ensure patients were captured at the earliest stages of episodic or long-term use. The status of opioid use in these patients was monitored every month by reviewing the EHR. This approach to follow-up limits the time interval between establishment of CONSORT criteria for episodic or long-term use and the final study assessment.

Figure 2. Flow diagram for establishing Consortium to Study Opioid Risks and Trends (CONSORT) criteria for opioid use.



A randomly selected group of patients meeting criteria for short-term use at day 90 were invited to participate in the study assessment. This group of patients was selected to be time-matched 1:1 to patients continuing to use opioids at day 90 (initial issue date ±2 weeks) Although it was not possible to accurately apply CONSORT criteria for short-term use until month 6 following issuance of the last prescription, the study assessment was performed at this time point to ensure that patients were captured in the earliest stages of short-term use. Because it was anticipated that the majority of the cohort would meet criteria for short-term use, it was not feasible to invite all patients to participate in the study assessment.

Study Assessments

Assessments were performed at 2 time points: 3 months following dispensing of the initial opioid prescription and 9 months following dispensing of the initial opioid prescription.

Demographics and Clinical Characteristics

Demographic and clinical characteristics were assessed including age, sex, ethnicity, marital status, education, employment status, BMI, and past medical and surgical histories including chronic pain.

Verification of Opioid Status and Dose

Opioid use and dose were verified by review of pharmacy and medical records. Opioid doses were converted to daily morphine equivalents using a conversion calculator as previously reported [15-17]. The opioid status was biochemically verified with a urine toxicology screen.

Occurrence and Risk of Opioid Misuse

The occurrence and risk for opioid misuse was assessed using 3 instruments. The Alcohol, Smoking, and Substance Involvement Screening Test (ASSIST) was administered. The ASSIST is validated [18] and used in the National Institute on Drug Abuse Quick Screen [19]. The Prescribed Opioid Difficulties Scale [20] was used to assess for substance use disorders associated with use of prescribed opioids [21]. The Opioid Risk Tool is a brief questionnaire that is validated [22] and was used to assess the risk of opioid misuse.

Symptoms of Opioid Withdrawal

Symptoms of opioid withdrawal were assessed using the Clinical Opiate Withdrawal Scale, which is an observer-rated instrument [23,24].

Opioid Craving

Opioid craving was assessed using responses (0 to 100 on a visual analog scale) to 3 questions: (1) How much do you crave opioids? (2) How often do you think about the next dose? and (3) How strong is your urge to take more medication than prescribed? This approach is validated [25] and was used to assess opioid craving [26-28].

Pain Intensity

Pain intensity was assessed using the 11-point verbal pain rating scale. The validity of the verbal pain rating scale is well established [29-31].

Michigan Body Map

The Michigan Body Map (MBM) is a self-report measure to assess body areas where pain is experienced. The MBM has demonstrated utility, reliability, and construct validity [32,33]. The MBM measure has been used to assess pain in a broad range of clinical settings [34-41].

Pain-Related Psychosocial Functioning

The Multidimensional Pain Inventory (MPI) measures the psychosocial impact of chronic pain [42]. The MPI has proven reliability and construct validity [43].

Negative Affect

Depressive symptoms and pain catastrophizing are key components of negative affect [44]. The Center for Epidemiologic Studies-Depression scale provides a validated measure of depressive symptoms [45] in patients with chronic pain [46,47]. The Pain Catastrophizing Scale provides a measure of negative cognitions and emotions associated with actual or anticipated pain experiences [48].

Baseline Smoking Status

Baseline smoking status was assessed using the techniques used by the Behavioral Risk Factor Surveillance System: (1) Have you ever smoked a cigarette, even a puff? (Yes or No); (2) Have you smoked at least 100 cigarettes in your entire life? (Yes, No, or Not sure); and (3) Do you now smoke cigarettes every day, some days, or not at all? (Every day, Some days, or Not at all) [49].

Quantitative Sensory Testing

Heat pain perception was quantified using the Computer Aided Sensory Evaluator IV (WR Electronics). This quantitative sensory testing device is validated [50-52], and we have used it to quantify opioid-induced hyperalgesia [15,16] and to study other pain-related states associated with altered heat pain perception [53-56].

Concomitant Treatments

Use of concomitant treatments for pain were assessed (eg, nonopioid medications, supplements, acupuncture, physical therapy, and chiropractic).

Sample Size Estimates

Based on our preliminary work [3,9,57-62], we estimated the rate of episodic opioid use would be 20% and the estimated rate of long-term use would be 7%. This would yield approximately 200 (780 × .27 = 210.6) patients developing some form of UPOU at each site. The analysis for specific aim 1 involved examining a wide variety of predictors of UPOU rather than 1 specific exposure. As a result, the minimum detectable odds ratios across a range of sample sizes were calculated. Setting the power at 0.8 and α at .05 (2-tailed), a total sample size of 1200 (600 cases and 600 controls) allowed detection of an odds ratio of 1.38 with a predictor that had a prevalence of 0.5 in controls and zero correlation in exposure between cases and controls. The detectable odds ratio (OR) goes up as the correlation between cases and controls becomes positive (detectable OR=1.48 with r=0.3), and it also increases as the prevalence of the exposure in the control group increases (detectable OR=1.55 with r=0.3 and prevalence of exposure=0.7 in controls).

Data Analysis Plan

The primary research question for specific aim 1 was to identify patient characteristics associated with UPOU. A case-control design was used with controls time matched to cases. The expectation was that multiple patient characteristics would be associated with UPOU. Descriptive statistics (means, medians, and ranges) were generated to compare cases and controls on all patient characteristics. Differences in patient characteristics between cases and controls were assessed using bivariate tests including the McNemar test for categorical variables and paired 2-tailed t tests (or Wilcoxon signed rank test, if needed) for continuous variables. The results of the bivariate analyses were used to select variables for conditional logistic regression analyses to regress UPOU on all variables identified as potentially associated with the UPOU. The regression models were constructed in stages by incorporating predictors in conceptual blocks and using standard selection methods to retain variables. All models included a fixed effect for site. ORs and 95% CI were used to evaluate the magnitude and statistical significance of the association between predictors and outcome.

Specific Aim 2

Overview

Clinicians prescribing opioids to patients in specific aim 1 were recruited for assessment of prescribing characteristics.

Clinician Recruitment

Clinician recruitment was site specific, but a similar stepped approach was used. First, an email message was sent to each clinician briefly explaining that they had issued an opioid prescription to a patient participating in the observational study. The email note contained a link to a validated self-report survey regarding clinician attitudes and beliefs about opioids, and clinicians were asked to complete the survey [6]. Clinicians who did not respond were sent a reminder email 1 week later. Clinicians who did not respond to the reminder email after an additional 1-week period were sent a final email. After a 2-week period, all clinicians not responding to the email messages were sent a paper version of the survey using each site's intracampus mail system. Clinicians not responding to the mailed survey after a 4-week period were considered nonresponders.

Study Assessment

Clinicians were assessed using the Clinicians' Attitudes and Beliefs About Opioids Survey (CAOS) [6]. The validity and test-retest reliability of the CAOS has been reported [6]. The CAOS also assesses clinician demographics and practice characteristics including sex, age, years in practice, professional training (physician surgeon, nonsurgeon physician, nurse practitioner, and physician's assistant), organization of practice (single specialty, partnership, solo, or multispecialty), practice structure (academic or university versus clinic or hospital based), proportion of weekly patient appointments involving management of chronic pain, and proportion of patients with chronic noncancer pain currently receiving opioids.

Sample Size Estimates

There was no information available to predict how many unique clinicians prescribe opioids to patients in aim 1. A 2013 meta-analysis of provider surveys estimated a survey response rate among health professionals of 53% [63]. Thus, we conservatively estimated the response rate would be between

35% to 65% and anticipated between 410 and 760 clinicians would complete the survey.

Data Analysis Plan

The primary research question for specific aim 2 was to identify clinician and practice environmental characteristics associated with UPOU. The analysis plan was similar to the plan described for specific aim 1. Descriptive statistics (means, medians, and ranges) were generated to compare cases and controls on all clinician and practice environmental characteristics. Differences in clinician characteristics between cases and controls were assessed using bivariate tests including the McNemar test for categorical variables and paired 2-tailed *t* tests (or Wilcoxon signed rank test, if needed) for continuous variables. The results of the bivariate analyses were used to select variables for conditional logistic regression analyses to regress UPOU on all variables identified as potentially associated with UPOU. The regression models were constructed in stages by incorporating predictors in conceptual blocks and using standard selection methods to retain variables. All models included a fixed effect for site. ORs and 95% CI were used to evaluate the significance of the associations between predictors and outcome.

Specific Aim 3

Overview

Using the data generated in aims 1 and 2, SEM was used to evaluate the associations between framework elements in each domain. Identified associations were further evaluated in a large national administrative claims database.

SEM Analysis

The primary goal of aim 3 was to combine the results from aims 1 and 2 and extend these by building a statistical model that synergistically integrated the three domains of the UPOU conceptual framework. The UPOU framework has a number of complexities that limit the use of regression including multiple correlated predictors and outcomes, unobserved constructs that are difficult to directly measure, and nesting of patients with clinicians who are nested within sites. SEM can estimate latent variables and include them as both exogenous and endogenous variables in the same model, use multiple observable and quantifiable indicators to estimate latent variables from the shared variability of these indicators, and accommodate multiple endogenous variables (ie, dependent variables or outcomes) in 1 model. Multilevel SEM can estimate latent variables at 1 or more levels (eg, patient and clinician levels) and appropriately test associations at and across these different levels for categorical and continuous outcomes.

The SEMs were developed in several steps. The number of measurement models were estimated for all constructs that potentially used latent variables. Descriptive statistics were examined including means, medians, SDs, ranges, measures of central tendencies, and normality of the distributions. Extensive preliminary analyses were conducted to evaluate possible inconsistencies in the data, outliers, and variations in the data, and clinically and statistically relevant cutoff points that may facilitate the analyses were identified. The primary outcome measure was UPOU, measured as a dichotomous variable of cases and time-matched controls. The predictors of interest were grouped into 3 domains: patient characteristics, practice environment, and clinician characteristics. Each of these domains contained a number of directly observable and directly unobservable constructs. Examples of directly observable variables in the patient characteristic domain included age, sex, and employment status. Examples of directly unobservable constructs in the patient characteristic domain included symptoms of opioid withdrawal, opioid craving, and the psychosocial impact of chronic pain. Analyses (eg, coefficient α, principal components analysis, and factor analysis) were conducted to determine how to optimally combine scale items into reliable measures.

After all measurement models were established, a comprehensive structural model describing the conceptual framework was developed. In the first step, models were fitted separately by domain. For example, a parsimonious model relating patient characteristics to UPOU was developed. This first step involved a model-testing approach to trim a saturated model containing all patient-level constructs to develop a final parsimonious model that maximally explained UPOU with the least number of parameters. The results from aim 1 analysis directly informed this stage, but models varied due to the use of latent variables and a different statistical model. The Akaike information criterion, Bayesian information criterion, and the root mean square error of approximation were used to guide decision model trimming and refinement. This process was conducted separately for all 3 domains. The second step combined the parsimonious, domain-specific models into an integrated model. This involved multilevel SEM with a patient-level outcome (eg, UPOU) and predictors at the patient level, the clinician level, and the practice environment level. This model started with the 3 parsimonious, domain-specific models but then was expanded to test for possible cross-level interactions. For example, the effects of pain management training on UPOU varied by patient age. The conceptual model, previous research, and empirical findings were used to guide the model-building process, particularly with regard to the direction of association and what interactions were tested. This was not a process for testing all possible interactions; rather, only specific indicated effect modifications were tested.

Missing data were evaluated to determine if the pattern was missing completely at random (MCAR) or missing at random (MAR). If missing data were MAR or MCAR, SEM techniques were used to estimate missing values using either full information maximum likelihood or multiple imputation. If missing data did not fit an MAR or MCAR pattern, other options were explored including pattern mixture models. To the extent possible, potential bias due to attrition and missing data over time were assessed. All analyses were conducted using Stata (version 15, StataCorp) or MPlus (version 7, Muthén & Muthén).

Sample Size Estimates

Common algorithms do not exist for assessing power for complex SEM; however, 3 aspects of sample size were considered. First, because of the iterative and complex nature of SEMs, it was important to verify that the sample size was

sufficiently large to produce stable model estimates. There are simulation studies suggesting that for models of the size and complexity proposed, minimum sample sizes for model stability would likely be in the hundreds [64]. Second, comparing models requires a certain sample size. Published estimates of model degrees of freedom suggest that sample sizes in the hundreds would be sufficient to discriminate competing models [64]. Finally, given a set sample size, an expected detectable effect size was estimated. Setting statistical significance at =.05 (2-sided tests) and power at 80%, a sample size of 500, for example, would allow detection effects of approximately 0.13 SD units across time (ie, considered a small effect). Even accounting for losses due to missing data, which can become an issue when combining multiple sources of data at multiple levels, the proposed sample size of 1200 patients, and the smaller number of clinician and practice environments in which they were nested, should be sufficient to estimate stable, comprehensive models and detect relatively small associations between constructs.

National Administrative Claims Database Analysis

The data collected prospectively on clinicians and patients at the 3 clinical sites provided detailed data on patients and clinicians from varied settings but were necessarily limited in sample size and derived from institutions affiliated with academic medical centers. As a result, a large national claims database was used to explore the findings of this study in a much larger and more diverse population.

The OLDW is an open, collaborative research and innovation center founded in 2013 [65]. The core linked data assets include deidentified claims data for privately insured and Medicare Advantage enrollees and deidentified EHR data from a nationwide network of provider groups. The database contains longitudinal health information on enrollees and patients, representing a diverse mixture of ages, ethnicities, and geographical regions across the United States. The EHR data are sourced from provider groups and reflects all payers, including uninsured patients.

The OLDW was used to estimate a structural model similar to that used in the analyses of clinical data from aims 1 and 2. The latent factors representing clinician, patient, and environmental factors associated with patients developing OPOU were estimated using OLDW data, and the results were compared with those estimated in the clinical data. The OLDW contains beneficiary characteristics including gender, age, race and ethnicity, household income, and geography (ie, state, county, or zip code). For beneficiaries submitting health insurance claims, a broad range of information is available including pharmacy claims (ie, prescribing clinician, drug type and date dispensed, days of supply), clinician and facility claims (ie, Current Procedural Terminology 4 codes, *International Classification of Diseases* [*ICD*]*-9* or *ICD-10* procedure codes, and *ICD-9* or *ICD-10* diagnoses), dates and place of service, cost data (ie, charges and patient and insurance amounts paid), and clinician type and specialty. In addition, OLDW includes laboratory data for 30% to 40% of patients whose clinicians have contracted with laboratories that provide data to OLDW.

Many of the concepts to be tested with clinical data were approximated using administrative claims data. Diagnostic codes were used to measure comorbidities including depression, anxiety and substance use disorders. Procedure and diagnostic codes were used to infer pain etiology from surgery, trauma, and other causes. Place of service and clinician specialty codes were used along with prescription fill information to determine the source of opioid prescriptions. Patient geographic information and prescription fill information were used to determine regulations governing the use of prescription drug monitoring programs.

Ethical Considerations

The Mayo Foundation Institutional Review Board served as the reliant international review board (IRB) of record for all participating institutions including Mayo Clinic, the University of Michigan, Yale University, and the University of Minnesota. Written informed consent, using a mobile platform, was obtained from all study participants before study participation. Use of the mobile platform to obtain informed consent and collect study outcomes was IRB approved (#18-010484). All patient-related research information was deidentified before data analysis. All patients were remunerated US $50 for the initial screening, US $150 for the first clinical assessment, and US $100 for the second clinical assessment.

Reporting Guidelines

The reporting of study methods and results adhered to the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) guidelines [66].

Results

Study Recruitment

Overview

The research proposal was funded on January 3, 2019, and patient recruitment began on August 1, 2019. However, due to the COVID-19 pandemic, patient recruitment was slowed in March 2020 and halted in April 2020 for a 4-month period. Over the next 2-year period, patient recruitment was slowed or interrupted at each clinical site based on the regional impact and the individual health care system response to the COVID-19 pandemic. Compared with the more urban setting of the University of Michigan and Yale University, the impact of COVID-19 pandemic on the rural catchment area of Mayo Clinic was less disruptive and associated with fewer interruptions. As a result, the majority of patient and clinician recruitment occurred at the Mayo Clinic site. Due to the unanticipated effects of the COVID-19 pandemic on clinical research activities, two 6-month, no-cost extensions were granted by the funding agency, and all recruitment and data collection were completed by August 2024.

Patient Recruitment

Table 1 depicts the total number of cases and controls recruited at each site. The Mayo Clinic site recruited 83% (855/1030) of the cohort, the Yale University site recruited 14.3% (147/1030), and the University of Michigan site recruited 2.7% (28/1030). Data analysis of patient characteristics associated with UPOU

has been completed and the manuscript is under active development.

Table 1. Patient recruitment by study site.

Study site	Patients, n (%)		
	Total (n=1030)	Cases (n=513)	Controls (n=517)
Mayo Clinic	855 (83)	422 (82.3)	433 (83.8)
University of Michigan	28 (2.7)	15 (2.9)	13 (2.5)
Yale University	147 (14.3)	76 (14.8)	71 (13.7)

Clinician Recruitment

A total of 148 clinicians completed the CAOS survey. The Mayo Clinic site recruited 146 (98.6%) clinicians, and 2 (1.4%) clinicians were recruited at the University of Michigan site. Recruitment of unique clinicians at the Mayo Clinic site was limited, in part, by clinicians who prescribed opioids to more than 1 patient. Due to unanticipated administrative barriers at Yale University, no clinicians were recruited at this site. The data analysis of clinician characteristics associated with UPOU has been completed and the manuscript is under active development.

SEMs and National Administrative Claims Database Analysis

The SEMs are under active development, and the results of the SEMs based on the case-control data will be submitted for publication in a peer-review journal. The administrative claims database from OLDW has been successfully retrieved and is actively being prepared for data analysis using the SEMs developed from the case-control data. The results of the SEM and OLDW analysis will be submitted for publication in a peer-review journal.

Discussion

Principal Findings

The anticipated results of this prospective, case-control study should provide ample data to understand how patient, clinician, and practice environment characteristics facilitate or impede development of UPOU. More specifically, multivariate logistic regression models will elucidate the individual influence of each domain (eg, patient, clinician, and practice environment) on UPOU and multilevel SEMs will provide an estimate of latent variables and test associations at and across these different levels for categorical and continuous outcomes. Widespread dissemination will be facilitated by the results derived from the broader analysis of the OLDW.

The results of this study will further build existing knowledge about the clinical characteristics associated with UPOU. For example, in a systematic review and meta-analysis of 33 studies comprised of 1,922,743 individuals, patient-level characteristics associated with UPOU after surgery included female sex; high school level education; previous mental health diagnosis of depression, anxiety, or posttraumatic stress disorder; cocaine or alcohol use disorder; tobacco use; and preoperative use of prescription opioids, antidepressants, benzodiazepines, or antipsychotic medications [67]. In addition, a history of back and neck pain, fibromyalgia, and migraine headache were associated with UPOU after surgery [67]. However, interpretation of these findings was limited by varying definitions opioid naivety and UPOU, clinical and statistical heterogeneity, and varying approaches for establishing baseline clinical characteristics. The imprecision of the meta-analysis was due, in part, to the use of large administrative and insurance claims data by studies included in the systematic review, which limited the number of studies that were available for inclusion in the subgroup analysis of patient characteristics. The results of our study will extend these findings by including surgical and nonsurgical patients and using uniform definitions of opioid naivety and UPOU. Finally, due to imprecision associated with establishing previous psychiatric diagnoses [68,69], the severity of current depressive symptoms, the presence of positive and negative affect, and the level of pain catastrophizing were included as study outcomes.

The clinical and research implications of the study results are important for 2 reasons. First, this study leveraged a conceptual framework and a case-control design to identify patient and clinician characteristics associated with UPOU. It is anticipated that the patient characteristics will have an immediate and significant impact on the clinical care of opioid-naive adults receiving appropriately indicated opioid prescriptions for short-term use. The identified clinician characteristics will provide the opportunity to develop and deliver targeted educational content to clinicians to raise awareness of UPOU. Second, development of SEMs and secondary testing in the much larger and more diverse cohort derived from the OLDW will facilitate the design of future research projects aimed at reducing development of UPOU.

Limitations

The timeline of the research project was disrupted by the COVID-19 pandemic, but data collection was facilitated by no-cost extensions and leveraging the rural catchment area of Mayo Clinic. This produced an imbalance in the number of patients and clinicians recruited between the 3 clinical sites. While the overall target sample size was largely attained and therefore target statistical power was met, the imbalance potentially limited generalizability and precludes site-specific analyses for Yale University and University of Michigan. The opioid use status of cases and controls were based on the number of prescriptions issued by clinicians. As a result, discrepancies could exist between the number of prescriptions issued compared with the number of prescriptions dispensed by pharmacies. Finally, the CONSORT criteria were adapted to categorize opioid use 3 months following the initial prescription.

Although it is possible that the status of opioid use could change over time, all patients were followed an additional 6 months to assess the stability of the opioid use category in cases and controls.

Conclusions

Following completion of data analysis, the study results will be immediately available for widespread dissemination in clinical practice and for use in ongoing research projects. It is anticipated that EHR systems will be leveraged to identify at risk patients receiving an initial opioid prescription and to send alert messages to members of the care team. This preemptive approach could also be used to develop direct-to-patient educational materials to raise awareness of the risk factors for developing UPOU.

Acknowledgments

The authors would like to thank the research coordinators that worked on this study including Brenda Anderson, Beth Martin, and Beth Montonye. This research project was funded by the National Institutes of Health National Center for Advancing Translational Sciences (U01TR 002743).

Data Availability

The study data will be presented in the main results sections of peer-review journals and as supplemental files when indicated.

Authors' Contributions

WMH, DJE, JFW, CMB, and MMJ contributed to conceptualization. WMH, DJE, MC, NAS, and MMJ handled data curation. WMH, DJE, MC, NAS, and MMJ conducted formal analysis. WMH, DJE, JFW, CMB, and MMJ managed funding acquisition. WMH, MC, JFW, CMB, and MMJ contributed to investigation. WMH, DJE, MC, NAS, and MMJ. WMH, DJE, and NAS managed project administration. WMH, DJE, MC, JFW, CMB, and MMJ handled resources. WMH, DJE, MC, NAS, and MMJ managed software. WMH, DJE, MC. JFW, CMB, and MMJ contributed to supervision. WMH, DJE, MC, and NAS managed validation. WMH, MC, NAS, and JJM handled visualization. WMH, DJE, MC, NAS, JFW, CMB, and MMJ wrote the original draft. WMH, DJE, MC, NAS, JFW, CMB, and MMJ conducted review and editing.

Conflicts of Interest

WMH has received funding from the National Institutes of Health (NIH) and the US Food and Drug Administration (FDA). DJE, MC, and JFW have received funding from the NIH. CMB has received funding from the NIH and he has served as consultant for Merck Pharmaceuticals and Vertex Pharmaceuticals, and he has provided expert medical testimony. MMJ has received funding from the FDA, NIH, Centers for Disease Control and Prevention, American Cancer Society, and Agency for Healthcare Research and Quality.

Abstract

Background: Stroke is a leading cause of serious, long-term disability and has a sudden onset. Upon discharge to the home setting, families are thrust into providing care, often without sufficient training from health care providers. Aligned with current patient and caregiver guidelines, the Telehealth Assessment and Skill-Building Kit (TASK III) is a nurse-led intervention designed to empower caregivers to address their own needs and those of the survivor using innovative skill-building strategies.

Objective: This study aims to test the short-term (immediately after the intervention at 8 wk) and long-term (12, 24, and 52 wk) efficacy of the TASK III intervention, compared with an information, support, and referral (ISR) group, to improve caregiver life changes (ie, changes in physical health, physical functioning, emotional well-being, and general health) as a result of providing care.

Methods: A randomized controlled clinical trial design will be used with baseline data collection from 296 family caregivers by telephone after the stroke survivor is discharged home. Caregivers randomly assigned to the ISR group (n=148, 50%) will receive information from the American Heart Association about stroke family caregiving. Caregivers randomly assigned to the TASK III group (n=148, 50%) will receive a TASK III resource guide and information from the American Heart Association. Both groups will receive 8 weekly calls from a nurse, with a booster call a month later. Outcomes will be assessed by blinded data collectors at 8, 12, 24, and 52 weeks. The primary outcome (at 8 wk) is caregiver life changes measured by the Bakas Caregiving Outcomes Scale. Secondary outcomes are depressive symptoms; other symptoms (eg, stress, fatigue, sleep, pain, and shortness of breath); unhealthy days; diet; exercise; and self-reported health care use. Mediators are task difficulty, threat appraisal, and self-efficacy. Program evaluation outcomes (satisfaction and technology ratings) will also be analyzed.

Results: The trial was registered on March 10, 2022. Enrollment and random assignment of the first participant was on November 30, 2022, with an anticipated completion of recruitment by November 30, 2025. Completion of the primary end point data analysis

is anticipated by August 31, 2026, with results expected to be reported on ClinicalTrials.gov by April 1, 2027. As of October 9, 2024, a total of 198 (66.9% of the proposed total sample of 296) family caregivers have been enrolled and randomly assigned to the TASK III group (n=98, 49.5%) or the ISR group (n=100, 50.5%). The last update was performed on January 25, 2024.

Conclusions: If the TASK III intervention is shown to be efficacious in the proposed randomized controlled clinical trial, our next goal will be to translate TASK III into ongoing stroke systems of care, providing a tremendous public health impact.

Introduction

Background and Rationale

Each year, approximately 795,000 Americans experience a stroke, which is a leading cause of serious, long-term disability [1]. Because of disability, approximately 68% to 74% of stroke survivors require the care of family members [2,3], who are suddenly thrust into providing care without receiving proper training from health care providers [4-6]. The lack of training contributes to difficulty with caregiving tasks and high threat appraisal, defined as caregiver perceptions of ability to provide future care [7-10]. These stressful experiences place caregivers at risk for depressive symptoms and major life changes as a result of providing care (eg, physical health, physical functioning, emotional well-being, and general health) [7-15]. Finally, stressful caregiver experiences have been reported to impede the survivor's rehabilitation [16-18] and to increase costs from premature long-term institutionalization [11,19,20].

Major scientific and policy statements from the American Heart Association [17,21-25] and other guidelines [26-30] recommend (1) assessment of stroke family caregiver needs and concerns; (2) education on stroke-related care; (3) attention directed toward caregivers' physical and emotional health; and (4) individualized caregiver interventions that combine psychoeducational strategies with skill building (eg, problem-solving, stress management, and goal setting). Aligned with the American Heart Association recommendations and other published guidelines [17,21-30], the Telephone Assessment and Skill-Building Kit (TASK) II is a nurse-led intervention enabling caregivers to build skills based on the assessment of their own needs [31-38]. Unlike existing stroke caregiver interventions that require costly face-to-face interactions [22,23,33,39-41] and that focus primarily on the survivor's care [22,23,39-41], TASK II is delivered completely via telephone and empowers caregivers to address both their own and the survivor's needs using innovative skill-building strategies (eg, problem-solving, stress management, realistic expectations, time management, and communication with health care providers) using a mailed TASK II resource guide and calls with a nurse. Evidence has been published regarding content validity [32], treatment fidelity [36], caregiver satisfaction [32], and efficacy of the TASK II program with 254 stroke caregivers in a randomized controlled clinical trial (R01; R01NR010388; ClinicalTrials.gov ID: NCT01275495) [34]. TASK II, in comparison with an information, support, and referral (ISR) group, reduced depressive symptoms up to a year after baseline (in caregivers with mild to severe depressive symptoms) and reduced unhealthy days, a reflection of caregiver's physical and mental health at 8 weeks [34]; however, further enhancements were needed to improve caregiver life changes (ie, physical health, physical functioning, emotional well-being, and general health) and to provide additional telehealth modes of delivery based on caregiver preferences [34,38,42-44].

Through a funded R21 (R21NR016992; ClinicalTrials.gov ID: NCT03635151) feasibility study, the Telehealth Assessment and Skill-Building Kit (TASK III) version has been optimized for delivery via various modes of technology [38] and provides a stronger emphasis on caregiver self-management [37,45,46] of their own symptoms and health care needs to sustain positive life changes and health outcomes over time. Caregivers can now choose how they want to access the TASK III resource guide (mailed hard copy, e-book, USB drive, or website) and how they would like to interact with the nurse (telephone, FaceTime, or web-based videoconferencing). Our published findings demonstrate the usefulness, ease of use, convenience, feasibility, and acceptability of our new TASK III telehealth technology [38]. Our published findings have also shown content validity, accuracy, feasibility, and acceptability of our new skill-building tip sheet on goal setting to enhance caregiver self-management of symptoms and health [37]. As part of the R21 feasibility study, a pilot study with 74 stroke caregivers randomly assigned to the TASK III (n=36) or ISR (n=38) group revealed successful recruitment, retention, treatment fidelity, high satisfaction ratings, and positive data trends.

In this larger randomized controlled clinical trial (R01NR020184; ClinicalTrials.gov ID: NCT05304078), we plan to enroll 296 caregivers to test the efficacy of the TASK III program (n=148, 50%), in comparison with the ISR group (n=148, 50%) for improving stroke caregiver life changes, symptoms, and health outcomes. The TASK III group will receive the TASK III resource guide along with information from the American Heart Association about stroke family caregiving. The ISR (attention control) group will only receive information from the American Heart Association. Both groups will receive 8 weekly calls from a nurse with a booster call a month later. The nurse calls for the TASK III group to focus on assessing and addressing stroke caregiver needs and concerns using the TASK III resource guide, along with information from

the American Heart Association; support through active listening; and provide referrals to their own health care providers. The nurse calls for the ISR comparison group to focus only on information from the American Heart Association, support through active listening, and provide referrals to their own health care providers. The ISR group procedures have been used successfully as a comparator for our previous trials (eg, R01 and R21). Data will be collected at baseline and at 8, 12, 24, and 52 weeks after randomization.

Objectives

Specific Aim 1

This study aims to test the short-term (immediately after the intervention at 8 wk) and long-term (12, 24, and 52 wk) efficacy of the TASK III intervention, compared with the ISR group, in improving the *primary outcome* of caregiver life changes (ie, physical health, physical functioning, emotional well-being, and general health) as a result of providing care.

Specific Aim 2

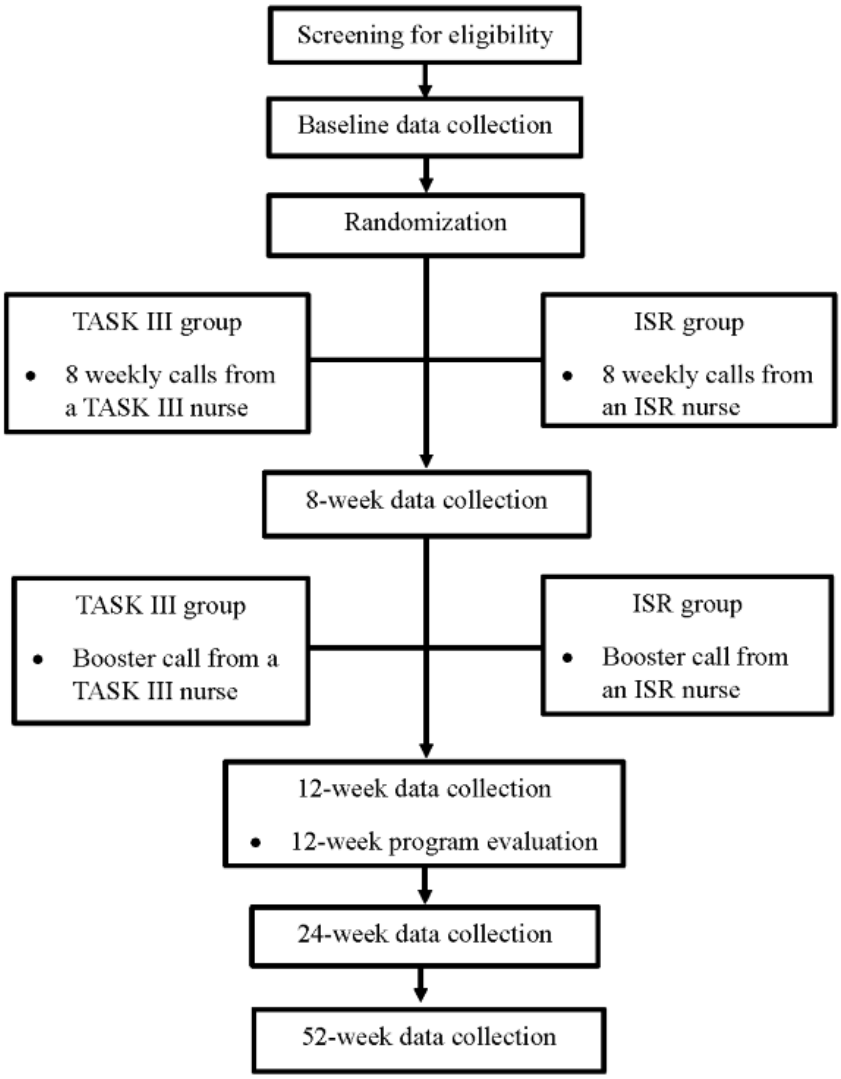
This study also aims to test the short-term (immediately after the intervention at 8 wk) and long-term (12, 24, and 52 wk) efficacy of the TASK III intervention, compared with the ISR group, in improving *secondary outcomes* including caregiver depressive symptoms (in caregivers with mild to severe depressive symptoms); other symptoms (stress, fatigue, sleep, pain, and shortness of breath); unhealthy days; self-management of diet and exercise; self-reported health care use; *mediators* (caregiver task difficulty, threat appraisal, and self-efficacy for exercise and diet); and *program evaluation outcomes* at 12 weeks (caregiver satisfaction and technology ratings).

Methods

Trial Design

An experimental, 2-group, randomized controlled clinical trial design based on a superiority framework will be used to test the efficacy of the TASK III program compared with an ISR group using an intention-to-treat design. We will randomly assign 296 stroke caregivers using a 1:1 allocation ratio to either the TASK III intervention group (n=148, 50%) or the ISR attention control group (n=148, 50%) following baseline data collection by telephone after the stroke survivor is discharged home (Figure 1). Follow-up data collection by telephone will occur by blinded data collectors after the 8 weekly TASK III or ISR calls, after the booster call at 12 weeks, and then at 24 and 52 weeks. Program evaluation by telephone will occur at 12 weeks after all the calls from the nurse have been completed while maintaining blinding of the data collectors.

Figure 1. Study flow diagram. ISR: information, support, and referral; TASK III: Telehealth Assessment and Skill-Building Kit.



Participants, Interventions, and Outcomes

Study Setting

Data will be collected from family caregivers living in the community caring for stroke survivors after discharge to the home setting. Recruitment sites are acute care and rehabilitation hospitals that provide care for stroke survivors located in the United States Midwest region. A list of our recruitment sites as of October 7, 2024, is provided in Multimedia Appendix 1. Further details regarding recruitment are provided in the *Recruitment* section.

Eligibility Criteria

Inclusion and exclusion criteria for stroke family caregivers are summarized in Textbox 1.

Eligibility criteria for the nurse interveners for both the TASK III and ISR groups include having a registered nurse license; strong interpersonal skills; and proficiency with technology, including Zoom (Zoom Communications) and Teams (Microsoft Corp) videoconferencing and basic computer skills. Blinded data collectors are required to have a high school diploma (college education preferred); strong interpersonal skills; and basic computer skills including the ability to type and enter data.

Textbox 1. Inclusion and exclusion criteria for stroke family caregivers.

Inclusion criteria

- Primary caregiver (family member or a significant other providing care for a stroke survivor at home)
- Fluent in the English language (ie, able to read, speak, and understand English)
- Access to a telephone or computer
- No difficulties hearing or talking by a telephone or computer
- Scores ≥4 on a 6-item cognitive impairment screener
- Willing to participate in 9 calls from a nurse and 5 data collection interviews (baseline, 8, 12, 24, and 52 wk)

Exclusion criteria if the following were true for the survivor

- Had not had a stroke
- Did not need help from the caregiver
- Resides in a nursing home or long-term care facility

Exclusion criteria if the following were true for the survivor or caregiver

- Aged <18 years
- Prisoner or on house arrest
- Pregnancy
- Terminal illness (eg, late-stage cancer, end-of-life condition, or renal failure requiring dialysis)
- History of Alzheimer disease, dementia, or severe mental illness (eg, suicidal tendencies, schizophrenia, severe untreated depression, or manic depressive disorder)
- History of hospitalization for alcohol or drug abuse within the past 5 years

Ethical Considerations

The study was approved by the University of Cincinnati Institutional Review Board (IRB; study 2022-0180). Lists of contact information for stroke survivors and next of kin will be obtained from each recruitment site. Approximately 1 week after study flyers and informed consent forms are mailed, stroke caregivers will be contacted via telephone by the TASK III study research staff to determine their interest in the study and to screen for eligibility. Flyers with response cards and informed consent forms may also be distributed by staff employed at each recruitment site.

The informed consent process will take place via telephone. The informed consent form is provided in Multimedia Appendix 2. The process will be explained to interested family caregivers, and if they are eligible and provide verbal consent, a baseline interview will be scheduled. All caregivers will be provided with full information about the nature, purpose, and possible risks and benefits of the study. Furthermore, caregivers will be informed that participation in the study is voluntary, and they are free to discontinue participation at any time. The principal investigator (PI) or research staff trained by the PI will obtain initial and ongoing consent. Training of research staff will include reading the informed consent and role-playing the consent process with the PI. All research staff having contact with the caregivers in the study will be trained on this process. The telephone calls to explain the consent will be scheduled at a time that is convenient for the caregiver using a telephone number provided by the caregiver. The PI or trained research staff will make the calls from a private location to protect the confidentiality of the caregiver. At the beginning of the baseline interview, the informed consent form will be reviewed again with caregivers, with verbal consent being verified before baseline data collection. Caregivers who are eligible, have provided verbal consent, and have completed baseline data collection will be enrolled and randomly assigned into either the TASK III or ISR group. Because this is a minimal risk study, the IRB has approved a waiver of written documentation of consent. We have previously conducted 4 IRB-approved studies using the same recruitment strategies as detailed in the current protocol [7,31,34,37,38]. Our procedures have not been found to be coercive by the IRB, and we have been successful in recruiting and retaining caregivers in our previous studies. In fact, we believe that approaching caregivers in person while the survivor is still hospitalized may be more coercive than requesting their participation by mail and telephone. Caregivers receiving their informed consent by mail approximately a week in advance have more time to read it and consider participation than if they were approached in person.

Only authorized study personnel will have access to the database or contact information for potential family caregivers, as well as family caregivers enrolled in the study. Study identification numbers will be generated to protect the identity of the participants. Participants will not be identified in any manner in reports or manuscripts from the study. Data from all data collection interviews and nurse calls will be audio recorded. Audio recordings will be uploaded to a secure password-protected OneDrive (Microsoft Corp) folder at the University of Cincinnati and then deleted from the digital recorders. Once the audio recordings are monitored for

adherence to the protocol or transcribed (deidentified), they will be deleted to protect the anonymity of the participants. Data entered on paper forms will be entered into REDCap (Research Electronic Data Capture; Vanderbilt University) by trained research staff using a secure log-in. Deidentified paper forms will be stored in a locked file cabinet accessible only to study personnel or shredded once data entry into REDCap is complete. REDCap is backed up nightly by the institution. Only authorized study personnel will have access to REDCap. All data collection calls to participants will be made to a telephone number provided by the participant at a time that is convenient for the participant. The TASK III and ISR group calls will be made via telephone, FaceTime, or Zoom videoconference using a secure link that is protected by the Health Insurance Portability and Accountability Act (HIPAA) based on caregiver preference. Research staff will make calls from a private location to protect confidentiality. All research staff will be trained in procedures to protect the confidentiality of the participants, including referring to caregivers using only their study ID numbers while communicating with the PI, project manager, or other approved research staff. Procedures for tracking completed interviews, determining the appropriate dates for follow-up interviews, and providing reminders for missed interviews will be specified and tracked in REDCap.

Although no compensation is provided for this study, participants are permitted to keep any study materials mailed to them, including a pedometer, Amazon Fire Tablet, USB drive, and a hard copy binder with either the TASK III or ISR content.

Interventions

Explanation for the Choice of Comparators

The comparator for this study will be the ISR program that has been used and validated as an attention control group in our previous studies testing the TASK, TASK II, and TASK III programs [31,32,34-36]. Caregivers randomly assigned to the ISR group have expressed high satisfaction ratings (ie, usefulness, ease of use, and acceptability) [32] with low attrition [31,34] and high fidelity of procedures [36]. Stroke caregivers randomly assigned to the ISR group for this study will receive a mailed copy of an American Heart Association brochure about stroke family caregiving and 8 weekly phone calls from a nurse with a booster call at 12 weeks. Calls will focus on providing ISR via the use of active listening strategies [31,32,34-36]. The ISR group can access the American Heart Association brochure through its website, which offers publicly available guidelines and web-based information for family caregivers. In addition, caregivers will receive a pedometer to track their daily steps, an Amazon Fire Tablet and a USB drive for use in the ISR program, and a unique username and password to log in to the ISR group on our TASK III website, which contains links to the American Heart Association materials for stroke family caregivers. Caregivers in the ISR group can choose to receive calls from their nurse via telephone, FaceTime, or Zoom videoconferencing. The length of each ISR session will vary based on the needs of the caregiver. As in our previous study with the TASK II program [34], our R21 feasibility trial showed that the total number of minutes on the ISR calls averaged about 17 minutes for each of the 9 ISR calls (mean 156, SD 103 min).

Intervention Description

Stroke caregivers randomly assigned to the TASK III intervention will receive a mailed copy of the TASK III resource guide, a mailed copy of an American Heart Association brochure about stroke family caregiving, a TASK III USB drive, and instructions for accessing a TASK III e-book and the TASK III interactive website. Screenshots of TASK III website are provided in Multimedia Appendix 3 [47].

TASK III Resource Guide

In a mailed binder with numbered tabs, the Caregiver Needs and Concerns Checklist (CNCC) [4] addresses 5 areas of needs: finding information about stroke, managing the survivor's emotions and behaviors, providing physical care, providing instrumental care, and dealing with personal responses to providing care (along with 35 corresponding tip sheets addressing each CNCC item) [4,32,34,35]. The Bakas Caregiving Outcomes Scale (BCOS) [7] with corresponding tip sheets addresses caregiver life changes, which is our primary outcome. Six skill-building tip sheets address the following: (1) strengthening existing skills, (2) screening for depressive symptoms, (3) maintaining realistic expectations and time management, (4) communicating with health care providers, (5) problem-solving, and (6) stress management [32,34,35]. The guide also includes (7) a new self-management skill-building tip sheet on goal setting designed for this study [37]. We will measure several key social determinants of health factors [48,49] at baseline, which will be useful in training caregivers on how to use skill-building strategies to address their needs and concerns within the context of their own social determinants of health. For example, 2 instrumental care tip sheets address managing finances and covering costs (financial strain is a key social determinant of health factors). The problem-solving skill-building tip sheet will help caregivers identify barriers and create new solutions to further mitigate financial strain. The goal-setting tip sheet helps caregivers set realistic goals to improve their own health (eg, setting a walking goal that considers neighborhood characteristics as another social determinant of health factor). Our original TASK, TASK II, and TASK III tip sheets have a large 14-point Arial font that is easily readable across all age groups. In our previous TASK II and TASK III studies, caregiver ages ranged from 21 to 83 years, representing a wide range of ages across the life span [34,38]. Our positive satisfaction data demonstrate that our materials are acceptable for a wide range of younger and older caregivers [38]. The TASK III resource guide is constructed to be appealing to both sexes. Male caregivers expressed high satisfaction ratings in our TASK II trial (>4.0 on a scale of 1 to 5), with positive qualitative comments (eg, "It's been such a help to me. It gave me an outlet that I could express my feelings."). Female caregivers also expressed high TASK II satisfaction ratings (>4.0) with positive TASK II qualitative comments (eg, "They're not just there for the person that's had the stroke, they're there for the caregiver too."). Our TASK II [34] and TASK III trials showed minority group representation consistent with the demographics of our Midwest populations, with 24.8% (63/254) in TASK II and 24% (18/74) in TASK III being Black or African American. When seeking input for the goal-setting tip sheet and technology preferences for our TASK

III program, we purposefully enrolled 50% Black or African American caregivers to ensure that our ratings and qualitative data reflected their views [34,35]. In our TASK III R21 feasibility trial, we employed a diverse research team, with our project manager, one of the TASK III nurses and one of the ISR nurses who identified as Black. We believe that these efforts enhanced the success of our TASK II and TASK III trials. Although not as well represented in our area, we will welcome other minority and ethnic group individuals.

TASK III USB Drive

A USB drive containing a searchable PDF file of the entire TASK III resource guide and separate PDF files of each of the TASK III tip sheets will be mailed to caregivers. Instructions and links to download the TASK III e-book and access the TASK III interactive website will also be provided on the USB drive.

Amazon Fire Tablet

In addition to the USB drive, we will provide all stroke family caregivers enrolled in the study with an Amazon Fire Tablet to access our materials. For the TASK III group, we will load the TASK III tip sheets as PDF files and provide links for the TASK III e-book, the TASK III website, and Zoom videoconferencing.

TASK III e-Book

An interactive multitouch e-book for the TASK III resource guide has been designed using Kotobee software [50] and tested for feasibility for use on multiple devices (eg, desktops, laptops, phones, tablets, and e-book readers). A download link automatically installs Kotobee Reader [50] and the TASK III e-book onto any Mac or PC laptop or desktop. The TASK III e-book will also be installed on the Amazon Fire tablets given to caregivers.

TASK III Interactive Website

We engaged the expertise of Oohology [51] to create in WordPress a searchable TASK III PDF library with TASK III tip sheets that appear on the website based on caregiver responses to an automated assessment process containing the CNCC and BCOS. Infrastructure for backend support of these technologies was provided during our TASK III R21 feasibility study, with continued support and ongoing hosting of the website provided by Oohology [51]. Most importantly, the tip sheets can be viewed on any laptop, tablet, or smartphone. Caregivers are instructed by research staff on how to access the TASK III interactive website through a unique username and password. *All materials created for the TASK III USB drive, e-book, and website are based on our TASK III resource guide.* Embedded within the TASK III resource guide tip sheets are links to additional resources available on the internet. We will ensure that the links are active and checked regularly during project implementation. Similar to the ISR group, the TASK III group can access the American Heart Association brochure through the American Heart Association website, which offers publicly available guidelines and web-based information for family caregivers. In addition, TASK III caregivers will receive a pedometer to track their daily steps.

TASK III Telephone Calls

The TASK III intervention calls will take place via telephone or videoconferencing using FaceTime or Zoom per caregiver preference [38]. Similar to the TASK II intervention [34-36], caregivers will receive 8 weekly calls from a nurse, with a booster call at 12 weeks. Caregivers will be assigned to a specific nurse for consistency. Nurses will train caregivers on how to assess and prioritize their needs, concerns, and life changes, then help them select corresponding content and skill-building tip sheets. The new goal-setting tip sheet will be used during each call to promote caregiver self-management of their symptoms and health.

TASK III FaceTime

Caregivers may receive calls using FaceTime [52]. Over Wi-Fi, FaceTime is accessible on iPhone 4 (Apple, Inc) or later, iPad 2 (Apple, Inc) or later, or iPad Mini (all models; Apple, Inc). Android-accessible apps such as Facebook Messenger (Meta Platforms, Inc), Google Duo (Google LLC), or Skype (Skype Technologies) will be considered.

TASK III Zoom

Caregivers can receive calls using Zoom videoconferencing [53]. Zoom unifies cloud videoconferencing, simple web-based meetings, and a software-defined solution into 1 easy-to-use platform, offering the best video, audio, and wireless screen-sharing experience across Windows, Mac, Linux, iOS, Android, and Blackberry devices [53]. Zoom allows real-time screen-sharing of TASK III resource guide materials during calls. The university has purchased secure Zoom links for research purposes to ensure the privacy of participants, which will be used in this TASK III R01 study. The length of each TASK III session will vary based on the needs of the caregiver. As in our previous study with the TASK II program [34], our R21 feasibility trial showed that the total number of minutes on the TASK III calls averaged about 43 minutes for each of the 9 TASK III calls (mean 389, SD 198 min).

Differences and Overlaps Between TASK III and ISR Groups

Both the TASK III group and the ISR group will receive the American Heart Association brochure, access to the American Heart Association website, a pedometer, an Amazon Fire Tablet, a USB drive, and 8 weekly phone calls from a nurse with a booster call at 12 weeks. Only the TASK III group will receive the TASK III resource guide that contains the CNCC and BCOS to assess caregiver needs, concerns, and life changes, as well as skill-building and content tip sheets that correspond to the CNCC and BCOS items. In the TASK III group, the nurses will train caregivers on how to assess and address their own needs, concerns, and life changes using the TASK III resource guide. This guide (containing the BCOS) informs our primary hypothesis that the TASK III group, compared with the ISR group, will have greater improvements in life changes (measured by the BCOS) from baseline to 8 weeks (after the intervention). We expect that these improvements will be sustained for a longer term from baseline to 12, 24, and 52 weeks. Including the BCOS as part of the TASK III intervention will enhance

the power to detect an effect on caregiver life changes as measured by the BCOS.

Criteria for Discontinuing or Modifying Allocated Interventions

Participation in the study is completely voluntary, and caregivers may withdraw at any time. Caregivers who ask to withdraw from the study will be given the option for a partial or full withdrawal. For example, participants may complete the rest of the calls with the nurse and withdraw from the remaining data collection interviews or participants may withdraw from the calls with the nurse and choose to complete the remaining data collection interviews. Participants may choose to completely withdraw from all study-related activities. Previously collected data from the participants will be withdrawn if specifically requested by the participant. Otherwise, collected data will be retained and analyzed, particularly for an intention-to-treat design. Participants will be withdrawn from the study if they are unable to be contacted after up to 10 attempts. A letter will be mailed to the participants notifying them that they have been withdrawn from the study.

Strategies to Improve Adherence to Interventions

Adherence to protocols for both ISR and TASK III groups will be a high priority for this study. The Treatment Fidelity Checklist [54] addressing design, training, delivery, receipt, and enactment will be used to maintain and track treatment fidelity for both TASK III and ISR procedures [36,54]. Training for the nurses will include detailed manuals and podcasts, training booster sessions, self-evaluation of recordings, evaluation by supervisors, quality checklists, and frequent team meetings [36]. TASK III nurses will attend an 8-hour training session to learn the intervention content and delivery processes and to role-play sessions with each other. The role-play sessions will be recorded and checked for competency before caregiver interaction. Beyond initial training, TASK III nurses will be monitored weekly during team meetings and asked to complete a self-evaluation of their recordings for adherence to the protocol on a monthly or bimonthly basis. Then, supervisors (ie, the PI or coinvestigator) will listen to recordings, analyze self-evaluations, and provide individualized feedback and retraining when necessary. ISR nurses will undergo a similar process, but the initial training session will last for 4 hours. Protocol adherence for the TASK II study was excellent at 80% (37.6/47) for the TASK II group and 92% (43.2/47) for the ISR group, and for common items on the checklist, 90% (42.3/47) in the TASK II group and 92% (43.2/47) in the ISR group [36]. Focus groups with nurses yielded further evidence for treatment fidelity [36]. The same procedures were used to track treatment fidelity in the TASK III R21 feasibility trial; this TASK III R01 study will follow the same rigorous treatment fidelity procedures with the nurses. Caregivers will be monitored for treatment fidelity regarding receipt (eg, the number of minutes spent on the calls with the nurse; ratings of the helpfulness of each call; the number of minutes of viewing TASK III or ISR materials; and the types of materials viewed, such as TASK III tip sheets or American Heart Association brochures or the website). Enactment will be monitored by asking caregivers whether their problems discussed with the nurse were unresolved, making progress, or resolved. In the TASK III group, the enactment will be further monitored by having caregivers evaluate their own progress on their goals to improve their own health based on our new TASK III goal-setting tip sheet [37].

Relevant Concomitant Care Permitted or Prohibited During the Trial

The trial will not interfere with any concomitant care or interventions that caregivers or their stroke survivors receive. No concomitant care or interventions are prohibited during the trial.

Provisions for Posttrial Care

There are no provisions for ancillary or posttrial care. This is a minimal risk study where the risk is not expected to be more than one would have in daily life.

Outcomes

Outcomes were selected based on a conceptual model derived from our previous research on caregiver needs and concerns [4,35]; our stroke caregiver outcomes work [8-10,31,34] informed by the transactional approach to stress proposed by Lazarus [55-57]; and our conceptual model that has empirical support from our previous research [8-10,31,34], including the original TASK and TASK II programs [31-36]. We added concepts from the self-efficacy theory based on the works by Bandura [58-60] and Lorig et al [61,62] to improve caregiver health. Our outcomes are clinically relevant, particularly our primary outcome of caregiver life changes (eg, physical health, physical functioning, emotional well-being, and general health) because of providing care [7]. Caregivers are known to neglect their own health needs while providing care [4-6,35,37], making them the hidden patients in our health care system. Difficulty with tasks threatens caregivers' ability to provide future care (ie, threat appraisal) [7-10] and is strongly associated with caregiver depressive symptoms and major life changes as a result of providing care (eg, physical health, physical functioning, emotional well-being, and general health) [7-15,17,39]. Finally, stressful caregiver experiences have been reported to impede the survivor's rehabilitation [16-18] and to increase costs from premature long-term institutionalization [8-11,19,20]. In addition to our primary outcome of caregiver life changes, we have included several secondary outcomes, such as caregiver depressive symptoms, other symptoms, unhealthy days, self-management of diet and exercise, and self-reported health care use. Further outcomes include our mediators of caregiver task difficulty, threat appraisal (ie, ability to provide future care), and self-efficacy for maintaining a healthy diet and exercise, as well as program evaluation outcomes. As listed on the ClinicalTrials.gov website (NCT05304078), Multimedia Appendix 4 [7-10,31,32,34,48,49,63-86] details measures and time points for our primary outcome, secondary outcomes, mediators, and program evaluation outcomes.

Participant Timeline

Table 1 provides the time schedule of enrollment, interventions, and data collection interviews for participants. Screening for eligibility and data collection interviews will take place via telephone. TASK III and ISR calls with the nurse will take place

via telephone or videoconference (eg, FaceTime or Zoom) based on caregiver preference. Data collection will take place at screening; baseline; and 8-week (after the 8 weekly calls with the nurse), 12-week (after the ninth booster call with the nurse), and 24- and 52- week follow-ups. Randomization will occur after the completion of the baseline interview.

Table 1. Schedule of the study period, including enrollment, interventions, and assessments.

[a]TASK III: Telehealth Assessment and Skill-Building Kit.

[b]ISR: information, support, and referral.

Primary, secondary, and other outcomes (ie, mediators and program outcomes) are detailed in the *Outcomes* section. Further information about these measures, as well as demographics, comorbidities, social determinants of health, and survivor impairment, is provided in Multimedia Appendix 4.

Sample Size

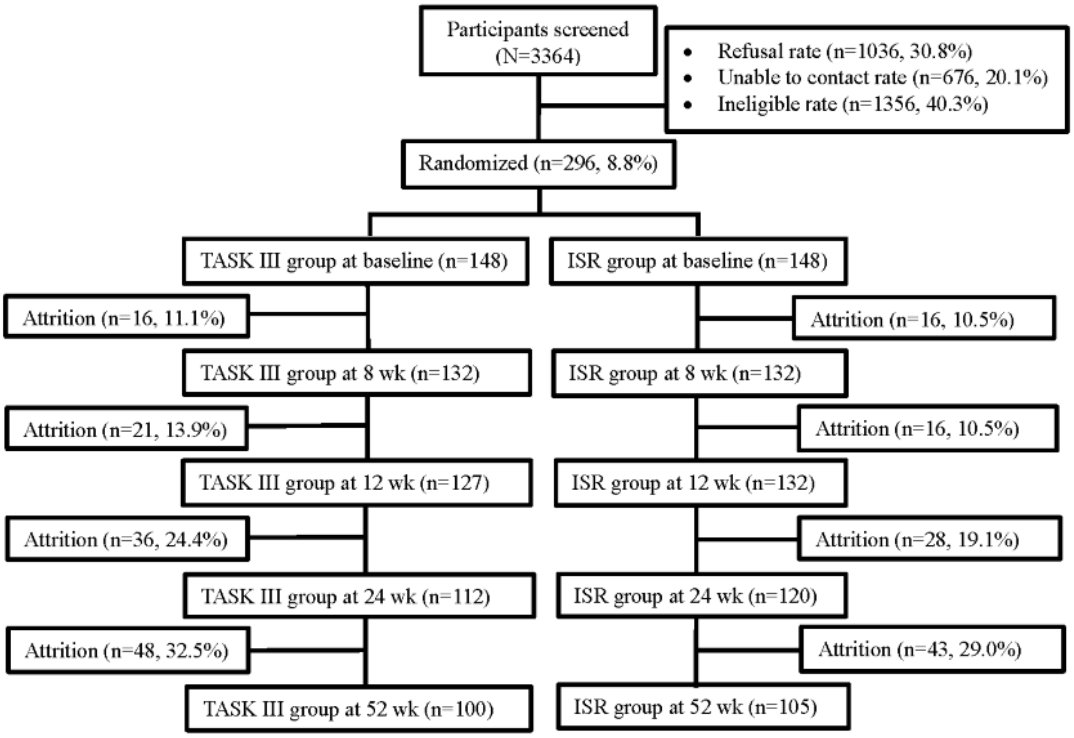
Sample size is based on the change in the total BCOS [7] scores from baseline to 8 weeks for the primary outcome of caregiver life changes because of providing care (ie, physical health, physical functioning, emotional well-being, and general health). For caregiver life changes (BCOS) [7], the sample size of 132 in each group will provide 80% power to detect a mean difference of 0.9 in the change from baseline, with the TASK III group showing a mean difference of 4.0 and ISR group showing a mean difference of 3.1 and an estimated SD of 2.6 [34]. We will also have sufficient power to address secondary outcomes. A sample size of 132 in each group will achieve 80% power to detect a mean difference of 0.20 in the change from baseline in depressive symptoms at 8 weeks between groups, with a mean difference of –0.80 in the TASK III group and –0.60 in the ISR group and an estimated SD of 0.70 in both groups using a 2-sample *t* test with a significance level of 0.05 [34]. This detectable difference is lower than the difference in depressive symptoms observed in the pilot TASK III R21 study. On the basis of pilot data, it is estimated that there will be 124 (42%) caregivers who screen positive for mild to severe depressive symptoms at baseline (ie, Patient Health Questionnaire-9 [PHQ-9] Depression Scale score >5). Because the randomization will be stratified by baseline depressive symptoms (see the *Sequence Generation* section), we estimate 62 caregivers with mild to severe depression in each group. A sample size of 62 in each group will achieve 80% power to detect a mean difference of 0.60 in the change from baseline in depression symptoms at 8 weeks between groups, with a mean difference of –2.60 in the TASK III group and −2.00 in the ISR group and an estimated SD of 1.20 in both groups, using a 2-sample *t* test with a significance level of 0.05 [34]. This detectable difference is lower than the difference in depression symptoms observed in the pilot TASK III R21 study. For unhealthy physical and mental days, the sample size will provide 80% power to detect a rate ratio of 0.85 (a 15% reduction in unhealthy days) [34]. The planned enrollment is 296 (n=148, 50% in the TASK III group and n=148, 50% in the ISR group) to account for 10.8% (16/148) attrition [34]. Power Analysis & Sample Size (version 12; NCSS LLC) was used to produce all power estimates. Power calculations were not performed for the additional secondary outcomes (ie, other symptoms, self-management steps, exercise self-management, diet self-management, and health care use).

Recruitment

Recruitment methods and retention rates were successful in our previous studies [31,34] and even better in our most recent TASK III R21 feasibility study. On the basis of our recruitment success with our TASK II and TASK III R21 feasibility studies, we plan to screen 3364 caregivers and randomly assign at least 296 caregivers to achieve our goal of 148 (50%) caregivers per

group (Figure 2). Accounting for 10.8% (16/148) attrition, this should allow us to have at least 132 (89%) caregivers per group at our primary 8-week time point.

Figure 2. Proposed participant flow diagram. The values are provided on the basis of the Telehealth Assessment and Skill-Building Kit (TASK III) R21 (R21NR016992; ClinicalTrials.gov ID: NCT03635151) feasibility study, except for the 24-week and 52-week values, which were based on the Telephone Assessment and Skill-Building Kit (TASK) II R01 (R01NR010388; ClinicalTrials.gov ID: NCT01275495) study. ISR: information, support, and referral.



Screening 3364 caregivers over 3 years (1121 per year) is feasible given our strong track record of collaboration and the large number of stroke survivors treated yearly at each recruitment site. As in our previous studies, bioinformaticians, stroke coordinators, or other employees from each recruitment site will provide us with lists of stroke survivors and their next of kin. As approved by our university IRB, study flyers signed by the stroke survivor's physician, nurse, director of the stroke team, along with copies of the informed consent form, will be mailed to caregivers of survivors receiving care from each recruitment site. A telephone number is provided for stroke caregivers to call if they do not wish to be contacted for the study. Approximately 1 week after the study flyers and informed consent forms are mailed, caregivers will be contacted via telephone by research staff to determine their interest and screen for eligibility. Flyers with response cards may also be distributed by staff employed at each recruitment site.

Assignment of Interventions: Allocation

Sequence Generation

Caregivers will be randomly assigned 1:1 to the TASK III or ISR group using a permuted block randomization stratified by type of relationship (spouse vs adult child or other) and baseline depressive symptoms (nondepressed vs depressed, with a PHQ-9 score ≥5) as in the TASK II trial [34]. Random permutations within each block within each stratum will be generated using a random number generator (SAS Proc Plan; SAS Institute).

Concealment Mechanism

The randomization scheme will be concealed in an Excel (Microsoft Corporation) document uploaded to the REDCap project site that will be accessible only to the biostatistician. Randomization will occur by logging into the REDCap project website and entering the type of relationship (spouse vs adult child or other) and baseline depressive symptoms (nondepressed vs depressed, with a PHQ-9 score ≥5) for group assignment (TASK III vs ISR).

Implementation

The biostatistician will generate the allocation sequence and upload it as an Excel file to the REDCap project site as a concealed file. The biostatistician will then program the REDCap project site to generate the group assignment once the PI or the project manager enters the type of relationship and baseline depressive symptoms. After baseline data collection, data collectors will notify the PI or the project manager that the caregiver is ready for randomization. Data collectors will not be involved in the randomization process.

Assignment of Interventions: Blinding

Who Will Be Blinded

Data collectors will be blinded to group assignment to mitigate potential bias during the 8-, 12-, 24-, and 52-week follow-up interviews. Blinding will be maintained by restricting data collector access to group assignments in REDCap. Separate weekly research team meetings will be conducted with the data

collectors. Caregiver participants will be instructed not to tell the data collectors which group they have been assigned to. Caregiver trial participants, the nurses, the project manager, the PI, and a coinvestigator will be unblinded so that the proper TASK III or ISR materials can be mailed to the participants and the correct TASK III or ISR protocol can be followed. The PI and the coinvestigator will closely monitor treatment fidelity for the TASK III and ISR groups. Separate nurses will be used for the TASK III or ISR groups to avoid treatment diffusion. We have a strong track record of keeping TASK III and ISR groups separate, including strict monitoring of treatment fidelity and adherence to protocol [36]. The lead biostatistician and her master's degree–prepared staff statistician will be unblinded to create reports, assess for missing data, and explore data trends in preparation for Data Safety and Monitoring Plan reports. While analyzing data trends for Data Safety and Monitoring Plan reports, the PI and the research team will be blinded as to which group represents each outcome variable within data tables by labeling each group by a letter rather than using the TASK III or ISR abbreviations.

Procedure for Unblinding if Needed

Only data collectors will be blinded during the trial. Unblinding the data collectors will not be permissible.

Data Collection and Management

Plans for Assessment and Collection of Outcomes

Multimedia Appendix 4 lists the study measures. Most measures were used in our previous studies [7-10,31,32,34]. All measures demonstrated acceptable evidence of reliability and validity, except the Caregiver Evaluation of Technology Scale, which was created specifically for this study. We will assess the reliability and validity of this scale, and if unacceptable, we will analyze it at the item level. Using the measures in Multimedia Appendix 4, the estimated time for telephone interviews for each time point is 60 minutes for baseline, 33 minutes for 8 weeks, 39 minutes for 12 weeks, and 33 minutes for 24 and 52 weeks. Telephone interviews of this length have not been found to be burdensome in our previous studies [7-10,31,32,34].

Plans to Promote Participant Retention and Complete Follow-Up

To promote participant retention and complete follow-up, data collection interviews and TASK III or ISR nurse calls will be made to caregivers at times that are convenient to them. Once a baseline interview is scheduled, REDCap will prepopulate a schedule for all remaining data collection interviews and nurse calls, usually on the same day of the week and time of the day. Using the calendar function in REDCap, the schedule will appear on the calendar while maintaining blinding of data collectors to group assignments. The schedule will be mailed to each caregiver, with assurance that days and times can be rescheduled as needed. A detailed calling protocol will be used by data collectors and nurses, along with call tracking entered within REDCap. To further promote retention and follow-up, caregivers who ask to withdraw from the study will be offered the option to participate in a final data collection interview that contains all the primary, secondary, mediators, and program evaluation outcomes, as specified for the 12-week time point as listed in Multimedia Appendix 4. Consistent with our intention-to-treat design, caregivers who do not complete all 8 weekly calls with the nurse or the ninth booster call with the nurse will still be asked to continue in the trial for the remaining data collection calls.

Data Management

Data management will be overseen by the PI, coinvestigator, project manager, and the lead biostatistician and staff statistician. All data collection interviews and TASK III and ISR nurse calls will be audio recorded for quality assurance. During monthly or bimonthly self-evaluations with nurses and data collectors, audio recordings will be checked for adherence to the protocol and accuracy in data entry. All study data and tracking will be entered into an electronic data system, REDCap [87], which is a secure research electronic data management system with validated data entry, audit trails for tracking data manipulation, and export procedures. It is HIPAA compliant, satisfying all local, state, and federal regulations for the capture and storage of private health information for research purposes. The biostatistician will run quarterly reports assessing for missing data and range checks for data values. Any missing data or suspected errors in data entry will be discussed with the PI and the project manager, who can then access the audio recordings to resolve any issues with data entry.

Statistical Methods

Recruitment, Attrition, and Fidelity Ratings of Data Collection and Intervention Procedures

Using procedures similar to the TASK II study and our TASK III feasibility study, we will monitor screening and recruitment rates, attrition rates, and fidelity ratings of all data collection and intervention procedures [34,36,54,88]. We will compute the number of participants screened and enrolled per month, the proportion of screened eligible participants who enroll, intervention assignment–specific retention rates at each follow-up visit, and the proportion of outcome measures completed. For fidelity ratings, we will use an itemized checklist to monitor adherence to the unique components of the TASK III study [36]. Adherence will be scored with dichotomous responses for the presence or absence of each item. Frequencies and percentages will be calculated for each item by group. Intervention dosage will be calculated for nurse call duration (min) and the time caregivers spend reading study materials (min) for each group. Descriptive statistics for intervention dosage will be computed by group, and between-group mean differences will be evaluated using 2-sample t tests or nonparametric alternatives if the normality assumption is violated.

Assessment of Scales and Descriptive Statistics

After initial data verification, cleaning, and scale scoring, the coefficient alpha will be calculated as a measure of internal consistency reliability on all multiple-item scales. Descriptive statistics (frequencies, measures of central tendency, and variability) will be produced for all variables. Data will be screened for outliers, multicollinearity, and statistical model assumptions.

Baseline Equivalence and Possible Covariates

Baseline differences in caregiver and survivor characteristics and social determinants of health will be explored to identify potential covariates for our analyses. As in our TASK II trial, stratified random assignment using the type of relationship and baseline depressive symptoms will ensure a balance between the 2 groups for those 2 factors [34]. Baseline differences between the 2 groups will be evaluated using 2-sample *t* tests or Wilcoxon rank sum tests, chi-square tests, or Fisher exact test as appropriate. Baseline variables that are significantly different between the 2 groups at the .05 level will be controlled for in all analyses. In our previous TASK II trial, the ISR calls, on average, were significantly shorter than TASK II calls ($P<.01$) [34]. As in our previous studies [31,34], the number of minutes on TASK III and ISR calls with the nurse may serve as a covariate in our analyses.

Primary Analyses for Specific Aims 1 and 2

Overview

The general modeling strategy for the analyses in aims 1 and 2 will be repeated measures regression modeling using the generalized liner mixed model (GLMM) framework. In GLMM, it is possible to use data from participants when some of the data are missing under the assumption of missing at random. In addition, this modeling strategy allows for time-varying covariates, flexible covariance structures, and participant-specific effects and thus will be able to accommodate the analyses proposed. Our primary goal will be to assess the overall intervention effects on the change from baseline. All primary analyses conducted will be based on the intention-to-treat principle. Analyses will be done using SAS software (version 9.4 or higher).

Specific Aim 1

The *primary outcome* is caregiver life changes as a result of providing care (ie, physical health, physical functioning, emotional well-being, and general health). Life changes are measured using the BCOS total score [7]. The explanatory variables used in the specific aim 1 model will be the intervention group, time, and the intervention group–by–time interaction. Covariates (including social determinants of health) identified using the process described above will be included as appropriate. The number of minutes spent on calls with the nurse in both TASK III and ISR groups will potentially be used as a covariate as well. The model examined will be a 2 (intervention: ISR and TASK III) by 5 (time: baseline and 8, 12, 24, and 52 wk) mixed factorial model, along with covariates. In the GLMM framework, an appropriate link function will be specified depending on the distribution of the dependent variable. Hypotheses related to the immediate postintervention time point at 8 weeks and long-term, sustained efficacy at 12, 24, and 52 weeks will be tested using relevant least square mean contrasts and simple effects constructed within SAS PROC GLIMMIX.

Specific Aim 2

S*econdary caregiver outcomes* are depressive symptoms; other symptoms (stress, fatigue, sleep, pain, and shortness of breath); unhealthy days; self-management of diet and exercise; and self-reported health care use. In the analyses for depressive symptoms, we will look at both overall and subgroup analyses for caregivers who screen positive for depressive symptoms (PHQ-9 score >5) [34]. *Mediators* are task difficulty, threat appraisal, and self-efficacy for exercise and diet. Each of these outcomes will be modeled separately. The models for secondary caregiver outcomes and mediators used in specific aim 2 are similar to those for life changes tested for aim 1 and will include the intervention group, time, and the intervention group–by–time interaction. Covariates (including social determinants of health) identified using the process described above will be included as appropriate, as well as potentially the number of minutes spent on the calls with the nurse in both TASK III and ISR groups. The full model consists of a 2 (intervention: ISR and TASK III) by 5 (time: baseline and 8, 12, 24, and 52 wk) mixed factorial, along with covariates. In the GLMM framework, an appropriate link function will be specified depending on the distribution of the dependent variable. Hypotheses related to immediate postintervention time point at 8 weeks and long-term, sustained efficacy at 12, 24, and 52 weeks will be tested using relevant least squares mean contrasts and simple effects constructed within SAS PROC GLIMMIX. *Program evaluation outcomes* consist of caregiver satisfaction and evaluation of technology ratings. Satisfaction ratings from the Caregiver Satisfaction Scale [32] (usability, ease of use, and acceptability) and evaluation of technology ratings will be summarized at the item and scale levels by intervention group using descriptive statistics, including mean and 95% CI. Caregiver Satisfaction Scale scores, total, and subscales will be compared between groups using 2-sample *t* tests or nonparametric alternatives if the normality assumption appears violated.

Interim Analyses

There are no plans for interim efficacy or futility analysis. There is little chance that we would find harm from the intervention, thus rendering interim efficacy and futility analysis inappropriate.

Methods for Additional Analyses, Including Subgroup Analyses

Age Across the Life Span

We will compare caregiver age between TASK III and ISR groups using 2-sample *t* tests and control for age as a covariate in our analyses if significant age differences are noted.

Sex as a Biological Factor

We will explore sex differences by careful description of subgroup effects.

Minority Group Representation

We will also explore racial differences (ie, Black or African American vs White individuals) by careful description of subgroup effects.

Methods to Handle Protocol Nonadherence and Statistical Methods to Handle Missing Data

We will make every effort to avoid missing data. If missing data are identified, the PI or the project manager will access the corresponding audio recording to determine whether missing

data were due to an error in data entry. We will assess the reasons, patterns, and distribution of missing data, allowing us to assess whether an assumption of missing completely at random is reasonable or whether missingness is conditional on another variable in the dataset (ie, missing at random). Descriptive statistics will compare the characteristics of patients with and without missing data. If missing at random, we will incorporate variables that are identified to be related to the missingness in the analysis using multiple imputations if the amount of missing data affects the study results. Missing data have been minimal for our original TASK study [31], TASK II randomized controlled clinical trial [34], and TASK III feasibility study; we will use the same procedures to avoid missing data in this study. As mentioned previously, we will use an intention-to-treat design and rigorous treatment fidelity procedures [36] to monitor all research staff for adherence to protocol.

Plans to Give Access to the Full Protocol, Participant-Level Data, and Statistical Code

We will make the full protocol, participant-level data, and statistical code available to others. Data will be shared with undergraduate honors students, graduate students, postdoctoral students, and interested faculty members at our university and other institutions. Special measures will be taken to ensure that family caregivers and stroke survivors are not identified by any data that are shared. Close collaboration with the PI and her research team will be necessary for the use of shared data. Project-generated resources will include our finalized REDCap database, intervention materials, and training manuals for the project manager, TASK III study nurses, ISR study nurses, data collectors, and screening and recruitment staff. Close collaboration with the PI and her research team will be necessary for the use of shared resources by other investigators.

Oversight and Monitoring

General Composition of the Research and Intervention Delivery Team

Overview

The study team will consist of TB (PI and nurse), who will lead the interdisciplinary team of coinvestigators, consultants, TASK III and ISR nurse interveners, project coordinators, and data collectors to successfully achieve the aims of the study. EM (coinvestigator and nurse) will help to guide and train the TASK III and ISR nurses, especially with respect to tracking and maintaining treatment fidelity throughout the intervention period. NK (coinvestigator and physician) will provide valuable expertise on stroke, facilitate recruitment of participants, and provide guidance on future implementation of TASK III intervention into stroke systems of care. BH (coinvestigator and biomedical informatics specialist) will facilitate accessing Epic medical records to obtain lists of stroke survivors and their next of kin for recruitment. HS (coinvestigator and biostatistician) will work with investigators and a staff statistician to develop and implement the statistical analysis plan and dissemination of results. MR (coinvestigator and IT and instructional designer specialist) will oversee the TASK III telehealth technologies and work with an information technologist and website or digital designer for ongoing support and hosting of the TASK III website. KD (coinvestigator and physical therapist) will help promote physical activity in caregivers, provide oversight and interpretation, and assist with the dissemination of physical activity–related data. BB (consultant and dietician) will provide ongoing expertise for study methods and materials related to the caregivers' dietary habits, as well as oversight of the interpretation and dissemination of nutrition-related data. MM (consultant and social worker) will consult on updating and maintaining equitable and accessible community resources and support for both TASK III and ISR. HJ (consultant and nurse) will provide consultation on culturally sensitive approaches for recruiting and interacting with diverse family caregivers. JKA and PHM (consultants and nurses) will be available for consultation as needed for the overall study design and methods.

In addition to the PI, coinvestigators, and consultants, the team will consist of the following staff.

Project Manager

The person selected for this role has a master's degree in public health and will coordinate all aspects of the study including all day-to-day project operations, first-line supervision of research staff, coordination of communication with all study personnel, research team meetings, preparation of agendas and minutes, assistance in the preparation of the training manuals and protocols, maintenance of study files, budget management, scheduling and coordination of all family caregiver calls and mailings, and study coordination with recruitment sites. Furthermore, they will conduct caregiver and stroke survivor screenings and informed consent procedures. Under the direction of the biostatistician and the PI, they will also assist in the development, testing, and maintenance of the REDCap database; conduct the query management process; provide data management documentation, such as the data management plan; and ensure that data are being entered and cleaned in a timely and appropriate manner.

Nurse Interveners

A total of 3 hourly nurse interveners will be hired and trained to deliver the 9 TASK III intervention calls to 148 stroke caregivers randomly assigned to the TASK III intervention group. Three additional hourly nurse interveners will be hired and trained to deliver the 9 ISR group calls to 148 stroke caregivers randomly assigned to the ISR group. Nurses will be required to have a current registered nurse license and excellent interpersonal skills. In addition to making caregiver calls, the nurses will be responsible for self-evaluation of their own audiotapes, further retraining procedures, and documentation of TASK III intervention or ISR content delivered to caregivers. They will also attend weekly research team meetings.

Research Assistants

A total of 4 hourly research assistants will be hired and trained to conduct participant screening and collect data via telephone for 296 stroke caregivers at the 5 time points specified for the project (baseline and 8, 12, 24, and 52 wk). The hourly research assistants will provide coverage for each other in the event of illness or time off, cover a wide range of availability times for caregiver data collection calls, and attend weekly research team

meetings while remaining blinded to group assignment of caregivers throughout the study.

Informatics Support Person

The informatics support person for this study is a data analyst from the Center for Health Informatics at the University of Cincinnati Department of Biomedical Informatics. The data analyst will be supervised by BH to extract lists of stroke survivors and their next of kin from Epic electronic medical records from the University of Cincinnati Health and University of Cincinnati Health West Chester Hospitals for recruitment.

IT Support and Website or Digital Designer

This person will be supervised by MR and will work closely with TB and her interdisciplinary team to refine and maintain the TASK III telehealth technologies for the TASK III resource guide (ie, mailed hard copy, USB drive, Amazon Fire Tablets, e-book, and TASK III website) and the technologies for nurse calls (ie, telephone, Zoom videoconferencing, and FaceTime on iOS devices). The IT support and website or digital designer will work with Kotobee [50] on the TASK III e-book and Oohology [51] for ongoing support and hosting of the TASK III website. He will also help to train TASK III and ISR nurses on the use of the TASK III telehealth technologies and provide ongoing IT support throughout the project.

Staff Biostatistician

The staff biostatistician will work with HS to carry out the statistical analysis plan to address the study aims.

Composition of the Data Monitoring Committee, Its Role, and Reporting Structure

This study was approved by the university IRB as "no greater than minimal risk." According to the funder's policy (ie, National Institute of Nursing Research; NINR), "Monitoring by the PI or designee may be appropriate for protocols involving minimal risk or no more than a minor increase over minimal risk which are conducted at a single site." For this study, the IRB- and NINR-approved data and safety monitoring plan will be the responsibility of TB (the PI). Members of the research team will provide input, particularly HS, the statistician coinvestigator; EM, the nurse coinvestigator; and NK, the physician coinvestigator. The PI (TB) and research team members (HS, EM, and NK) are well-qualified and will meet quarterly (and more frequently as needed) to review data and the safety of the study procedures and involvement of participants. TB (the PI) will consult with the research team members (HS, EM, and NK), but she will be the monitoring entity for this study. She will collaborate closely with our local IRB throughout the study and will submit the approved IRB-continuing review, including the dates and summarized reports generated from data and safety monitoring meetings with the research team to the National Institutes of Health (NIH) along with the yearly NIH progress report. There are no conflicts of interest with or financial stakes in the research outcome with the PI (TB) or any members of the research team.

Adverse Event Reporting and Harms

The PI (TB) will be seeking input from members of the research team (HS, EM, and NK), and will meet quarterly (and more frequently as needed) with them to (1) review any deviations in the study protocol; (2) review any adverse events; (3) track any negative trends in data that may indicate harmful effects of the study procedures; (4) review study recruitment and retention; and (5) review data management procedures, particularly those designed to protect the privacy of participants. All protocol deviations, adverse events, and unanticipated problems will be reported by the PI (TB) to the local IRB and NINR yearly or more frequently as needed. At the time of the yearly IRB-continuing review, a summary of the frequency and dates of the data and safety monitoring meetings with the PI (TB) and the research team (HS, EM, and NK) will be provided, along with reviews and reports generated from each meeting. The approved IRB-continuing review, including the dates and summarized reports generated from the data and safety monitoring meetings with the PI and the research team, will be submitted to the NINR along with the yearly NINR progress report. The PI (TB) will provide a report of the following to IRB and NINR within 48 hours: (1) unanticipated problems or unexpected serious adverse events that may be related to study protocol; (2) IRB-approved revisions to the study protocol that indicate a change in risk for participants; (3) a summary of recommendations made by the PI and the research team as appropriate and, if applicable, the action plan for response; and (4) notice of any actions taken by the IRB or regulatory bodies regarding the research and any responses to those actions. All personal identifiers will be removed from any documents sent to the NINR. Identifiable data will be stored in locked file cabinets and within our secure, password-protected, HIPAA-compliant REDCap database.

Frequency and Plans for Auditing Trial Conduct

The PI (TB), with inputs from the research team (HS, EM, and NK), will provide auditing of at least 50% of all cases for compliance with IRB requirements, conformance with informed consent requirements, verification of source documents, and investigator compliance. Recommendations concerning the continuation or conclusion of the trial will be made during each quarterly meeting, based on the results of monitoring. The process will involve both the investigators and the sponsor (NINR).

Plans for Communicating Important Protocol Amendments to Relevant Parties

The PI will communicate important protocol modifications with the coinvestigators, consultants, project manager, and research staff as appropriate. All modifications will be approved by the local IRB before implementation and reported to the NINR on the yearly NIH progress report.

Dissemination Plans

This clinical trial is registered (ClinicalTrials.gov ID: NCT05304078), and information about the results will be submitted to ClinicalTrials.gov, which is available to the public. The IRB-approved informed consent form will include the following statement: "A description of this clinical trial will be available on ClinicalTrials.gov, as required by the US Law. This website will not include information that can identify you. At most, the website will include a summary of the results. You

can search this website at any time." Participants will be encouraged to check back with the ClinicalTrials.gov site for a lay summary of the results after completion of the study. Participants contacting the PI for results will be referred to the ClinicalTrials.gov website. We anticipate that there will be manuscripts, not only from the findings addressing specific aims 1 and 2 but also from secondary analyses of data generated from this study. We will disseminate results from specific aims 1 and 2, as well as results from secondary analyses, in peer-reviewed journals. We will make the data available to others as detailed in the Plans to Provide Access to the *Full Protocol, Participant-Level Data, and Statistical Code* section.

Results

Enrollment and random assignment of the first participant was on November 30, 2022, with an anticipated completion of recruitment by November 30, 2025. The primary end point data analysis is anticipated to be completed by August 31, 2026, with reporting of results in ClinicalTrials.gov anticipated to be by April 1, 2027. As of October 9, 2024, a total of 198 (66.9% of the proposed total sample of N=296) family caregivers have been enrolled and randomly assigned to the TASK III group (n=98, 49.5%) or the ISR group (n=100, 50.5%). On the basis of reviewer comments during the funding process, the exclusion criteria were changed from caregivers or survivors aged <21 years to those aged <18 years. An IRB modification was added to remove the word "unpaid" from the inclusion criteria for family caregivers because some states provide financial resources to family caregivers. Additional IRB-approved recruitment sites have been added, including the use of social media (eg, Facebook; Meta Platforms, Inc) for recruitment [89]. The protocol reported in this paper is protocol version 5, as approved by the IRB on May 9, 2024.

Discussion

Anticipated Results and Interpretation

This study protocol builds upon our findings from our previous studies with both the TASK [31,32] and TASK II R01 programs [34-36], as well as our most recent refinement and feasibility testing of the TASK III R21 program [37,38]. In caregivers with mild to severe depressive symptoms, the TASK II (in comparison with ISR) intervention was found to reduce depressive symptoms up to a year after baseline; however, improvement in caregiver life changes (ie, physical health, physical functioning, emotional well-being, and general health) occurred only from baseline to 12 weeks in this subsample [34]. Furthermore, TASK II caregivers typically waited until nurse calls 5 through 9 to address their own physical and emotional health needs [36]. To strengthen our findings regarding caregiver life changes, we refined the TASK III intervention to include an assessment of life changes using the BCOS [7], starting with nurse call 2, and added a goal-setting tip sheet to improve caregiver health [37]. Promising data trends indicating stronger caregiver life changes in the TASK III R21 intervention compared to the ISR intervention were reported on the ClinicalTrials.gov website. In this proposed trial, relative to the ISR group, we anticipate that caregivers randomly assigned to the TASK III group will show greater improvements in our primary outcome of caregiver life changes from baseline to 8 weeks (immediately after the intervention) in the total sample, which is sustained for a long term from baseline to 12, 24, and 52 weeks. This study will enable us to (1) successfully conduct a large efficacy trial of the TASK III intervention and (2) further refine the TASK III intervention via program evaluation data (satisfaction and technology ratings) for future implementation. Findings will provide evidence of efficacy for the TASK III program, which is a necessary step toward implementing the TASK III program into stroke systems of care.

Potential Pitfalls, Alternative Approaches, and Future Directions

We have a strong track record of recruitment and retention in our previous TASK, TASK II, and TASK III studies [31,34]. Nevertheless, we will closely monitor recruitment and retention and will secure additional recruitment sites if needed. Our study does not require face-to-face interactions with caregivers; therefore, we are not limited by geographic boundaries for recruitment. Some caregivers might be reluctant to try the new technologically enhanced TASK III resource guide (TASK III USB drive, e-book, and interactive TASK III website) or use videoconferencing (FaceTime and Zoom) for calls with the nurse. During the first TASK III session, we will instruct and demonstrate how to use the new Amazon Fire Tablet; how to connect with the nurse via FaceTime (if they have an iOS device); how to connect with the nurse via Zoom; and how to use each TASK III resource guide delivery mode (TASK III USB drive, e-book, and interactive TASK III website) and the American Heart Association website. We will encourage caregivers to explore these newer technologies during each call from the nurse but respect their preferences [38] and suggest that they call us if they have difficulties. We will have IT support available for caregivers. For the ISR group, during the first call, we will instruct and demonstrate how to use the new Amazon Fire Tablet, how to connect with the nurse via FaceTime (if they have an iOS device), how to connect with the nurse via Zoom, and how to access the American Heart Association website.

Our future directions include procedures detailed in the *Dissemination Plans* section that include reporting our findings in ClinicalTrials.gov (ID NCT05304078) and peer-reviewed journals and making our data available to others. Once we are able to demonstrate that TASK III intervention is efficacious, our next goal is to translate the optimized TASK III intervention into stroke systems of care to meet recommendations and guidelines for follow-up care for survivors and caregivers.

Acknowledgments

Research reported in this publication was supported by the National Institute of Nursing Research of the National Institutes of Health (NIH) under award number R01NR020184. The Center for Clinical and Translational Science and Training at the University of Cincinnati is funded by the NIH Clinical and Translational Science Award program, grant UL1TR001425. This program is led by the NIH's National Center for Advancing Translational Science. The content is solely the responsibility of the authors and does not necessarily represent the official views of the NIH. NIH was not involved in the design of the study; the collection, analysis, and interpretation of data; or writing the manuscript.

Data Availability

The datasets generated or analyzed during this study are available from the corresponding author on reasonable request. The SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) checklist based on the SPIRIT guidelines [89-91] and the CONSORT-EHEALTH (Consolidated Standards of Reporting Trials of Electronic and Mobile Health Applications and Online Telehealth) checklist [92] based on the CONSORT (Consolidated Standards of Reporting Trials) guidelines [88] are available upon request.

Authors' Contributions

All authors have contributed to the planning and designing of the trial and writing, reading, and editing of the manuscript. All authors have read and approved the submitted version and agree to be personally accountable for their own contributions, as well as those in which they were not personally involved.

TB, JKA, and PHM contributed to the conception of the study. All authors contributed to the design of the work. TB, NK, JI, and BH were involved in the acquisition of data. TB, HS, and KD analyzed the data, and TB, EM, HS, NK, and KD were involved in the interpretation of data. All authors drafted and substantially revised the work.

Conflicts of Interest

NK was associated with the Astra Zeneca Speaker Bureau (this conflict has ended) and is a National Football League unaffiliated neurotrauma consultant. All other authors declare no other conflicts of interest.

Abstract

Background: Adolescent girls and young women constitute a priority population disproportionately affected by HIV, accounting for 25% of annual HIV incidence among people older than 15 years in Kenya. Although oral preexposure prophylaxis (PrEP) is effective in reducing HIV acquisition, its protective benefit has been limited among adolescent girls and young women in sub-Saharan Africa because of low uptake, adherence, and persistence. Intimate partner violence (IPV) and relationship power inequities are widespread among adolescent girls and young women and contribute to higher HIV incidence and lower PrEP use. Interventions are needed to support sustained PrEP use among adolescent girls and young women by addressing IPV and relationship dynamics.

Objective: This study aims to test the effectiveness of Tu'Washindi na PrEP ("We are Winners with PrEP"), a multilevel community-based intervention, to increase uptake and adherence to PrEP and reduce IPV among adolescent girls and young women in Siaya County, Kenya.

Methods: The Tu'Washindi na PrEP intervention was co-designed by our team and adolescent girls and young women using participatory methods and includes 3 components delivered over 6 months: an 8-session, empowerment-based support club for adolescent girls and young women, community sensitization targeted toward male partners, and PrEP education events for couples. The intervention will be evaluated using a cluster randomized controlled trial across 22 administrative wards in Siaya County, Kenya, enrolling 72 adolescent girls and young women per ward (total N=1584). The primary objectives are to test the effectiveness of the intervention on PrEP uptake and adherence immediately after delivery (month 6 after enrollment) and 6 months later (month 12). As secondary objectives, we will test the intervention effect on IPV. A rigorous process evaluation will explore mechanisms of change, contextual factors, and implementation considerations to inform future refinement and scale-up, using programmatic data, participant questionnaires, and qualitative interviews with participants and intervention providers.

Results: Data collection started in September 2022. As of December 2024, enrollment has been completed in 16 of the 22 study wards, with 72.6% (1150/1584) of participants enrolled. We anticipate that data collection will be completed in May 2026 and results will be available by mid-2027.

Conclusions: The study builds directly on our promising formative and pilot research to develop the evidence base for this youth-designed, multilevel HIV prevention intervention. If effective, Tu'Washindi will be ideally positioned for sustainable integration into existing youth-focused programming to expand and support PrEP use in this priority population.

Introduction

Background

Optimizing the effectiveness of proven biomedical prevention interventions is critical to decreasing the high incidence of HIV among adolescent girls and young women aged 15 to 24 in sub-Saharan Africa, a priority population for HIV prevention. More than 1 in 4 new HIV infections in this region are among adolescent girls and young women [1], who are over twice as likely to acquire HIV as their male counterparts [2]. Oral preexposure prophylaxis (PrEP) is an effective, female-initiated biomedical HIV prevention intervention, but its protective benefit has been limited among adolescent girls and young women across sub-Saharan Africa by challenges to uptake, adherence, and persistence [3-17]. In western Kenya, a study of adolescent girls and young women attending family planning clinics found that 76% met PrEP eligibility criteria, but only 4% initiated PrEP [16], and the proportion of adolescent girls and young women persisting with PrEP for 3 months postinitiation ranged from 5% to 37% across studies [7,10,11,15,17]. In samples of PrEP users at an average of 6 months postinitiation, only 4% to 8% had tenofovir diphosphate (TFVdp) levels suggesting high adherence [4-6]. The public health impact of PrEP will be determined by concurrent interventions that address critical barriers to uptake and adherence.

Adolescent girls and young women who live in a context of heightened gender inequality and risk of intimate partner violence (IPV) represent a large subpopulation who are uniquely vulnerable to HIV infection. IPV is widespread among adolescent girls and young women in western Kenya: 19% reported experience of sexual IPV in the past year, 25% reported physical IPV, and 34% reported emotional IPV [18-20]. Experience or fear of IPV in sexual relationships is associated with having limited relationship power [20,21] and with 28% to 55% higher HIV incidence in adolescent girls, young women, and adult women [21-23]. Studies have found that IPV and other partner-related social harms are associated with 1.5- to 2.5-fold higher risk of poor adherence to oral PrEP and the dapivirine ring for HIV prevention. Similar to HIV treatment and contraception [19,20,24-29], IPV and relationship inequality introduce barriers to uptake of and adherence to PrEP at multiple levels. At the individual-level, restricted access to information and health services, poor negotiation skills, low self-efficacy, and fear of violence or relationship dissolution hinder adoption of health-promoting behaviors [30-32]. Dynamics at the partner level, such as poor communication and low decision-making power, limit disclosure about PrEP use and reduce partner support, which can impact adherence [33-35]. These challenges are further compounded at the community level by a lack of PrEP awareness, inequitable gender norms, and stigma associated with taking PrEP, which contribute to partner and community opposition to female PrEP use [36-39]. A multilevel context-specific intervention to address barriers to PrEP use is needed to ensure that adolescent girls and young women experiencing relationship inequality and IPV benefit from this effective biomedical prevention strategy.

In response, our intervention, Tu'Washindi na PrEP (We are winners with PrEP), was designed in close partnership with local adolescent girls and young women and incorporates strategies targeted to address relationship dynamics and IPV at multiple levels [40,41]. This intervention has 3 components: an empowerment-based support club for adolescent girls and young women, PrEP education events for couples offered in the context of a health fair (Buddy Days), and community sensitization about PrEP targeted toward adolescent girls and young women's partners [40]. The pilot cluster randomized controlled trial (cRCT) of Tu'Washindi at 6 Determined, Resilient, Empowered, AIDS-free, Mentored and Safe (DREAMS) spaces demonstrated feasibility, high acceptability, implementation with fidelity, and promising effects on PrEP and IPV outcomes [42]. PrEP uptake and adherence were both approximately twice as high in the intervention arm as in the control arm ($P<.05$) [43]. Although the adherence was still lower than desired in the intervention arm, with Wisepill openings on 25% of days on PrEP, they still represented substantial improvement over programmatic outcomes [6,17]. We also observed less frequent or severe IPV among intervention arm participants [43].

Because our pilot findings suggested that Tu'Washindi shows promise as an acceptable intervention that can be implemented with fidelity to promote PrEP uptake and adherence among adolescent girls and young women without concomitant increases in IPV, we designed a fully powered effectiveness trial to determine whether these gains translate to increases in biomarker measures of PrEP adherence and whether the intervention can reduce IPV risk.

Study Objectives

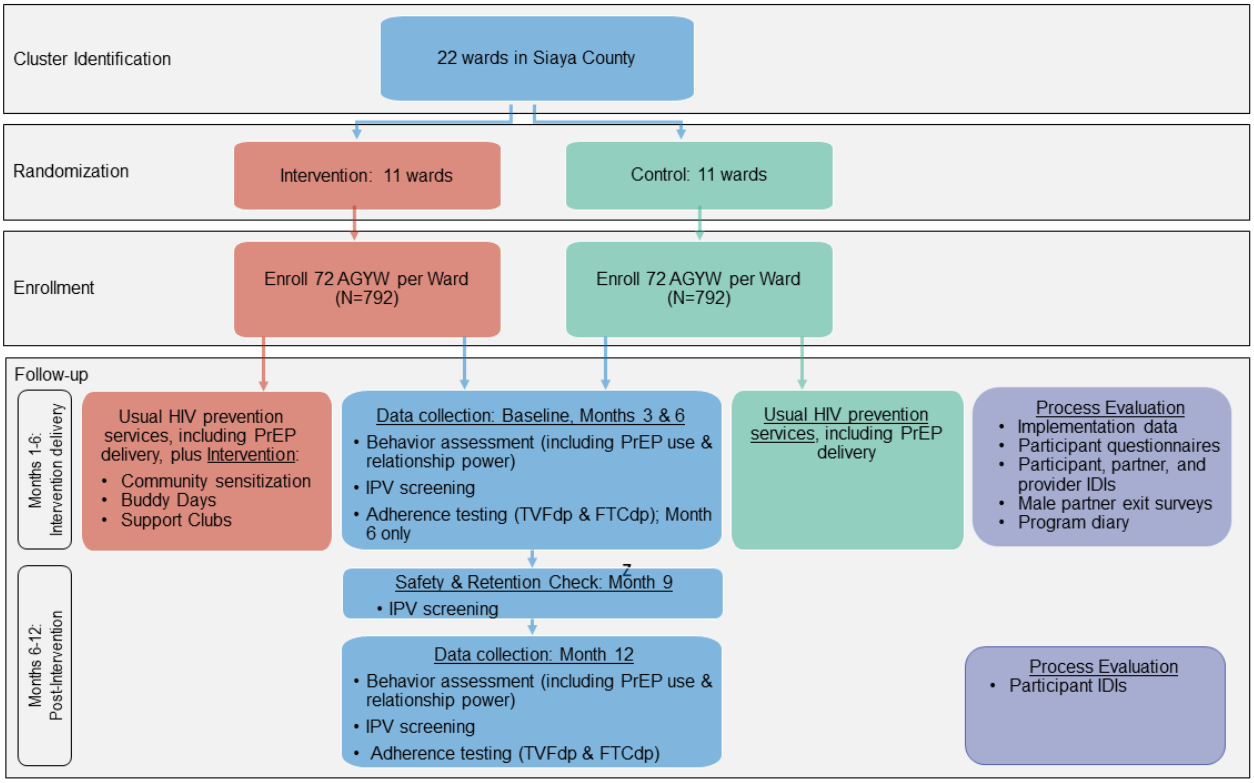
The objective of this study is to test the effectiveness of the multilevel Tu'Washindi intervention to increase effective PrEP use and reduce IPV among Kenyan adolescent girls and young women by addressing relationship dynamics and partner opposition to PrEP. A process evaluation will assess the implementation processes and theorized mechanisms of change influencing intervention effectiveness and identify implementation challenges and strategies to facilitate future scale-up in programmatic settings to maximize public health impact. Study findings will contribute to the limited evidence base for effective PrEP adherence interventions to reduce HIV acquisition in this priority population.

Methods

Design

This study has a 2-arm parallel cRCT design (Figure 1). We have randomized 22 administrative wards in a 1:1 ratio and aim to enroll about 72 adolescent girls and young women from each (total N=about 1584) to receive either the Tu'Washindi intervention plus usual HIV prevention services, or usual HIV prevention services alone. Because of the urgent need for interventions to support PrEP use among adolescent girls and young women in a real-world context, the intervention is delivered outside of DREAMS to evaluate its impact on adolescent girls and young women accessing PrEP from Ministry of Health (MoH) facilities. This pragmatic study design enables us to determine effectiveness of the intervention when layered onto ongoing county-wide HIV prevention programming [44]. After informed consent and baseline data collection, the Tu'Washindi intervention is implemented in each intervention cluster while the control cluster continues with usual HIV prevention services. The duration of study participation is 12 months, with data collection visits at intervention midline (study month 3), intervention endline (study month 6), and at 6 months postintervention (study month 12). A prospective process evaluation is being conducted to characterize intervention implementation, explore theorized mechanisms of change, and capture contextual factors influencing study outcomes. The protocol was written following the 2013 SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) guidelines (Multimedia Appendix 1).

Figure 1. An overview of the study design. AGYW: adolescent girls and young women; FTCtp: emtricitabine triphosphate; IDI: in-depth interview; IPV: intimate partner violence; PrEP: preexposure prophylaxis; TFVdp: tenofovir diphosphate.



Study Setting

Siaya County is located in the former Nyanza Province in western Kenya, along the shores of Lake Victoria. The county is primarily periurban and rural, and agriculture and fishing are the main economic activities [45]. Siaya County has the second highest HIV incidence in Kenya (2.5% per year); it is the site of 12% of new HIV infections but comprises just 2% of the national population [46]. In addition, the former Nyanza Province has the highest prevalence of gender-based violence in Kenya: 22% of women aged 15 to 49 have reported sexual violence and 56% have reported physical violence at least once since the age of 15 [18].

Study Organization

The Tu'Washindi study leadership is comprised of investigators from RTI International and Impact Research and Development Organization (IRDO) and meets monthly. This group is

ultimately responsible for the design and conduct of the trial, including intervention updates, protocol preparations and revisions, and protocol and safety monitoring. The trial management committee meets weekly, and it is responsible for the day-to-day conduct of the trial. It includes the principal investigator (PI) and site PI, project director and project coordinator, intervention leads, and quantitative and qualitative data management teams. The University of North Carolina Center for AIDS Research Clinical Pharmacology and Analytical Chemistry Core is responsible for analysis of the dried blood spot (DBS) samples. The study is further supported by a 5-member national-level technical advisory committee who meet annually and advise on design considerations to ensure a smooth transition from research to implementation if the intervention is effective; a 15-member youth advisory board that meets quarterly and provides feedback on study design and methods, data collection tools, and recruitment and retention of study participants; and a 12-member stakeholder advisory board made up of PrEP technical staff from MoH and other delivery partners, IPV referral agency representatives, and other community leaders that meets twice yearly to advise on effective integration of the study into existing structures and on linkage to PrEP and other referral services.

cRCT Component

Site Selection and Randomization

The study clusters comprise 22 of the 30 administrative wards in the county. The 30 wards were categorized into 5 strata based on community type (ie, periurban, rural fishing, or rural nonfishing) and whether the proportion of girls on PrEP is above or below the median, using MoH programmatic data. (Although the geography and PrEP use criteria define 6 strata, only 1 ward in the county fell within the urban, low PrEP use stratum. Because it was not possible to create a pair of intervention and control wards in this stratum, it was excluded.) The 22 study wards were purposively selected to ensure an even number of wards within each stratum and a balanced distribution of wards across strata. Randomization was completed by RTI statisticians once the 22 study wards are selected and placed into strata. Within each stratum, wards were randomly allocated to the intervention or control arms in a 1:1 ratio. After randomization, we created pairs of intervention and control wards within each stratum and determined the order in which they would be enrolled in the study based on the location of each ward, to minimize the risk of contamination while ensuring the feasibility of implementation. Subsequently, one intervention and control site pair were randomly selected from each stratum for inclusion in the qualitative component. Allocation was revealed to the investigators before community mapping (see the Recruitment and Screening section) and to the participants after their enrollment into the study.

Eligibility Criteria

To be eligible, potential participants must be females aged 15 to 24, currently in a sexual relationship with a male partner for at least 1 month, and vulnerable to HIV per a modified version of the DREAMS eligibility screening tool. To reflect the population most likely to participate in this intervention in a programmatic setting, they must be either taking PrEP or interested in taking PrEP (ie, she thinks that she would benefit from PrEP but is not currently taking it). In addition, they must be residents of the applicable study ward; willing and able to attend support clubs; willing and able to provide adequate contact information; fluent in English, Dholuo, or Kiswahili; and able and willing to provide informed consent (or assent and parental consent for nonmature minor participants aged 15 to 17). Potential participants are excluded if they are living with HIV (by self-report); planning any long-term travel or relocation in the next 12 months; or have any condition that the site PI or designee determines would preclude participation.

Individuals who do not meet the criteria for participation in this trial (ie, screen failure) because of criteria that are likely to change over time may be rescreened. Examples include not being resident of the ward or not being interested in taking PrEP.

Recruitment and Screening

Recruitment occurs simultaneously in each pair of wards before moving on to the next pair and focuses on the catchment areas of 2 to 4 health facilities in each ward. Before recruitment, community mapping is conducted to identify key stakeholders, referral resources, locations where adolescent girls and young women gather, and locations where men gather. Recruitment takes place at venues identified through community mapping, including health facilities, schools, churches, DREAMS Safe Spaces, youth groups, and community markets. To ensure that the study findings are generalizable to adolescent girls and young women across the 15- to 24-year age range, we aim to enroll at least 25% of the study participants from the 15- to 19-year age group who have lower rates of PrEP use but have similar HIV incidence to the 20- to 24-year age group [47,48]. Attendees interested in the study are invited to meet with the research assistant after the recruitment meeting to discuss questions, obtain additional information, and schedule an appointment for informed consent, eligibility screening, and, if eligible, for enrollment.

Retention

Once a participant is enrolled in the study, the study team makes every reasonable effort to retain her to minimize bias associated with loss to follow-up. To ensure high retention, IRDO tracks retention rates and follows standard study operating procedures detailing strategies, such as clear explanation of the visit schedule at all visits, collection of detailed locator information with multiple means to contact participants, appropriate and timely visit reminders, offering weekend hours for study visits, and conducting immediate follow-up on missed visits through phone, home or other off-site visits.

Intervention and Control Conditions

Intervention Design

Tu'Washindi was developed by our team using a participatory process with adolescent girls and young women and service providers in Siaya County to ensure that it was responsive to adolescent girls and young women's stated needs for PrEP support in the context of their relationships [40]. The intervention components are informed by social cognitive theory [49] in combination with a socioecologic framework for PrEP

introduction [50] to address factors at the individual, partnership, and community levels that influence adolescent girls and young women's response to IPV and their PrEP use (Figure 2 [50,51]).

Social cognitive theory informs support club activities to enhance individual-level behavioral capability (eg, knowledge and skills to use PrEP and IPV safety planning), improve outcomes expectations (eg, that PrEP use will prevent HIV without threats to safety or relationship security), and increase self-efficacy to use PrEP safely and consistently. At the partnership level, support clubs also aim to develop skills for healthy communication and PrEP disclosure. Drama activities are integrated into each session to allow participants to practice these skills and build self-efficacy. Adolescent girls and young women follow suggested storylines from the intervention manual, developed by youth in the formative phase [40], to create and enact plays about overcoming partner-related barriers to PrEP use, including one to be performed at the Buddy Days. Buddy Days also work at this level to facilitate disclosure and build male partner support for PrEP use by engaging couples in discussions about PrEP, healthy relationships, and promoting HIV prevention as part of family well-being. To increase men's receptiveness to information provided at the Buddy Days or from their female partners, community sensitization events deliver accurate information about PrEP (eg, safety, effectiveness, and eligibility), discuss common myths and misperceptions, and encourage men to support their partners' PrEP use [53]. At the community level, the community sensitization activities aim to increase PrEP knowledge, reduce PrEP stigma, and reduce the acceptability or normalization of IPV as a response to adolescent girls and young women's PrEP use. Support clubs aim to increase social assets, including peer support for PrEP use and access to IPV resources in the community. Table 1 illustrates the intervention's alignment with the conceptual framework.

Figure 2. The conceptual framework; adapted from Pettifor et al [51] and Mathur et al [50]. IPV: intimate partner violence; PrEP: preexposure prophylaxis.

Intervention Delivery

Before delivery, the intervention manual and training tools were updated to reflect lessons learned during the pilot and the change to implementation outside of DREAMS. Because age restrictions on PrEP in DREAMS did not permit us to pilot the intervention with adolescent girls aged 15 to 17 years, we pretested the activities with 12 to 15 adolescent girls in this age range over a 1-month period to obtain feedback on comprehension and relevance of the content and how best to support participation.

Delivery takes place in 4 phases, with activities occurring concurrently in 2 wards during phase 1 and in 3 wards during phases 2 to 4. In each ward, the intervention is conducted over a 6-month period with intervention implementation beginning about 1 week after enrollment concludes. Each new phase of the intervention commences immediately after the activities in the previous phase are concluded. This phased approach minimizes staff burden and allows for close monitoring of implementation to identify and correct problems early on.

The intervention activities include sensitization of MoH clinics, intervention staffing and training, community sensitization sessions, Buddy Days, support clubs, and monitoring and quality assurance.

For sensitization of MoH clinics, before study initiation in each intervention ward, we collaborate with the facility in-charges from each of the 2 to 4 health facilities selected for study recruitment to identify PrEP delivery staff and schedule a half to one day training to introduce the study and discuss relationship-related challenges to PrEP use, with the goal of ensuring that the counseling support offered at the clinics complements the messages provided through the intervention. We also review PrEP adherence and couples' counseling and disclosure approaches to more comprehensively address adherence challenges commonly experienced by adolescent girls and young women.

Intervention staffing and training within each ward is delivered by a set of 2 to 4 mentors (ie, women slightly older than the participants who have completed at least some secondary education and are rooted in their communities), an experienced male community organizer, and clinicians and counselors with experience in PrEP provision to adolescent girls and young women (hereafter "intervention providers"). Staff supervisors train each cadre over 1 to 3 days to review the intervention manual and to practice the required activities.

Community sensitization sessions are conducted by the community organizer approximately weekly over the first 3 months of the intervention period, lasting about 60 minutes to 90 minutes each. Sessions occur in places where adolescent girls and young women's male partners are known to gather [54]. Content focuses on PrEP information and dispelling myths and rumors. When time allows, additional content on healthy relationship communication is also included. Clinicians may attend larger sessions to support the organizer.

Buddy Days take place around month 3 of the intervention period, with about 2 to 3 events per ward to maximize participation. The sessions are cofacilitated by the community organizer and clinician and include provision of information about PrEP; facilitated discussion of reasons to support adolescent girls and young women's PrEP use, healthy relationship communication, and acceptability of IPV; and an interactive drama, designed and performed by volunteer Tu'Washindi participants based on story guides in the intervention manual, to illustrate real-world partner-related challenges to PrEP use. The cofacilitators foster audience engagement both during and after the performance by soliciting reflections on the drama, discussions of alternate storylines, and experiences from audience members [55]. To encourage and destigmatize participation, Buddy Days are open to all community members and offer health services, such as HIV testing services and screening for hypertension and diabetes. In addition, all adolescent girls and young women and their

partners who attend the Buddy Days together as a couple receive a small basket of foodstuffs worth about US $5 as an incentive.

Support clubs meet for approximately eight 2-hour sessions over the 6-month intervention period, facilitated by the mentor or by 1 or more participants with mentor support. About 3 to 4 support clubs are offered at varying times and locations to maximize convenience and maintain a small enough number of attendees (18-24) to build community and trust. The support clubs aim to be youth-friendly and nonjudgmental, with an emphasis on ground rules and confidentiality, and support for PrEP uptake and adherence are integrated throughout. Each interactive, participatory session follows the same basic format: a check-in and activity to build community; recap of the previous session; a new topic related to PrEP and relationships, led by the mentor, clinician, or counselor (Table 2); drama activities; and a closing activity to reflect on lessons learned and build confidence and support.

Table 2. Sample support club topics and coleaders.

Session and topic	Leaders
Session 1: PrEP[a] information	Mentor and clinician
Session 2: disclosure	Mentor and counselor
Session 3: undisclosed PrEP use	Mentor and clinician
Session 4: healthy relationships	Mentor and counselor
Session 5: IPV[b] and PrEP use	Mentor and counselor
Session 6: open session[c]	Mentor
Session 7: open session[c]	Mentor
Session 8: future goals and closing ceremony	Mentor

[a]PrEP: preexposure prophylaxis.

[b]IPV: intimate partner violence.

[c]Participants' choice of topics.

Monitoring and quality assurance involves closely monitoring intervention delivery for quality and fidelity. Staff supervisors will observe at least 15% of community sensitization activities, 100% of Buddy Days, and at least 20% of support clubs using activity-specific observation forms to document assessments of fidelity (ie, adherence to the intervention manual), quality of facilitation (eg, facilitator maintains focus and nonjudgmental delivery), participant engagement, and any factors that may have affected implementation. Intervention staff receive feedback and coaching after each observed session. Findings will inform staff retraining and implementation refinement for subsequent phases. For example, training of intervention providers may be bolstered if gaps are identified.

Usual Care Services

Participants in the intervention and control clusters will have access to a range of evidence-based HIV prevention services offered in the county, including Global Fund–supported services, such as HIV testing services, syndromic management of sexually transmitted infections, family planning and postviolence care services; ongoing DREAMS programming; and PrEP [56]. Participants in both arms receive information about available services and are referred to these services upon request. PrEP is available to adolescent girls and young women aged ≥15 at >100 MoH facilities throughout the county [57], and all the participants who choose to use PrEP in the study can access it through these MoH facilities. In keeping with our study design, this choice of usual services as the comparator condition is realistic, ethical, and relevant [58] because it represents a wide range of evidence-based services to reduce HIV risk. However, PrEP uptake and persistence have been suboptimal in this context, indicating that the intervention is warranted, and that the comparator condition is not sufficiently robust to preclude our ability to detect an effect [59].

Data Collection

Data collection visits occur simultaneously in each pair of wards at enrollment, and months 3, 6, and 12 (Table 3). At enrollment, interviewer-administered questionnaires are used to assess sociodemographics, relationship characteristics, IPV, behavioral HIV risk factors, and history of PrEP use. Measures are repeated in follow-up questionnaires to document changes in relevant characteristics, attitudes, and behaviors.

DBS samples are collected via fingerprick at months 6 and 12 from all participants who report initiation or continuation of PrEP since the last visit. For participants who report discontinuation of PrEP, reasons for discontinuation are recorded, but DBSs are not collected. Due to storage and transport challenges, DBS samples are also not collected for participants who have relocated outside the county and have follow-up visits conducted by phone or at a remote location. DBS samples are stored in freezers at the IRDO laboratory and then shipped to the laboratory at the University of North Carolina Center for AIDS Research Clinical Pharmacology and Analytical Chemistry Core for quantification of drug concentrations by liquid chromatography-tandem mass spectrometry technology [60].

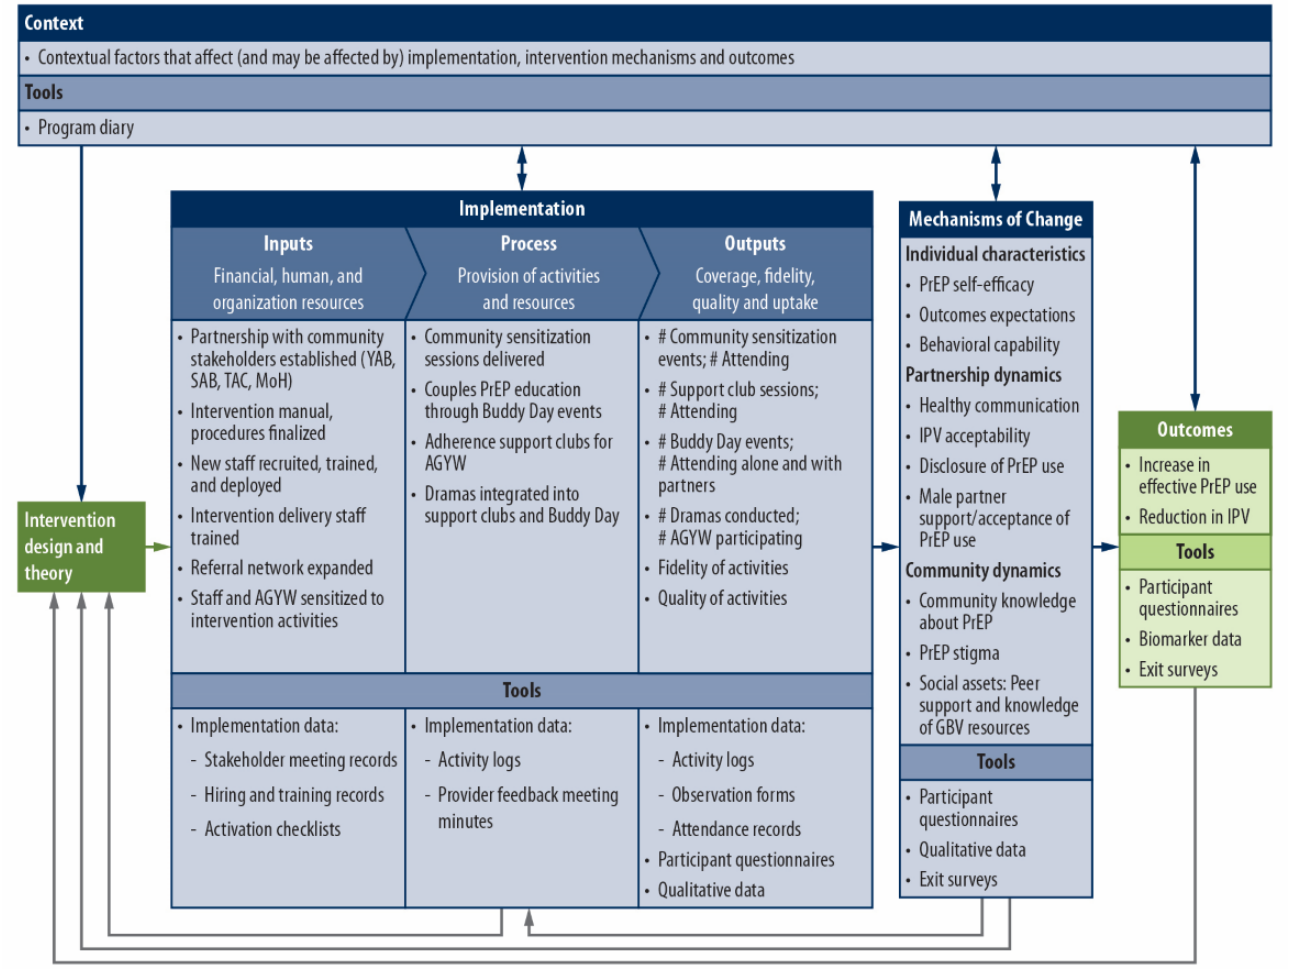
Process Evaluation Component

Overview

The mixed methods process evaluation uses implementation data; quantitative adolescent girls and young women participant questionnaires; exit surveys with men who attend intervention activities; qualitative in-depth interviews (IDIs) with adolescent girls and young women participants, their male partners, and intervention providers; and a project diary. Our process evaluation framework (Figure 3 [61]) highlights the key evaluation components, relationships between them, and key measures and data sources [62-65].

Figure 3. Process evaluation framework and key measures. Adapted from the Medical Research Council guidelines for process evaluation of complex interventions [60]. IPV: intimate partner violence; MoH: Ministry of Health; PrEP: preexposure prophylaxis; SAB: Stakeholder Advisory Board; TAC: Technical Advisory Committee; YAB: Youth Advisory Board.



Participants and Eligibility

Eligibility criteria for adolescent girls and young women participants are described in the Eligibility Criteria section. Participants in exit surveys or male partner IDIs must be males aged ≥15 years. In addition, the exit survey participants must have attended a study Buddy Days or community sensitization event and have been present for at least half of the event, while IDI participants must be a sexual partner of the adolescent girls and young women clinical trial participant and that adolescent girls and young women participant must have provided permission for the study staff to contact the male partner. Intervention providers must be aged ≥18 years and have been involved in delivering Tu'Washindi intervention activities. In addition, all participants must be fluent in English, Dholuo, or Kiswahili; willing and able to provide informed consent; and not have any condition that the site PI or designee determines would preclude participation.

Participant Selection and Recruitment

Exit Surveys

At all intervention sites, all men who attend a Buddy Days event as a couple are approached while waiting for incentive distribution and asked to complete a survey. A research assistant approaches about 20% of men who attend community sensitization events and asks them to complete survey after the event.

In-Depth Interviews

For each of the 5 intervention and control ward pairs randomly selected for qualitative research, we use data captured at month 3 to purposively select a subset of adolescent girls and young women participants (n=30; 4 per intervention ward and 2 per control ward) who are behaviorally eligible for PrEP, per self-report, and have attended at least one support club meeting (intervention wards only). We aim to ensure representation of

PrEP users and nonusers and those with and without a history of IPV. Participants who are selected for IDIs are contacted by a research assistant before their month 6 visit, informed that they have been selected, and invited to participate in the IDI.

On the basis of the information provided by the adolescent girls and young women at the month 6 visit, we purposively select male partners (n=20; 4 per intervention ward) for IDIs to represent a range of exposure to the Buddy Days and community sensitization activities.

Male partners are only contacted with the permission of the adolescent girls and young women participants, who provide contact information. A research assistant then contacts the male partner and invites him to participate in the IDI. Study staff do not disclose the PrEP use status of adolescent girls and young women participants to any partner whom they recruit for the IDIs.

Intervention providers are purposively selected for IDIs by the study coordinator to represent a variety of job functions, including mentors, community organizers, counselors, and clinicians (n=20, 4 per intervention ward).

Data Collection

Implementation data includes staff hiring and training records; minutes from youth advisory board, stakeholder advisory board, and technical advisory committee meetings; and study activation checklists to track activities, materials, and systems required for successful implementation, such as community introductions, final intervention manuals, and vetted lists of referral agencies. Providers maintain activity logs and attendance records for each meeting or event, and supervisors record minutes from feedback and coaching meetings. Quality and fidelity of intervention activities is documented on observation forms as described above.

Participant questionnaires are administered to adolescent girls and young women participants at each visit to assess mechanisms of change (for all participants) and perceived intervention quality (intervention arm) or potential contamination (control arm). The hypothesized mechanisms of change include PrEP self-efficacy and outcome expectations, PrEP knowledge, healthy communication, disclosure of PrEP use to male partner and partner reaction, community knowledge of PrEP, PrEP stigma, and social assets.

Exit surveys are brief, anonymous, quantitative, interviewer-administered questionnaires that gather information on men's views of PrEP, their willingness to support their partner's PrEP use, and feedback on intervention activities.

IDIs are conducted in a private location and facilitated by trained female interviewers following a semistructured guide as follows:

- Serial IDIs with adolescent girls and young women participants are conducted at 2 time points (months 6 and 12). Key topics include relationship quality and experiences of IPV, patterns of PrEP use and barriers and facilitators to PrEP access and use, experiences with the intervention, and perceptions of how the intervention has affected the hypothesized mechanisms of change and study outcomes.
- Male partner IDIs take place at the end of the intervention period and explore men's experiences with the intervention. Interviews also aim to identify mechanisms through which their attitudes toward PrEP were shifted, or reasons why they were not.
- Intervention provider IDIs are conducted at the end of intervention delivery to elicit their perceptions of the adequacy of inputs (eg, training and resources), fidelity and quality of delivery, and challenges and perceived benefits to delivering each intervention component.

A program diary is maintained by the study coordinator to record external events (eg, elections, police activity, festivities, and health campaigns) and internal events (eg, increased funding or supply shortages) that may affect intervention delivery or study outcomes. Before intervention implementation in each ward, the study coordinator identifies a set of sources, including study staff, health facility personnel, community members or others who are well-positioned to provide this contextual information, and contacts them at regular intervals to record any updates.

Data Management

Most questionnaire data are collected on tablets using REDCap (Research Electronic Data Capture; Vanderbilt University) or collected on paper forms and entered into REDCap at the study offices, with hard copies securely stored at the field site [66,67]. RTI implements a quality assurance plan, including routine generation of quality control reports by the data manager and communication of findings for resolution. IDIs are audio-recorded, with debriefing reports completed immediately after each interview and quickly shared with the study team to highlight preliminary findings. Interviews are translated and transcribed at the study site. Electronic copies of forms are securely transmitted to RTI and reviewed for quality control, with weekly query resolutions.

Sample Size Considerations

The study is powered to identify an absolute difference of 15% between intervention and control arms for the primary outcomes: the proportion with effective PrEP use at month 6 and month 12. Power calculations are conducted using simulations based on the logistic model with normally distributed ward (cluster) effects and assuming 11 wards per treatment arm with type 1 error of 0.025 to account for separate analyses at each of 2 time points. With 60 participants per ward, we will have ≥80% power to detect a 15% difference in the outcome as long as the SD for ward variation is ≤10% and the level of effective PrEP use in control wards remains <50% (far higher than observed in recent trials and demonstration projects). To allow for up to 20% loss to follow-up, our total sample size will be 1584 participants: 72 adolescent girls and young women in each of the 22 wards (11 wards per arm).

Data Analysis: Clinical Trial

Outcomes and Hypotheses

The primary outcomes of the study will be the proportion of study participants with effective PrEP use, defined in Table 4, evaluated immediately postintervention, at month 6, and at

month 12 to gauge the persistence of intervention effect. TFVdp levels will be dichotomized by Clinical Pharmacology and Analytical Chemistry Core laboratory specialists to delineate between consistent (≥4 doses per week) versus inconsistent (<4 doses per week) adherence [68]. The aim 1 hypothesis is that the proportion of participants with effective PrEP use at (a) month 6 and (b) month 12 will be *higher* in the intervention versus control arm.

Table 4. An overview of key measures for the cluster randomized controlled trial, collected at enrollment and months 3, 6, and 12, unless otherwise noted.

Measure	Method
Primary outcomes	
Effective PrEP[a] use (biomarker assessment)	Percentage of all study participants with biomarker TFVdp[b] levels indicating consistent PrEP use (≥4 doses per week) for the past 2 months. [68,69]. Represents a composite outcome of PrEP initiation and high execution to capture these key steps in the HIV prevention continuum. Collected at months 6 and 12 only.
Secondary outcomes	
IPV[c] prevalence	Percentage of participants reporting IPV since the last study visit, measured with the WHO VAWI[d] [70] and classified by the STRIVE consortium definition [71]: any act of severe physical or sexual violence or ≥2 acts of moderate physical violence.
IPV severity	Percentage of participants reporting any sexual or severe physical IPV since the last study visit, measured with WHO VAWI [70].
IPV intensity	Continuous score calculated from the number of specific violent acts reported and the reported frequency of each act (0=never; 1=once; 2=a few times; and 3=often) since the last study visit, measured with WHO VAWI [70].
Exploratory outcomes (subcomponents or alternate measures of primary and secondary outcomes)	
PrEP uptake	Percentage of participants initiating PrEP *among those not on PrEP at baseline*, self-reported and validated by Ministry of Health records.
PrEP execution	Percentage of participants with TFVdp levels indicating consistent use *among those reporting current PrEP use.*
PrEP persistence	Percentage of participants with any detectable TFVdp *among those who ever initiated PrEP.* Participants who self-report discontinuation will be categorized as having undetectable TFVdp levels.
Recent PrEP use (biomarker)	Percentage of all study participants with biomarker FTCtp[e] levels indicating consistent PrEP use (≥4 doses per week) for the past 2 wk. Collected at months 6 and 12 only.
IPV type	Percentage of participants reporting each IPV type (physical, sexual, emotional, and economic) since the last visit, per WHO VAWI [70].

[a]PrEP; preexposure prophylaxis.

[b]TFVdp: tenofovir diphosphate.

[c]IPV: intimate partner violence.

[d]WHO VAWI: World Health Organization's Violence Against Women instrument.

[e]FTCtp: emtricitabine triphosphate.

The secondary outcomes of the study will be the proportion of participants reporting any IPV and severe IPV (Table 4) between enrollment and month 6, and between month 6 and month 12, and the difference in IPV intensity scores at months 6 and 12. The aim 2 hypothesis is that the proportion of participants reporting any IPV and severe IPV and IPV severity scores will all be *lower* at both time points in the intervention arm versus control arm.

In exploratory analyses, we will first explore effect modification by age (15-19 vs 20-24) and DREAMS participation (current, former, or never) for the primary and secondary outcomes. Second, we will break down the primary outcome into steps along the continuum (PrEP uptake, execution, and persistence) and IPV outcomes by type—physical, sexual, emotional, and economic—to understand where the intervention had its strongest effects. Third, we will compare the proportion of participants per arm with emtricitabine triphosphate (FTCtp) levels indicating consistent PrEP adherence over the past 2 weeks. Comparing TFVdp and FTCtp levels will yield insights on adherence patterns over both a long and short window of time before collection. We will also analyze the alignment of adherence measures with HIV risk perception and behavior to better understand adherence patterns.

Analysis Approach

Descriptive and bivariate statistics will be used to compare participant characteristics in the intervention and control arms and those who completed the study versus those lost to follow-up. Outcomes will be modeled using an intent-to-treat approach with mixed effect logistic and linear regression models. Model predictors will include treatment assignments, randomization strata, and a random effect for ward (cluster) within stratum that is assumed to be independent and normally distributed with mean 0. If the cluster randomization does not adequately balance baseline characteristics across arms, we will conduct exploratory analyses controlling for those characteristics. We will analyze the data from each of the 2 time

points separately and the primary outcomes analyses will use a type I error rate of 0.025 at each time point.

Missing Data

In any situation with missing data, we will perform appropriate secondary analyses adjusting for variables that may be related to the missingness mechanism. If missing data rates are higher than anticipated (>10%), we will include covariates that are related to missingness in regression models. We will also perform sensitivity analyses to assess the potential impact of the missing data.

Data Analysis: Process Evaluation

Quantitative Data

Implementation inputs, processes, and outputs will be analyzed descriptively, and we will draw comparisons across intervention wards. Intervention effects on each mechanism of change will be modeled individually following the approach described for the cRCT. We will regress each mechanism on the exposure (intervention arm assignment), controlling for baseline levels of the mechanism. If the primary analyses show no effect of the intervention on PrEP or IPV outcomes, the results will inform our interpretation of whether the intervention failed to affect the intended mechanism or whether the change in mechanism did not lead to the hypothesized outcome. If the primary analyses suggest a positive intervention effect on PrEP or IPV outcomes, we will conduct causal mediation analysis [72,73]. Coverage, uptake, and exit survey data on perceived impact will also be evaluated as moderators of intervention effectiveness at the site level in exploratory analyses of mechanisms of change.

Qualitative Data

The coding process will involve a core group of about 2 to 5 analysts from IRDO and RTI who will develop one or more codebooks and establish qualitative coding procedures. Data will be coded using a qualitative software package, such as Dedoose (SocioCultural Research Consultants, LLC). A set of preliminary codes will be developed based on key themes or topics identified a priori and the findings highlighted in the debriefing reports for each of the 3 datasets (eg, adolescent girls and young women, male partners, and providers). Each group member will apply the initial set of thematic codes to a common transcript, discuss their coding experiences, and agree on expanding and modifying code names and definitions when necessary. We will continue with an iterative process of revising the codebooks as we continue to read and code the data. Once finalized, the codebooks will be used for a final recoding of all transcripts.

A preselected number of transcripts will be double-coded by 2 coders to establish intracoder and intercoder reliability. Following this process, the coding team will discuss discrepancies, which will ultimately be resolved through consensus. This process will continue until the intercoder reliability is at least 80%. Thereafter the remaining texts will primarily be coded by 1 analyst only, with one or more rounds of consistency checks and regular discussions among the coding team to ensure that coding remains standardized and reliable.

Comprehensive listings of all coded quotations for every code or code “family” will be generated in the qualitative analysis software. Coding memos will be used to summarize and explore the relationship between the constructs of the evaluation framework (eg, the relationship between implementation processes and hypothesized mechanisms of change, or between mechanisms of change and outcomes). Analysts will also review and analyze coded serial IDI content within each participant’s dataset to look specifically for patterns over time. The findings and interpretations of the data will be critically discussed until there is group consensus on the dominant themes and meanings contained in the data [74].

Integrated Synthesis of Quantitative and Qualitative Data

For each construct of the evaluation framework, findings from the qualitative and quantitative analyses will be integrated to build a more comprehensive picture of whether the target intervention inputs, processes, and outputs were achieved, whether these resulted in the hypothesized changes in mechanisms of action, whether these changes resulted in the intended outcomes, and how external contextual factors influenced implementation, thereby both evaluating the success of study implementation and testing the theory of change.

Study Monitoring

Protocol Oversight

The study team continuously reviews recruitment and follow-up data to ensure compliance with the protocol and ethical standards. The IRDO study coordinator regularly monitors protocol compliance at study sites. The IRDO internal research monitor conducts quarterly spot checks of 100% of informed consent forms and 10% of data files. Any issues are documented in quality control logs and reviewed with the study staff. Protocol deviations or violations are reported to the study leadership and institutional review board (IRB) within 5 business days.

Data and Safety Monitoring Board

The trial is monitored by a data and safety monitoring board (DSMB) composed of 4 members: a statistician, a medical physician, a researcher with content expertise in IPV, and a researcher with expertise in PrEP use among adolescent girls and young women. All DSMB members are independent from any professional or financial conflict of interest with the research project, study investigators, and study institutions. The DSMB established a charter that outlines their responsibilities and meets approximately semiannually to review data quality and integrity, protocol adherence, participant safety, study conduct, and progress. On the basis of their review, they make recommendations on study continuation and modifications.

Safety Monitoring

This study adheres to the World Health Organization Ethical and Safety Recommendations for Intervention Research on Violence Against Women [75]. All data collection staff receive training on IPV assessment, recognizing warning signs of immediate danger, discussing sensitive topics with participants, managing distressed participants, legal reporting requirements,

and referral protocols. We aim to ensure that all communication with participants protects against unintentional disclosure of PrEP use, study participation, or reported IPV and does not place participants at additional risk of harm. To increase confidentiality, the study is presented to the community and to the participants as a study on HIV prevention methods in young women, and the focus on IPV is not advertised.

The MoH clinics conduct clinical safety monitoring for PrEP according to Kenyan guidelines. This study focuses on monitoring for adverse events that could be associated with the intervention, including IPV, social harms, serious adverse events, and unanticipated problems. All instances of these events are recorded on case report forms and followed up until resolution or 30 days after the participant exits from the study. These adverse events are reviewed monthly by the protocol team and reported to the IRB and DSMB according to their established protocols.

All staff have been trained to respond to any reports on IPV and social harms using the World Health Organization's Listen, Inquire, Validate, Enhance Safety, and Support (LIVES) approach through referrals [76]. Staff follow up by phone or during subsequent visits to check on referral uptake and provide additional assistance if needed. Participants who report being in immediate danger or feeling unsafe returning home are offered an immediate escorted referral to vetted rescue or shelter services, and study staff follow up with the participant weekly until their situation is resolved or stabilized, or until 30 days after their exit from the study. If staff have concerns about the safety of a participant's enrollment, they alert the site PI or designee to make a final determination about eligibility.

Ethical Considerations

The trial is being carried out in accordance with International Council on Harmonization Good Clinical Practice and the United States Code of Federal Regulations applicable to clinical studies (45 CFR part 46).

Ethics Approval

The study protocol and associated documents have been reviewed and approved by the Maseno University Ethical Review Committee (MUERC; MSU/DRPI/MUERC/00991/21). The RTI International Committee for Human Subjects Research established a reliance on MUERC for the study under a signed IRB authorization agreement. No amendment to the protocol or informed consent forms is implemented without prior ethics committee approval. Protocol violations are reported in writing to MUERC in accordance with their policy.

Informed Consent Process

IRDO study staff obtain informed consent or assent from all participants taking part in the cRCT or IDIs. Study staff explain the study purpose and procedures, risks and benefits to the eligible participants, and compensation for their participation. They emphasize that their participation is voluntary and that there is no penalty if the individual decides not to participate. Participants aged ≥18 years provide written consent in English, Kiswahili, or Dholuo. The IRB has granted a waiver of parental consent for adolescent girls and young women participants who meet the criteria for "mature minors" outlined in MoH guidelines for Conducting Adolescent HIV Sexual and Reproductive Health Research in Kenya [77], and for male partners aged 15 to 17 years to take part in IDIs, because they constitute a minimal-risk research activity. All minor participants may choose to involve their parent in the consent process. For minor participants not meeting the above criteria, or who involve their parents, we obtain parental consent and child assent. The IRB has also granted a waiver of written consent for the brief and anonymous exit interviews focused on program acceptability.

Confidentiality

All study procedures occur in private settings. Each participant receives a unique study identification number, and personally identifiable information does not appear on study data. All electronic data and study records are stored on secure, password-protected devices and uploaded to a secure RTI project server. Access to the system is restricted to trained study staff. Hard-copy data, consent and contact information forms with personally identifiable information are kept in separate double-locked files at the site and not transmitted to RTI.

To minimize confidentiality risks during the follow-up visits, we use contact methods agreed to by the participants, including aliases for study staff. To protect confidentiality during group activities, participants are asked to follow ground rules and pledge not to disclose others' personal details outside the group. At each session's start and end, participants are reminded to respect confidentiality and that there is a risk that others may disclose what they say.

Participants' study information will not be released without their written permission, except as required by law or as necessary for review, monitoring, and auditing by the following:

1. Representatives of the US federal government, including the United States Office of Human Research Protections, the National Institutes of Health (NIH) and contractors of the NIH, and other local, United States, and international regulatory entities
2. Representatives of RTI
3. Study staff
4. Site IRBs

Criteria for Early Termination of Study Participation

Participants can withdraw from the study at any time for any reason. The PI, site PI, or designee may also withdraw participants for safety or noncompliance reasons, with the DSMB notified of such terminations. Efforts are made to complete a final evaluation for participants who withdraw. Staff document withdrawal reasons in study records. Participants who withdraw may rejoin and resume intervention or follow-up visits up to their original exit date, with PI and DSMB consultation.

Study Discontinuation

The study may be suspended or terminated at any time by the NIH, RTI, site IRBs, or other authorities due to funding issues or substantial concerns, such as DSMB recommendations. If this occurs, the PI will be notified in writing with the reasons, and will inform participants, the IRB, and the sponsor. The

study may resume if safety, protocol compliance, and data quality issues are resolved and approved by the relevant parties.

Dissemination and Use of Findings

Study findings will be disseminated to the study communities, the scientific community, and HIV service and advocacy organizations via peer review publications, professional meetings, research briefs, and stakeholder meetings. All media, presentations, and publications resulting from data collected during this study will be collaborative in nature but require approval from the study leadership. All publications will be submitted to PubMed Central, in accordance with NIH Public Access Policy.

Results

The study was funded in August 2021, and data collection started in September 2022. As of December 2024, enrollment has been completed in 16 of the 22 study wards, with 72.6% (1150/1584) participants enrolled. We anticipate that data collection will be completed in May 2026 and results will be available by mid-2027.

Discussion

Innovations and Future Application

This study offers 4 key innovations. First, it offers the opportunity to address the lack of evidence-based interventions that explicitly confront the role of IPV and relationship dynamics in supporting PrEP use among adolescent girls and young women. Current interventions have focused largely on instrumental adherence support (eg, pill-taking reminders and strategies), motivational interviewing, and peer support, with limited evidence of success [4,5,78-83]. If found effective, the Tu'Washindi intervention will be one of the first to successfully address critical partner-related barriers to uptake and adherence and to directly involve male partners to build their support for PrEP use among adolescent girls and young women. Second, our intervention approach is youth-designed and tailored to meet the specific needs of adolescent girls and young women, qualities that have been specifically called for in recent literature to address shortcomings in existing interventions [84,85]. The intervention components of male engagement and couples' education were added to the design in direct response to the formative research findings, and our participatory design methods resulted in high intervention acceptability and uptake among adolescent girls and young women and high ratings for relevance and perceived effectiveness. Third, our multilevel approach recognizes that IPV and relationship power create barriers to HIV prevention at the individual, partnership, and community levels. Tu'Washindi supports adolescent girls and young women to respond to experienced or anticipated IPV at each level by fostering self-efficacy, improving relationship communication, developing support systems, and encouraging action to maintain safety and HIV prevention adherence [86-88]. Fourth, we assess short- and long-term adherence with biomarker measurements of 2 active PrEP metabolites, TFVdp and FTCtp to gain a more thorough understanding of adolescent girls and young women adherence behavior. Although the field has focused on TFVdp levels to classify long-term (ie, previous 1-3 months) PrEP adherence [89], FTCtp concentrations can delineate between consistent (≥4 doses/week) versus inconsistent (<4 doses/week) PrEP adherence over 2 weeks before sample collection with ≥89% accuracy [90]. Thus, we will have the ability to classify adolescent girls and young women by short-term (2 weeks) adherence in addition to the long-term (2 months) adherence measured by TFVdp levels.

Our intervention and evaluation have been designed from the start to facilitate scalability, sustainability, and rapid adoption. Tu'Washindi was designed to be delivered by trained community members with support from clinicians and counselors, and to integrate into ongoing national or donor-funded youth-focused programs prioritizing HIV prevention. The proposed study uses a pragmatic, rather than exploratory, design to maximize generalizability and ensure results are applicable to real-world settings [44,91]. In addition, our design includes a rigorous process evaluation to document implementation process, quality and fidelity of delivery, resource requirements, and contextual factors to provide valuable guidance to program and policy stakeholders who wish to replicate or adapt the intervention outside of the research setting. In combination, the intervention design and process evaluation approach will reduce the "know-do gap" [92] and accelerate Tu'Washindi's translation from research to practice.

Limitations

Several limitations to this study should be noted. First, there is a risk of PrEP and HIV test kit shortages in MoH clinics, which could interfere with adherence and complicate interpretation of results. We will carefully document shortages as part of the program diary, and study staff will help link participants to other sources of PrEP provision if necessary. Second, cluster randomized studies carry a risk that individual participant characteristics may differ at baseline in important ways. Our design stratifies on 2 important community characteristics (ie, geographic type and baseline PrEP use) to reduce this risk, and our analysis plan incorporates exploratory analyses to control for baseline differences between randomization arms.

Conclusions

Tu'Washindi has demonstrated feasibility and acceptability in pilot research and shows promise to promote PrEP use and reduce IPV among adolescent girls and young women. The proposed study builds directly on our intervention development work to conduct a rigorous effectiveness trial, a critical step in developing the evidence base for this youth-designed, multilevel HIV prevention intervention. Our rigorous process evaluation will clarify mechanisms of change, and implementation considerations to inform policy and practice. If effective, Tu'Washindi will be ideally positioned for sustainable integration into existing youth-focused HIV prevention programming to expand and support PrEP uptake and adherence in this priority population.

Acknowledgments

Research reported in this publication was supported by the National Institute of Mental Health of the National Institutes of Health under award number R01MH125671. The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health. Abstract

Background: Parkinson disease (PD) has been described and studied extensively in White populations, with little known about how the disease manifests and progresses in patients from the Black community. Studies investigating disease features in Black populations are uncommon, with some suggesting that the Black population with PD is more disabled and has greater disease severity and different clinical features compared with the White population with PD. These health disparities are likely to influence the quality of care for Black patients with PD.

Objective: This study aimed to investigate the motor and nonmotor symptoms and quality of life in Black and White participants with PD in a case-case design.

Methods: This is an observational, prospective, multicenter, case-case design study. Other aims will investigate the management of PD in Black individuals and the presence of shared or unique genetic risk factors among the Black PD population. A total of 400 Black and 200 White participants with PD will be recruited. Data will be collected at 7 US sites and entered into a Research Electronic Data Capture database. Linear multivariate regression analysis will be used, except for comparing PD management, which will be analyzed using the chi-square test or Fisher exact test. Bonferroni correction will be applied. This protocol also describes plans for educational programming for clinicians and patients at the end of the study in partnership with national PD organizations.

Results: The Rush Institutional Review Board approved the project as the single-site institutional review board in February 2022, and it was funded by the National Institute of Neurological Disorders and Stroke in April 2022. Recruitment began in July 2022. At the time of submission of this manuscript, 131 participants had been recruited.

Conclusions: To our knowledge, this is the largest study of PD phenotype and management in Black patients in the United States. The planned collaboration with the Global Parkinson's Genetics Program and PD GENEration will enhance our understanding of genetic risk factors for PD in this understudied population.

Introduction

Background

Parkinson disease (PD) is a progressive and incurable neurodegenerative disorder affecting 1 million people in the United States [1]. Health care resource usage costs for patients with PD in the United States are high and rise 2 to 3-fold in individuals with advanced disease [2]. Our current understanding of PD is disproportionately based on studying populations of European ancestry, leading to a significant gap in our knowledge about the clinical characteristics, life experiences, functional outcomes, and pathophysiology in individuals of African descent. The cumulative incidence of PD in African Americans has been estimated at 23/100,000, compared with 54/100,000 in European Americans [3]. Direct comparison of Black and White patients suggests greater disability and disease severity in Black individuals [4], and our data suggest that quantitative measures may be more sensitive in detecting these differences [5]. Factors proposed to account for phenotypic differences include barriers to access to care and methodological confounds due to inconsistent diagnostic criteria or ascertainment bias [6-8]. It is also possible that population-specific genetic variation modifies PD risk and clinical manifestations of PD in Black individuals. Approximately 90 common susceptibility loci for PD and a growing number of rare gene variants are now well-established in White populations [9]. Still, the impact of these factors on the Black population is largely unknown.

In our pilot work, Black and White patients with PD participated in a clinical phenotyping study, and the results showed no significant differences between the groups in sex, education, disease duration, Hoehn and Yahr stage, or Movement Disorder Society-Unified PD Rating Scale (MDS-UPDRS) part III Motor scores [10]. However, quantitative NIH Toolbox performance measures detected differences in gait and balance between Black and White participants with PD: gait speed (0.8±0.3 vs 1.1±0.2, $P<.001$), pegboard (41.4±15.6 vs 33.2±10.9, $P=.04$, and standing balance (32.7±13.1 vs 47±12, $P<.01$) [5]. In the nonmotor assessments, the Montreal Cognitive Assessment (23.4±3.1 vs 27±2.1, $P<.005$) and Symbol Digits Modalities Test (39.4±14.1 vs 49.6±9.1, $P=.01$) scores were worse in Black participants after correcting for education level. Hamilton Depression scale scores were worse in Black participants with PD compared with White participants (7±5.6 vs 4±3.5, $P=.04$), but other neuropsychiatric scales were similar between groups. The PD Quality of Life (PDQ-39) scores were higher (worse) in Black participants with worse ratings in participation in social roles and activities.

In summary, this pilot data showed differences in the motor examination, nonmotor features, and quality of life of Black patients with PD that warranted the current larger study. In our previous work and this protocol, race is self-identified by the patient as Black or White. Traditionally in the Chicago metropolitan area, this includes Black patients who are African, Afro-Caribbean, African American, or who report a mixture of races.

Racial disparities in the clinical management of PD include inequitable access to care and disparities in therapeutic interventions. Previous studies show that Black individuals with parkinsonism are less likely to see a neurologist, have less access to telemedicine, and are less likely to receive treatment, including antiparkinsonian medication, surgical procedures, and rehabilitation therapy. Black patients are 30% less likely to see an outpatient neurologist for neurologic conditions [11], and both Black persons and those with lower socioeconomic status are less likely to receive specialized care for PD [4]. Compared with White persons with PD, Black patients with PD were 40% less likely to receive any rehabilitation therapy (physical therapy, occupational therapy, and speech therapy). Black persons with parkinsonism were less likely to be receiving any antiparkinsonian medication on their initial visit to a movement disorders center [12]. They were half as likely to receive newer antiparkinsonian medications but twice as likely to be on antipsychotic medication. African Americans were 4 times less likely to receive any treatment for PD (medication or physical therapy) in a cohort with the same health care insurance (Medicaid) [13], and White persons were nearly twice as likely to be prescribed medications for PD in a study of racial disparities in stroke (National Institute of Neurological Disorders and Stroke [NINDS] Reasons for Geographic and Racial Differences in Stroke study) [14]. African Americans were also found to be 5 to 8 times less likely to undergo deep brain stimulation surgery for PD than White patients [15,16]. Notably, racial disparities in access to care and clinical management are likely to be associated with adverse outcomes, including greater severity of Parkinsonian symptoms and greater disability [4].

Genetic susceptibility loci and genetic variants causing monogenic PD have been explored in populations of European, Latino, and Asian ancestry [17]. Based on preliminary work, it appears that the cumulative genetic risk for Black and African American patients with PD shows significantly different distributions compared with European populations when applying the genetic risk score composed of the 90 risk loci previously linked to European populations [17].

More recent work from the Global Parkinson's Genetics Program confirms this differential risk, identifying a novel genetic risk factor in *GBA1* in patients with PD of African ancestry [18]. This supports the need for additional work in this area.

Objective

The overall objectives of this study are to perform comprehensive phenotyping, compare Black and White persons with PD, and investigate causes of racial disparities, including differences in clinical management and responsible genetic risk factors. The study is partnering with the ongoing Global PD Genetics Program (GP2) [19], which contributes samples and granular phenotypic data from the enrolled participants to enhance our understanding of the genetic architecture of PD in

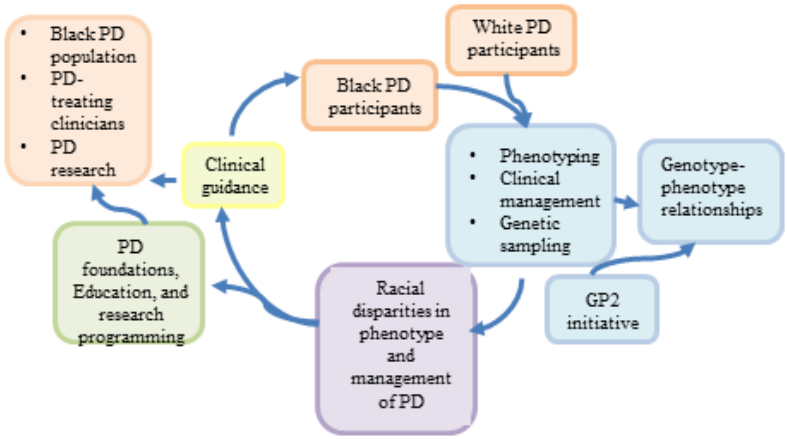
the Black population. The long-term goal of this application is to address the critical gap in knowledge of PD in this underserved population to improve diagnosis, optimize treatment, and plan for clinical trials. The central hypothesis is: PD is phenotypically and genetically different in Black versus White populations, and Black patients receive different and suboptimal clinical management. The research questions this study hopes to answer are as follows: (1) whether Black participants with PD have worse quantitative motor function and cognition, higher levels of depression and disability, and reduced quality of life compared with White participants with PD; (2) whether pharmacological, surgical, rehabilitation, mental health, and telehealth interventions differ by race with underuse of newer or more costly interventions in Black participants with PD; and (3) whether the contribution of genetic factors to PD risk and heterogeneity differs by race.

Methods

Overview

The overall strategy is to describe clinical phenotypes, genetic risk profiles, and treatment disparities in the American Black PD population and use the results to develop guidance for educating Black patients and their treating clinicians on how to prevent racial disparities in PD and foster future research opportunities in racial disparities and improve management (Figure 1). This is a multicenter, cross-sectional, case-case, nonrandomized, observational study.

Figure 1. Conceptual model. GP2: Global Parkinson's Genetic Program; PD: Parkinson disease.



Study Setting and Design

The 7 study sites are Rush University, University of Maryland, University of Cincinnati, University of Pennsylvania, University of Chicago, Emory University, and Morehouse University (Figure 2). The sites were chosen based on US census data showing higher populations of Black persons in these geographic regions. A total of 400 Black patients with PD and 200 White patients with PD will be recruited. Patients who consent to enroll will have a single study visit encompassing data and sample collection for all 3 aims. A virtual option can also be used to complete questionnaires, followed by an in-person visit for the remaining measures.

Figure 2. Overview of the organizational structure. GP2: Global Parkinson's Genetic Program; PD: Parkinson disease.

Eligibility Criteria

The eligibility criteria are intentionally broad to facilitate the inclusion of diverse samples and ensure the achievement of enrollment targets. Inclusion criteria include age >18 years and fulfilling the Movement Disorder Society Clinical Diagnostic Criteria for Parkinson's Disease [20]. Patients must self-identify as being Black or White race. Patients must also be able to sign an evaluation to sign consent [21] or have a legally authorized representative (LAR) sign on their behalf. Exclusion criteria include insufficient English to complete study activities or inability to meet idiopathic PD criteria. Eligibility criteria are broad to include representative samples and ensure meeting enrollment targets.

Recruitment and Screening Strategies

Recruitment will occur in the outpatient movement disorder clinics at the 7 study sites. Treatment clinicians or study coordinators will approach potential participants to discuss participation. Potential participants will be identified by prescreening medical records or by referral to the treating provider. Each White participant was initially matched to be within 5 years of age of the mean age of every 2 Black participants enrolled at the same site. Each time 2 Black

participants were enrolled at a site, the study statistician would contact the site with the age range of the next White participant. Part-way through the study, propensity matching replaced this manual process. Potential participants will be interviewed to determine if they meet the eligibility criteria for enrollment.

Black patients with PD have been underrepresented in clinical research [22]. Therefore, study planning includes targeted strategies to facilitate recruitment and foster participant satisfaction with research participation. An advisory board of 6 individuals comprised of Black individuals with PD and family members of affected individuals assists in developing outreach strategies and providing feedback on their study visit experience, with protocol modifications as needed. The patient advisory board members will have participated in the study at 1 of the study sites. Educational strategies include initiatives for both study participants and study staff. A brief video and flip charts with culturally appropriate information are used to improve understanding of participation in research, including the informed consent process [23]. Participation of Black study coordinators is encouraged to foster rapport and cultural sensitivity. Teaching cross-cultural sensitivity is part of the prestudy and annual activities for all site investigators and coordinators [24]. Barriers to recruitment and enrollment will be explored, with each enrolled participant completing a Participations in Clinical Trials Questionnaire that includes a question on barriers to research participation [25]. During quarterly Steering Committee meetings with all site investigators, recent publications on minority recruitment and research are reviewed with the study author.

Study Assessments and Outcome Measures

Study participants will have a single visit with the site investigator and coordinator after obtaining consent or a hybrid combination of in-person and virtual visits. Recommendations of the NINDS PD CDE Working Group informed the choice of measures, scales, and questionnaires. Data will be collected and entered into a REDCap (Research Electronic Data Capture) system that uses electronic data entry forms. General assessments include demographic data (age, sex, education, and income), medical history, and a confirmatory neurological examination. The remaining assessments fall into 3 categories, namely motor and nonmotor symptoms (Table 1), quality of life and social determinants of health (Table 2), and management of PD (Table 3, Multimedia Appendix 1).

Table 1. Motor and nonmotor measures for phenotyping.

Data type or domain and measure or instrument	Description
Parkinson disease severity	
MDS-UPDRS[a] parts I to IV[b]	Revised, improved version of the MDS-UPDRS for use in PD[c] studies [26]
Hoehn and Yahr stages	Common system for staging PD [27]
Physical function	
2-minute walk, 4-meter gait speed, 9-hole pegboard, grip strength, and balance test[b]	To quantitate physical performance relative to available age and gender norms [28]
Functional reach	A single-item assessment of balance [29]
Schwab and England Activities of Daily Living Scale	A single-item rating of independent function [30]
PROMIS Profile-29 Physical Function version 2.0 4a[b]	Measure of disability [31,32]
Cognitive function	
Montreal Cognitive Assessment version 8.3[b]	Detects mild cognitive impairment in PD [33,34]
Benton Judgment of Line Orientation 15-items	Measure of spatial perception and orientation [35,36]
Hopkins Verbal Learning Test	Test of verbal short-term memory requiring rapid encoding of information [37]
Digit span	Measure of verbal working memory [38]
Semantic fluency	Measures semantic fluency using animal categories [39]
Symbol Digit Modalities Test[b]	Screens for cognitive impairment [40]
Mental health	
PROMIS Profile-29 depression, anxiety	Measures depression and anxiety
Pain	
PROMIS Profile-29 Pain Interference version 1.1	Measures pain interference with daily life [41]
PROMIS Profile-29 Pain Intensity version 1.0	Measures severity of pain
Sleep	
Epworth Sleepiness Scale	Measures daytime sleepiness in adults [42]
PROMIS Profile-29 version 1.0 Sleep Disturbance 4a, PROMIS Profile-29 version 1.0 Fatigue 4a	Measures sleep disturbance and fatigue [43,44]
Autonomic	
Scales for Outcomes-PD Autonomic[b]	Measures autonomic function [45]

[a]MDS-UPDRS: Movement Disorder Society Unified Parkinson's Disease Rating Scale.

[b]Minimum dataset.

[c]PD: Parkinson disease.

Table 2. Quality of life and patient health expectations measures.

Data type or domain and measure or instrument	Description
Health-related quality of life	
The Parkinson's Disease Questionnaire-8[a]	PD[b]-specific quality of life scale [46]
Patient health expectations	
Expectations Regarding Movement Scale	Expectations regarding movement with aging [6]
Participation in medical research	
Trust in Medical Researchers Scale	Likelihood of participation in medical research [47]
Social determinants	
PROMIS Informational Support version 2.0 4a	Measures access to information and resources [48]
Health Stressors Rush Survey	Covers food security, utilities, insurance, transportation, and housing instability
PROMIS Profile-29 Ability to Participate in Social Roles and Activities version 2.0 4a	Measures satisfaction with social roles and activities [48]

[a]Minimum dataset.

[b]PD: Parkinson disease.

Table 3. Study assessments for management of Parkinson disease.

Data type or domain and measure or instrument	Description
Pharmacological management	
Parkinson's Disease Medications Questionnaire[a]	Antiparkinsonian drugs[a]
Prescribed Non-Parkinson's Medications Questionnaire[a]	Non-Parkinson drugs
Unprescribed Drugs Questionnaire	Vitamins, dietary supplements, alternative therapies, recreational drugs, drugs of abuse
Surgical management	
Surgical Questionnaire[a]	DBS[b], FUS[c]
Rehabilitation therapy	
Rehabilitation Referral Questionnaire[a]	Physical, occupational, speech therapy
Godin Leisure-Time Exercise Questionnaire, Activity Questionnaire	Exercise and activity [49]
Mental health and social services	
Mental Health and Social Services Referral Questionnaires[a]	Psychiatrist, psychologist, social worker
Telehealth use and acceptance	
Telehealth Use and Acceptance Questionnaire[a]	Perceived usefulness and ease of use [50]
Participation in clinical trials	
Participation in Clinical Trials Questionnaire	Clinical trial participation and barriers to participation
History of treating clinicians for PD	
History of treating clinicians for Parkinson's disease[a]	Number and types of clinicians, medical visit frequency
Medical comorbidities	
Cumulative Illness Rating Scale-Geriatrics (CIRS-G)[a]	Medical comorbidities [51]
Self-efficacy	
PROMIS Self-Efficacy for Management of Chronic Conditions	Self-efficacy for managing daily activities, symptoms, medications, and emotions [52]
Health literacy	
Rapid Estimate of Adult Literacy in Medicine	Health literacy [53]
eHealth Literacy Scale	eHealth literacy [54]

[a]Minimum dataset.

[b]DBS: deep brain stimulation.

[c]FUS: focused ultrasound.

Participants who used a LAR for consent can complete assessments with assistance from a research assistant or proxy (care partner). All scales and questionnaires include a check box to document proxy assistance. The scales are administered by the neurologist (site investigator), study coordinator, or other staff as appropriate. The investigator completes the following assessments: MDS-UPDRS [26], Hoehn and Yahr Staging [27], Schwab and England Activities of Daily Living Scale [55], and the Cumulative Illness Rating Scale [51]. The investigator will also complete a questionnaire for the GP2 study that includes demographic and disease-specific information, such as disease duration. The study coordinator administers the rest of the study assessments.

Participants have blood samples drawn and sent to the National Institutes of Health for genetic studies. All participants are also offered enrollment into the Parkinson's Foundation PD GENEration study in which seven PD genes are examined and results are disclosed to the participant. If the participant consents, an additional blood sample is shipped to the PD GENEration sequencing vendor (Fulgent Genetics). For these participants, genetic counseling, including results disclosure, is performed by either a PD GENEration genetic counselor from Indiana University or the genetic counselor at the Rush University site (either live or through telemedicine).

To optimize recruitment, all Black patients with PD are eligible for enrollment regardless of physical or cognitive impairment level. Therefore, not all patients can complete all study assessments. A minimum dataset, including the primary outcome measures, must be completed, as well as the sample collected for all study participants. The recommended order of study assessments prioritizes outcome measures such that primary outcome measures are completed first, cognitive measures are

completed early, and the minimum dataset for all study aims is collected. When a participant cannot complete all study assessments, the site investigator must be contacted. The investigator and coordinator should arrive at a consensus about what assessments will be omitted, and coordinators should record the omitted assessments. The patient can only complete selected study assessments (no proxy assistance permitted), including the cognitive assessments and the "Rapid Estimate of Adult Literacy in Medicine" [25].

Outcome Measures

The primary outcome measures to characterize PD phenotypes include the NIH Toolbox Motor assessments (2-minute walk, 4-meter walk, balance test, pegboard test, and grip strength) [28]; the Montreal Cognitive Assessment (MoCA), Symbol Digit Modalities Test (SDMT), PROMIS Profile-29 Physical Function, Parkinson's Disease Questionnaire-8 (PDQ-8), and the MDS-UPDRS. The primary outcome measures to assess PD clinical management include the proportion of participants with antiparkinsonian medications prescribed at the initial visit to the neurologist, the proportion of participants with initial treatment of depression, and the proportion of participants with PD surgical interventions. To characterize genetic risk variants in our sample, the frequencies of the 90 established common PD genetic risk variants based on published genome-wide association studies in a predominantly White population will initially be examined. The study team will also aggregate and summarize sequencing results from PD GENEration, including potential rare variants among 7 established PD genes. The proportion of LRRK2- and GBA-PD will be summarized based on either PD GENEration, which permits comprehensive detection of potential pathogenic alleles, or GP2 genotyping, which can detect many of the most common, recurrent pathogenic variants. Finally, exploratory genotype–phenotype analyses will determine whether established PD risk variants modify clinical manifestations in Black individuals.

Sample Size

The sample size was calculated for each primary outcome measure described above with 80% power and a 2-sided test to detect a similar effect size observed from our pilot data (Table 4). Bonferroni correction was applied to control the overall significance level at .05. The minimal sample size for these analyses requires 365 Black and 183 White participants to complete this aim. The data observed in 3 studies guided the sample size calculation for PD clinical management (White vs non-White or Black: 78% vs 62% for measure 1 [4], 92% vs 80% for measure 2 [56], and 10% vs 0.4% for measure 3 [57]). The sample size was calculated using 90% power and a 2-sided test for each primary measure. Bonferroni correction was applied to control the overall significance level at .05. With a 1:2 ratio, the largest sample size required among all 3 measures is 173 White patients with PD and 346 Black patients with PD. For the genetic studies, our sample size will permit exploratory analyses, and all data will be contributed to GP2 for fully-powered meta-analysis.

Table 4. Pilot data effect sizes for sample size calculation.

Primary measures	White patients with PD[a] (n=25), mean (SD)	Black patients with PD (n=25), mean (SD)
4-meter walk computed score	1.1 (0.2)	0.8 (0.3)
Balance *t* test score	47 (12)	32.7 (13.1)
Pegboard dominant score	33.2 (10.9)	41.4 (15.6)
MoCA[b]	27 (2)	23.3 (3.1)
SDMT[c]	49.6 (9.1)	39.4 (14.1)
PDQ-39[d]	12.8 (7.9)	22.5 (12.3)

[a]PD: Parkinson disease.

[b]MoCA: Montreal Cognitive Assessment.

[c]SDMT: Symbol Digit Modalities Test.

[d]PDQ-39: Parkinson's Disease Questionnaire.

Data Collection and Monitoring

The co-principal investigators (DH and LS), core administrative, and coordinating personnel meet weekly to identify potential issues with consent or assessment procedures, manage any reported adverse events, and monitor the sites' progress. The REDCap database created to house the data is audited weekly to ensure fidelity. All study data are directly entered into the REDCap database in real time unless internet connectivity is an issue at the site.

Statistical Analysis

Each primary outcome measure will be compared between Black and White patients with PD. Bonferroni correction will be applied. The primary outcome measures are a 4-meter walk computed score, Balance test *t* score, Pegboard dominant *t* score, MDS-UPDRS motor score [26], MoCA [33], SDMT [58], PROMIS Profile-29 Physical Function, and PDQ-8 [46]. For significant measures, linear regression analysis will be performed to examine further the difference between the 2 groups with adjustment for age, sex, and disease duration. The interaction effects of race with these 3 variables will be explored. Regression analysis for cognitive measures will adjust for depression and anxiety scales in addition to these demographics. Regression will also be adjusted for comorbidities using the Cumulative Illness Rating Scale-Geriatrics score. The study site effect will be controlled as a random effect in the model. All analyses will be done using SAS (version 9.4).

For the PD management analysis, each primary outcome measure will be compared between Black PD and White PD groups using the chi-square test or Fisher exact test. Bonferroni correction will be applied. A hierarchical logistic regression analysis will assess the determinants of racial disparities in management. Besides race, age, sex, and education, income, symptom severity, and comorbidities will be included in the model. The interaction effect of race with those variables will be explored. The study site effect will be controlled as a random effect in the model. Secondary analyses will investigate differences between White PD and Black PD groups in other clinical management measures, including telehealth, participation in clinical trials, and rehabilitation therapy.

Genetic Analysis

This study will leverage a quality control and analysis pipeline established for the GP2 program. After standard quality control of raw genotyped data, data will be imputed to the most recent build of the multiethnic 1000 genomes reference panel using the default settings of miniMac2. This will yield ~15 million variants to test after additional quality control. These data will be contributed to GP2 for genome-wide association meta-analysis and admixture mapping. Within the RaDPD sample, ~90 currently established common PD risk variants to examine frequencies will be extracted. For analyses of PD genetic modifiers, linear regression—with an initial focus on outcome phenotypes with established evidence from the published literature, including age of onset, motor progression, and cognition—will be performed [59-65]. These outcomes will be supplemented with the most promising outcomes based on the results from aim 1 analyses identifying clinical features that differentiate PD in Black versus White patients. Sequencing results will be available for participants in PD GENEneration for 7 genes associated with PD: *GBA*, *LRRK2*, *PRKN*, *SNCA*, *PINK1*,*PARK7*, and *VPS35*. Comprehensive genome sequencing of all samples is planned for a future project.

Ethical Considerations

This study was approved by the Rush Institutional Review Board (IRB; ORA 20121005), which serves as the single-site IRB for this study. Each participant will sign a consent form, which includes blood and genetic analysis, before participation. Each participant also signs permission for the DNA results from sequencing to be housed in the PDGeneration database and the National Institutes of Health (deidentified) through GP2. If the participant requests genetic results, they are identifiable to PDGeneration, facilitating the return of results. Potentially vulnerable study populations are patients with cognitive impairment and socioeconomic disadvantages. Given the study aims to investigate racial disparities in the phenotype–genotype differences between Black and White patients with PD, it is necessary to include these populations. Study participants must be able to provide informed consent as determined by the Evaluation to Sign Consent to confirm they understand the risks and benefits and can provide their informed consent. This low-risk study does not present a greater risk to potentially vulnerable populations. Given the short duration of this study (1 study visit), it is not expected that significant cognitive decline will occur throughout the study to impact a participant's ability to provide ongoing consent. Participants unable to achieve a passing score on the Evaluation to Sign Consent will be excluded unless a LAR is present to provide consent.

A human subjects research ethics review will occur at the time of IRB approval. The informed consent process occurs with the study team live during the study visit. Data are entered directly into a password-protected, Health Insurance Portability and Accountability Act–compliant REDCaP database, with the participant having an assigned site-specific study ID. Participants are compensated US $100 for the study visit plus US $25 for travel expenses, and some sites arrange transportation with established institutional programs.

Results

The Rush IRB approved the project as the single-site IRB in February 2022 and funded by NINDS in April 2022. Recruitment began in July 2022. At the time of submission of this manuscript, 131 participants had been enrolled. One of the original study sites has been replaced by a new site due to issues with regulatory approval. Other activities have included quarterly steering committee and monthly coordinator meetings. Steering committee meetings include discussing recent publications and speakers focused on racial disparities.

Discussion

Study Rationale

The study rationale is that the knowledge gained will improve clinical diagnosis and management for Black persons with PD, drive programming to improve access to care and management, and inform research strategies in PD in the Black community. It is anticipated that the main findings of this study will be that Black patients with PD will have more gait abnormalities and higher rates of genetic variants for PD specifically seen in the Black population. It is also anticipated that Black individuals with PD will be less likely to have been referred or have access to specialized care for PD, including surgical treatments and nonmedication therapies. This protocol was structured as a one-time visit to encourage participation and to optimize the likelihood of full data collection. Aim 3 is a collaborative effort with the Global Parkinson's Genetics Program (GP2), a worldwide consortium funded by the Aligning Science Across Parkinson's initiative to understand the genetic architecture of PD. This collaboration enables samples collected in this study to be part of a larger gene discovery effort with investigators from African and Afro-Caribbean patients with PD to foster a greater understanding of genetic variation specific to the Black population [17]. This study fills a unique niche by performing deep phenotyping to study racial disparities and analyze genotype–phenotype relationships in PD.

The recruitment of Black patients into research studies is historically much lower than White patients [22]. Contributory factors include distrust owing to historical research abuse and institutional racism, lack of information and understanding of research studies and informed consent, insufficient recruitment efforts by researchers, social stigma, and financial considerations [66]. In 1993, the National Institutes of Health established the

Revitalization Act, which mandated minority inclusion in randomized clinical trials. An important strategy to promote study recruitment in both Black and White patients with PD is raising awareness of previous studies showing evidence of racial disparities in access to care, disease features, and clinical management.

A potential barrier to participation in PD research is motor and cognitive impairments, present in patients with PD of all racial and ethnic backgrounds. To accommodate the needs of patients with more severe motor and cognitive impairment, the protocol was designed to allow for the collection of a "minimum dataset." The goal is to complete as many study assessments as possible. However, implementing more limited data collection will enable the successful completion of enrollment targets and ensure the inclusion of a representative range of disease severity. The typical time of the study visit is between 3 to 6 hours, and more limited data collection, focused on the primary outcome measures for each of the study aims, reduces the visit time to 1 to 2 hours.

Conclusions

Many unique challenges arise in clinical research in the Black PD community, but the importance of understanding racial disparities warrants focus on this population. Given what little is known about how PD manifests in Black patients, this will be the most comprehensive study of the phenotype and management of PD in the US Black population, with the potential to improve clinical diagnosis and management and to foster future research directions. It is not clear what the true implications of the study will be, but improvement of study recruitment in this population, education of patients, caregivers, and clinicians on disparities, and ultimately, changes in practice will drive the final impact of the study and drive health policy recommendations at a national level.

Acknowledgments

The authors thank all the patients and caregivers participating in the RaDPD study and colleagues at the collaborating sites for recruitment. This research is supported by the National Institutes of Health/National Institute of Neurological Disorders and Stroke R01 NS125294. The authors would like to acknowledge RaDPD study group members: DH, Bichun Ouyang PhD, MHST, Sharlet Anderson PhD, David Gonzalez PhD, Jacob Hawkins MS, Staci Davis BS (Rush University); LS, Rebecca Weimer BS, Christina Griffin MS (University of Maryland); Alberto Espay MD, Emily J Hill MD, Kelly DeLano MS, Lauren Wingler BS, Ayesha Shaik (University of Cincinnati); Nabila Dahodwala MD, Whitley Aamodt MD MPH MSCE, Amanda Cruz BS, Ritikha Vengadesh BE (University of Pennsylvania); Stewart Factor DO, Elaine Sperin LPN (Emory University); Tao Xie MD PhD, Tomas Mercado BS, Crystal Mercardo BS (University of Chicago), Chantale Branson MD, Tamiko Durham MS (Morehouse University); Josh Shulman MD PhD (Baylor University); SBC, and AS (National Institutes of Health).

Data Availability

The datasets generated and analyzed during this study will be available upon reasonable request. These will be distributed to individual investigators on approval of the principal investigators (distribution costs covered by the requesting investigator). The study teams will use common data elements and a REDCap system to maximize the ability to share these data. Other products of the blood samples (serum, etc) may be shared if there are remaining samples. Research results will be disseminated publicly through publication in scientific journals and in the context of scientific meetings at which project findings will be reported. Such data publication will occur during the term of the project or after its conclusion, as appropriate and in keeping with normal scientific practices for reporting results.

Authors' Contributions

DH and LS conceived the program and wrote the protocol with JH's help. JS, SBC, AS, and RaDPD study group members provided ongoing critical review. BO aided in sample size calculation and analyses. DH and MHST drafted the manuscript, and all authors reviewed and approved the final version.

Abstract

Background: Access to methadone treatment can reduce opioid overdose death by up to 60%, but US patient outcomes are suboptimal. Federally allowed methadone treatment accommodations during the COVID-19 public health emergency were not widely adopted. It is likely that staff-level characteristics such as trauma symptoms influence the adoption of treatment innovation.

Objective: Methadone Patient Access to Collaborative Treatment (MPACT) is a 2-phased project (pilot and field trial) to develop and test a staff-level, multimodal intervention to increase staff adoption of low-barrier, patient-centered methadone treatment practices and ultimately improve treatment retention and patient outcomes.

Methods: A pilot and national trial will measure implementation feasibility, acceptability, and effects of the MPACT intervention on treatment practice change, clinic culture, patient retention, and patient posttraumatic stress symptoms (PTSS). The pilot will be a single-arm 5.5-month pilot study of MPACT conducted in 2 Arizona methadone treatment clinics (rural and urban) among 100 patients and 22 staff. The national trial will be a 20-month cluster randomized trial conducted among 30 clinics, 600 patients (20 per clinic), and 480 staff (18 per clinic). Data will be gathered by staff and patient surveys and patient chart review. The primary study outcome is increased patient methadone treatment retention measured as (1) time to first treatment interruption from study enrollment; (2) active in treatment at enrollment, day 30, 60, 90, and 120; and (3) continuous days in treatment during

the study period. Secondary study outcomes include reductions in vicarious trauma and PTSS among enrolled opioid treatment program staff and PTSS among enrolled patients.

Results: The pilot study was funded by the National Institute on Drug Abuse (award R61DA059889, funded September 2023), and the field trial will be funded under the associated R33 mechanism in September 2025. The pilot study was completed in March 2025. The randomized controlled trial will begin in December 2025. Both the pilot and trial have been approved by the University of Arizona Human Subjects Protection Program and have been registered with the clinical trials network.

Conclusions: The MPACT study will provide a foundation for an evidence-based, staff-level intervention aimed at improving patient retention in methadone treatment. Future studies should examine the individual components of MPACT to determine their differential contributions to the primary outcome of patient methadone treatment retention and to secondary outcomes of staff and patient reduction in stress symptoms.

Introduction

Background

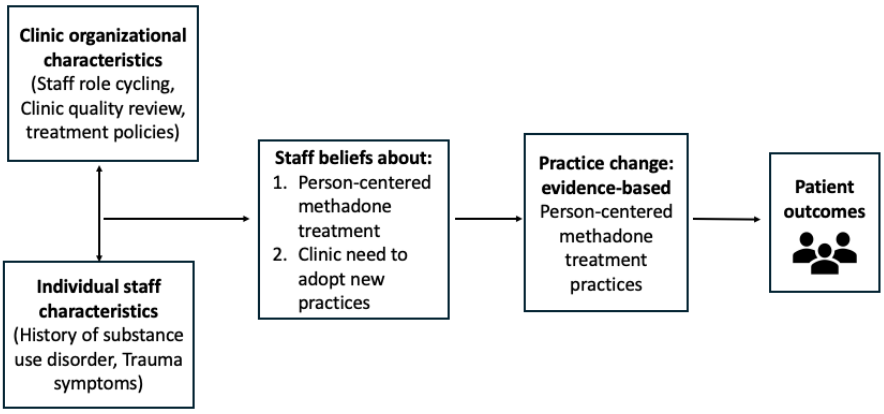
Methadone is one of the most essential tools available to reduce opioid overdose deaths because it is safe, effective, and patient-preferred for the treatment of opioid use disorder (OUD) [1-3]. Access to methadone, one of 2 safe and effective OUD treatments, can reduce overdose mortality by up to 60% [4,5]. However, the promise of methadone is significantly diminished by geographic maldistribution of clinics and variations in the delivery of methadone maintenance treatment (MMT) across the country [6-8]. Treatment variations likely produce the observed wide-ranging MMT retention rates (30%-84%) [9,10].

MMT in the United States is delivered only by opioid treatment programs (OTPs; "methadone clinics") certified and accredited by the federal government [11]. Variation in treatment quality and access maldistribution means that the impact of poor MMT outcomes is felt most acutely in rural communities as well as among populations who are Black, Hispanic, or Indigenous [12]. Unlike other health care environments, OTPs serve a daily average of more than 100 people in a narrow time window [13] and have been described as feeling "like bus stations" [14] rather than medical clinics. OTPs have been criticized as being unresponsive to patient need for treatment flexibility [15] and are not equipped to address what we know to be higher rates of patient trauma exposure and posttraumatic stress symptoms (PTSS) compared to the general population [16,17]. While MMT outcomes can be impeded by patient trauma [18], it is also possible that poor MMT outcomes and patient trauma are exacerbated by OTP practice and culture [19,20]. Patients report disenfranchisement from treatment decision-making through language referring to dosing as "privileges," staff behavior described as "carceral" [21], and being tied to the OTP by "liquid handcuffs" due to daily required in-clinic supervised dosing [22].

Policy and systems evolution is occurring to improve the way MMT is delivered in the United States. Unprecedented US regulatory change during the COVID-19 public health emergency [23] and again in February 2024 [11] permitted and then further clarified methadone dosing and delivery flexibility so that treatment was more individualized and patient-centered. However, as has been observed, policy changes during the COVID-19 public health emergency were insufficient to ensure sustained changes [24-26]. This is likely the result of multiple factors hindering the implementation of MMT innovation. Implementation science suggests that in addition to the outer setting factor of federal policy, there are inner setting factors that likely influence the adoption of MMT treatment innovation [27]. These include clinic organizational characteristics and culture as well as staff characteristics and staff beliefs. Figure 1 displays our current thinking about hypothesized relationships between and among inner setting factors, adoption of innovation, and patient outcomes.

Staff trauma is one particular inner setting factor that is linked to the adoption of innovation and quality of treatment delivery. A preliminary study by several authors here suggests that OTP staff trauma may play a central role in shaping clinic culture and methadone treatment practice changes [14]. Evidence from studies among other types of health professionals demonstrates that vicarious trauma (VT), or work-related trauma (ie, coexperiencing patient distress and change in worldviews because of ongoing distress), is associated with reduced staff empathy and increased PTSS [28]. VT outcomes include burnout, reduced patient empathy and compassion satisfaction, low morale, impaired clinical decision-making, and compromised patient care [29-31]. The only extant study of OTP staff trauma histories and symptoms found that 63% of staff exhibited PTSS at clinical levels, indicating a need for treatment [32]. Therefore, a potential strategy to facilitate the adoption of MMT innovation is to implement staff-level interventions aimed at reducing PTSS and VT while providing training about low-barrier, patient-centered methadone treatment.

Figure 1. Potential inner setting factors impacting methadone treatment outcomes.



To this end, we developed Methadone Patient Access to Collaborative Treatment (MPACT): a multimodal intervention to increase staff awareness of and readiness to adopt MMT treatment innovation. MPACT promotes treatment flexibilities allowed by federal regulators and patient-centered, trauma-informed MMT and seeks to empower OTP staff and clinic groups to adopt these treatment flexibilities by addressing staff VT and PTSS, which will improve treatment quality and ultimately MMT retention. The objective of this study is to test the adoption, feasibility, and impact of MPACT on methadone treatment delivery and patient outcomes. There are 6 specific aims for the MPACT study over the 6-year project period. The specific aims are listed here and will be described in the following subsections.

Phase 1, Years 1-2: MPACT Intervention Development and Pilot Testing

Phase 1 aims (1) to develop MPACT through multilevel, iterative planning with methadone clinic staff and people with recent methadone treatment experience; (2) to determine MPACT implementation feasibility, acceptability, and preliminary effect on methadone treatment practice change and clinic culture; and (3) to determine the preliminary effect of MPACT on methadone treatment retention and patient PTSS.

Phase 2, Years 3-6: Hybrid, Cluster Randomized Controlled Trial

Phase 2 aims (4) to quantify the effects of MPACT on methadone treatment practice change and clinic culture, (5) to determine the efficacy of MPACT on methadone treatment retention and patient and staff PTSS outcomes, and (6) to evaluate the effect of patient and staff trauma on primary outcomes and staff MPACT implementation.

Methods

Ethical Considerations

The MPACT study protocol and related documents were reviewed and approved by the University of Arizona Human Subjects Protection Program (pilot: #STUDY00003631 and trial: #STUDY00005677), the single institutional review board overseeing all sites participating in the study: University of Arizona, Indiana University, Western Michigan University, and Columbia University. All participants will engage in a web-based informed consent process prior to study enrollment. The consent will be downloaded and retained by the study as documentation. Patient participants will consent to both survey participation and the release of specified elements of their clinic medical record for the purpose of the study. Confidentiality of staff and patient participants in the enrolled MPACT clinics will be preserved by making every effort to prevent the clinic leadership and staff from knowing which patients are enrolled as study participants and keeping clinic leadership and patients from knowing which staff are enrolled as study participants. Unique identifiers will be created at the time of enrollment and used throughout the study period. All study personnel (staff and investigators) have been trained in human participant protection through the completion of Social Behavioral Research and Biomedical Research modules with the Collaborative Institutional Training Initiative program and the completion of conflict of interest training and have annually declared conflicts of interest for review by the University of Arizona Human Subjects Protection Program. All reported data will be aggregated and deidentified. All information will be stored in a secure and encrypted drive and accessible only by the principal investigator (BEM) and the study coordinator (SY). The study was registered under ClinicalTrials.gov (NCT06513728 for the phase 1 pilot and NCT06556602 for the phase 2 trial). Participants will be offered financial remuneration totaling US $100 for the completion of all 5 surveys on time and during the pilot study period and US $160 for the completion of surveys on time and during the trial study period.

Phase 1, Years 1-2: MPACT Intervention Development and Pilot Testing

Overview

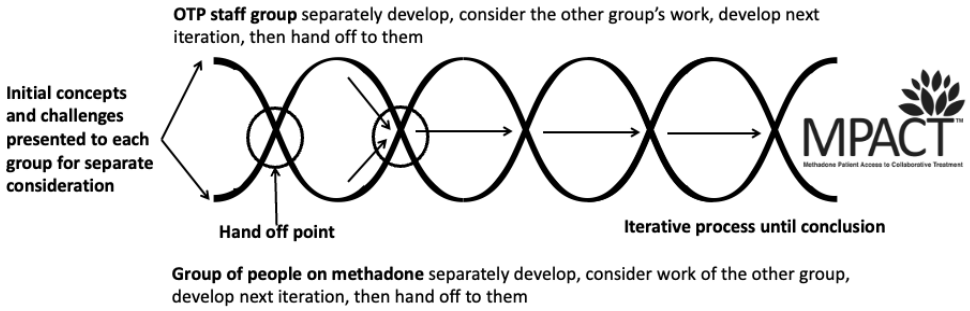
- Aim 1: Develop MPACT through multilevel, iterative planning with methadone clinic staff and people with recent methadone treatment experience.

MPACT is an experimental intervention comprised of 4 evidence-based components adapted by a group of people who have been in methadone treatment within the past 5 years in Arizona, a group of OTP staff in all clinic roles (front desk, peer support staff, case management, counseling, clinical supervision, medical, and administrative) from 3 Arizona OTPs (2 urban and 1 rural), and a group of subject matter experts focused on clinical supervision, human resources, and employee education.

The adaptation of MPACT components was accomplished through an iterative codevelopment process involving OTP staff and methadone community (patient) groups. The creation of a trauma-informed codevelopment space was crucial to facilitate safer and more open discussions. To accomplish this, we established a parallel, intervention refinement process using a helical structure developed by this team and based on our prior research with structural indicators for community-based participatory action research [33]. As shown in Figure 2, the "hand off" of work drives an iterative (helical) thinking process. This structure provides distinct spaces for thoughtful dialogue within and between each group.

The outcome of the codevelopment process was a robust multimodal intervention (MPACT) comprised of the following 4 elements.

Figure 2. Trauma-informed, collaborative development structure to refine MPACT components. MPACT: Methadone Patient Access to Collaborative Treatment; OTP: opioid treatment program.



Accredited Psychoeducational Training

A jointly accredited, self-paced, 3-module psychoeducational training focused on (1) the definition and application of low-barrier, patient-centered, trauma-informed methadone treatment; (2) public and clinic policy (federal and state); and (3) clinic staff opportunities to increase patient-centered, trauma-informed methadone treatment. The training seeks to empower staff to initiate any positive change at the individual and staff group levels. Joint accreditation offers continuing medical education for physicians and nurses as well as continuing education credits for social workers, psychologists, peer support specialists, case managers, and administrators. Training completion is incentivized by the award of 3 free continuing education credits according to professional discipline. While training is voluntary, to receive the continuing education credits, staff of MPACT-enrolled clinics must complete the training within 2 weeks of the MPACT launch within the clinic. New staff can complete the training as they are hired during the MPACT intervention period. This modular training approach was adapted from a prior successful project focused on increasing pharmacy syringe sales to people who use drugs [34].

Staff Wellness Education and Assessment

All staff in MPACT-enrolled clinics will receive training about trauma exposure and reactions, trauma-informed methadone treatment, availability and modalities of trauma treatment, and VT through curated presentation materials. These materials will be accessible to all staff through an MPACT web portal and through training or communications as determined by the enrolled clinics. The training materials include video and visual content designed for easy integration into clinic employee training, onboarding, or as refresher training. As part of the training, staff will be introduced to an anonymous web-based "wellness" screener, which includes an 8-item posttraumatic stress disorder symptoms screener (Posttraumatic Stress Disorder Checklist [PCL-5]) [35,36] and an 8-item Vicarious Trauma Scale [37]. Individual screening outcomes (results) trigger a curated and immediately presented message regarding self-care, referral to the VA PTSD Coach [38,39] (a downloadable, free application) and referral to the employee assistance program offered as a behavioral health benefit to employees where indicated. Employees will have access to wellness training throughout the MPACT intervention period and can use the self-screener repeatedly if desired. The screener will also be "advertised" in staff-only areas with a curated poster on stress, including a link or QR for easy access.

Trauma-Informed Clinic Self-Assessment

A trauma-informed clinic self-assessment (TICA) will be conducted quarterly during the study period. TICA assessment outcomes are generated by data from aggregated responses to a 16-item anonymous survey of staff measuring staff development, available resources, support, safe physical environments, trauma-informed policies, and patient-centered practices specific to methadone clinics. Items were selected and modified by the study team using an organizational trauma-informed practice tool as a reference instrument [40]. Summarized results are discussed with clinic leadership who will decide how and when to share them with clinic staff.

Reflective Supervision Consultation

Reflective supervision is an evidence-based professional development intervention focusing on the relationship and process of collaborative case consultation and reflection for clinicians providing psychosocial support [41,42]. Reflective supervision provides strategic guidance to increase self-reflectiveness and self-awareness and encourages participants to independently process clinical encounters and solve challenges. These skills have been shown to improve patient care [43,44]. To our knowledge, there are no existing reflective supervision consultation models tailored to OTP staff. Therefore, we adapted the standard reflective supervision practices to apply and be accessible to all OTP staff who have intensive and consultative interactions with patients. These staff roles include case managers, counselors, and peer support. Reflective supervision will begin in month 1 of the intervention period and will continue on a biweekly basis throughout the

intervention period for each MPACT-enrolled clinic. Sessions are facilitated by a trained reflective supervisor who will also be trained by the MPACT study clinician.

- Aim 2: Determine MPACT implementation feasibility, acceptability, and preliminary effect on methadone treatment practice change and clinic culture.
- Aim 3: Determine the preliminary effect of MPACT on methadone treatment retention and patient PTSS.

A single-arm 5.5-month pilot study of MPACT will address aims 2 and 3 and involves 2 Arizona-based OTPs (1 rural and 1 urban), 100 patients, and 22 staff (25 patients and 6 staff of the rural clinic and 75 patients and 16 staff of the urban clinic). Data collection will be accomplished through a web-based survey of staff and patient participants monthly during the pilot study period, which began in October 2024 and ended in March 2025. The 4 elements of MPACT intervention were delivered during the 4-month period following study recruitment. Eligibility criteria for study inclusion included being 18 years of age or older, being a staff member or a patient at 1 of the 2 pilot clinics, being willing to participate in monthly surveys during the pilot study period, and (for patients) agreeing to share selected components of their medical charts with the study team.

Measures

The primary study outcome is increased patient methadone treatment retention. This outcome is measured in three ways: (1) time to first treatment interruption, calculated as the number of days to first missed dose from day 0 (MPACT enrollment); (2) evidence of being active in treatment, a binary (yes or no) if receiving dose at points in time on day 0, 30, 60, 90, and 120; and (3) continuous days in treatment during the study period, calculated as time (days) to discharge. Data measuring this outcome are gathered by patient surveys and chart reviews.

Secondary study outcomes include reductions in VT and PTSS among enrolled clinic staff and PTSS among enrolled patients. Data measuring secondary outcomes are gathered by a survey of staff and patients enrolled in the study. For staff and patients, PTSS are measured using the 8-item posttraumatic stress disorder symptoms screener otherwise known as the PCL-5 [35]. Staff VT is measured by the Vicarious Trauma Scale [37], burnout is measured by a 3-item scale [45], and compassion satisfaction and compassion fatigue are measured by the shortened, 9-item Professional Quality of Life Scale for staff [46].

The degree to which methadone treatment is patient-centered is also a secondary outcome measured through staff surveys (assessing whether they believe they are providing it) and patient surveys (assessing whether they feel they are experiencing it). Patient-centered care competency is measured by a 19-item scale [47] including the following subscales: respecting patient perspectives, promoting patient involvement in the care process, providing patient support, and advocating for patients. Patient-centered care, as defined by the study team, is measured using a 5-item instrument that reflects the concepts of patient-centered care introduced during the accredited training modules. This scale is administered to staff, with an adapted version used for patients.

Other individual-level variables of interest for the staff participants include (1) personal characteristics—demographics, personal substance use disorder and treatment experience, and trauma exposure history (measured by the Life Events Checklist-5) [48]; (2) work characteristics—training, education, and licensure related to their clinic role; (3) empowerment using a 5-item empowerment scale [49]; (4) stigma—toward people with OUD with a 9-item scale [50], self-stigma with a 9-item scale [51], and fear of enacted stigma through a 9-item scale [52]; (5) beliefs—about trauma-informed care measured by the attitudes toward trauma-informed care [53] and about abstinence measured by the Abstinence Orientation Scale [54]; (6) comfort with targeted practices related to the most recent federal changes to methadone treatment delivery measured by items adapted from prior studies measuring comfort with practices [34,55,56]; and (7) fidelity to MPACT—the degree to which the clinic implements the MPACT intervention.

Other individual-level variables of interest for the patient participants include (1) personal characteristics—demographics, housing, trauma history (Life Events Checklist-5), and trauma symptoms (PCL-5); (2) methadone treatment—time in treatment and dose sufficiency; (3) empowerment—as measured by a 15-item scale [57] and through an adapted 16-item Kim Alliance Scale [58]; and (4) fidelity to MPACT—the degree to which the clinic implements the MPACT intervention.

As this is a hybrid (implementation and effectiveness) pilot and trial, we are specifically focused on reach, implementation, adoption, and (in the trial) maintenance using the RE-AIM (Reach, Effectiveness, Adoption, Implementation, and Maintenance) framework [59]. Measures collected for the pilot will also be collected for the trial.

Data Collection

Primary and secondary study outcomes will be measured by surveys and patient chart reviews. Surveys will be administered monthly for the pilot study: assessment 1 (baseline at enrollment) and assessment 2-5 in 30-day sequences through the study period, with a contact reminder at day 27 and a completion forgiveness period of 5 days (day 35). Table 1 displays the sequencing of measures across the 5 pilot surveys.

Table 1. Sequencing of Methadone Patient Access to Collaborative Treatment (MPACT) primary and secondary measures (assessment 1-5).

For the 20-month trial, there will be 8 surveys from baseline assessment at enrollment through the remaining 7 assessments conducted every 77 days. Survey responses will be collected using the Qualtrics platform, accessible directly by participants.

For all enrolled patients, a review of their methadone clinic medical chart will include the duration of their treatment at the clinic, from treatment initiation to discharge or study end, whichever occurs first. This review will take place at the conclusion of the study period in accordance with the data sharing agreement (DSA) established between the clinic organization and the University of Arizona. A feasibility test with a sample of 50 charts with deidentified data was conducted in June 2024 and confirmed timely data transfer, data completeness, and utility for outcome measurement for the pilot clinics. Our national survey of OTP clinic directors found that 22.2% of clinics allowed DSAs with researchers, but the vast majority (77.3%) indicated that such agreements were not allowed or that they were not aware of the clinic organization's position on them [60]. For the purposes of the trial, then, only clinics allowing DSAs will be eligible for study enrollment. The following medical chart segments will be requested for each patient participant: (1) the digest of the patient history of starting and leaving treatment at that clinic (dates), (2) case notes, (3) discharge summary, (4) treatment plans, (5) milligram dosing, and (6) take-home medication status over time. Case notes include qualitative data on patient stability, challenges reported by the patient (eg, housing, transportation, safety, and dosing sufficiency), and instances of missed doses. For the trial, the data will be transferred using unique identifiers that will correspond with the study unique identifiers. No personally identifying information (name and street address) will be transferred.

Study Recruitment

Recruitment is stepwise for both the pilot and the trial. For the national trial, clinics will first be recruited through email from a national list of methadone clinics responding to a prior survey by this team during 2024 [60]. A second strategy will involve an email to the state opioid treatment authority with a request to forward study information and the recruitment flyer to methadone clinic directors in their state. State opioid treatment authorities are the single opioid regulator in each state. Clinics that allow study recruitment among staff and patients, establish a DSA for the transfer of patient participant methadone treatment chart data at the conclusion of the 20-month trial, and identify a clinic "champion" to assist with study enrollment and study contact will be eligible for randomization as described below.

Following clinic enrollment, each clinic champion will post recruitment flyers in staff-only areas (for staff participants) and in patient-only areas (for patient participants). Recruitment flyers for staff lead to a study portal (web-based) presenting information about the study and requesting agreement to participate. If agreement is made, staff participants will immediately complete the enrollment survey (baseline assessment 1). The same process will occur for patients. Payment for timely completion of each survey is US $20 for patients and staff. This cost was determined by a group of staff and patients who completed the work associated with aim 1.

Patient and staff confidentiality will be maintained by centralizing the enrollment process. Recruitment flyers will be displayed in staff-only and patient-only areas with a QR code or URL leading to information for potential participants to learn more about the study and to voluntarily enroll. This process ensures the anonymity of study participants within the clinic, meaning that patients and staff participants will not be known to the study clinic. Further, at the time of enrollment, a unique identifier will be established by the participant and will be used

henceforth. At no time will the clinic leadership or clinic champion know the identity of the study participants. The only exception to this is at the conclusion of the study when patient chart data transfer will occur, and at that time, only 1 person handling data transfer will have the name and dates of birth of the participants whose charts will be transferred for study purposes.

Fidelity Tracking and Application of RE-AIM

MPACT fidelity tracking will assess the degree to which clinics assigned to the intervention arm implement MPACT components. This will be evaluated by a fidelity tracking instrument and video conversations with the clinic champions—biweekly during the pilot study and monthly during the trial period. A fidelity tracker will first be populated with data from study databases, including accredited training completion, TICA survey participation (number and ratio of staff completing surveys), number of anonymous wellness self-screenings, and reflective supervision participation (number of staff by role per biweekly session). During fidelity conversations, the clinic champion will indicate the number of wellness trainings offered to staff (current or new staff) in the past 2 weeks, whether posters for the wellness screener were shared in the staff-only areas, and whether there were other issues raised by staff about MPACT participation that may require troubleshooting.

MPACT feasibility will be measured through fidelity tracking (what the clinic does and does not implement and the feedback about issues related to that) and through items measured in the staff survey. The RE-AIM framework will guide the assessment of reach, adoption, implementation, effectiveness, and maintenance. Reach is focused on staff and patient participants in the MPACT study. Measures of reach include the number and proportion of clinics participating in the study (number participating/number in recruitment sample) and the number and proportion of staff and patients participating by the study clinic. Adoption is focused on the participation in MPACT intervention overall and by the MPACT component. This is measured by reported staff participation through the surveys and through completion data gathered through the intervention components. Examples include accredited training completion or progress toward completion, reflective supervision participant reports, and wellness assessment completion reported through study surveys and through wellness screening data output (duplicated unless noted by the participant by selecting “I have taken this assessment before,” and if selected, the participant can select the number of times the assessment has been completed prior). Implementation is measured through the fidelity check meetings with champions and reported MPACT activity (such as posting flyers about particular intervention components). Effectiveness is measured by primary and secondary outcomes related to the aims of this study. Maintenance will not be measured in the pilot study (4-month period) but will be measured through a survey conducted 6 months after the conclusion of the trial period.

Phase 2, Years 3-6: Hybrid, Cluster Randomized Controlled Trial

Overview

- Aim 4: Quantify the effects of MPACT on methadone treatment practice change and clinic culture.
- Aim 5: Determine the efficacy of MPACT on methadone treatment retention and patient and staff PTSS outcomes.
- Aim 6: Evaluate the effect of patient and staff trauma on primary outcomes and staff MPACT implementation.

Findings from the pilot study will determine the preliminary effect size to confirm power analyses and final sampling for a hybrid type 1, 20-month cluster randomized controlled trial among 30 clinics, 600 patients (20 per clinic), and 480 staff (18 per clinic). This hybrid type 1 trial will focus primarily on MPACT’s effect outcomes while examining the association of MPACT implementation fidelity and acceptability and identifying the multilevel factors influencing implementation.

For the trial, the clinic is the unit of randomization. The intervention condition will be the MPACT intervention, and the control condition will involve accredited training about methadone that does not overlap aspects of the MPACT intervention. As shown in Table 2, we will allow a 20-month study period to accommodate staggered trial initiation through month 12 of year 2. Given the 20-month trial period, we will allow for new staff members to enroll through the end of the 7th month of their site’s trial period.

Table 2. Cluster randomized controlled trial of Methadone Patient Access to Collaborative Treatment.

	Year 1		Year 2		Year 3		Year 4

Clinic Stratification Factors

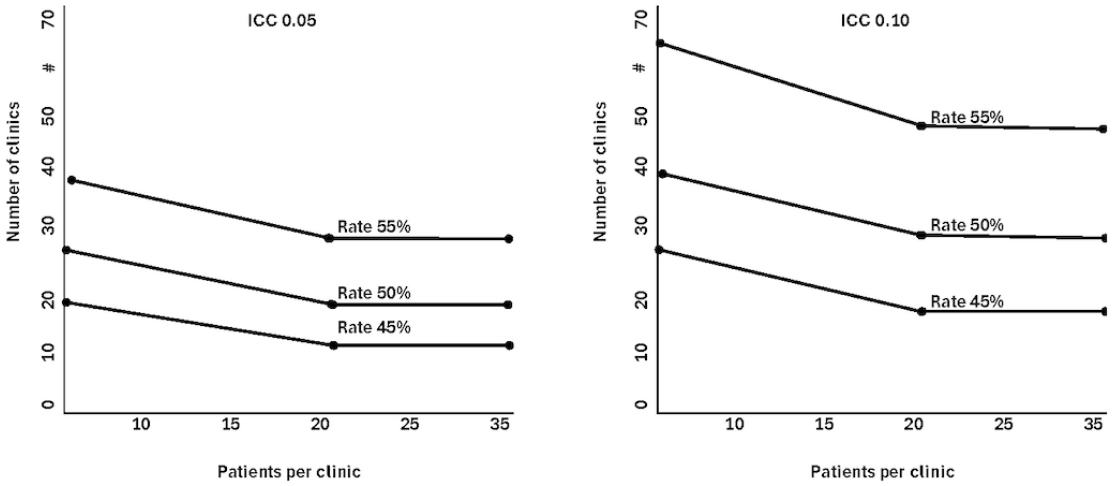
By the time of trial planning finalization, we anticipate that the state regulatory environment in each trial location will be a likely outer setting impact. Given the importance of state policy for regulating OTPs and methadone treatment, we will measure state regulatory favorability toward OTPs using a 2-level coding structure used in prior studies by this team [60]. We will code state laws based on the Pew state regulatory review [8] as "expanding methadone access" or "not expanding or limiting access." Randomization to trial condition will be stratified based on outcomes of this state regulatory coding.

Statistical Analysis

Our primary outcome is patient time to first treatment interruption (confirmed in the pilot). Secondary outcomes include treatment retention (yes or no) at selected time points (1, 3, 6, and 12 months) and time to treatment discontinuation. To accommodate the clustering induced by nesting patients within clinics, we will use a mixed effects Cox proportional hazards model (shared frailty model) [61,62] to accommodate differential survival probability among clusters. The mixed model will include a random intercept for the clinic and a fixed treatment effect for MPACT or control assignment. We will also include patient-level covariates for age, sex, and time in MMT.

Our initial sample size calculation uses asymptotic normal results for log hazard ratio as well as sample size inflation factors (eg, Donner) [62] for cluster randomized trials. In designing the future R33 trial, we will make use of specific sample size methods for cluster randomized trials with time-to-event outcomes [63,64]. The relative frequency of first treatment interruption [65] is estimated as 66% at 12 months of MMT until we have confirmation from the pilot. We evaluate the number of clinics and number of patients, assuming that MPACT intervention reduces this frequency to 45% (n=240), 50% (n=300), and 55% (n=330). The power curves based on independent observations (no cluster effect) are shown in Figure 3. The graph shows that the recruitment of 30 clinics, with 20 patients per clinic, provides greater than 80% power to detect a difference in treatment interruption rates of 66% (control) and 55% (MPACT) with α=.05. Consistent with the cluster randomization trial design, we also consider the average number of patients per clinic as 10, 20, and 40 and different degrees of intraclinic clustering using intraclass correlation coefficients of 0.05 and 0.10.

Figure 3. Number of clinics and patients for 80% power (vs 66% treatment interruption rate), MPACT trial. ICC: intraclass correlation coefficient; MPACT: Methadone Patient Access to Collaborative Treatment.



Results

The pilot study is funded by the National Institute on Drug Abuse (award R61DA059889, funded September 2023), and the field trial will be funded under the associated R33 mechanism in September 2025. The pilot study was completed on March 17, 2025. We are currently analyzing the pilot study findings. The randomized controlled trial will begin in December 2025.

Discussion

The MPACT study will provide a foundation for an evidence-based, staff-level intervention aimed at improving patient retention in MMT. We anticipate a decrease in reported levels of VT and PTSS among staff and an increase in methadone treatment retention among patients. The pilot outcomes are focused primarily on implementation with a preliminary indication of impact or effectiveness. The preliminary outcomes from the pilot will inform the final sampling to properly power the study. The trial outcomes are focused both on the implementation and effectiveness of the MPACT intervention. Future studies should examine the individual components of MPACT to determine their differential contributions to the primary outcome of patient MMT retention and to secondary outcomes of staff and patient reduction in stress symptoms.

Acknowledgments

The authors are grateful to the group of people with methadone treatment experience and the OTP staff group who collaboratively advised the development of Methadone Patient Access to Collaborative Treatment. The authors also thank the Drug Policy Research and Advocacy Board for their support and direction to improve the health of people who use drugs in Arizona. Research reported in this publication was supported by the National Institute on Drug Abuse of the National Institutes of Health (award R61DA059889). The content is solely the responsibility of the authors and does not necessarily represent the official views of the National Institutes of Health.

Data Availability

The datasets generated and analyzed during this study will be made available in the HEAL data ecosystem through the Inter-University Consortium for Political and Social Research within 1 year of the pilot and of the trial conclusion, or at the time of first publication from the pilot (or trial), whichever occurs first.

Authors' Contributions

BEM led the study conceptualization, data curation, funding acquisition, investigation, and methodology and provided project administration and supervision of study staff and investigators. BEM also led the visualization and original writing and editing of the manuscript. AD supervised data curation and conducted formal analysis. AD also advised the methodology and conducted data validation. AD participated in the editing of the manuscript. RAC advised study conceptualization, data curation, funding acquisition, investigation, and methodology. RAC also participated in the editing of the manuscript. LBLK assisted study conceptualization, funding acquisition, investigation, and methodology and participated in the editing of the manuscript. BRB and ANM assisted study conceptualization, funding acquisition, and methodology and participated in the editing of the manuscript. GAC assisted study conceptualization, funding acquisition, investigation, and methodology and participated in the editing of the manuscript. Abstract

Background: Wearable activity monitors are increasingly used to characterize physical behavior. The development and validation of these characterization methods require criterion-labeled data typically collected in a laboratory or simulated free-living environment, which does not generally translate well to free-living due to limited behavior engagement in development that is not representative of free living.

Objective: The Free-Living Physical Activity in Youth (FLPAY) study was designed in 2 parts to establish a criterion dataset for novel method development for identifying periods of transition between activities in youth.

Methods: The FLPAY study used criterion measures of behavior (direct observation) and energy expenditure (indirect calorimetry) to label data from research-grade accelerometer-based devices for the purpose of developing and cross-validating models to identify transitions, classify activity type, and estimate energy expenditure in youth aged 6-18 years. The first part of this study was a simulated free-living protocol in the laboratory, comprising short (roughly 60-90 s) and long (roughly 4-5 min) bouts of 16 activities that were completed in various orders over the span of 2 visits. The second part of this study involved an independent sample of participants who agreed to be measured twice (2 hours each time) in free-living environments such as the home and community.

Results: The FLPAY study was funded from 2016 to 2020. A no-cost extension was granted for 2021. A few secondary outcomes have been published, but extensive analysis of primary data is ongoing.

Conclusions: The 2-part design of the FLPAY study emphasized the collection of naturalistic behaviors and periods of transition between activities in both structured and unstructured environments. This filled an important gap, considering the traditional focus on scripted activity routines in structured laboratory environments. This protocol paper details the FLPAY procedures and participants, along with details about criterion datasets, which will be useful in future studies analyzing the wealth of device-based data in diverse ways.

Introduction

Device-based assessment of physical behavior has become common in health research [1-6]. Despite significant advancements in this field, a major challenge remains: the translation and generalization of device outputs, which are crucial for accurate interpretation and use [1,7]. This challenge arises partly from the methodological approaches used, as well as from the way data are collected to calibrate and validate these methods. Traditional static regression models for physical behavior assessment, such as those used in the 2003-2006 National Health and Nutrition Examination Survey [8], rely on population-, attachment site-, and device-specific cut points or regression equations to estimate energy expenditure (EE) and physical activity intensity [9]. However, these models tend to perform poorly when applied to the dynamic and complex nature of real-world behavior, as well as when tested on out-of-sample datasets [10,11]. For example, legacy models such as the Freedson equation for children [12] have been shown to underestimate moderate-to-vigorous physical activity by up to 51% during free-living conditions [11], highlighting a key limitation in the field. This discrepancy arises because these models were developed using structured laboratory data, which fail to capture the sporadic and irregular movement patterns typical of free-living environments. Furthermore, traditional methods often segment accelerometer data into fixed time intervals (eg, 1-min epochs), assuming that each data point is independent and represents a continuous bout of activity—an assumption that is rarely valid in real-world settings [13-15].

Advancements in sensor technology, including the use of wrist-worn accelerometer-based devices and the integration of additional sensor types (ie, gyroscopes and magnetometers), have improved the potential ability to capture a broader range of movement behaviors with different characteristics, such as the discrimination of sedentary behavior [16-18]. These innovations offer promising solutions for improving physical behavior assessment, particularly in youth populations. However, challenges remain in using raw data from these devices to accurately predict EE and categorize activity types [1,19,20]. The use of machine learning algorithms has been an interesting development in this space, showing potential for improving activity classification and EE estimation [21-24]. However, as with traditional methods, these machine learning algorithms have been primarily trained on structured laboratory activities, leading to poor performance when applied in free-living conditions and to new datasets [21,25]. The key issue lies in the segmentation of activity bouts and the identification of transitions between activities, which are much more subtle and irregular in free-living environments compared to the abrupt transitions typical of laboratory-based protocols [26-28].

The Free-Living Physical Activity in Youth (FLPAY) study was an effort to address these gaps by collecting transition-rich data in free-living conditions for calibration and validation of device-based models of physical behavior. The purpose of this paper is to describe the methods and data associated with the FLPAY study, thereby encouraging procedural replication in future studies and providing a comprehensive background for future analyses of data from this study. By addressing the complexities of free-living data, particularly the segmentation of activity bouts and transitions, this study aims to improve the accuracy, precision, and applicability of device-based physical behavior assessments and contribute to the development of more effective methods for characterizing physical behavior in youth.

Methods

Study Design

The FLPAY study was a 2-part investigation to develop and validate sensor-based methods for detecting transitions between activities as a precursor to predicting EE. The first part of this study took place in a simulated free-living laboratory environment conducive to method development (calibration), while the second took place in unstructured free-living environments conducive to method validation. Both studies were for youth participants aged 6-18 years who were recruited through word of mouth and flyers. The overall study design was conceived to address common limitations of prior method development studies, which have focused on the collection of steady-state laboratory data and structured ambulatory activities, rather than allowing naturalistic transitions and data collection in free-living.

Below, we present protocol and data summaries for each component of this present study in separate subsections. Portions of the information have been reported previously [26,29-31]. This present study was not a clinical trial. Due to the overlap in the methods for each part of this study (eg, similar equipment), the following sections are focused primarily on unique elements of each part, while recurring elements are presented in Multimedia Appendix 1.

Ethical Considerations

Both parts of this study were approved by the University of Tennessee Knoxville Institutional Review Board (UTK IRB-15-02487-FB). For all participants, written informed consent was obtained from a parent. Participants also provided written informed assent. Both parts of this study involved video recording on an opt-in basis, and thus, there were separate consent and assent signatures for general enrollment and video recording. However, for both parts of this study, the consent and assent documents did not include language for public data sharing, and thus, only deidentified data will become available from the FLPAY study. For screening, parents filled in a health history questionnaire, with participants being excluded if they had medical conditions or musculoskeletal injuries that prevented engagement in physical activities. Additional exclusion criteria included conditions or medications affecting metabolism. Participants were compensated for their participation in this study. Details on compensation are included within the subsections for each study component.

Part 1: Laboratory-Based Component

Participants—Laboratory-Based Component

A total of 100 participants were recruited. Approximately even distributions were recruited across sex and age groups (6-9, 10-12, 13-15, and 16-18 years). Participant characteristics are shown in Table 1.

Table 1. Physical characteristics of participants from the laboratory study.

	Full sample (N=100)	Male (n=48)	Female (n=52)
Age (years)			
Mean (SD)	12.1 (3.53)	12.3 (3.32)	11.9 (3.74)
Median (IQR)	12.1 (9.3-15.2)	12.4 (9.9-15)	11.7 (9-15.2)
Age group (years), n (%)			
6-9	33 (33)	13 (27.1)	20 (38.5)
10-12	25 (25)	15 (31.3)	10 (19.2)
13-15	23 (23)	12 (25)	11 (21.2)
16-18	19 (19)	8 (16.7)	11 (21.2)
Height (cm)			
Mean (SD)	150 (19.2)	152 (20.5)	148 (17.9)
Median (IQR)	151 (134-166)	156 (140-167)	150 (133-162)
Sitting height (cm)			
Mean (SD)	74.9 (9.5)	75.4 (9.7)	74.3 (9.5)
Median (IQR)	74.5 (66.5-83.1)	74.5 (68.6-84)	74.4 (65.9-82.6)
Leg length (cm)			
Mean (SD)	75 (11.4)	77 (11.8)	73.2 (10.8)
Median (IQR)	76 (66-82.8)	77.5 (69.6-85.8)	74.3 (63.8-80)
Weight (kg)			
Mean (SD)	44.7 (18.7)	46.5 (20.3)	43 (17.2)
Median (IQR)	40.5 (29.6-55.7)	41 (34.1-56.3)	38.3 (29.3-55.7)
Fat mass (kg)			
Mean (SD)	10.4 (7.5)	9.2 (6.8)	11.4 (7.9)
Median (IQR)	7.5 (5.7-12.1)	7 (5.6-10)	9.5 (6.5-13.7)
Body fat (%)			
Mean (SD)	21.9 (6.4)	18.7 (4.8)	24.9 (6.3)
Median (IQR)	20.8 (17.5-24.5)	17.5 (15.6-19.7)	23.7 (21.1-27.5)
Fat-free mass (kg)			
Mean (SD)	34.3 (12.9)	37.2 (14.6)	31.6 (10.6)
Median (IQR)	32.7 (23.3-42.8)	33.8 (27.3-48.1)	30.3 (22-41.6)
BMI (kg/m^2)			
Mean (SD)	19 (4.4)	19.1 (4.4)	19 (4.5)
Median (IQR)	18 (16.2-20.5)	18 (16.3-19.9)	17.9 (16.2-20.6)
BMI percentile (%)			
Mean (SD)	51.6 (27.4)	50.9 (26.8)	52.3 (28.2)
Median (IQR)	49.4 (33.6-73.3)	48.8 (34.2-72.2)	49.6 (33.6-74.6)
BMI classification			
Underweight	5 (5)	2 (4.2)	3 (5.8)

Laboratory-Based Component Procedures

All research visits were conducted in the Applied Physiology Laboratory and the surrounding area at the University of Tennessee Knoxville. The protocol entailed 2 visits on separate days, each lasting approximately 2-2.5 hours. The main feature of the protocol was the completion of 16 activities (Table S3 in Multimedia Appendix 1) that were divided across the 2 visits. A key goal of this study's design was to simulate realistic transitions between activities. Therefore, each activity was performed twice, with 1 instance lasting approximately 60-90 s and the other lasting approximately 4-5 min. Within those ranges, participants self-selected when they transitioned to the next activity unless guidance was needed from the research team (eg, if the upper limit of 90 s or 5 min was reached or if the walking circuit reached a specific stopping point to facilitate speed calculations). They also self-selected the order of the 8 activities they were prescribed each day, except that the same activity could not be performed twice in a row, and the activities were grouped by location (ie, in an upstairs laboratory or a separate recreation area) to minimize total transition time. The order of short and long bouts for each activity was randomized.

Throughout each research visit, participants wore a portable indirect calorimeter and a variety of activity monitors. Participant behavior and posture were coded by direct observation, using a focal sampling approach that allowed continuous logging of behaviors, transitions, and posture. Video recording was also performed for most participants. The video recordings served as a backup in case the live coded observation records needed to be reviewed and revised for any reason (eg, adjusting timestamps if an error was noted during the live coding process).

Laboratory-Based Component Detailed Timeline

For the first visit, participants were asked to refrain from eating or drinking (except water) for 2 hours before the visit and to wear lightweight athletic clothing and closed-toed shoes. After completing the enrollment and consent processes, they removed their shoes and socks and had anthropometric measurements taken. Standing and sitting height (cm) were measured using a wall-mounted stadiometer. Body mass (kg) and body fat (%) were measured using a Tanita BC-418 bioelectrical impedance analyzer (Tanita Co. of America, Inc).

Following the anthropometric measurements, participants were fitted with this study's equipment and completed a 30-minute assessment of resting metabolic rate (RMR). The remainder of the visit involved completing the 8 activities assigned for that day. Participants received a US $30 gift card at the end of the visit.

For the second visit, participants were given the same previsit instructions. Upon returning to the laboratory, they were fitted with the same study equipment as visit 1 before performing the remaining 8 activities, such that all participants completed the full set of 16 activities under normal circumstances (ie, assuming there is no withdrawal, refusal, or space unavailability due to scheduling). Participants received a US $45 gift card at the end of the visit.

Laboratory-Based Component Equipment

All participants wore 5 ActiGraph GT9X devices (GT9X; ActiGraph LLC), which were the primary activity monitors of interest for this study. One was placed on the right hip, 1 on each wrist, and 1 on each ankle. The hip-worn device was worn on an elastic belt and positioned over the right iliac crest along the anterior axillary line and secured using a manufacturer-specific belt clip. The wrist-worn devices were worn in manufacturer-specific watch bands that the devices clipped into. The watch bands were positioned proximal to the styloid processes with the devices oriented where the LCD could be read naturally by the participant, as a standard watch face would be. The ankle-worn devices were clipped into manufacturer-specific clips worn on slip-through Velcro bands. The clips were positioned so that the devices were on the lateral aspect of the ankle proximal to the lateral malleolus. Additional detail is given in Section S1.1 in Multimedia Appendix 1.

Secondary activity monitors, both research- and consumer-grade, were also worn in various locations on the body as detailed in Sections S1.2 and S1.3 in Multimedia Appendix 1.

Criterion Measures

Participants were observed using the Noldus Observer XT and Pocket Observer software platforms (Noldus Information Technology), which served as a criterion measure of behavior and posture. Participants also wore a Cosmed K4b^2 (COSMED s.r.l.), which was the criterion measure of EE. General details of these tools can be found in Sections S1.4 and S1.5 in Multimedia Appendix 1. Specific details applicable to part 1 of this study are discussed below.

The Observer XT desktop platform (version 12.5) was used to create a 2-class focal sampling coding scheme, which was then exported for use in the Noldus Pocket Observer application (version 3.2). The latter application was run on Samsung Galaxy Tab 4 tablets (Samsung) and used for real-time coding of participant behavior and posture. Several activity monitoring

studies have taken a similar approach to direct observation using Noldus products [22,28,32-34].

The coding scheme included a 19-item list of activity behaviors (ie, for the 16 activities listed in Table S3 [Multimedia Appendix 1], plus labels for the start time of the observation period, transitions between activities, and unknown activities) and a 6-item list of postures (lying, reclining, sitting, standing, stepping, or unknown). The label for unknown activities was used whenever an unlisted activity occurred, such as a water break or bathroom break, and was accompanied with a posture label of unknown.

Whenever a new activity was initiated, users tapped the corresponding label in Pocket Observer, which issued a timestamp for the new activity and then prompted the user to indicate the participant's posture. This created a continuous and timestamped record of activities and postures. After finishing the protocol, live-coded observations were imported back into the Noldus Observer XT software program for conversion to Excel format. The resulting files were then processed in R (R Foundation).

Section S1.5 in Multimedia Appendix 1 describes the procedures that were used when syncing data from the various sources.

Processing of Criterion Data for Laboratory-Based Component

While the activity monitor data were collected for flexible use (eg, to be processed and tested in different ways across future studies), the criterion data from direct observation and indirect calorimetry were designed for consistent usage across future studies. Therefore, we describe the processing and aggregation of criterion data in the sections that follow, while monitor data processing is left for future studies to describe according to the unique needs of the study.

Direct Observation Data

Each participant was observed by a single trained observer in real time during each study visit. The observation files were inspected for comments and anomalies that indicated errors (eg, the user entered a comment indicating a button was pressed at the wrong time or that the activity duration was outside the expected range). Corrections were made by a senior reviewer cross-referencing the video recordings and adjusting labels or timing accordingly. For participants without video recordings, observations were used as they were created from the live coded direct observation (n=3). Each row of the observation files indicated a start time and duration for the corresponding activity and posture, and by definition, there were no gaps between activities. Thus, every second of the data collection period could be mapped to a specific activity and posture label that was active at that time, allowing a second-by-second record to be constructed from the information in the observation files.

Portable Indirect Calorimeter Data

EE was calculated based on oxygen consumption (VO_2) and RMR, both measured by the K4b^2. The values were expressed in youth metabolic equivalents (MET_y), where

As described in the Sections S2.1 to S2.3 in Multimedia Appendix 1, calculations for RMR and continuous VO_2 were the same for parts 1 and 2 of the FLPAY study. Below, we provide additional detail about calculating steady state EE as this was unique to part 1 of this study.

Steady state periods were defined for the longer activity bouts. All bouts longer than 3 minutes, 40 seconds were included in the analysis. The steady state period was defined as the last 60 seconds of each activity, after discarding the final 10 seconds. For each of these periods, the corresponding K4b^2 data were extracted in breath-by-breath format. An average VO_2 was then calculated using manufacturer-specified procedures (Section S2.1 in Multimedia Appendix 1). This value was divided by RMR to obtain MET_y for the steady state period. Posture was determined by cross-referencing the direct observation data from the steady state period.

Activity intensity was derived from EE (MET_y) and posture, using the following accepted definitions [35]: for sedentary behavior, ≤1.50 MET_y and seated, lying, or reclining posture; for light physical activity, 1.51-2.99 MET_y regardless of posture (or ≤1.50 MET_y if posture was upright); and for moderate-to-vigorous physical activity, ≥3.00 MET_y regardless of posture. For each activity and age group (ie, those aged ≤12 versus >12 years), data were cleaned by removing values <0.2 MET_y, or >2 SD above or below the mean.

Part 2: Unstructured Free-Living Study

Unstructured Free-Living Study Participants

A total of 84 participants were recruited to this study, of whom one was excluded (final N=83). Participant characteristics are shown in Table 2.

Table 2. Physical characteristics of participants from the free-living study.

	Full sample (N=83)	Male (n=39)	Female (n=44)
Age (years)			
Mean (SD)	11.2 (3.4)	11.1 (3)	11.3 (3.7)
Median (IQR)	10.6 (8.5-13)	10.5 (8.9-12.7)	11.2 (8.4-13.6)

Unstructured Free-Living Study Procedures

The overall goal of this part of this study was to collect free-living data with diverse activities and transitions between them. Therefore, research visits were conducted in varied settings, such as in the community, participants' homes, local parks, and approved facilities of community partners. Data were collected across 2 separate days, with the goal to have one in the participant's home and the other somewhere else.

The first study visit was generally conducted in the participant's home environment and began with the informed consent and assent process and participant screening. Once enrolled, participants had anthropometric measurements taken, including standing and sitting height (cm) using a portable stadiometer and body mass (kg) and body fat percentage measured using a Tanita BF-350 bioelectrical impedance analyzer. Anthropometric measurements were taken with shoes and socks removed. Following the completion of the anthropometric measurements, a 30-min RMR assessment was conducted using a Cosmed K4b^2 or K5 (used in breath-by-breath mode to align with the K4b^2) portable indirect calorimeter before participants engaged in activities of their choice for up to 2 hours. In some cases, the RMR assessment was conducted on a separate visit (for a total of 3). Participants were compensated US $25 for the RMR assessment and US $25 for the free-living data collection period.

For the second study visit, an alternative environment was sought for each participant. When this was not possible, participants were asked to engage in different activities than what they chose during their initial visit, which helped to mimic different environments and promote engagement in a wide range of activity behaviors. Similar to the first visit, the participants engaged in behaviors of their choice for up to 2 hours. An additional US $25 of compensation was given for completing the second study visit.

Throughout this study's visits, participants were given free rein to select activities, so long as they had parental permission, did not put the equipment at risk (eg, from water damage), and did not risk harming themselves or others.

All participants wore the same research-grade devices as described in the equipment portion of part 1 including the primary devices of interest (ActiGraph GT9X on the hip, both wrists, and both ankles; see also Section S1.1 in Multimedia Appendix 1) and the secondary research- and consumer-grade monitors (see Sections S1.2 and S1.3 in Multimedia Appendix 1, respectively). Participants wore a Cosmed K4b^2 or K5 portable indirect calorimeter, both of which collected breath-by-breath data as a criterion measure of EE (see Section S1.5 in Multimedia Appendix 1 for more detail). During the consent process, participants were able to opt-in to be video recorded throughout each research visit, and only 3 participants did not do so. Live coding was performed for those who did not opt into the video recordings. For the others, the video recordings were later used for direct observation to obtain a record of the behaviors and postures they engaged in, along with relevant contextual factors (eg, indoors versus outdoors and alone versus with others). These video-based observations were performed using the Noldus Observer XT software program for Windows desktop computers.

Unstructured Free-Living Study Equipment

Most equipment matched what was used for part 1 of the FLPAY study, with the addition of the Cosmed K5 alongside the K*4b^2*. The main difference in part 2 was the coding scheme used for direct observation and the reliance on video recordings for direct observation rather than live-coded observations. For participants who did not opt into video recording, real-time observations were performed using similar procedures to those described in part 1 above, except that a new coding scheme was used (Table S2 in Multimedia Appendix 1). Otherwise, the video recordings were coded using the Noldus Observer XT Direct Observation software program (version 12.5) for Windows desktop machines.

The coding scheme for part 2 included a longer list of potential activities and postures, as discussed below. It also included prompts about the activity context (eg, indoor or outdoor and alone or with others). Otherwise, the general structure of the coding scheme matched with part 1, such that every second of the data collection period could be mapped to a single entry in the observation record.

Table S4 in Multimedia Appendix 1 lists the main activities that were included in the coding scheme. As before, extra labels were included for coding the start of the observation period, transition behaviors, and unknown activities (ie, activities not previously defined), and events where the participant was off-camera (ie, in a private space, bathroom, etc). After the primary activity behavior was coded, posture was coded as lying, sitting, standing, standing or stepping, squatting or kneeling, reclining, mixed posture, or unknown (used only when the activity behavior was "off camera"). Section S1.5 in Multimedia Appendix 1 describes the procedures that were used when syncing data from the various sources.

Unstructured Free-Living Study Processing of Criterion Data

The data processing procedures for part 2 broadly mirrored what has already been discussed in part 1 resulting in a second-by-second dataset with information about EE, behavior, posture, and context. The direct observation procedures differed from part 1 due to the open-ended nature of this study and the reliance on video recordings. Specifically, at least 2 trained reviewers coded each video, and a third senior reviewer then compared their observations side-by-side. Additional detail is available in S1.4.3 in Multimedia Appendix 1.

Results

The FLPAY study was funded in June 2016, and recruitment and data collection for part 1 began in January 2017. Funding ended in March 2019, and the project and data collection concluded in March 2020. Some preliminary and auxiliary findings have been reported previously [26,29-31], whereas the protocol described herein will serve as the authoritative guide for ongoing research with the finalized dataset. Part 1 of this study enrolled 100 individuals, and part 2 enrolled 84 individuals. Data loss is described in Section S3 in Multimedia Appendix 1. The overall sample characteristics are shown in Table 1 and Table 2, whereas sample sizes for individual analyses may differ depending on overlap with additional missing data for different activity monitors. Table 3 provides an overview of prior completed analyses and current and ongoing analyses.

Table 3. Summary of research activities related to the FLPAY[a] study.

Component	Notes
Completed analyses	• Please see references [26,29-31].
Ongoing analyses	
ActiGraph, GENEActiv, and Axivity	• Please see references [36-38]. • Ongoing analyses include the development and testing of models to predict energy expenditure [36,37] and classify activity type [38]. • Additionally, we are preparing the dataset such that it can be used for out-of-sample validation of models developed by other research groups.

[a]FLPAY: Free-Living Physical Activity in Youth.

Discussion

Contributions

The design of the 2-part FLPAY study emphasized naturalistic behaviors and periods of transition between activities. This filled an important gap in prior development studies focused on physical behavior characterization. In this paper, we summarized the FLPAY procedures and participants, along with details about criterion datasets that will be useful in future studies that look at various aspects of the data from the activity monitors. Future studies can proceed with novel method development and testing for a variety of research-grade and consumer-grade wearable devices. These data may be especially useful for ongoing work to refine methods involving transition detection for data segmentation [27,30].

It is worth noting that the main device from this study (ActiGraph GT9X) has been replaced by a newer model (ActiGraph LEAP). Although the manufacturer remains committed to backward compatibility, testing will be necessary to compare outputs from the GT9X and LEAP. Such comparisons should include not only direct factors such as agreement of the accelerometer and gyroscope outputs but also indirect factors such as battery life, memory consumption, and participant acceptability. Unpublished data from our laboratory showed that the GT9X battery life was <36 hours when collecting data from both the accelerometer and gyroscope. The LEAP includes a different gyroscope sensor that may be longer-lived, and it also includes additional sensors for richer monitoring (eg, barometer and microphone). These factors may affect usability in lengthy protocols (eg, >1 week) and vary from study to study depending on what sensor configuration is selected. It will also be important to consider the volume of data collected by LEAP, as our unpublished data showed that the GT9X was able to generate >1 GB of data before depleting its battery. As future studies begin to draw on the wearable data from the FLPAY study (especially, but not exclusively, the ActiGraph GT9X data), the implications of these decisions will be important to consider.

Strengths and Limitations

The FLPAY study had notable strengths, including its collection of data from both laboratory and free-living contexts, with realistic transition periods and behavioral patterns. Another

strength was the inclusion of criterion measures for EE, behavior, and posture. These will substantially benefit future work toward the development and validation of novel methodological approaches for the variety of research-grade devices that were used in this study.

Despite its strengths, the FLPAY study also had limitations. A key limitation was the limited diversity of the samples along the lines of racial and ethnic background. While the recruitment strategy was designed to mirror the census makeup in the surrounding area, results may not be fully generalizable for youth who come from underrepresented backgrounds. The open-ended nature of the free-living component could also be viewed as both a strength and a limitation, as the heterogeneity of the data may create a high level of variability that is difficult to address or interpret in future analyses. Lastly, we emphasized detailing the criterion data measurements of RMR, EE, and direct observation in the FLAY study as these will be foundational for a wealth of secondary research that is possible when paired with the monitor data collected in this study.

Acknowledgments

The authors would like to thank the participants from both parts of this study. We also gratefully acknowledge the contributions of Andrew Kaplan, MS, Minttu Hukka, MS, Andrew Blythe, PA-C, Brice Walkowski, BS, B Jesse Clendenin, DO, Josephine Jennings, PA-C, Marisa Varrone Mengel, BS, Polina Krassovskaia, PhD, and Brianne Clure Taylor, PA-C. Wei Ding, PhD, and Eamonn Keough, PhD, were collaborators.

This study was supported by the National Institutes of Health (grant R01HD083431). The funder was not involved in designing this study or analyzing the data. No financial support was received from any of the activity monitor manufacturers, importers, or retailers.

Data Availability

Deidentified data from the FLPAY study may be available upon reasonable request from the corresponding author. Video data cannot be deidentified and cannot be shared under any circumstances.

Conflicts of Interest

PRH has received funding from ActiGraph LLC. This study predates said funding, representing no conflict of interest. The authors have no conflicts of interest to report.

Abstract

Background: End-stage kidney disease (ESKD) or kidney failure is a condition where the kidneys lose the ability to function. African American individuals are 4 times as likely to develop ESKD compared to White American individuals. In addition, African American patients are less likely to have an optimal dialysis start and to choose renal replacement therapy modalities that align with their goals and values. Our prior work shows that culturally tailored, in-person education improves patient outcomes. This is the foundation for our innovative intervention using an African American virtual patient educator as an option for hospitalized patients with chronic kidney disease (CKD).

Objective: The Interactive Computer-Adaptive Chronic Kidney Disease (I-C-CKD) study will determine whether the computerized adaptive education and usual hospital care impact the health literacy of African American patients with kidney disease. It will also assess how patients' lifestyle and commitment to health goals are impacted by the method of health literacy education.

Methods: We will screen, recruit, and enroll hospitalized patients who self-identify as African American and have advanced CKD based on their estimated glomerular filtration rate. Eligible patients who verbally consented will be randomly assigned into either the computerized adaptive education intervention group or the control group (usual hospital care). Patients in the intervention group will receive a culturally tailored, adaptive education module. To analyze pretest, posttest, and follow-up survey results on patient CKD knowledge, ESKD treatment options, and health goals, we will use a paired, 2-tailed *t* test with a Bonferroni adjustment for multiple comparisons.

Results: Recruitment for the I-C-CKD study began on May 2, 2023. We are currently recruiting and have enrolled 96 patients who completed both pretest and posttest surveys as of December 2024. This includes 50 patients in the control group and 46 patients in the intervention group. Data analysis has not occurred.

Conclusions: African American individuals often receive less patient education about self-care and treatment options for CKD. We hope this study provides a solution to increase hospitalized African American patients' knowledge of CKD and motivation for CKD self-care through computerized adaptive education, reduce disparities, and improve patient outcomes.

Introduction

Background

End-stage kidney disease (ESKD) or kidney failure is a condition where the kidneys lose the ability to function. African American individuals are 4 times as likely to have ESKD compared to White American individuals [1]. African American patients are more likely to have comorbidities such as diabetes, obesity, high blood pressure (hypertension), and heart failure, which all increase the risk of developing kidney disease [1].

Hemodialysis can help patients with ESKD feel better and live longer. However, dialysis is not a cure for ESKD, and patients on hemodialysis have high morbidity and mortality rates [1]. Patients on hemodialysis can also experience side effects such as low blood pressure (hypotension), muscle cramps, sleep problems, anemia, bone disease, high blood pressure (hypertension), and access-site complications [2]. In-center hemodialysis (IHD) with thrice weekly sessions in a dialysis unit is the most common treatment for ESKD. Patients who use IHD experience greater inconvenience, worse waste clearance, and more issues with transportation in comparison to other ESKD options. Alternatives to IHD include home hemodialysis, peritoneal dialysis, and kidney transplantation. These methods are associated reduced morbidity and mortality, or improved quality of life, compared to IHD [3].

There are racial disparities in the use of these renal replacement therapy (RRT) modalities. African American patients are less likely to be informed about better RRT options. African American patients are 47% less likely to use peritoneal dialysis and 3.5 times less likely to have a kidney transplant [4]. Often, African American patients are less likely to receive information from their provider about their CKD stage, treatment options, and self-care to prevent and treat CKD [3]. The hospital can be an important intervention site because hospitalization rate rises sharply in the 3 months before dialysis initiation. In addition, even patients who are not connected to primary or specialty care can present to the hospital.

Our previous work to was to develop and test a hospital-based CKD intervention, PREP RRT (Patient Referral and Education Program Prior to Renal Replacement Therapy). To develop the intervention, we interviewed African American patients about CKD knowledge and barriers to RRT preparation [4,5]. The intervention in that study includes an in-person African American health educator and written materials [2]. Our results showed an increase in knowledge in the intervention group compared to control group. We also found that culturally tailored interventions improved patient outcomes [6]. Drawing from insights gained in our prior work, our research team developed and implemented the Interactive Computer-Adaptive Chronic Kidney Disease (I-C-CKD) education as a patient education intervention to inform hospitalized African American patients with advanced CKD about their CKD and RRT options. This computer-based education is predicted be more accessible for hospitalized patients through videos that are culturally tailored with a virtual African American narrator, as in-person educators have some limitations.

Primary Hypothesis

Our primary hypothesis is that the computerized adaptive education will be more effective than usual hospital care in improving knowledge about CKD, CKD self-care, and RRT options (primary outcome).

Secondary Hypothesis

Our secondary hypothesis is that the computerized adaptive education will increase patients' intent to participate in CKD self-care compared to usual hospital care. We also believe that the computerized adaptive education will increase patients' action and commitment to CKD health-seeking behavior, access planning prior to dialysis initiation, initiate home dialysis modalities, and/or have a transplant evaluation after discharge and beyond 30-day follow-up.

Methods

Trial Design

The I-C-CKD study is a hospital-based, randomized controlled trial of a computerized patient education intervention compared to usual hospital care. After obtaining verbal consent (Multimedia Appendix 1), each patient will be randomly assigned into two groups: usual hospital care (control group) and the computerized adaptive education (intervention group), which is assisted by a research assistant (RA).

The usual hospital care control group will feature a baseline General Health Knowledge and Intent survey. Participants in the usual hospital care control group will receive the pretest survey and education materials but will not receive specific knowledge about CKD or their CKD condition. Participants in the control group will receive printed patient education materials informing them of the importance of a general healthy lifestyle, including diet, physical activity, and medication adherence. The printed materials for the usual hospital care control group are meant for patients with cardiovascular conditions and do not have any information about CKD. Participants who receive the control condition will also be able to speak with the patient educator if they want to.

The computerized adaptive education intervention group will receive the advanced CKD education module with information on the risk factors, stages, treatment options, and lifestyle of patients with CKD (see Figures 1 and 2). The RAs will assist with the program but not offer any information or knowledge about CKD. Following the patient's review of the advanced CKD education module, the RAs will administer the posttest General Health Knowledge and Intent survey.

Figure 1. Screenshot of the computerized adaptive education intervention featuring a personal story.

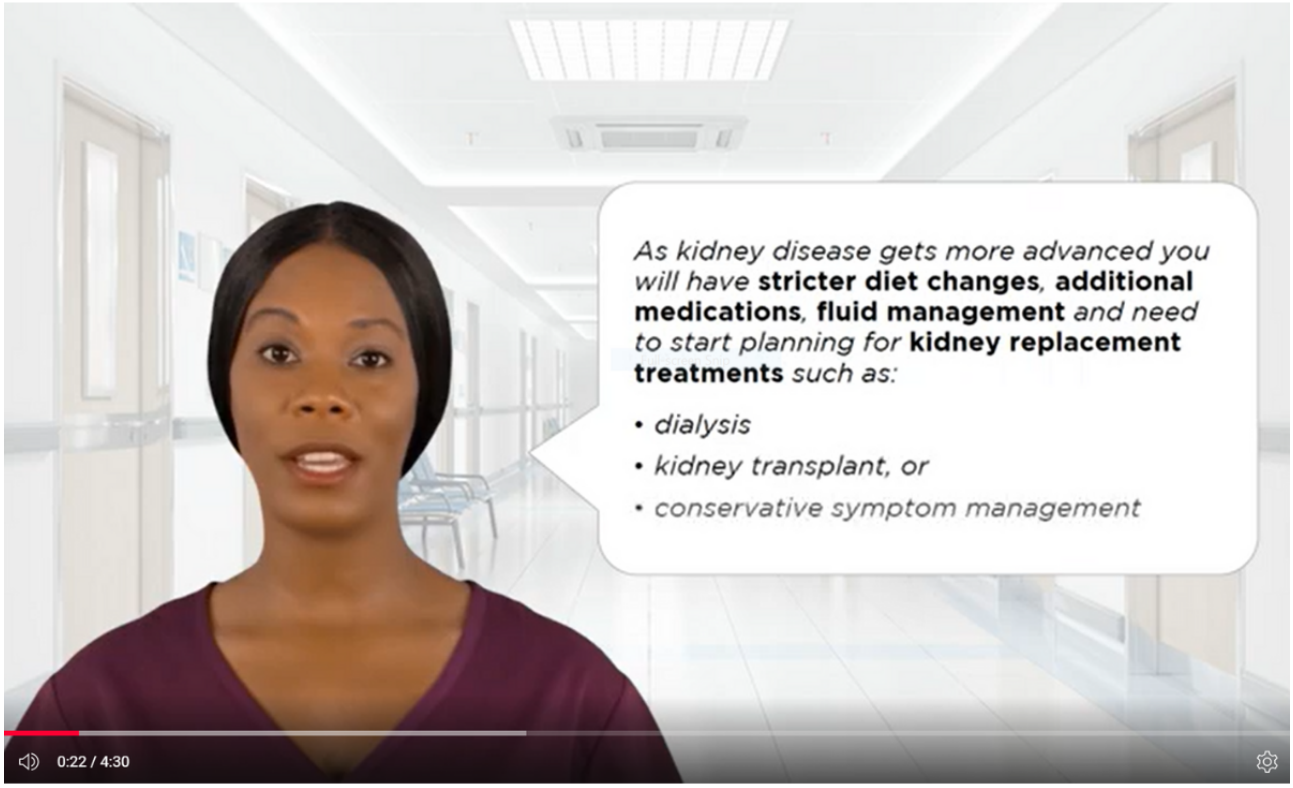

Figure 2. Screenshot of the computerized adaptive education intervention regarding treatment options. CKD: chronic kidney disease.

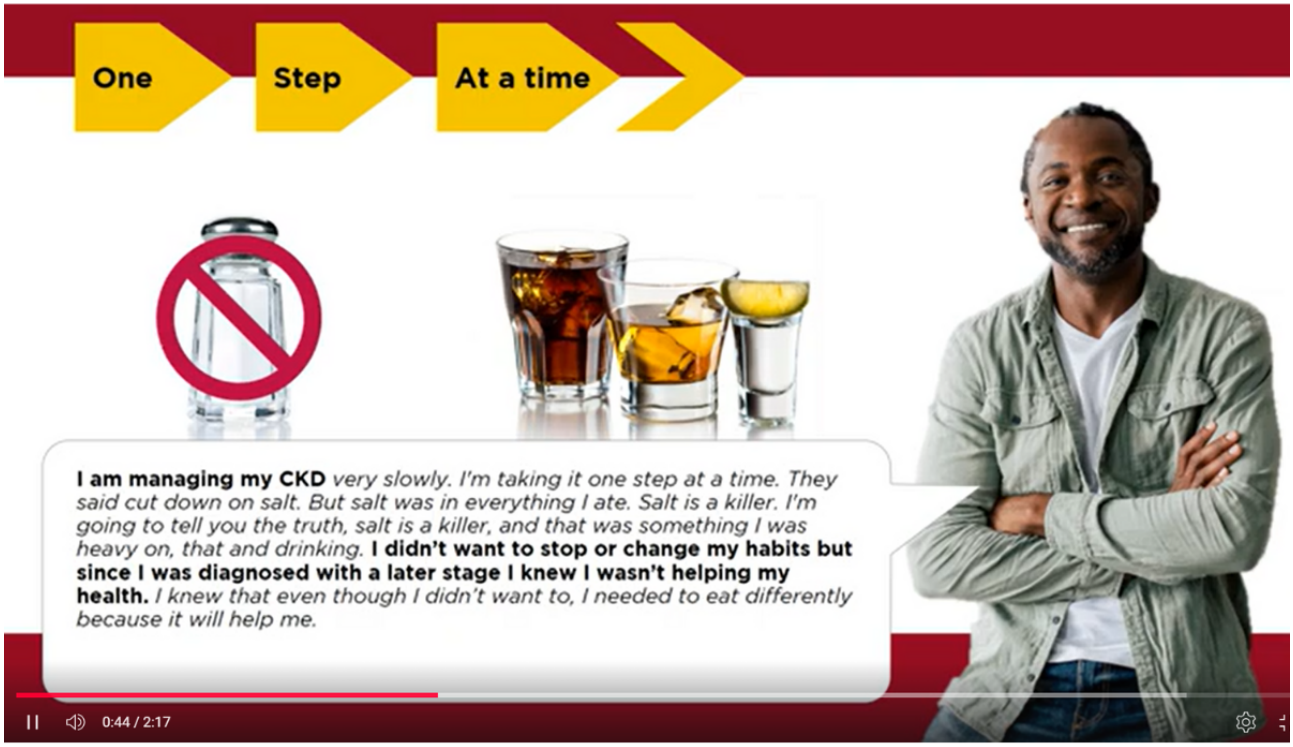

Both the usual hospital care control group and the computerized adaptive education intervention group will complete the "What's Next" form, to assess the patient's commitment to specific self-care activities. Patients will select their top-3 health goals, rate how confident they are about each goal, and identify how important each goal is to them. Patients will also report on their health resources. All the forms will be sent to the patient educator, a trained nephrology social worker.

Each patient will be contacted 30 days after discharge to ask about their commitment to health goals, barriers to self-care, and treatment plans.

The SPIRIT (Standard Protocol Items: Recommendations for Interventional Trials) checklist is provided in Multimedia Appendix 2.

Participants and Eligibility

The study will take place at the University of Chicago Medical Center (UCMC). We will approach hospitalized, English-speaking, African American patients at UCMC, aged 18-70 years, who meet the criteria for advanced CKD (Stage 3b or greater) with an estimated glomerular filtration rate (eGFR) <45 mL/min/1.73 m^2; they must not be on dialysis yet or have a history of kidney transplant. In order to be eligible, patients must have an eGFR <45 mL/min/1.73 m^2 during the current hospitalization in addition to prior hospitalizations and/or outpatient visits. We will have access to prior UCMC inpatient and outpatient laboratory values. We will also have access to some inpatient and outpatient laboratory values from other medical centers through Epic Care Everywhere. The exclusion criteria include patients who are hospitalized in the intensive care unit, meet the Montreal Cognitive Assessment criterion for cognitive impairment, or require a proxy for study consent. We will enroll 170 participants and randomly assign 85 to the computerized adaptive education and 85 to usual hospital care.

Recruitment

This study will be a substudy of the Hospitalist Project, an ongoing clinical study that examines a variety of outcomes of patients hospitalized in our general internal medicine services, and includes the analysis of administrative data, inpatient interviews, and 30-day follow-up by phone [7]. Hospitalist Project staff will obtain basic demographic information and medical history. Per the Hospitalist Project protocol, staff will also obtain permission to contact patients after discharge and to access their medical records (ie, at UCMC, from other medical systems, and through Medicare linkage). All inpatients recruited to the Hospitalist Project will be screened daily by the RA to identify patient eligibility for the study.

We will approach all Hospitalist Project–enrolled patients who meet study criteria and obtain informed verbal consent.

Randomization

Participants will be randomly assigned using a computerized spreadsheet, assigning each participant a random number. Participants who are assigned an odd number will be assigned to the intervention group. Participants who are assigned an even number will be assigned to the control group. The RA will begin by identifying an eligible participant who consented to the Hospitalist Project. Then, they will use the randomization spreadsheet to determine if the participant will be part of the intervention group or the control group. They will then approach the patient with the appropriate form and study packet.

The RA will complete the randomization, assignment, and enrollment process.

Blinding

Trial participants will be blinded after group assignment. Participants will view the survey as a Google Form and will not be informed whether they are part of the intervention or control group. They will also receive a study packet, which will not identify if they are part of the intervention or control group. The research team will not be blinded.

Intervention Group

The RA will meet each participant and conduct the pretest survey in the participant's private hospital room. The computerized adaptive education intervention group will receive an advanced CKD education module with information about CKD risk factors, stages, treatment options, and lifestyle modifications. The RA will assist in advancing program modules but not offer any information or knowledge about CKD. The avatar will be an African American woman who will present statistics about African American individuals and CKD. The interactive component will allow participants to personalize the information received based on prior CKD knowledge, diabetes status, and the level of motivation. The interactive CKD video can be completed in 30-45 minutes. Following the patient's completion of the advanced CKD education module, the RA will then readminister the General Health Knowledge and Intent survey.

The computerized adaptive education intervention group (and the usual health care control group) will complete the "What's Next" form, to assess the patient's commitment to specific self-care activities. Patients will select 3 health goals from a list of 10 options, rate their level of confidence in the ability to make change, and identify an action plan to accomplish each goal. Moreover, patients will be asked to report their needs from the medical care team and for community assistance, and they will be provided a resource list. The study will also ask if patients would like a primary care doctor and/or a nephrologist. This information will be relayed to the primary inpatient team. All the forms will be sent to the patient educator, a trained nephrology social worker.

We will encourage participants to complete the voluntary study in one visit. At 30 days after discharge, both groups will complete a follow-up call with the project RA. Participants will be queried about progress on goals set on the health commitment form, knowledge, and health intent.

Control Group

The RA will meet each patient and conduct the pretest survey in the participant's private hospital room. The usual hospital care control group will receive the General Health Knowledge and Intent pretest survey and printed education materials without explicit CKD information or knowledge about their CKD condition. The distributed education materials were intended for patients with cardiovascular conditions and focus on the importance of a general healthy lifestyle, including diet, physical activity, and medication adherence, and does not include CKD specific information. Following the patient's completion of the general health education video module, the RA will then readminister the General Health Knowledge and Intent survey.

The usual hospital care control group (and the computerized adaptive education intervention group) will complete the "What's Next" form, to assess the patient's commitment to 3 participant-selected self-care activities. Participants also will

be contacted 30 days after discharge to complete the follow-up survey.

Outcomes

Primary Outcome

The primary outcome of this study is the changes in patient knowledge, attitudes, and behavior about CKD and RRT. To evaluate CKD and CKD self-care knowledge, we will use a modified Kidney Knowledge Survey; the CKD Self-Management Knowledge Toolkit, which is a validated instrument [8,9]; and an investigator-developed ESKD knowledge survey. We will measure the change from the baseline observed via the pretest, posttest, and follow-up surveys. The pretest and posttest surveys comprise 20 mixed format multiple-choice and Likert-scale questions (ranging from strongly agree to strongly disagree; from no knowledge to a great deal of knowledge; and from extremely unlikely to extremely likely) to examine the patient's basic understanding of their health, general CKD knowledge, and health management.

Secondary Outcomes

The secondary outcomes are patient motivation and intent. We will administer the CKD Self-Efficacy Scale [10], the Patient Activation Measure [11], and the Kidney Failure Treatment Preferences [12] before the intervention, immediately after the intervention, and at 30 days after discharge. We will administer the General Health Knowledge and Intent survey, an investigator-developed instrument, to assess RRT preferences and commitment to CKD self-care activities, including intent to seek a nephrologist, noncatheter dialysis access initiation, and completion of a transplant evaluation. Each patient will be contacted 30 days after discharge to discuss their commitment to each selected health goals, barriers, and treatment plan.

Data Collection and Management

We will retrieve baseline survey information from the Hospitalist Project, which includes patient demographics and comorbidities. The initial trial data will be collected, stored, and saved in Google Forms with linked Google Sheets for the pretest and posttest surveys on the computer. The RA will photograph and save participants' written packet responses digitally. The RA will deidentify the packet responses and save them according to their initials, study visit date, and enrollment number. We will ensure participant responses remain confidential. Information about the patient's medical status, enrollment, and participation will be maintained through a password-encrypted file.

The RA will use password-encrypted laptops to conduct the study. The participant's responses on the study packet will be photographed, deidentified, and saved in a password-encrypted digital folder. The analysis file will not be attached to protected health information to protect patient privacy. We will conduct analysis in a locked office with a password-protected computer. All transcripts and surveys will be deidentified.

Statistical Methods

The planned total sample size is 170 (85 per group), which accounts for participant dropout due to unexpected discharges, changes in clinical status, or study disenrollment. The primary outcome will be measured by the change in baseline observed via the pretest, posttest, and follow-up surveys. Using a 2-sample, 2-tailed *t* test, a total of 154 (77 per group) participants is required to obtain >90% power to detect at least a 10% difference with the most conservative SD of 21% with a 1-sided type-1 error of 5%.

Our team will use the paired, 2-tailed *t* test with a Bonferroni adjustment for multiple comparisons with the usual hospital care and computerized adaptive education groups. We will use one-way ANOVA and chi-square tests to examine the significance between the usual hospital care and computerized adaptive education groups. This will determine whether there is a statistically significant difference between the two groups. We will also determine if the difference between observed and expected data is because of chance or a relationship between the usual health care and computerized adaptive education groups.

Data analysis will take place in an UCMC office. We will continue to monitor patient medical records after the study to determine whether they may be later included or excluded from the study.

Data Tracking

Data will be tracked in Google Sheets, linked to each survey. This will also help identify participant's responses with the date, time, and enrollment number. Study packet responses will be saved in a password-protected box. Retrospective review will also be done to ensure each enrollment number matches the correct medical record number. Our research team will have access to the final trial dataset, and we will keep the data for 5 years after the study is completed.

Ethical Considerations

We obtained institutional review board (IRB) approval for this protocol (IRB 23-0385), and the parent study (the Hospitalist Project) is also IRB approved (IBR 16-1131). Written, informed consent to participate in the Hospitalist Project will be obtained from all participants. Participants will also verbally consent and be enrolled in the I-C-CKD study.

Patients will be informed that the study is completely voluntary and may withdraw at any time. Discontinuation will also occur if patients are in acute distress or experience declining health conditions during hospitalization. For example, if the patient is transferred to intensive care unit, is intubated, or has an altered mental status and can no longer participate, then we will withdraw them from the study. Patients will also be able to meet with patient educator who is a licensed clinical social worker if they are interested in additional information, are under distress, or want posttrial care.

Patients will receive US $25 gift cards upon completion of the pretest and posttest surveys and US $10 for partially completed surveys. All participants will be compensated. This study is minimal risk, as an education intervention is the only experimental procedure involved. Additionally, reports will be made to the IRB in the case of an adverse event, along with any

protocol modifications to the investigators, IRB, trial participants, journals, and regulators.

Results

Recruitment for the I-C-CKD study began May 2, 2023. We are currently recruiting and have enrolled 96 patients who completed both pretest and posttest surveys as of December 2024. This includes 50 patients in the control group and 46 patients in the intervention group. Data analysis has not occurred. We will communicate trial results to trial participants, health care professionals, and the public via a journal publication.

Discussion

We believe our study will result in the computerized adaptive education intervention group experiencing a greater improvement in CKD knowledge, CKD health-seeking behavior, and self-care in comparison to the control group. The goal of this study is to increase hospitalized African American patients' knowledge of CKD and motivation for CKD self-care. We have created and will assess a culturally tailored, computerized adaptive education intervention that expands on the information gathered from in-person interventions. Computerized adaptive education can evaluate patients' concerns and provide personalized education. Customized patient education information is more likely to be recalled and significantly influence a patient's motivation and behavior modification.

African American patients diagnosed with CKD experience inequities in the quality of health education, self-care, and medical treatment for ESKD [13]. Patient education can encourage African American patients with advanced-stage CKD to make informed decisions and take control of self-care and health decisions to delay progression to ESKD. Providing CKD education during hospitalization can address gaps in care to help patients initiate preventative care, plan for future RRT, and build a treatment team that aligns with their health and lifestyle preferences.

This intervention focuses on hospitalized African American patients who represent more than 80% of the general medicine population at our medical center. The intervention is culturally tailored to African American patients. The hospital also serves patients who are not followed by routine medical providers and have trouble accessing outpatient care due to limited transportation, limited or no insurance, mobility issues, and socioeconomic constraints [14]. Hospitalized patients may be more open and responsive to CKD education efforts when they are focused on their health during a hospital stay. The intervention can also link these patients to outpatient care. We will also ask if patients would like a primary care doctor and/or a nephrologist. This information will be relayed to the primary inpatient team.

Limitations of this study include the single-hospital study design, which reduces the generalizability of the results. In addition, we are testing the intervention only among hospitalized African American patients who are generally admitted with urgent or acute health concerns, which may reduce their ability to fully participate or complete this study. An additional barrier for inpatient kidney education to be disseminated on a large scale is that the results may differ among a different group or in a different health care setting.

In conclusion, African American individuals often receive less patient education about self-care and medical treatments for CKD. We hope our study provides one way to reduce this disparity. However, to improve CKD outcomes, African American patients—and all patients with CKD—require frequent, understandable education about CKD across all sites of care.

Acknowledgments

The authors appreciate the faculty and staff of the Hospitalist Project, particularly Ms Neha Khadka, who made this study possible. The study was funded by the National Institutes of Health's National Institute of Diabetes and Digestive and Kidney (R21DK121262). The project is sponsored by the University of Chicago Medical Center's General Internal Medicine department. This research did not receive any specific grant from funding agencies in the commercial or not-for-profit sectors.

Data Availability

The datasets generated or analyzed during this study are not publicly available as data analysis has not occurred at this time but are available from the corresponding author on reasonable request.

Authors' Contributions

MS is the primary investigator. All authors read and approved the final manuscript.

Abstract

Background: Municipalities play a crucial role in population health due to their community connections and influence on health determinants. Community-campus engagement (CCE), that is, collaboration between academic institutions and communities, is a promising approach to addressing community health priorities. However, evidence of CCE's impact on population health remains limited. Measuring the impacts of CCE is inherently complex due to factors such as diverse stakeholders, context-specific variables, and dynamic interactions within a community.

Objective: This study aims to develop robust evidence on the impacts of CCE on population health outcomes in Ottawa and Thunder Bay, Ontario, Canada, focusing on 5 shared health priorities: housing, discrimination, poverty, violence, and mental health.

Methods: We will use a proven CCE model called CityStudio, which has been implemented in both cities. We will use Mayne's mixed methods contribution analysis in three stages: (1) formulating a theory of change that outlines the expected contributions of CCE to population health outcomes; (2) gathering qualitative and quantitative data in line with the established Theory of Change; the data will be collected from various sources, including case studies of existing CityStudio projects, a web-based CCE stakeholder survey, a literature review, and population and community health data; and (3) reviewing the gathered evidence to determine the extent of CCE impacts on population health.

Results: Ethical approval for this project was granted in May 2023. We have since initiated stage 1 by reviewing the literature to inform the development of the theory of change. We expect to complete this study by May 2026.

Conclusions: This study will address two critical gaps about how improving health outcomes depends on CCE: (1) how academic institutions can best engage with their communities to improve population health outcomes, and (2) how municipalities can engage with academic institutions to address their community health priorities. Conducting our work in differing contexts will allow us to consider a broader range of other influences on outcomes, thus making our work applicable to various settings and outcomes.

Introduction

Background

Achieving improved population health outcomes requires a comprehensive, multisectoral approach beyond healthcare [1-3]. With their robust community ties and influence over various health determinants, municipalities are well-positioned to drive progress [1-3]. In Canada, local governments and community partners often identify their communities' priority health needs through established safety plans or social policy frameworks [3]. These needs are expressed in Ontario, the country's most populous province, through provincially mandated Community Safety and Well-Being Plans (CSWBPs) [4]. Updated every 4 years, these plans serve as strategic roadmaps, guiding municipalities' efforts to improve population health outcomes [4,5].

Collaborations between municipalities and their local academic institutions have the potential to contribute positively to the health of the local community [6-9]. Through collaborative efforts, community-campus engagement (CCE) fosters mutually beneficial relationships between local stakeholders (eg, community organizations, city representatives, and residents) and academic institutions (eg, universities and research centers) [6-8]. Municipalities can contribute their deep understanding of local needs and priorities to such engagement, while academic institutions provide research expertise and resources [6,8,10]. This collaborative framework facilitates shared decision-making, efficient resource allocation, and the development of tailored strategies to directly address specific health concerns within the community, ultimately leading to improved health outcomes [6,10].

CCE can take various forms, such as community-based research and service learning [6,10]. Community-based research involves collaboration between faculty members, students, and local communities to address critical issues [6,10]. On the other hand, service-learning integrates classroom learning with community service, equipping students with the skills to tackle real-world challenges while also improving their communities [6,10]. Each form can potentially contribute to the community's health in different ways. For instance, community-based research can identify emerging health disparities in specific neighborhoods, while service-learning programs can equip future health care professionals with the skills to address these issues.

While CCE shows promise in supporting municipalities' health agenda goals, there remains significant uncertainty about the specific mechanisms and pathways through which it influences population health outcomes, underscoring the need for further research to understand its impact at the municipal level [11]. Existing literature in this area is mainly reflective [12,13] or qualitative [14,15], primarily focusing on health outcomes resulting from individual partnerships [16-19] and the perspectives of faculty and students involved in CCE [10,14,20,21]. Although these studies provide valuable insights, they offer only a partial understanding of CCE's broader impact on population health because they do not fully investigate the pathways, conditions, and contextual factors that influence outcomes.

Some studies have reported positive health outcomes, such as reduced substance misuse [16] and increased physical activity [17]. However, these studies often fail to clearly outline the change processes that explain these positive outcomes, focusing mainly on end results. This emphasis on outcomes, with insufficient attention to the processes, limits our understanding of how specific actions, stakeholder interactions, and contextual factors contribute to health improvements. Consequently, the complexity of the mechanisms driving these changes remains underexplored, making it difficult to pinpoint the pathways through which CCE initiatives achieve their impact. This knowledge gap highlights the need for more robust research to evaluate the impact of CCE on population health at the municipal level that specifically focuses on the contexts and mechanisms that result in change.

Contribution Analysis: a Promising Approach for Evaluating the CCE Impacts

As with community engagement in general, the complexity of measuring CCE impacts on population health makes experimental approaches to measuring CCE impacts neither practical nor feasible, as many factors cannot be controlled for [22], such as the involvement of diverse stakeholders with diverging interests (eg, local governments, faculty and students, community groups) [15,23,24], the evolving dynamics of operations [25], and the influence of external factors like governmental policies and local socioeconomic conditions [15,26,27]. Experimental approaches may thus overlook the underlying causes of an intervention's success or failure, providing limited insights into the causal mechanisms at play [28,29].

Contribution analysis is a theory-based impact evaluation approach that is particularly suited to contexts of high uncertainty, where the goal is not to prove causation definitively but to reduce uncertainty by establishing a plausible association between interventions and outcomes [28-32]. This emphasis on reducing uncertainty makes CA particularly suitable for evaluating the CCE impact on population health [11].

An integral component of contribution analysis is the theory of change, which outlines the causal mechanisms in a results chain running from inputs to impact and illustrates how the intervention being examined is expected to bring about change [31]. However, the theory of change goes beyond a standard results chain or logic model by elucidating assumptions, risks, unintended effects, and other vital factors underpinning the relationships [30,31].

Narrative statements, known as contribution claims, are generated once the theory of change has been developed [32]. These claims are presented as hypotheses, proposing how the intervention's activities and outputs contribute to the observed outcomes while considering influencing factors and context [30]. The theory of change and contribution claims are refined and validated iteratively using qualitative and quantitative data and stakeholder participation [22,32]. This process alternates between theory development and empirical testing, resulting in a robust, evidence-based theory of change [30]. The ensuing theory is the foundation for the contribution story, which offers a detailed account of the intervention's impact and the stakeholders' perspectives [33].

Contribution analysis may be carried out at 3 levels: minimalist, direct influence, and indirect influence, each tailored to the complexity of the intervention and the depth of the assessment [22]. Minimalist contribution analysis is ideal for interventions with clear, measurable outcomes. It formulates a theory of change, confirms output delivery, and validates contribution claims using existing data and evidence [22,32]. Direct influence contribution analysis is suitable for complex interventions with diverse outcomes, as it builds on minimalist analysis by using empirical data to confirm the intervention's contribution to the impact [22]. Indirect influence contribution analysis, suitable for complex interventions with uncertain, emergent outcomes, builds on direct influence analysis by further testing contribution claims against alternative explanations, offering a more comprehensive understanding of what caused an observed impact [31,32].

Objective

This research project uses contribution analysis to rigorously assess and reduce uncertainty about whether, how, and to what extent CCE has contributed to improving population health in Ottawa and Thunder Bay, Ontario, Canada. The study will focus on 5 specific shared population health priorities for both municipalities: housing, discrimination, poverty, violence, and mental health. Our specific objectives are as follows.

- Identify and outline the key mechanisms and processes through which CCE is anticipated to impact population health outcomes in Ottawa and Thunder Bay.
- Assess the extent to which CCE has contributed to the targeted population health outcomes, evaluating their impact against the mapped mechanisms and processes.

Methods

Study Setting

Our study will be conducted in Thunder Bay and Ottawa, 2 Ontario municipalities with medical schools and health education institutions. These cities have developed CSWBPs by reviewing local data comprehensively and holding community consultation sessions to identify their population's unique needs and characteristics [34,35]. Despite differences between the Ottawa and Thunder Bay CSWBPs, both cities have identified 5 similar priorities related to population health, as outlined in Table 1.

Table 1. Shared priorities in the Thunder Bay and Ottawa Community Safety and Well-Being Plans.

Priority areas	Description
Housing	Ensuring all residents have access to safe, affordable, and suitable housing.
Discrimination	Addressing systemic issues perpetuating discrimination, marginalization, and racism within the community.
Poverty	Achieving financial security and reducing poverty for community members.
Violence	Preventing and reducing gender-based violence and violence against women in the community.
Mental health	Promoting positive mental health and well-being for all community members.

To help address these priorities, both municipalities have adopted CityStudio, a transferable, nonprofit, project-oriented, evidence-based model of CCE [36,37]. This model aims to innovate how cities are co-created to become healthier communities and assist community stakeholders in improving their neighborhoods [38]. The model is demand-driven, leveraging expertise and resources from educational institutions to meet the priority needs identified by the city. The CityStudio project cycle encompasses 5 stages, from initial collaboration for project development and confirmation through work on a real site to final project design for scalability [36].

The cities of Ottawa and Thunder Bay have formally launched CityStudio and initiated and completed various projects. To date, 63 projects have been carried out involving community groups, city staff, and faculty and students from 6 academic institutions in these regions. CityStudio Ottawa and CityStudio Thunder Bay are engaged in this research study, providing full access to a list of stakeholders involved in their projects and data on an inventory of CCE projects.

Study Design

We will apply Mayne's contribution analysis within a convergent parallel mixed methods design to assess the contribution of CCE to population health in Ottawa and Thunder Bay [39]. A convergent parallel design allows for the simultaneous collection and independent analysis of both qualitative and quantitative data, with results from each strand analyzed for congruence and integration during the interpretation phase [40]. Mayne's approach is particularly suited for complex interventions such as CCE and has been effectively used in assessing the impacts of interventions and policies in fields such as international development [41] and public administration [42]. However, our recent scoping review suggests that this approach is infrequently applied in health-related interventions [43]. Therefore, our research aims to both generate rigorous

evidence of CCE's impact on health and provide valuable insights for using contribution analysis in health research and evaluation.

The following preliminary evaluative questions will direct our analysis. These questions will be refined further upon the completion of stage 1.

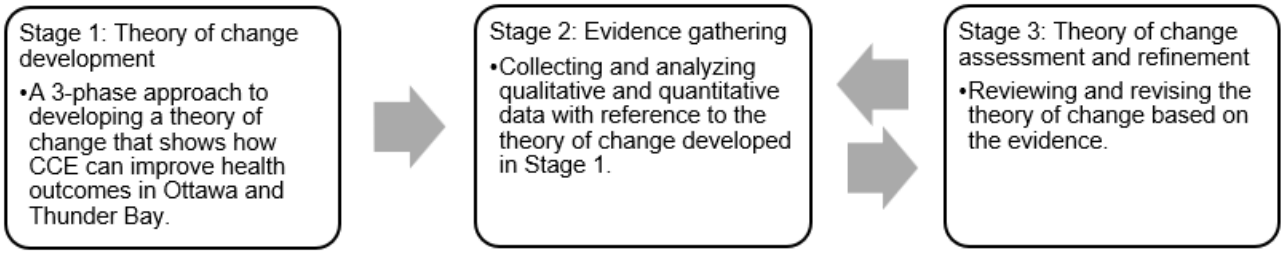
- What are the specific mechanisms and pathways by which CCE influences population health outcomes in Ottawa and Thunder Bay?
- To what extent does CCE contribute to changes in population health outcomes relative to other factors in both cities?

We will specifically use the cause-to-effect strategy, which begins with CCE and works forward to understand how it contributes to health outcomes. The cause-to-effect strategy focuses on identifying "causal packages"—combinations of CCE activities and other contributing factors that collectively explain the observed changes [44]. We will adopt a streamlined version of Mayne's 6-step approach to contribution analysis, condensing it into the 3 crucial stages described by Delahais [30]. The 3 stages are as follows.

- Stage 1—theory of change development: This stage involves using a 3-phase approach to developing a robust theory of change that accurately represents the potential pathways and external factors describing how CCE is expected to contribute to improved population health outcomes in Ottawa and Thunder Bay. This stage is expected to last 7 months.
- Stage 2—evidence gathering: Both qualitative and quantitative methods are used to generate evidence in line with the established theory of change. The collected evidence forms the basis for empirical examination. This stage is expected to last 11 months.
- Stage 3—theory of change assessment and refinement: This stage involves reviewing the gathered evidence to determine the extent of CCE impacts on population health. Any identified limitations lead to a return to stage 2 for additional data collection until satisfactory evidence is gathered. This stage is expected to last 5 months.

Figure 1 provides a visual overview of the research process, illustrating the dynamic relationship between data collection (stage 2) and theory testing (stage 3) [30].

Figure 1. Overview of the research process. CCE: community-campus engagement.



This study adheres to the Good Reporting of A Mixed Methods Study (GRAMMS) guidelines [45] to ensure comprehensive and transparent reporting of the mixed methods design, including the justification for the approach, the integration of qualitative and quantitative data, and the insights gained from their convergence (Multimedia Appendix 1).

Stage 1: Theory of Change Development

Overview

Stage 1 will use a 3-phase approach to construct a credible theory of change. Each phase corresponds to one of the approaches proposed by Funnell and Rogers [46] for purposeful theory development: (1) deductive, (2) articulation of mental models, and (3) inductive, which will be implemented sequentially in the theory of change development process, with the potential for iteration to accommodate evolving requirements. An overview of each phase and corresponding methods is presented in Table 2. While our approach follows a structured sequence, we acknowledge that the evolving nature of developing a theory of change requires flexibility, allowing for iteration as needed. Each step of the theory of change development will be carefully documented to maintain transparency in this iterative process. This includes tracking the initial assumptions, the evolution of claims based on stakeholder input and empirical evidence, and the methodological adjustments made throughout the process. The documentation will highlight how and why specific claims were refined, discarded, or validated, ensuring that the process remains transparent and aligned with best practices in contribution analysis.

Table 2. Overview of the study's 3-phase approach to developing the theory of change.

Phases	Description	Proposed methods
Phase 1: Deductive	Draft an initial theory of change based on existing theories and knowledge.	Conduct a narrative literature review on the health impacts of CCE[a], focusing on the 5 shared Ottawa and Thunder Bay priorities.
Phase 2: Mental model articulation	Express the implicit assumptions or mental models of stakeholders.	Hold stakeholder workshops to provide feedback on the drafted theory of change and identify context-specific factors influencing outcomes.
Phase 3: Inductive	Validate and refine the theory of change using practical insights and external expertise.	Conduct semistructured interviews with experts in CCE and program evaluation for validation and refinement.

[a]CCE: community-campus engagement.

Phase 1: Deductive

Phase 1 uses Funnell and Rogers' deductive approach [46] to formulate an initial theory of change based on existing theories and knowledge, ensuring a solid theoretical foundation. To accomplish this, we will conduct a narrative literature review chosen for its flexibility and capacity to identify critical theories, concepts, and findings related to CCE and its impact on population health concerning the five identified areas of population health [47]. The results of this review will lay the groundwork for the development of the theory of change, as detailed in the subsequent sections.

Narrative Literature Review Procedures

In collaboration with a librarian, we will design and execute a comprehensive search strategy that encompasses relevant health databases and sources. The selected literature will be imported into Covidence (Veritas Health Innovation Ltd), a web-based literature review tool, for screening by independent reviewers [48]. At least 3 research team members will review various sources, including academic papers, reports, and policy documents, to inform the initial development of the theory of change. Screening criteria will include relevance to the 5 key population health priorities and use for the theory of change.

Team members will create an annotated bibliography for each paper using a standardized template based on Bennett's hierarchy [49], a framework that categorizes program outcomes (inputs, activities, outputs, and impacts) [50]. The template will be divided into three sections: (1) CCE implementation, focusing on inputs, activities, participation, and reactions; (2) knowledge and practice change, focusing on knowledge, awareness, skills, attitude, and practice change; (3) results and impact, focusing on final health impacts or changes for individuals, communities, systems, or organizations. Team members will hold weekly meetings to share insights from the literature and discuss potential pathways.

Development of the Initial Theory of Change

Following the literature review, team members will convene to create the initial theory of change using Vogel's team-based approach, which is specifically designed to develop theories of change for research projects. This approach includes guiding questions on 5 key areas: context analysis, long-term change, sequence of events, assumptions, and diagram and narrative summary [51]. To document decisions and track modifications, the team will use Theory of Change Online 3.0 (ActKnowledge), a web-based software designed explicitly for the collaborative theory of change building [52]. This initial theory of change will remain adaptable, allowing for iterative revisions based on feedback and new data. Once the initial draft of the theory of change is completed and agreed upon, the team will proceed to the mental model articulation phase.

Phase 2: Mental Model Articulation

In phase 2 of the theory of change development, we will use Funnell and Rogers's mental model articulation approach [46]. This approach will help us integrate stakeholder insights, ensuring they are context-specific, comprehensive, and account for relevant influencing factors. To achieve this, we will conduct participatory workshops with stakeholders involved in CCE through CityStudio Ottawa and Thunder Bay [53,54].

Recruitment of Stakeholders

We will use a purposeful sampling strategy to invite stakeholders based on specific criteria such as their location (Ottawa and Thunder Bay), experience with CCE, stakeholder roles (academics, community partners, and city staff), and knowledge related to the 5 shared population health priorities. This approach will ensure a diverse representation of stakeholders, balancing their professional backgrounds, geography, and CCE experience. [55].

Our initial outreach will target CityStudio Ottawa and CityStudio Thunder Bay stakeholders who expressed interest in our workshops during 2 information sessions held in May 2023, which aimed to gather feedback on the proposed protocol and identify potential workshop participants. The participants will include academics, community partners, and city representatives involved in CCE who expressed interest and shared their contact details through a web-based survey during their participation in the information session.

We will engage CityStudio coordinators in Ottawa and Thunder Bay if additional participants are needed. They will circulate an invitation email to their contact lists, which include a broader network of individuals involved in CCE. The email will provide information about the project, the purpose of the workshops, and the importance of their participation. All participants will be asked to sign a consent form before their involvement.

Stakeholder Workshops Procedures

We plan to conduct 2 separate workshops conducted via Zoom. The first workshop will assemble 10-12 stakeholders from Ottawa, and the second will gather a similar group from Thunder

Bay. Each workshop, lasting 3 hours, will be divided into 2 parts.

- Introduction and overview: We will provide essential details about contribution analysis and the theory of change. We will then present an overview of our draft theory of change and explain the process used to develop it.
- Feedback and identification of context-specific factors: We will use Kranias' participatory facilitation techniques [56] to collect feedback on the plausibility of our initial theory of change and, for each city, identify the roles of other influencing factors and alternative explanations that could affect the theory of change's impact pathways. To identify specific contextual factors with participants, we will use the classification of Pawson et al [57], which divides these factors into 4 categories: individual, interpersonal, institutional, and infrastructure. This classification has proven helpful for identifying contextual factors in a workshop setting in previous applications of contribution analysis [50,58]. This classification and stakeholder input will be revisited iteratively as needed, ensuring the theory of change remains aligned with emerging contextual insights.

At least 2 research team members will facilitate each workshop, following a facilitation guide based on Vogel's approach [50]. With participant consent, workshops will be recorded for review purposes. Workshop participants will receive CAD $100 compensation (approximately US $71 at the exchange rate at the time of the study: CAD $1=US $0.71) for their time and contribution and a summary of the key outcomes and changes made to the theory of change for validation.

Phase 3: Inductive

Phase 3 involves assessing the theory of change's coherence, logic, and theoretical foundations and identifying potential gaps or areas for enhancement. Following Funnell and Rogers [46], we will conduct semistructured interviews with experts. This method is particularly effective for gathering in-depth, expert-based insights, which will be instrumental in refining our theory of change and ensuring its robustness and relevance.

Recruitment of Experts

We will use a snowball sampling strategy to identify 5-6 experts in population health, CCE, and theory-based evaluation. Our research partners will provide us with a list of potential interviewees. These individuals will receive an invitation via email, including a detailed description of the study and their expected participation. Before participating, they must sign a consent form and declare no conflict of interest. Each expert will be compensated CAD $150 (US $105.87) for their time.

Data Collection and Analysis

We will send a documentation package to the experts for review 3 weeks before the interview. This package will include the drafted theory of change and its narrative, the development process used, and an assessment grid based on Mayne's validated criteria for an in-depth theory of change analysis [31]. The assessment grid will contain questions to assess the overall logic and structure of the theory of change, the clarity of its expected outcomes, the validity of its assumptions, and the independence of assumptions for each causal link [31]. A research team member will contact the experts to ensure they understand the documentation and answer any questions.

The semistructured interviews will combine structured questions from the assessment grid with open-ended questions for comprehensive feedback [53]. To avoid potential bias, the interviews will be conducted by research team members who were not involved in the theory of change development process. During the interview, we will collect their comments and suggestions. All interviews will be recorded for accuracy.

Formulation of Contribution Claims

Upon completion of the interviews, we will collate and discuss the differences and similarities between the reviewers' assessments and the feedback received. Based on their suggestions, we will adjust the theory of change and formulate initial contribution claims. As mentioned, these claims are narrative statements derived from the theory of change that articulates the anticipated pathways through which CCE is expected to improve population health outcomes in the specific contexts of Ottawa and Thunder Bay [30]. The initial theory of change and contribution claims developed during this phase are considered provisional. As new evidence is gathered and stakeholder insights are integrated, these claims will be iteratively refined. This flexibility is essential to capturing the complex and context-specific pathways through which CCE impacts population health. We will proceed to the second stage of the study once we reach a consensus that the theory of change and the generated contribution claims are sufficiently articulated, credible, plausible, and logical.

Stage 2: Evidence Gathering

Overview

In this stage, we will use a mixed methods approach to gather substantial evidence that will be used to examine the theory of change and the associated contribution claims developed in stage 1 [30]. The evidence-gathering process is designed to be adaptive. If emerging data suggest new pathways or causal mechanisms, earlier stages may be revisited, and claims adjusted accordingly. This iterative approach ensures that the contribution claims remain aligned with the evolving evidence base. We will create a data collection plan to identify specific indicators, data sources, and methods for examining each contribution claim and its assumptions. The plan will identify at least three evidence sources for each claim, using Delahais' triangulation approach [30] for validation, to allow examination from multiple perspectives.

Data Collection

We will collect qualitative and quantitative data from various sources: (1) case studies, (2) a web-based stakeholder survey, (3) pathway-specific literature review, and (4) population and community health data. Flexibility in data collection will be maintained by revisiting or expanding data sources as necessary, based on initial analyses or gaps identified during triangulation. Table 3 provides an overview of the data sources and their respective aims.

Table 3. Overview of data collection and sources for stage 2.

Data collection	Aim	Data sources
Case studies	Examine the impact of existing CCE[a] projects with high potential for positive health outcomes in Ottawa and Thunder Bay on the 5 population health outcome areas.	Interviews and document reviews from appropriately 30 CityStudio projects.
CCE Health Impact Survey	Identify the perceived health impacts of CCE projects not selected for case studies.	A web-based survey for stakeholders involved in or impacted by CCE projects through CityStudio Ottawa and CityStudio Thunder Bay.
Pathway-specific literature review	Assess the evidence for CCE's impact on population health outcomes.	Peer-reviewed research and evaluation literature related to health outcomes in CCE.
Population and community health data	Identify trends in disparities to understand CCE's impact on health outcomes.	Data from Community Safety and Well-Being Plans of Ottawa and Thunder Bay and other health indicators.

[a]CCE: community-campus engagement.

Case Studies

Aim

Case studies involve a detailed examination of a selection of CCE projects with the most significant potential to positively influence Ottawa and Thunder Bay health outcomes. They can provide evidence on the theory of change and have often been used in contribution analysis to understand the factors contributing to intervention success or failure in different contexts [46,50].

Case Selection

We will collaborate with CityStudio Ottawa and Thunder Bay coordinators to identify and rank approximately 15 CCE projects from each city with the most promise for positively impacting at least one of the shared population health priorities. We aim to have at least 1 case study for the 5 health priorities. We will create a checklist based on a review of existing tools and measurement instruments to evaluate projects on successful engagement, possible health impact, and data reliability and accessibility. The final selection of projects will be determined through group consensus using the checklist. The rationale for each selection will be documented in a report for transparency and accountability. The case study pool may be expanded or adjusted accordingly if new CCE projects emerge during data collection that shows high potential for positive outcomes.

Data Collection Tools for Case Studies

As suggested by Yin [59], we will use 2 sources to enhance the rigor of case studies: semistructured interviews and organizational documents.

Semistructured Interviews

We will conduct semistructured 1-hour interviews with key stakeholders in each selected case using an interview guide based on the components of our theory of change. Each interview will focus on uncovering the initiative's perceived impacts, foundational mechanisms, and broader outcomes. We will record each interview and take notes during the interviews. Participants will be asked to sign a consent form before the interview and receive CAD $25 (US $17.64) compensation for their contribution. The interviews will be transcribed, with copies uploaded to a secure database in PDF format.

Project Document Review

Our study team will review documents related to selected CityStudio projects, such as project descriptions, monitoring and evaluation reports, output reports, progress reports, and annual reports. We will obtain project documentation from our research collaborators, CityStudio Ottawa and CityStudio Thunder Bay. This review will help us identify expected activities, outputs, and outcomes and provide insights into the strategies used, challenges encountered, and the overall progress and impact of the projects. The total number of documents we will review will depend on the number of projects and their complexity. However, we aim to review as many relevant documents as possible to understand the projects comprehensively. All project documentation will be securely stored for future reference and analysis.

CCE Health Impact Survey

Aim

The CCE Health Impact Survey is designed to collect insights from diverse stakeholders involved in or impacted by CCE projects in Ottawa and Thunder Bay. The survey aims to understand potential health outcomes related to housing, discrimination, poverty, violence, and mental health.

Sampling Strategy

We plan to gather data from individuals who have actively participated in or been affected by projects from CityStudio Ottawa or CityStudio Thunder Bay. Individuals must not be case study participants to be eligible for the survey. They must also belong to one of the following stakeholder groups: students, faculty or researchers, city representatives, or community members. If survey participation is lower than expected or new stakeholder groups are identified, the sampling strategy may be adjusted to ensure comprehensive data collection.

Potential participants will be selected for our survey through convenience sampling. The CityStudio coordinators from Ottawa and Thunder Bay will email these individuals, outlining the project's objective and emphasizing the importance of their participation. Before participating in the survey, individuals must complete a consent form.

The recruitment for the survey will conclude once we have received a sufficient number of completed surveys to ensure

robust statistical analysis. The exact number will be determined using the Cochran formula [60], which accounts for a 95% CI and a 5% margin of error. Additionally, we will aim to ensure a diverse and representative sample by including participation from each stakeholder group and maintaining balanced representation from both cities.

Measures

The survey will consist of 3 sections. The first section will collect details about the respondents' involvement in the CCE project, such as their role, duration of participation, and affiliation with the organization. The second section will delve into the specifics of the CCE project, including its objectives, the strategies used for its implementation, the deliverables, and the stakeholders involved. The final section will focus on the perceived health impacts of the CCE project. Respondents will be asked to share their observations and experiences and to report any noticeable changes they have observed in 5 key areas: housing, discrimination, poverty, violence, and mental health.

Before launching the survey, we will conduct a pretest with potential participants from all targeted groups to ensure its clarity and relevance. The survey will include Likert scales and open-ended questions, and we anticipate it will take approximately 15 minutes to complete. Participants will receive a CAD $25 (US $17.64) compensation upon completion.

Pathway-Specific Literature Review

Aim

We will synthesize peer-reviewed literature to evaluate the significance and evidence level for each pathway in the theory of change. This will help us understand how these pathways influence the impact of CCE on population health outcomes. Our process will include an analysis of studies that have investigated similar pathways. We will scrutinize their methodologies, findings, and conclusions and assess the overall robustness and limitations of the existing literature. The literature review process will be iterative, allowing for additional rounds of review if new gaps or needs are identified during data collection or analysis. The review procedure for pathway-specific literature will adhere to the guidelines for the narrative literature review outlined in stage 1.

Population and Community Health Data

Aim

We will collect health data to evaluate the impact of CCE on health outcomes in Ottawa and Thunder Bay. This will include information on health behaviors, outcomes, access to health care services, and social determinants of health. By examining population characteristics, health measures, and factors influencing health outcomes, we aim to understand how CCE affects immediate and downstream health outcomes. We will also draw on indicators, results, and performance measures developed and tracked by the municipal CSWBP teams. Domains of eligible indicators include (1) socioeconomic environment (income, social support, education, and employment); (2) physical environment (green space, air quality, housing, and transportation); (3) healthy child development (birth weight, immunization, and early development indicators); (4) health behaviors (smoking, substance use, diet, and physical activity); (5) individual capacity and coping skills; (6) biology and genetic endowment; (7) health services; and (8) sociodemographic environment (culture, race or ethnicity, and sex or gender).

Data Analysis Approach

Our data analysis approach involves qualitative and quantitative analysis, followed by aggregation.

Qualitative Data Analysis

At least 2 research team members will perform a thematic analysis of project documents and semistructured interviews. We will adhere to the 6-step thematic analysis coding framework proposed by Braun and Clarke [61], which includes (1) familiarization of data, (2) generation of codes, (3) combining codes into themes, (4) reviewing themes, (5) determining the significance of themes, and (6) reporting of findings [57]. The thematic analysis will be conducted iteratively, allowing for additional rounds of coding and theme development if new insights or patterns emerge. For example, if initial analysis reveals unexpected causal pathways or unanticipated factors, further in-depth analysis will be conducted to explore these themes. We will focus on identifying linguistic indicators of change or cause-effect relationships in interviews using Nour et al's argumentative discourse analysis [62]. This process entails a detailed examination of specific linguistic markers such as "it is obvious/clear that" and "compared to." These markers serve as indicators of patterns or relationships in the data. We will use NVivo software (Lumivero) [63] for data organization and analysis.

Quantitative Data Analysis

We will collect quantitative data from CityStudio projects, the CCE Health Impact Survey, and existing, deidentified publicly available population and community health indicators. We will use descriptive and appropriate inferential statistical analysis using statistical software (STATA version 14.2, StataCorp LLC) [64] to describe and analyze patterns, relationships, and impacts pertinent to the contribution pathway.

Aggregation of Evidence

We will use Delahais and Toulemonde's Evidence Analysis Database [32] to combine, examine, and summarize the evidence gathered for our theory of change and the contribution claims and related assumptions or risks associated with it. Triangulation will be conducted iteratively, allowing for the inclusion of new evidence sources or reexamination of previously collected data if discrepancies are identified during the analysis. The database will be structured as a digital spreadsheet, with each row corresponding to a piece of evidence linked to a specific contribution claim from our theory of change. For each piece of evidence, we will record the following details: label (an identifier for the evidence), statement (a brief description of the evidence), data source (case studies, CCE Health Impact Survey, pathway-specific literature review, and population and community health data), type of evidence (primary or secondary), interpretation (confirming or refuting the claim), strength of evidence (rating of the evidence's strength and

justification), and comments (additional notes or observations about the evidence or implications based on the city).

Stage 3: Theory of Change Assessment and Refinement

Overview

In this stage, our objective is to assess and refine the contribution claims formulated from our theory of change based on the evidence gathered and analyzed in the preceding stage. To ensure a rigorous assessment, we will adopt Downe's approach [65] of using an independent review panel, consisting of experts recruited in the inductive phase of the theory of change development (stage 1). If those experts are unavailable, we will use a snowballing strategy to find other relevant experts.

Review Panel Procedures

We will send a review package to the experts 3 weeks before the panel meeting. This package will include the draft theory of change and its narrative, the development process used, and an assessment grid for the contribution claims. The number of claims will be determined based on the theory of change. The assessment grid will contain questions to assess the plausibility and strengths of these claims, along with the overall logic and structure of the theory of change. A research team member will contact the experts to ensure they understand the documentation and answer any questions they may have. Workshop participants will be asked to sign a consent form and will receive compensation of CAD $200 (US $141.15) for their time.

The panel meeting will last 4 hours and will be facilitated by 2 research team members who were not involved in data collection and analysis. It will be divided into 2 parts.

- Introduction and question-and-answer: Panel members will receive presentations from the research team on the methods and contribution claims, followed by a question-and-answer session where they can ask for clarifications or additional information about the presented materials.
- Assessment: Panel members will be invited to share their feedback on the contribution claims and rate them by consensus according to their plausibility and rigor on a scale from 1=very weak to 4=very strong. They will use the aggregated data in Delahais and Toulemonde's Evidence Analysis Database [32] to verify the coherence of the contribution claims by contrasting both qualitative and quantitative data collected on them. Contribution claims with low scores will be used to prompt panel members for additional information sources. This feedback leads to another round of targeted data collection using data sources described in phase 2, ensuring our findings are reliable, accurate, and context specific.

Refinement and Reporting

After the panel meeting, the research team will compile a detailed report that includes the theory of change, the supporting evidence, and the panel's ratings and feedback. By documenting the evidence and the narrative of how it substantiates the theory of change, along with the expert panel's evaluations, this report aims to present a comprehensive and credible account of the contribution story. The report will also highlight the iterative nature of the process, documenting how contribution claims were progressively refined, validated, or adjusted based on new evidence. This transparency in the evolution of claims is crucial for demonstrating the credibility and robustness of the evaluation findings.

Ethical Considerations

This study adheres to the ethical guidelines and principles relevant to human research. It has been granted ethical approval by the Bruyère Research Ethics Board (M16-23-009) on May 4, 2023. Ethical approval for our site in Thunder Bay is currently pending, and as such, no data will be collected at the site until we receive the necessary approval. This research is supported by the Canadian Institutes of Health Research (PJT-180529). All participants will provide written informed consent after being fully informed of the study's purpose, procedures, potential risks, and their right to withdraw at any time without consequence. Identifiable information will not be disclosed in study publications or presentations. Our approach to compensation is described in the Method section.

Results

Our study is in the second stage, focusing on evidence gathering. We anticipate study results will be available by the end of May 2026. The findings will provide insights into the impact of CCE initiatives on population health in Ottawa and Thunder Bay, contributing to the broader understanding of these complex relationships.

Discussion

Expected Findings

CCE is increasingly recognized for its potential to address local health needs. However, a more rigorous and precise understanding of its impact on population health is needed. This research uses a 3-stage, convergent parallel mixed method design combined with contribution analysis to provide robust evidence on how CCE has improved population health in Ottawa and Thunder Bay, 2 distinct settings in Ontario, Canada. The study will provide evidence for CCE's impact on 5 shared population health priorities for both municipalities: housing, discrimination, poverty, violence, and mental health. By focusing on reducing uncertainty and disentangling the complex interactions among contributing factors, our study will provide a clearer and more nuanced understanding of how and under what conditions CCE contributes to these health outcomes. This approach goes beyond simply assessing whether CCE has an impact and delves into the mechanisms, contexts, and pathways through which these contributions occur.

While Mayne's approach has been effectively used in assessing the impacts of interventions and policies in fields such as international development [32] and public administration [39], its application in health research is less explored. Our study aims to generate rigorous evidence of CCE's impact on health and provide valuable insights for applying contribution analysis in health research and evaluation. Our protocol ensures robust findings using 3 triangulation types: data triangulation using a mixed methods approach, analyst triangulation by involving various members of the research team and stakeholders in all 3

stages of the study, and external validation for an objective evaluation of our theory of change and contribution story. This ensures reliable and context-specific results.

The implications of these findings are substantial. Policy makers will be equipped with evidence-based insights that can be used to refine community engagement strategies and optimize resource allocation for improved population health outcomes. Health education institutions can leverage these insights to strengthen their community engagement endeavors, enrich curricula, and demonstrate their commitment to social accountability. Furthermore, communities will gain invaluable evidence for a scalable CCE model that can be applied across diverse settings.

While this study focuses on CCE initiatives in Ottawa and Thunder Bay, the findings are intended to be transferable to other contexts. By identifying common configurations, mechanisms, and contextual factors that contribute to health outcomes, this study offers insights that can be adapted and tested in different settings. For instance, understanding the conditions under which CCE initiatives are most effective can inform similar efforts in municipalities with comparable socioeconomic conditions or health challenges. The transferability of findings will be discussed in detail, emphasizing the specific aspects of the intervention that may be generalizable across contexts.

Limitations

The precision of our analyses may be constrained by the challenge of obtaining high-quality data for CCE projects. Contribution analysis is relatively novel, adding complexity to our study. Stakeholder participation in participatory research presents challenges such as ensuring effective communication, equitable authorship access, and fair compensation mechanisms. The potential for participant bias exists, which could affect data objectivity but will be mitigated by maintaining neutrality during data collection and analysis and providing clear study guidelines to participants. Another limitation is the dependence on perceived outcomes and correlational relationships, which will be addressed through triangulation methods involving multiple data sources to cross-verify findings and provide a comprehensive understanding of impacts.

Conclusions

This protocol outlines a novel approach to assessing the impact of CCE on Ottawa and Thunder Bay population health. The study aims to provide robust evidence on how CCE contributes to population health improvements by using a convergent parallel mixed methods design and contribution analysis. The study's findings are expected to fill critical knowledge gaps regarding the specific pathways, configurations, and contextual factors that influence CCEs. These insights will be valuable for policy makers, health education institutions, and communities seeking to optimize their engagement strategies. Despite the limitations, such as geographical scope and potential participant bias, the iterative, flexible, and rigorous design enhances the reliability and applicability of the findings. The research team anticipates that the findings will validate and refine the contribution claims derived from the theory of change and guide future research and interventions in community engagement and health. This study represents a significant step forward in understanding and harnessing the potential of CCE in improving population health.

Abstract

Background: The centralization of decision-making power in the public health care system has a negative impact on the practice of professionals and the quality of home care services (HCS) for seniors. To improve HCS, decentralized management could be a particularly promising approach. To be effective, strategies designed to incorporate this management approach require attention to 3 elements: autonomy of local stakeholders, individual and organizational capacities, and accountability for actions and decisions. Not many studies have focused on strategies for integrating decentralized and collaborative management at the local level in HCS.

Objective: The overall aim of this study is to coconstruct HCS management strategies and explore decentralized practices in the day-to-day work of low-level managers and professionals. The specific objectives, in collaboration with local HCS stakeholders, are to (1) identify concrete and achievable strategies for decentralized management, and (2) describe factors (facilitators and obstacles) that could potentially influence their integration.

Methods: This participatory action research involves a cyclical process. Before initiating the cycles, a preliminary stage consists of forming a steering committee composed of managers (n=3), professionals (n=3), seniors (n=3), informal caregivers (n=3), and the research team (n=3). This committee will facilitate multistakeholder consultation to coconstruct local management strategies based on a real-life problem identified by the committee. The steering committee will also guide the research process. The first cycle will consist of establishing an initial plan of decentralized management strategies. During the observation phase, meetings of 4 homogeneous focus groups, including managers, professionals, seniors, and informal caregivers, will be held. During the reflection phase, a thematic analysis will be carried out, and data will be interpreted and validated by the steering committee. Then, in the action phase, results will be presented to managers and professionals so that they can coconstruct a plan of decentralized management strategies to prioritize. The second cycle will explore the factors involved. The observation, reflection, and action phases will be repeated. Ultimately, the results of the 2 cycles will be integrated in a model coconstructed by the steering committee.

Results: Data collection is in progress; the partnership officially began on February 1, 2024, and the plan is to continue data collection through 2025. The steering committee will validate the data to ensure that they are accurate and that the results reflect the reality of local stakeholders.

Conclusions: By identifying decentralized and collaborative management strategies at the local level as well as factors to facilitate their integration in HCS, this approach can be used for other decentralized management projects in different areas of the health care system. This study will give decision makers insight into strategies aimed at improving the management of their institution, which will enhance seniors' well-being and the quality of their health care services.

Introduction

Background

Over the past 4 decades, health care systems in most countries have been reshaped by reforms based on new public management (NPM) [1]. NPM aims to improve the effectiveness, efficiency, and quality of services by focusing on results-based management and cost control [2]. Inspired by NPM [3,4], the last 2 health and social service reforms in the Canadian province of Québec made a shift toward the centralization of management practices [5,6]. With the aim of improving health system performance, the 2003 [7] and 2015 reforms [8,9] gradually concentrated decision-making power, responsibilities, and control, and moved them from lower management to the senior management level of the health system [3,6]. The trend toward centralized management seems to be continuing with the new 2024 reform [10-12], which will concentrate decision-making power in the hands of a new agency called *Santé Québec* [13]. Such centralization of decision-making power necessarily relies on management by results, accountability, and partial privatization of services [9,14]. Consequently, departmental priorities focus on effectiveness and efficiency [14]. The changes resulting from centralized management can have an impact on the conditions of practice of local stakeholders [14], including low-level managers, professionals, seniors, and informal caregivers. These changes also influence the quality of home care services (HCS) for seniors [14], a sector where demand is increasing as the population ages [15,16]. Centralization reduces the latitude of managers and professionals [5], which in turn is associated with a reduction in how meaningful they find their work [14,17]. Their ability to offer services that are accessible and adapted to the needs of the population diminishes [18-20]. Professionals and seniors agree that the continuity and quality of HCS must be improved [18].

To address the present challenges faced by HCS, decentralization could be a particularly promising approach [5,21]. Decentralization implies the delegation of decision-making, power, and responsibilities [21]. The decentralization process involves reconfiguring relations among the national, regional, and local levels to work toward collaborative vertical and horizontal management [22]. A decentralization process involves decentralized management strategies, which are management practices that promote the delegation of decision-making, power, and responsibilities from a higher to a lower level [23]. To be effective, local decentralized management involves three elements: (1) delegating authority to lower-level managers and professionals, (2) strengthening their individual and organizational capacities, and (3) sharing accountability for decisions to be made [23]. Decentralization has the potential to improve the performance of the health system [21,24], the efficient allocation of material and human resources, and responsiveness to the needs of seniors [22].

Moving toward decentralized management is particularly relevant when we consider the main effects of the current centralized management on the health system in Québec. First, administrative reforms and a centralized management approach can reduce the autonomy of professionals [4,14], whose decisions must be approved by senior management, which delays the taking of concrete action in the field [5,19]. The centralization of decision-making power and formalized communication mechanisms limit direct relationships between different local stakeholders [19]. Second, the standardization of practices and use of statistics have increased the focus on performance optimization (eg, cost-effectiveness) [19]. On the one hand, the management and organizational techniques put in place to optimize the work of professionals (eg, standardized clinical tools) [14] require them to invest a great deal of time in their daily tasks [15,19], which decreases the time they devote to direct care for seniors [14,19]. On the other hand, this standardization leads to a tightening of HCS allocation criteria, which impacts the accessibility of services [19]. Some seniors are being denied services, although they were eligible before the 2015 reform [19]. Third, there is a wide gap between the expectations of professionals and managers [15]. Professionals are mainly concerned with improving the quality of care and services for seniors [15]. Managers are more focused on the performance of HCS. For example, HCS must contribute to reducing hospitalization times and increasing the number of seniors who received services [15]. Fourth, services are developed in silos, without any overall coordination [25,26]. This leads to the duplication of services, blurred roles for each HCS provider, a lack of coordination, and competition between service providers [27]. As a result, overly centralized management has negative effects on the practice of professionals and the quality of services for seniors.

Now that the Québec government has made decentralization a priority [28-30], documenting decentralized management in its HCS becomes relevant. Some studies have examined the integration of decentralization in a health care system but generally only from the viewpoint of evaluating this in a specific context. However, each health system has its own management context and structure [31]. Thus, in today's hypercentralized system, bringing decision-making closer to Québec managers, professionals, seniors, and informal caregivers requires finding a way to integrate decentralized management strategies at the local level of HCS. This study aims to answer the following question: To integrate decentralized management in HCS effectively, what potential strategies should be used and what factors should be considered? The overall aim of this study is to coconstruct HCS decentralized management strategies in the day-to-day work of low-level managers and professionals. The specific objectives, in collaboration with local HCS stakeholders, are to (1) identify concrete and achievable strategies for decentralized management, and (2) describe factors (facilitators and obstacles) that could potentially influence their integration.

Theoretical Model

According to the theoretical model of Ohrling and colleagues [24], decentralization is a dynamic process that evolves over time and in which three elements interact: (1) delegation of authority to local stakeholders, (2) strengthening of individual and organizational capacities, and (3) accountability for actions and decisions. *Authority* refers to the different degrees of decision-making power and autonomy delegated to lower levels

of managers and professionals [24]. To achieve a balanced distribution of authority at different levels of management, managers need to identify tasks and decisions that can be delegated. To ensure that the selection of priorities is in line with the needs of seniors, managers must have a certain amount of latitude in their decision-making [32]. Thus, strategies that support effective decentralized management involve low-level managers having sufficient authority to select those priorities, identify tasks and decisions that can be delegated, and allocate resources [24]. *Capacities* involve the possibility of strengthening individual and organizational abilities to assume delegated decision-making power and responsibilities [24]. The individual ability of managers and professionals to take the initiative is based on their personal aptitudes [33]. As for organizational capabilities, certain norms and culture help encourage the initiatives of managers and professionals [24]. Finally, managers and professionals need to be *accountable* for their decisions and their impacts on HCS [24]. This element involves specifying how responsibilities will be integrated and distributed between managers at all levels and professionals [24]. Also, to facilitate the delegation of authority and sharing of responsibility, managers and professionals should coordinate services, ensure quality, and meet institutional standards [24]. To be effective, strategies must include a sufficient degree of delegation, combined with the capacity on the part of local stakeholders and institutions to make choices in line with optimized performance and to be accountable for these choices aligned with local needs and priorities [34].

Literature Review

This study addresses the question: What potential strategies should be used and what factors should be considered to effectively integrate decentralized management into HCS? Based on the 3 elements of the model of effective decentralization (authority, capacity, and accountability) [24], the literature review presents these strategies and factors.

Decentralizing Management: Strategies to Be Explored at the Local Level

The main strategy of *authority* involves establishing clear policies that contain guidelines regarding the changes to be made to the degree of autonomy and decision-making power at each management level (provincial, regional, and local) [35-37]. When local stakeholders are involved in developing them, these policies are closer to local needs and improve the quality of services [38]. However, these policies often have gray areas that make them difficult to integrate at the local level [37], such as poor communication between provincial, regional, and local levels regarding policy applications [35,39]. Furthermore, it is important to consider the financial dimension of HCS with respect to managers' decision-making power over budget allocation [23]. This strategy involves increasing local control and autonomy over budget management, including the choice of how to allocate funds [40,41]. This control enables choices to be made in line with local needs, which leads to more responsive services [41].

Capacity strategies comprise ways to increase managers' individual capabilities. For example, training programs should focus on managerial leadership skills, health management organization, and organizational changes to come with decentralized management strategies [33,35]. To increase organization capacity and sustain local control and autonomy with respect to budget management requires a system for allocating financial resources [37]. Under such a system, the provincial level retains the power to divide tax revenues equitably between various local institutions [40,42].

Accountability calls for a variety of strategies that are easier to integrate at the local level and have more lasting positive effects [40]. The most promising of these strategies is, first, the creation of clinical networks or committees that give local stakeholders a voice with HCS senior management [38,43]. Second, one of the most common strategies is to reorganize responsibilities between the central government and the local institutions to increase the latters' autonomy [24,36,37,41,44,45]. Third, the reorganization of human resources management responsibilities includes increasing the decision-making power of local organizations in recruiting and training professionals [36,37,46]. A fourth strategy is to have provincial and regional levels use a bottom-up approach to plan health priorities that involve local managers and communities in identifying initiatives and projects for strategic planning of HCS [47,48]. A fifth strategy involves local managers using clear report cards that include objectives, concrete strategies, and performance indicators for decentralization-related changes in the institution [24].

Factors Influencing the Integration of Decentralized Management Strategies

Factors facilitating (n=8) the integration of decentralized management strategies are presented first, followed by factors representing obstacles (n=7). Regarding *authority*, 2 facilitators encourage the delegation of decision-making power to lower-level managers and professionals [24]. The willingness of managers at different levels to delegate certain tasks and responsibilities encourages their participation in the integration of decentralized management strategies [32]. Coaching senior managers through monthly meetings can help build a relationship of trust between the provincial and local levels [49]. Senior management's commitment helps motivate lower-level managers to take on accountability [39]. Two facilitators can help strengthen organizational *capacities*, leading to enhanced integration of decentralized management strategies [24]. First, the institution must have the material, human, and financial resources needed to put the strategies into practice [35,46,48,50]. For example, quality equipment (such as a high-performance IT system) [39], the right infrastructure, a qualified workforce, and budget planning facilitate the integration of changes linked to decentralization [35]. Creating a culture of mutual trust within the institution encourages managers and professionals to take the initiative and make decisions [33]. In terms of individual capacities, 2 facilitators reflect the personal skills of managers at different levels and professionals [33]. The first concerns coping strategies for managers and professionals, which are methods they can put in place to help them reorganize their work routines [51]. These methods enable them to spend more time on their new tasks and responsibilities, for instance, by reducing the number of meetings they need to attend [41,51]. Senior managers can help by limiting the amount of bureaucracy they have to deal with [33,52]. The second facilitator is the

leadership skills of managers at different levels. These skills can facilitate the integration of decentralization to define new relationships with provincial and regional levels, plan resource allocation, build a new shared vision, and lead change [43,53]. Two facilitators are associated with *accountability*. Clarity of roles and responsibilities between provincial and local levels regarding resource allocation and accountability for action enables proactive integration of decentralized management strategies [33,47]. Collaboration between provincial and local levels facilitates the integration of a budget that respects local needs, strategic direction, and government priorities [46].

Several factors stand in the way of integrating decentralized management strategies. Regarding *authority*, 2 factors make it more difficult for the provincial level to delegate to lower levels [24]. Difficulties communicating between the provincial level and local institutions regarding the execution of a policy or reform can lead to confusion [37,41,51]. As a result, a gap may be created between policy and its implementation [39]. Good communication means that information about the new policy to be implemented is clear, accurate, and transmitted to the right individuals [39]. Moreover, when the provincial level decides to retain a high degree of control over local institutions, it is more difficult to integrate decentralized management strategies [41,47]. Local managers then lack autonomy [41] and decision-making power [36], which makes it difficult to lead change. As for organizational *capacity*, lack of resources and funds can limit the changes to be integrated [46,49,51,52]. Concerning individual capacity, limited managerial skills [49,54], and lack of preparation [48,51] can affect managers' ability to make decisions in their new role and demotivate them [48]. In addition, 2 obstacles are associated with *accountability* for coordinating quality services aligned with local needs [24]. A lack of clarity in roles and responsibilities is a source of confusion when new responsibilities linked to decentralized management strategies are added [37,38]. Managers and professionals then find it difficult to assume their new responsibilities, for which they may be accountable. The second obstacle concerns budget allocation based on the central government's political motivations. This factor can create a gap between government funding and actual budgetary needs at the local level [46].

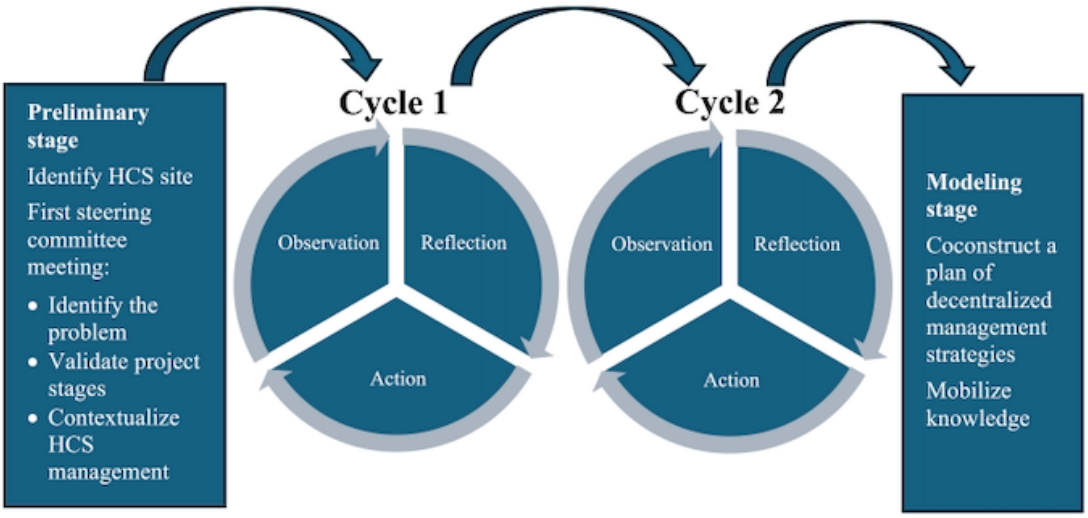
The studies discussed in the aforementioned literature review are useful as they focus on decentralized management strategies and factors likely to influence their integration. However, some of them were carried out in countries where the political, organizational, and legal structures of the health care system differ from those in Canada and Québec [24,29,55]. Furthermore, some studies did not involve the participation of all local stakeholders in developing decentralized management strategies. As a result, none of them fully captures the complexity of the dynamic and evolving process of decentralization and the factors that can influence it in the Québec context.

Methods

Design

To meet our objectives, a participatory action research (PAR) design was chosen [56]. The PAR design gives HCS stakeholders the power and the tools to explore and coconstruct management strategies adapted to their context and to solve a specific problem that they have identified [56]. The study will start with a preliminary stage, followed by 2 cycles, each composed of 3 phases (observation, reflection, and action), and end with a modeling stage (Figure 1 [57]). The preliminary stage consists of selecting the research site and forming a steering committee. The first cycle will establish a plan of decentralized management strategies (objective 1). The second cycle will consolidate the decentralized management strategy plan and anticipate its integration in HCS by describing factors that could potentially influence the integration of these strategies (objective 2). Finally, the modeling stage will combine the results of the 2 cycles and consolidate the decentralized management strategy plan. A cyclical reflective process is necessary for PAR to ensure constant 2-way feedback between theory and practice [58,59].

Figure 1. Cyclical process of participatory action research based on the participatory action research model developed by Roy and Prévost [57]. HCS: home care services.



Study Components (Preliminary Stage)

To define the problem and initiate the PAR process, a steering committee will be set up, composed of 3 managers, 3 professionals, 3 seniors, and 3 informal caregivers identified at the site as well as 3 members of the research team (VS, JQ, and AC). Each type of stakeholder will be equally represented to encourage constructive exchanges and ensure that all steering committee participants feel free to express themselves [56]. The committee will enable a concerted stakeholder approach to the study, aimed at coconstructing [56] decentralized management strategies based on a real-life problem identified by the committee. Before starting the PAR cycles, an initial meeting of the steering committee will be held to discuss everyone's role and involvement [56]. In addition, this meeting will provide an opportunity to contextualize current HCS management and identify a target problem to be addressed in this study. Committee members will be invited to comment on the proposed research process [56]. Members of the research team on the steering committee will play a facilitating role and support the other members in the effective search for solutions [56].

Cycle 1: Identify Decentralized Management Strategies (Objective 1)

Observation Phase: Data Collection

A convenience sample of 24 participants will be recruited to form 4 focus groups of 6 participants each (managers, professionals, seniors, and informal caregivers) to collect data [60]. Each group will be homogeneous to encourage participants to express themselves freely [61]. The qualitative research literature recommends having 6-8 participants in each focus group to ensure interesting exchanges and the opportunity for each participant to answer questions and share their point of view and experience [60]. These focus groups will be used to gather views on decentralized management strategies and the factors influencing their integration as identified in the literature, according to their different status (manager, professional, senior, or informal caregiver) [62]. A member of the steering committee will be present during the discussions to assist the research team. Focus group meetings will last 90 minutes [62]. The aim will be to identify decentralization strategies to solve the target problem. Focus group interviews will be recorded and conducted with the help of a guide [60]. In addition, the student researcher (VS) will document her reflections and the different stages of the study in a research journal [63].

Reflection Phase: Data Analysis

First, an initial list of potential codes will be drawn up from the literature review on decentralized management strategies (objective 1), for example, establishing clear policies [64]. Second, initial deductive codes will be generated by identifying the units of meaning linked to a list of codes based on the literature review. The emergent initial codes will be generated by identifying the units of meaning in the data relating to decentralized management strategies that are not included in the list of codes (objective 1). Third, to search for themes, codes will be selected to create potential themes. Relevant coded data extracts will be collected for the created themes [64]. To ensure that the themes and subthemes are meaning-based interpretative stories [65], each will have a definition based on the extracted codes. Fourth, the themes will be examined in relation to the coded data extracts and the data as a whole [64]. Themes and subthemes will be organized in a chart to think creatively and reflexively the data and facilitate communication with steering committee members [56,65]. Fifth, the themes, subthemes, and overall chart will be revised and defined [61]. Sixth, relevant and illustrative data extracts will be selected to represent the themes [64]. The 6 steps of the Braun and Clarke's [65] analysis will be carried out by the student researcher (VS) and validated by 2 members of the research team (AC and JQ). Seventh, a meeting will be held with steering committee members to validate and enrich these analyses. The validation will enable us to make sure that the themes that have been created represent the perspective of field stakeholders [65]. The chart resulting from the data analysis will be presented to the steering committee and will help members reflect on the solutions and decentralized management strategies to be integrated.

Action Phase: Identify and Coconstruct Decentralized Management Strategies

During this phase, the results of the reflection phase will be shared with all HCS stakeholders involved in the strategies identified (ie, professionals on the HCS team). These stakeholders will be identified by the steering committee. A meeting will be held with these stakeholders led by the student researcher (VS) and a member of the steering committee. First, the student researcher will present the decentralized management strategies. Then she will invite the stakeholders to prioritize the strategies according to 3 criteria: strategy's relevance to the problem identified, strategy's feasibility in terms of accessibility of the necessary resources, and strategy's acceptability to all stakeholders (managers, professionals, seniors, and informal caregivers) [66]. Finally, a plan of decentralized management strategies will be drawn up with the stakeholders [56,67]. This will identify the decentralized management strategies to be prioritized, the associated tasks, the resources needed, and the time required [56].

Cycle 2: Identify Factors Influencing the Integration of Decentralized Management Strategies (Objective 2)

Observation Phase: Data Collection

With the same 24 participants, meetings of 4 homogeneous focus groups of 6 participants each (managers, professionals, seniors, and informal caregivers), lasting 90 minutes [62], will be conducted. In the second cycle, the focus groups will be used to anticipate and coconstruct factors that could potentially influence the integration of decentralized management strategies in HCS.

Reflection Phase: Data Analysis

A thematic analysis using Braun and Clarke's 6 steps [64] will be conducted to interpret the data collected and will be carried out in the same way as in the first cycle. Both deductive and inductive approaches will be used to define an initial list of potential factor codes based on the literature and to allow new themes to emerge [64]. The analysis will generate a chart of factors linked to the decentralized management strategies

identified in the first cycle. A steering committee meeting will then be held to present the chart and validate the factors involved in integrating decentralized management strategies [56].

Action Phase: Describe the Factors Influencing Integration of the Strategies

In the second cycle, the action phase will consist of a meeting with the same stakeholders as in the first cycle. This meeting will provide an opportunity to share the factors (facilitators and obstacles) identified and to reflect on those most likely to influence the integration of the decentralized management strategies identified in the first cycle. This discussion will lead stakeholders to consolidate the plan of decentralized management strategies and anticipate their integration [56,67]. Thus, at the end of the 2 cycles, the data collected should enable empirical saturation to be reached, with further collection no longer providing sufficiently new or different information to justify another PAR cycle [68].

Modeling Stage

The PAR process will end with a fourth meeting of the steering committee. At this meeting, the results (decentralized management strategy plan and factor figures) will be integrated into a model coconstructed by the steering committee [56,67]. Based on this model, the decentralized management strategy plan will be converted into recommendations regarding which strategies to prioritize to resolve the management issues identified.

Recruitment and Sampling

The participants will be main HCS stakeholders: managers, professionals, seniors, and informal caregivers. They will be recruited with the help of steering committee members, who will explain the research project to them and verify their interest in participating. Convenience sampling will then be used to target a total of 6 managers, 6 professionals, 6 seniors, and 6 informal caregivers (n=24) [64]. Participants will be recruited according to the following inclusion criteria: (1) they must have received services or worked in HCS for a continuous period of at least 6 months; (2) they must have an interest in HCS management; (3) they must be able to express themselves in French; and (4) they must be able to consent to participate in the study. They will participate in the observation phase in both cycles.

Ethical Considerations

This study was approved by the research ethics board of the integrated university health and social services center (#2024-5221/Carrier). All participants will be required to provide free and informed written consent for each cycle. Participants will be able to withdraw from the study at any time without any repercussions. They will also be informed of the confidential nature of the data collected and the procedures followed to ensure confidentiality and anonymity. The data collected will be secured (on a password-protected computer or in a locked fireproof filing cabinet at the Research Centre on Aging) and only the research team will have access to them. Members of the steering committee will fill out a collaboration protocol, based on the one developed by Fortier et al [69]. As a PAR, the impact of change on participants must be considered. The study, which is conducted in partnership with the participants [61], who are treated with respect throughout the research process, cannot be used to evaluate their work [61]. Seniors and informal caregivers will receive financial compensation of CAD $25 (US $17.67) for their transportation to a point of service offering HCS.

Results

The study started in February 2024 and will be carried out according to an optimal schedule over a 1½ period (Table 1). In the preliminary stage, we obtained ethical approval and developed the interview guides. We also developed a research partnership with an HCS site. Initially, one meeting of the steering committee was planned. However, 2 additional meetings were necessary to contextualize the management and organization of the HCS site. The first cycle began in July, with the first focus group in July 2024. We had recruited 12 managers and 7 home care workers. We are currently at the stage of conducting focus groups with seniors and caregivers. Each cycle will last approximately 4 months. To ensure knowledge mobilization, the research team will prepare scientific papers and make presentations. Members of the steering committee will be invited to participate. This study received financial support (June 2023) from a major Canadian funding body, the Social Sciences and Humanities Research Council of Canada (#430-2023-00783/Carrier).

Table 1. Tasks and timeline for each cycle of the participatory action research.

Task	Time
Preliminary stage	
Ethics approval	December 2023[a]
Development of interview guides	December 2023[a]
Development of research partnership	February 2024[a]
First meeting of steering committee	March 2024[a]
Second and third meetings to contextualized HCS[b]	June-July 2024[a]
First cycle	
Focus group	July-October 2024[a]
Thematic analyses	November-December 2024[a]
Fourth (initially second) meeting of steering committee	December 2024[a]
Meeting with local stakeholders	January 2025
Second cycle	
Focus group	January 2025
Thematic analyses	February-March 2025
Fifth (initially third) meeting of steering committee	March 2024
Meeting with local stakeholders	April 2025
Modeling stage	
Sixth (initially fourth) meeting of steering committee	April 2025
Dissemination and mobilization strategies	June-October 2025

[a]Tasks completed at the time of publication of this paper.

[b]HCS: home care services.

Discussion

Strengths and Limitations

This study is designed to explore decentralized management strategies that are concrete and adapted to the realities of local stakeholders as well as to anticipate factors involved in integrating the strategies. The methodological choices are scientifically rigorous and will be validated in each phase of the study by members of the steering committee [68,70]. To encourage greater reflexivity on the part of the student researcher (VS), the focus group interviews will be cocoded with at least 1 member of the research team, and the analyses will be validated by the steering committee. The research team's experience in the health care system is an asset as they are familiar with the management context [61,68,70]. However, decentralized management strategies will be developed in a centralized management context, which could present an obstacle to the integration of some strategies. In addition, given the power relationship between managers and professionals, social desirability is a potential bias. Nonetheless, the views of various local stakeholders will enrich the steering committee's discussions [56]. In addition, the research team members will play a facilitating role and support other members in effectively identifying decentralized management strategies and the factors involved [56]. The research team will pay attention to power issues during discussions to ensure that all members can express themselves freely [56].

Broad Implications

The research project will address a gap in the literature by identifying concrete decentralized management strategies adapted to the local reality of an HCS site and anticipating factors involved in integrating these strategies. The results will advance practical knowledge regarding decentralized management, which can serve as a basis for further studies designed to advance knowledge in this field.

This study will provide recommendations for innovative solutions to a management issue identified by an HCS site. It considers the main stakeholders in HCS in the search for innovative solutions and helps identify decentralized management strategies that meet the needs of the institution. The strategies identified can also be adapted to other environments with similar characteristics [71]. Knowledge of decentralized management will be transferred between participants and members of the steering committee [58]. In addition, this project will increase the self-determination of steering committee members through the PAR process, which will encourage them to get involved in the search for strategies [58]. By involving seniors and informal caregivers in the steering committee and focus groups, this study encourages

community participation in the search for management strategies. As a result, the decentralized management strategies identified will undoubtedly meet seniors' needs [72].

Acknowledgments

Financial support for this study is provided by the Social Sciences and Humanities Research Council (SSHRC; grant 430-2023-00783). AC is a Fonds de recherche du Québec—Santé Junior 1 researcher (#296437).

Abstract

Background: Artificial intelligence (AI)–based clinical decision support systems (CDSS) have been developed for several diseases. However, despite the potential to improve the quality of care and thereby positively impact patient-relevant outcomes, the majority of AI-based CDSS have not been adopted in standard care. Possible reasons for this include barriers in the implementation and a nonuser-oriented development approach, resulting in reduced user acceptance.

Objective: This research project has 2 objectives. First, problems and corresponding solutions that hinder or support the development and implementation of AI-based CDSS are identified. Second, the research project aims to increase user acceptance by creating a user-oriented requirement profile, using the example of sepsis.

Methods: The research project is based on a multimethod approach combining (1) a scoping review, (2) focus groups with physicians and professional caregivers, and (3) semistructured interviews with relevant stakeholders. The research modules mentioned provide the basis for the development of a (4) survey, including a discrete choice experiment (DCE) with physicians. A minimum of 6667 physicians with expertise in the clinical picture of sepsis are contacted for this purpose. The survey is followed by the development of a requirement profile for AI-based CDSS and the derivation of policy recommendations for action, which are evaluated in a (5) expert roundtable discussion.

Results: The multimethod research project started in November 2022. It provides an overview of the barriers and corresponding solutions related to the development and implementation of AI-based CDSS. Using sepsis as an example, a user-oriented requirement profile for AI-based CDSS is developed. The scoping review has been concluded and the qualitative modules have been subjected to analysis. The start of the survey, including the DCE, was at the end of July 2024.

Conclusions: The results of the research project represent the first attempt to create a comprehensive user-oriented requirement profile for the development of sepsis-specific AI-based CDSS. In addition, general recommendations are derived, in order to reduce barriers in the development and implementation of AI-based CDSS. The findings of this research project have the potential to facilitate the integration of AI-based CDSS into standard care in the long term.

Introduction

The first clinical decision support systems (CDSS) date back to the 1970s. Early systems, such as MYCIN, a program designed to advise on the choice of therapy selection for patients with infections [1], were rule-based expert systems. Nowadays, a wide variety of CDSS exist. These can be categorized as either knowledge-based or non–knowledge-based systems.

Knowledge-based systems operate on logical decision rules (IF <condition> THEN <action>). The system retrieves data and transforms it into an output following distinct rules. Further segmentation can be made into Bayesian networks, causal-probabilistic networks, and rule-based systems: The latter are usually based on medical guidelines [2].

Non–knowledge-based CDSS require a clinical data source and generate recommendations using artificial intelligence (AI) including machine learning or statistical pattern recognition [3,4]. The potential of AI models to sustainably improve patient care is estimated to be enormous for almost all aspects of the clinical decision-making process (prevention, diagnostics, and therapy) [5]. Based on big data analytics, AI-based CDSS offer the ability to pool, link, and combine data, that would be impossible for humans to interpret due to its complexity. In this way, these models can improve medical outcomes by optimizing care [6].

While AI is established in some disciplines, such as radiology (eg, automated image recognition), the transfer of AI-based CDSS into clinical use is lagging behind. Due to the inhomogeneity of different disease patterns, AI-based CDSS are often developed specifically for a target disease or a selected group of disease patterns, such as sepsis [7,8].

Sepsis is a life-threatening organ dysfunction caused by a dysregulated immune response to infection. It is a leading cause of mortality, with 49 million cases and 11 million deaths each year [9]. So far, only symptomatic therapies are available, that attempt to replace the function of the failed organ systems. Treatment of the dysregulated immune response as a cause of sepsis has not been successful in large trials and subsequently has therefore not found its way into clinical practice or sepsis guidelines.

AI-based CDSS could be particularly useful in sepsis care due to the high heterogeneity and complexity of the disease [10]. Non–knowledge-based respectively data-based CDSS are subject to a trade-off between model complexity and interpretability. As sepsis is an extremely complex condition, a majority of machine learning–based CDSS for this disease can be considered “black box” systems. Their treatment recommendations cannot or can only be interpreted by health care providers, with relatively high effort [11,12]. Health care providers may have to rely on these systems without understanding how the algorithms reach their conclusions, due to their black box nature. This lack of transparency can negatively impact the acceptability of such systems [13-15].

In addition to the black box nature of AI-based CDSS, there may be other possible reasons why such systems do not manage the transition into standard care, such as a nonuser-oriented development approach without or at least without sufficient consideration of the needs and preferences of future users [16-18], resulting in reduced user acceptance and implementation barriers (eg, computer literacy of the future users, data availability or legal issues) [4].

These may be possible reasons why there is still no AI-based CDSS for sepsis in Germany that is included in the standard care of the statutory health insurance (SHI) system and is used nationwide. Currently, only a few prototypes in the form of individual solutions are in use or under development (eg, [19,20]).

The reluctance to adopt AI-based CDSS does not appear to stem from the performance of such systems. The sepsis prediction algorithm InSight, developed by AI start-up Dascena, has been demonstrated in several articles to outperform traditional rule-based scores such as the Systemic Inflammatory Response Syndrome, the Sequential Organ Failure Assessment or the quick Sequential Organ Failure Assessment [21,22]. This and other developed algorithms have the potential to improve patient-relevant outcomes. In particular, this encompasses a reduction of sepsis-related mortality, a reduced average length of hospitalization, or an earlier treatment, for example, in the form of the timely administration of antibiotics [21,23,24]. Instead, the reluctance to implement AI-based CDSS can be attributed to a number of factors that are independent of their performance. These include a paucity of evidence, particularly prospective studies [22], a lack of capacity in health care systems to integrate AI into current workflows [25], and ethical concerns, such as the risk of discrimination against certain populations [25-27]. Also in other indications, despite a high frequency of development, only a marginal proportion of such systems successfully transition from the development phase into standard care.

Therefore, the multimethod research project “User-Oriented Requirement Profile for AI-Based Clinical Decision Support Systems Using the Medical Example of Sepsis – KI@work,” seeks to investigate AI-based CDSS in the above-mentioned disease context. In the framework of this research project, it is assumed that there are 2 reasons for the lack of implementation. First, there are administrative and organizational barriers (data availability, data collection, knowledge gaps among potential users) as well as legal and institutional hurdles (implementation of European and national legal requirements, [medical] liability law, competent bodies) within the German health care system that make it difficult to transfer and integrate AI-based CDSS

into the SHI system. Second, to ensure (sustainable) use and acceptance of AI-based CDSS, the system must have a high perceived usefulness according to the Technology Acceptance Model [28]. In addition, future users should be involved in the development phase, as suggested by the Recursive Innovation Management Model [18]. Due to the strongly technology-driven development of AI-based CDSS, this is currently only done in a fragmentary manner, so that the requirements and preferences of users are only insufficiently taken into account within the framework of such systems.

The multimethod research project addresses both aspects, resulting in two equally important research objectives, that are (1) to identify and remove or overcome barriers by developing health policy recommendations for action to facilitate the transfer of AI-based CDSS across all indications in the German health care system in the future and (2) to develop a clinical requirement profile that can be incorporated into the initial development of CDSS or can be considered in the further development of existing systems. This should enable an increase in usability and thus the acceptance of AI-based CDSS. The requirement profile is developed using the example of sepsis and is, therefore, indication-specific.

In order to achieve the objectives, 3 research questions and 3 sub-questions were determined (Textbox 1).

Textbox 1. Research questions of the multimethod research project.

- What insights can be gained from AI-based clinical decision support systems (CDSS) that are already established in health care and which best practices can be derived?
  - What is the data basis of these CDSS (input)?
  - How are the decisions and recommendations of the CDSS presented to the health care providers (output)?
  - How does the interaction between health care providers and CDSS take place (setting)?
- What specific problems exist or are seen in the establishment of AI-based CDSS in patient care, with a particular focus on clinical sepsis care as well as on the German health care system?
- What are the preferences of health care providers regarding the use and design of CDSS in the prevention, diagnosis, and treatment of patients with sepsis?

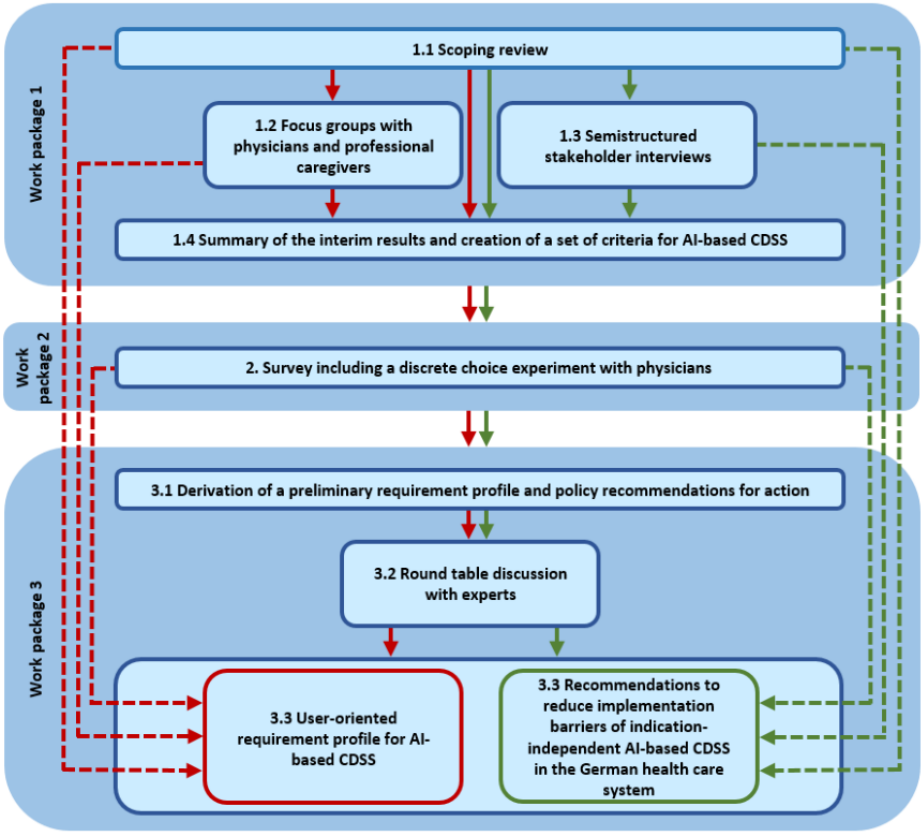
The research project is conducted by the Institute for Health Care Management and Research at the University of Duisburg-Essen. Consortium partners are the Department of Anesthesiology, Intensive Care Medicine and Pain Therapy at the University Hospital Knappschaftskrankenhaus Bochum, the Knappschaft Kliniken GmbH, the Department of Medical Informatics, Biometry and Epidemiology at the Ruhr University Bochum and the German Sepsis Society. The research project is funded by the Innovation Fund of the German Joint National Committee (funding code: 01VSF22050).

Methods

Overview

The research project is conducted over a period of 36 months (cf Multimedia Appendix 1) and uses a multimethod approach. It is separated into 3 work packages. Work package 1 combines a scoping review, focus groups with physicians and professional caregivers, and semistructured interviews with relevant stakeholders of the German health care system. At the end of this work package, the interim results (problems, barriers, and corresponding solutions) of the research project are summarized and a set of criteria for AI-based CDSS is derived. Based on the results of the preceding work package, work package 2 includes the central element of the research project: a survey of physicians, including a discrete choice experiment (DCE). Work package 3 involves the development of a requirement profile for AI-based CDSS and the derivation of health policy recommendations for action, which are discussed in an expert roundtable discussion. The research project concludes with a summary of the results in a white paper (cf Figure 1).

Figure 1. Overview of the multimethod research project. The results of work packages 1 and 2 are indirectly incorporated into module 3.3, as indicated by the dashed lines. AI: artificial intelligence; CDSS: clinical decision support system.



Work Package 1

Work package 1 addresses both research objectives. It serves to identify problems and barriers regarding the transfer of AI-based CDSS into the SHI system (first research objective) and to create a preliminary set of criteria for AI-based CDSS in sepsis care (second research objective). Work package 1 is divided into 4 modules.

Scoping Review (Module 1.1)

The scoping review combines systematic and structured research. The focus of the scoping review lies on research questions 1 and 2, thus addressing both research objectives.

Scoping Review

The actual scoping review examines the currently available evidence on the patient-relevant benefit of AI-based CDSS in the field of sepsis. Furthermore, it aims to identify factors that pose barriers to the transition of CDSS into the health care system and to identify solutions that reduce or overcome these barriers. Methodically it is based on the Joanna Briggs Manual for Evidence Synthesis [29]. Further development of the foundational work of Arksey and O'Malley [30] and Levac et al [31]. The documentation of the scoping review is based on the PRISMA Extension for Scoping Reviews [32]. The search strategy is designed using the PCC (Population, Concept, and Context) framework. The population encompasses individuals with or at risk of sepsis, the concept used is AI and the context are CDSS. Relevant search terms according to the predefined PCC framework are identified and linked with "OR" operators in order to form search blocks. The search blocks are linked with "AND" operators to generate search strings. All search terms are restricted to their occurrence in the abstract, the title, or as a keyword, and in the case of existing index terms (eg MeSH and Emtree), the corresponding terms are added. The databases examined are Medline and Embase as well as ACM Digital Library and IEEE Xplore. This proceeding is to ensure that the interdisciplinary character of the research project can be adequately investigated from both the medical and the informatics perspectives. Following the identification and removal of duplicates, 2 reviewers (GDG and PR) independently screen the titles and abstracts against predefined inclusion and exclusion criteria (cf Textbox 2) to determine whether an article is eligible for full-text screening. Subsequently, the same 2 reviewers conduct a full-text screening of the included articles against the same criteria.

The reviewer PR then uses the program MAXQDA (VERBI Software GmbH) to identify and tag relevant content in the included articles. The final categories are then discussed and systematized in a workshop (NB, GDG, and PR). The results of the workshop are recorded in Microsoft Excel.

In order to add further evidence, the reference lists of the articles identified in the scientific databases are screened. In addition, a structured search is conducted for gray literature (eg, working papers and guidelines) from various governmental and nongovernmental stakeholders, such as associations or public institutions, and their websites.

Textbox 2. Inclusion and exclusion criteria for the scoping review.

Inclusion criteria

- Articles focusing on sepsis and
- involving AI-based clinical decision support systems, that
  - describe patient-related benefits
  - describe problems with development, implementation, or application, or
  - describe approaches to overcome identified problems

Exclusion criteria

- Exclusively technical description of systems.
- Focus on the description of the evaluation of binary classifiers.
- Articles describing AI-based clinical decision support systems for neonates and children or animals.
- Not addressing any of the research questions in more detail.
- Research protocols, conference abstracts, letters to the editor, or expression of opinions.
- Article published before 2008.
- Language other than English or German.

Additional Structured Medical Device Database Search

The additional structured search aims to provide an overview of authorized AI-based CDSS already in use (irrespective of the indication area of sepsis). In order to identify such systems, the European Database on Medical Devices is analyzed. The filters “system,” “software,” and “risk class (IIa, IIb, III)” are used. The structured search examines the data on which the decisions of the systems are based (input), how the results are presented (output), and how the CDSS are integrated into the clinical context (setting). Particular focus is placed on the search for best practice examples and the identification of clinical areas where the use of AI is already established. These examples are used to recognize aspects that increase the likelihood of such systems being implemented.

Focus Groups With Physicians and Professional Caregivers (Module 1.2)

The focus groups with physicians and professional caregivers build on the interim findings of the scoping review (module 1.1). The findings of the focus groups contribute to the preparation of a standardized questionnaire for the survey in work package 2. Relevant aspects of input, output, and setting in the context of AI-based CDSS in the field of sepsis diagnosis and therapy are collected and derived, thus addressing the second research objective.

Five web-based focus groups are held using the conferencing tool integrated in Microsoft Teams. The participants include physicians and professional caregivers familiar with the care and treatment of adult patients with sepsis, as well as those who contribute to the prevention and diagnosis of sepsis. During the process of participant recruitment, attention is paid to ensure the inclusion of a heterogeneous group of hospitals, representing various levels of care (from primary to quaternary care). In addition, a balanced composition of focus groups in terms of gender is prioritized. Furthermore, participants with differing levels of experience are integrated into the individual focus groups. Three focus groups are conducted with physicians and 2 with professional caregivers. The discussions are based on semistructured guidelines. The focus groups are led by a moderator team according to Krueger and Casey [33], recorded and transcribed. They are then subjected to thematic qualitative content analysis based on Kuckartz and Rädiker [34] using the program MAXQDA (VERBI Software GmbH). The aspects of input, output, and setting represent deductive codes and are defined before data analysis. Inductive codes are supplemented during the process of analysis. A final categorization is conducted in a workshop (NB, GDG, and PR). The findings of the workshop are recorded in Microsoft Excel.

Recruitment of participants is supported by the Department of Anesthesiology, Intensive Care Medicine, and Pain Therapy of the University Hospital Knappschaftskrankenhaus Bochum and the Knappschaft Kliniken GmbH. In addition, participants from other hospital providers are also invited in order to represent a broad and provider-independent perspective of physicians and professional caregivers.

Semistructured Stakeholder Interviews (Module 1.3)

Semistructured interviews with stakeholders from different domains of the German health care system are conducted to complement the results of the scoping review (module 1.1) with the perspectives of various stakeholders. The expert interviews are undertaken to identify problems and barriers related to the implementation of AI-based CDSS in standard care (first research objective). Experts in the field of medical device law, representatives of the SHI system, patient representatives, physicians, and professional caregivers, representatives of quality management, data protection, and ethics, and various research institutions as well as private developers are interviewed. Similar to the focus groups, the interviews are recorded, transcribed, and subjected to qualitative content analysis according to Kuckartz and Rädiker [34].

Summary of the Interim Results (Problems, Barriers, and Corresponding Solutions) and Creation of a Set of Criteria for AI-Based CDSS (Module 1.4)

Based on the results of the first work package, a set of criteria for AI-based CDSS in sepsis care is developed in module 1.4 (second research objective), which is based on national and international evidence and qualitative survey methods. Furthermore, the identified problems and barriers as well as corresponding solutions are systematized and summarized (first research objective).

Work Package 2

The central element of work package 2 is a cross-sectional survey to identify perceived problems and barriers to the integration and usage of AI-based CDSS (first research objective) and to ascertain physicians' preferences regarding the design of AI-based CDSS in sepsis care (second research objective). The results of work package 1 serve as a basis for the development of the survey, including the DCE.

The questionnaire is divided into 3 sections. First, sociodemographic data and general attitudes toward AI applications are collected; the second section aims to identify potential barriers to the integration of AI-based CDSS into care; and third, a DCE is conducted to determine preferences for the criteria in the preliminary AI requirement profile. In particular, preferences are sought regarding the preferred information content and the appropriate integration into the care process.

The sociodemographic section comprises personal details, such as age groups or gender of the respondents, in addition to occupational data. This includes, for instance, professional experience in intensive care medicine (in 5 groups from none to >10 years), the medical specialty in which the participants are active as well as an evaluation of the degree of digitalization within the hospital where the respondents work. This procedure ensures the anonymity of the participants. The section concludes with an evaluation of general attitudes toward AI.

The second section of the questionnaire focuses on the potential barriers and problems associated with the integration of AI-based CDSS into standard care. It begins with questions concerning non–AI-based CDSS and then progresses to questions related to the use of AI in health care in general. The section concludes with questions on AI-based CDSS. In this part of the questionnaire, problems are primarily assessed using the Likert scale.

The last section of the questionnaire is intended to ascertain the requirements and preferences of physicians with regard to AI-based CDSS. For this purpose, a DCE is conducted to determine preferences regarding the design of such systems. Participants are presented with 2 fictitious systems and asked to indicate their preference.

The sample size of the survey could not be defined before the development of the questionnaire as it depends on the attributes queried in the DCE in the third section. The attributes are derived from the results of work package 1 and were thus not available at the time of the preparation of the grand proposal. Moreover, no comparable research projects could be identified from which recommendations for the required sample size and estimates of the utility of the items could have been derived [35]. Nevertheless, for orientation, initial sample size planning was done according to the heuristics developed by Johnson and Orme [36]. Therefore, 12 choice decisions, 2 selection sets per task, and a maximum of 3 levels were assumed, for which 125 evaluable questionnaires must be available. Since an additional evaluation according to subgroups such as gender (male, female, or diverse), age, or occupational group is to be conducted, the necessary number increases to 125×8=1000 completed questionnaires. Once the exact number of choice decisions, tasks, and levels is known, a statistical assessment is made to ensure statistical power for the given sample size.

In accordance with Pöge et al [37] gender identity is used as a binary variable, so transgender and cisgender people are evaluated together. Gender-diverse people are not reported separately in order to avoid identifiability due to the expected low number of cases but are included in the overall category of all respondents.

A total of 6667 physicians must be contacted, assuming an average response rate of 15% (1000/6667). Therefore, approximately 400 members of the German Sepsis Society and 250 physicians from the Knappschaft Kliniken GmbH who fulfill the inclusion criteria—(1) familiarity with adult medical care and (2) experience in intensive care medicine—are included. The sample is supplemented by randomly selected records of an address register. Based on the inclusion criteria, only addresses of physicians from the medical specialties of intensive care medicine, anesthesiology, orthopedics and trauma surgery, general surgery, visceral surgery, and internal medicine are selected. The Knappschaft Kliniken GmbH hospitals are excluded during the address data extraction process of the address register, as the hospital addresses are known and can be defined as an exclusion criterion to prevent duplicates. Furthermore, a duplicate check is conducted between the address register and the German Sepsis Society to avoid duplicates and to ensure that all physicians are not contacted twice.

In order to reach "offliners," it is possible to take part in the survey both online (LimeSurvey) and on paper. A pretest is conducted before the distribution of the survey in order to identify potential deficiencies and implement necessary modifications. A think-aloud protocol is used to ascertain the comprehensibility, manageability, completeness, and time required to complete the questionnaire [38]. In addition, the online version undergoes several functional tests for layout and usability.

Univariate or bivariate descriptive analyses are carried out as part of the evaluation of the second part of the questionnaire. Depending on the type of variable, frequency distributions, mean values, or medians are compared with simultaneous testing of statistical significance. Subgroup analyses are also conducted, for example, in relation to age or gender. The DCE (third section of the questionnaire) is expected to be analyzed using logit or mixed logit models. As both the absolute influence of the attributes and the relative influence of the levels are of interest, dummy coding is used.

Work Package 3

In work package 3, a white paper is developed. It includes (1) the final requirement profile for AI-based CDSS and (2) the determined health policy recommendations for action to reduce implementation barriers. Therefore, a preliminary requirement profile and health policy recommendations for action are developed (module 3.1), discussed with experts (module 3.2), and finally summarized in a white paper (module 3.3).

Derivation of a Preliminary Requirement Profile and Health Policy Recommendations for Action (Module 3.1)

The preliminary requirement profile for AI-based CDSS in the treatment of sepsis is developed based on the results of module 1.4 (summary of interim results and creation of a set of criteria for AI-based CDSS) as well as the results of the survey from work package 2 (second research objective). Furthermore, the identified barriers to the implementation and integration of AI-based CDSS in the German SHI system are used to develop targeted strategies for the removal and reduction of implementation barriers and translated into health policy recommendations for action (first research objective).

Expert Roundtable Discussion on the Requirement Profile and Corresponding Health Policy Recommendations for Action (Module 3.2)

In module 3.2 an expert roundtable is held. The aim of the discussion is to evaluate and optimize the preliminary requirement profile for AI-based CDSS as well as the corresponding health policy recommendations for action. In order to gain a comprehensive perspective, different stakeholders involved in the development and provision of AI-based CDSS are invited. In the context of the requirement profile for AI-based CDSS for sepsis care, the expert roundtable discussion focuses on input (data basis), output (presentation of decisions or recommendations), and setting (context of interaction between AI-based CDSS and user). Besides technical requirements, the results can include further requirements such as organizational, procedural, legal, or medical content.

The discussion is divided into four parts, after (1) introductory presentations, the (2) preliminary requirement profile for AI-based CDSS and (3) the health policy recommendations for action for the use of these systems in the German SHI system are presented. The workshop then provides an opportunity for (4) open discussion of the partial results of the requirement profile and the health policy recommendations. In addition, selected topics can be discussed in small groups with relevant experts, and the results of the discussions are presented in a plenum to reach a consensus among the stakeholders on the main issues.

A maximum of 30 stakeholders are invited to the workshop. In addition, there are at least 2 moderators and a technical and organizational staff member from the Institute for Health Care Management and Research from the University of Duisburg-Essen, as well as representatives from the University Hospital Knappschaftskrankenhaus Bochum and the German Sepsis Society. Discussions are led by a team of facilitators using prepared guidelines. The results of the workshop are recorded, transcribed, and subsequently analyzed.

Finalization of the Requirement Profile as Well as the Health Policy Recommendations for Action and Preparation of a White Paper (Module 3.3)

Based on the results of the expert roundtable discussion (module 3.2), the requirement profile for AI-based CDSS is finalized using the example of sepsis care. This enables a user-oriented development of AI-based CDSS in this context. Wherever possible, generic aspects are elaborated and presented in order to include indication-independent and therefore generalizable information in the requirement profile.

In addition, the health policy recommendations for action are concretized. It is discussed how to reduce or overcome barriers to the implementation and establishment of AI-based CDSS in clinical care and finally, proposals for legal adaptations are derived.

The results of both research project objectives, the requirement profile for an AI-based CDSS, and the health policy recommendations for action, are published in a white paper.

Ethical Considerations

In agreement with the ethical review committee of the Medical Faculty of the University of Duisburg-Essen, an ethics vote is not required as only physicians and experts are surveyed or interviewed within the project and no patient data is collected or used.

Results

The research project started in November 2022. The scoping review has been completed and the qualitative modules have been subjected to analysis.

As part of the scoping review, factors that pose barriers to the transition of CDSS into the health care system as well as solutions that reduce or overcome these barriers are analyzed. The review also sought to investigate the potential patient-relevant benefits of AI-based CDSS. The scoping review thus serves both to develop the guidelines for the qualitative modules and to derive potential problems for the survey (section 2 of the questionnaire).

The expert interviews, conducted between June and August 2023, aim to identify further problems and possible solutions for AI-based CDSS in the context of the German SHI system. The findings derived from the expert interviews are subsequently employed in the development of the survey (section 2 of the questionnaire).

The objective of the focus groups, conducted in June 2023, is to ascertain the preferences and requirements of health care providers with regard to the input, output, and setting of AI-based CDSS. The findings of the focus groups are used in the development of the DCE (section 3 of the questionnaire).

The conception of the survey, including the DCE, is finalized. It focuses on the preferences and requirements of physicians regarding the design of AI-based CDSS and the potential

problems associated with their implementation. The questionnaire is subjected to a series of comprehensive pretests. Furthermore, it is implemented on the web-based survey platform LimeSurvey (LimeSurvey GmbH) to facilitate digital participation.

Recruitment of the 6667 survey participants was initiated at the end of July 2024 and the results of the scoping review, and the qualitative modules are expected to be published at the end of 2024.

Discussion

Principal Findings

AI-based CDSS are developed for various diseases. These systems possess the potential to enhance the quality of care and thereby positively impact patient-relevant outcomes (such as a reduction of sepsis-related mortality, a reduced average hospital length of stay, or an earlier administration of antibiotics) [21,23,24]. Nonetheless, despite extensive development efforts, the majority of CDSS developed have not been adopted in standard care and do not make a significant contribution to improving care in their current form.

There may be 2 primary reasons for this. First, it is assumed that a technology push development is currently taking place, wherein AI-based CDSS are being developed without or only insufficiently considering the requirements and preferences of users [16]. Such requirements may relate to the complexity of the algorithm, with simpler algorithms potentially being preferred to more complex approaches that are incomprehensible and may be perceived as black boxes by users. Requirements related to the design and layout of AI-based CDSS may vary depending on professional experience or age. An analysis of current evidence reveals that other authors have identified various requirements for AI-based CDSS among health care providers in qualitative studies. These criteria include ease of implementation, predictive capability, and costs [39]. In addition, workload requirements [40] and the need for training programs [41] have also been highlighted.

Second, the implementation of such systems may face various barriers during the transition from the developmental phase to standard care, for instance, operational problems or regulatory uncertainties [4]. These and other hindrances may have a negative effect on the successful integration of AI-based CDSS and need to be identified and addressed before AI-based CDSS can be sustainably integrated into care.

Based on these 2 hypotheses it is necessary to analyze potential barriers, as well as the requirements and preferences of health care providers for AI-based CDSS. The results are summarized in health policy recommendations for action to reduce barriers and a requirement profile for AI-based CDSS in order to develop user-oriented systems and thereby optimize user acceptance.

Since the requirements for AI-based CDSS vary depending on the indication, the requirement profile is developed using the specific example of sepsis. Sepsis is a suitable subject for investigation due to its heterogeneity and complex pathophysiological processes, which pose challenges for health care providers in terms of diagnosis and treatment [10]. In addition, the intensive medical treatment and the continuous monitoring of patients with sepsis in the intensive care unit generate a large amount of data suitable for use in AI-based analysis.

The requirement profile for sepsis-specific AI-based CDSS, which is developed based on the requirements and preferences of health care providers, can help to ensure that future CDSS development is aligned with medical practice needs. Involving future users of such systems may counteract the current technology-push development and contribute to greater user acceptance. Following completion, the requirement profile is evaluated in terms of generalizability, and transferability to other indications. In addition, indication-independent health policy recommendations for action are developed based on the identified inhibiting factors for the implementation of AI-based CDSS.

Strengths and Limitations

The results of this multimethod research project, combining qualitative and quantitative research methods, represent the first attempt to create a comprehensive user-oriented requirement profile for the development of sepsis-specific AI-based CDSS. In addition, general recommendations are derived to reduce barriers to the development and implementation of such systems. Thus, this research project has the potential to promote future technology and facilitate the transfer of AI-based CDSS into standard care.

Despite the comprehensive design of the research project, it is not free of limitations. International literature is analyzed in the scoping review to provide an international perspective. However, all subsequent modules are limited to the perspective of health care providers and stakeholders in the German health care system, which may limit international comparability.

Qualitative and quantitative methods each have inherent limitations. Combining both is expected to leverage their strengths and mitigate their weaknesses. For instance, the predominantly qualitative findings from work package 1, which tend to be subjective and nongeneralizable, are tested for generalizability through the quantitative survey conducted in work package 2. However, not all nuances obtained through the qualitative approaches can be fully reflected in the quantitative survey. The combination of various research approaches—scoping review, expert interviews, focus groups, quantitative survey, and expert workshop—ensures that the project delivers comprehensive and well-founded results.

Furthermore, recruitment for the survey and the DCE may lead to selection bias. Although the majority of respondents are randomly selected from an address register, there is a risk of overrepresentation of physicians from the German Sepsis Society and Knappschaft Kliniken GmbH.

Dissemination Plan

The dissemination plan for this research project includes publishing the findings of the scoping review, the qualitative modules, the survey including the DCE, and the white paper in peer-reviewed open access journals dedicated to health

informatics, digital health, data science, and emerging health technologies. The results will also be presented at national and international conferences focusing on digitalization, sepsis, and health services research.

Conclusion

Based on the results of this research project, developers are provided with guidelines for the development of new AI-based CDSS or the revision of existing systems in order to make their products more user-oriented. In addition, the research project culminates in the development of health policy recommendations for action to reduce barriers to the implementation of AI-based CDSS. Ultimately, this enables AI-based CDSS to become a future standard in health care practice, providing benefits to patients.

Acknowledgments

This research is part of a wider research project (Multimethod Research Project on Requirements for Artificial Intelligence-Based Clinical Decision Support Systems Using the Medical Example of Sepsis (="KI@work")) funded by the German Federal Joint Committee (funding code: 01VSF22050 –KI@work). We acknowledge support by the Open Access Publication Fund of the University of Duisburg-Essen and Mr Björn Koos for his support in preparing the grant proposal.

The large language models ChatGPT (GPT-3.5) and DeepL (classic language model) were used exclusively to support the translation of the manuscript from German to English.

Data Availability

The datasets generated during and/or analyzed during this study are not publicly available for privacy reasons but are available from the corresponding author on reasonable request.

Authors' Contributions

Authors CA, GDG, JW, MA, HN, SM, NT, MT, FMB, and NB obtained the necessary funding and developed the design of the research project. All authors contributed to the organization of the research project. NB is responsible for project administration and supervision. PR drafted the study protocol. All authors reviewed, read, and approved the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: Cancer is the leading cause of death in Canada, responsible for 28.2% of all deaths. Based on surgical candidacy and disease status, both lung and esophageal cancer are treated through surgical resection by a thoracic surgeon. Although surgery contributes to improved outcomes, the 30-day postoperative mortality risks are as high as 10% and 2.8%, respectively. Evidence has shown that prehabilitation is a way in which patients can have improved postoperative outcomes. Prehabilitation is multimodal, often including some form of movement, nutrition, stress management, and smoking cessation. Given the complexity of the health care system, pragmatic trials are important methodological tools to assess internal validity and improve current practice under real-world conditions. Concurrently, using community resources is imperative to keep people active in their community and create sustainable programming.

Objective: The Boosting Recovery and Activity Through Early Wellness (BREATHE WELL) study aims to explore the feasibility, implementation, and preliminary effectiveness of a clinically integrated, community-based, prehabilitation health coaching program. This includes nutrition, smoking cessation, sleep hygiene, and movement for individuals scheduled to undergo surgery for lung or esophageal cancer.

Methods: This is a pilot, nonrandomized, pragmatic, repeated measures, mixed methods trial. We will recruit 32 participants diagnosed with lung or esophageal cancer and are scheduled to undergo surgical resection into the prehabilitation program, with 32 additional participants who decline participation to act as a control group. Participants who agree will then go through an 8-week tailored prehabilitation program (in person or virtual), covering movement, nutrition, stress management, nutrition, goal setting, and smoking cessation. They will complete 6 sessions prior to surgery and then have 4 sessions, 1×/week following surgery. Following the completion of the program, they will have 3 booster sessions via phone or Zoom (Zoom Video Communications). The primary outcome is feasibility: (1) recruitment feasibility—recruitment rate (the number of participants referred per month), enrollment rate (the number of enrolled participants divided by the number of referred participants), reasons for declining, and prehabilitation window (time between consent and surgery); and (2) intervention feasibility—adherence to the movement intervention, attrition, safety, study completion rate, and adverse events. Secondary outcomes include measures of

preliminary effectiveness including patient-reported outcomes, such as well-being, fatigue, and functional measures. All measures will be assessed before, during, and after the prehabilitation program.

Results: Enrollment has begun in January 2025, with 2 participants enrolled in the health coaching program. The full study is expected to be completed in approximately 3 years and be published in winter 2027.

Conclusions: This study will inform the feasibility, implementation, and preliminary effectiveness of a clinically integrated, community-based, prehabilitation program in Nova Scotia, Canada, for people scheduled to undergo curative intent surgery for lung and esophageal cancer.

Introduction

Cancer is the leading cause of death in Canada, responsible for 28.2% of all deaths [1]. Among these cancers, lung cancer is the most frequently diagnosed in the country, resulting in 25% of cancer-related deaths [2]. Esophageal cancer, while less common, presents unique challenges due to its effect on patients' nutritional status, its tendency to metastasize rapidly, and, consequently, its poorer prognosis [3]. Based on surgical candidacy and disease stage, surgical resection by a thoracic surgeon is a mainstay of treatment for lung and esophageal cancers. Although surgery contributes to improved outcomes, the 30-day postoperative mortality risk are as high as 10% and 2.8% for lung and esophageal cancers, respectively [4,5]. Postoperative complications (eg, pneumonia and pain) pose a significant risk to patients undergoing curative-intent, lung and esophageal cancer surgeries [6]. These events not only increase the length of hospital stay but also negatively impact the patient experience, decrease quality of life, and result in substantial financial burdens for health care [7-10]. Therefore, it has been proposed that completing a prehabilitation program prior to undergoing surgery may lead to improved postoperative outcomes for patients. Prehabilitation refers to assessments and interventions initiated prior to treatment to create a physiological and psychosocial buffer against anticipated deconditioning, complications, and other comorbidities that typically occur as a result of treatment [11,12]. Prehabilitation is multimodal, often including some form of movement, nutrition, stress management, and smoking cessation.

Previous research has found that older adults (aged 70 years and older; American Society of Anesthesiologist score III/IV) who participated in prehabilitation experienced 50% less postoperative complications relative to the control group; this type of intervention was safe and feasible and showed cost-savings of up to €800 (~US $833.62) per patient [13]. Although prehabilitation interventions have generally shown benefit [14], there is still little uptake into the standard of care. This could be due to a wide variety of factors, including the complexity of implementing programs in a health care setting. Therefore, there needs to be more consideration for clinical care pathways, delivery strategies, and infrastructure and personnel for the local uptake of these programs.

Given the complexity of the health care system, pragmatic trials are important methodological tools to assess internal validity and improve current practice under real-world conditions [15]. Concurrently, using community resources is imperative to keep people active in their community and create sustainable programming. Practice-based evidence is an emerging field that strives to ensure research is applicable to real-world settings [16,17]. Practice-based evidence is derived from implementation science research methods, which assess effective intervention in real-world settings and provide insights into the system's capacity and preparatory needs for dissemination and scalability [18]. The purpose of Boosting Recovery and Activity Through Early Wellness (BREATHE WELL) is to explore the feasibility, implementation, and preliminary effectiveness of a clinically integrated, community-based prehabilitation health coaching program, including nutrition, smoking cessation, sleep hygiene, and movement for individuals scheduled to undergo surgery for lung or esophageal cancer. Central to our research endeavor is the driving question: "How can a clinically integrated, community-based prehabilitation program be successfully implemented in the community, and can it lead to improved functional outcomes in patients undergoing surgery for lung or esophageal cancer?" This overarching question provides the study with its core focus and serves as a guiding force throughout the research process. The aim of this study is to investigate the implementation, feasibility, and effectiveness of BREATHE WELL, a community-based prehabilitation health coaching program specially designed for individuals scheduled to undergo surgery to address lung or esophageal cancer.

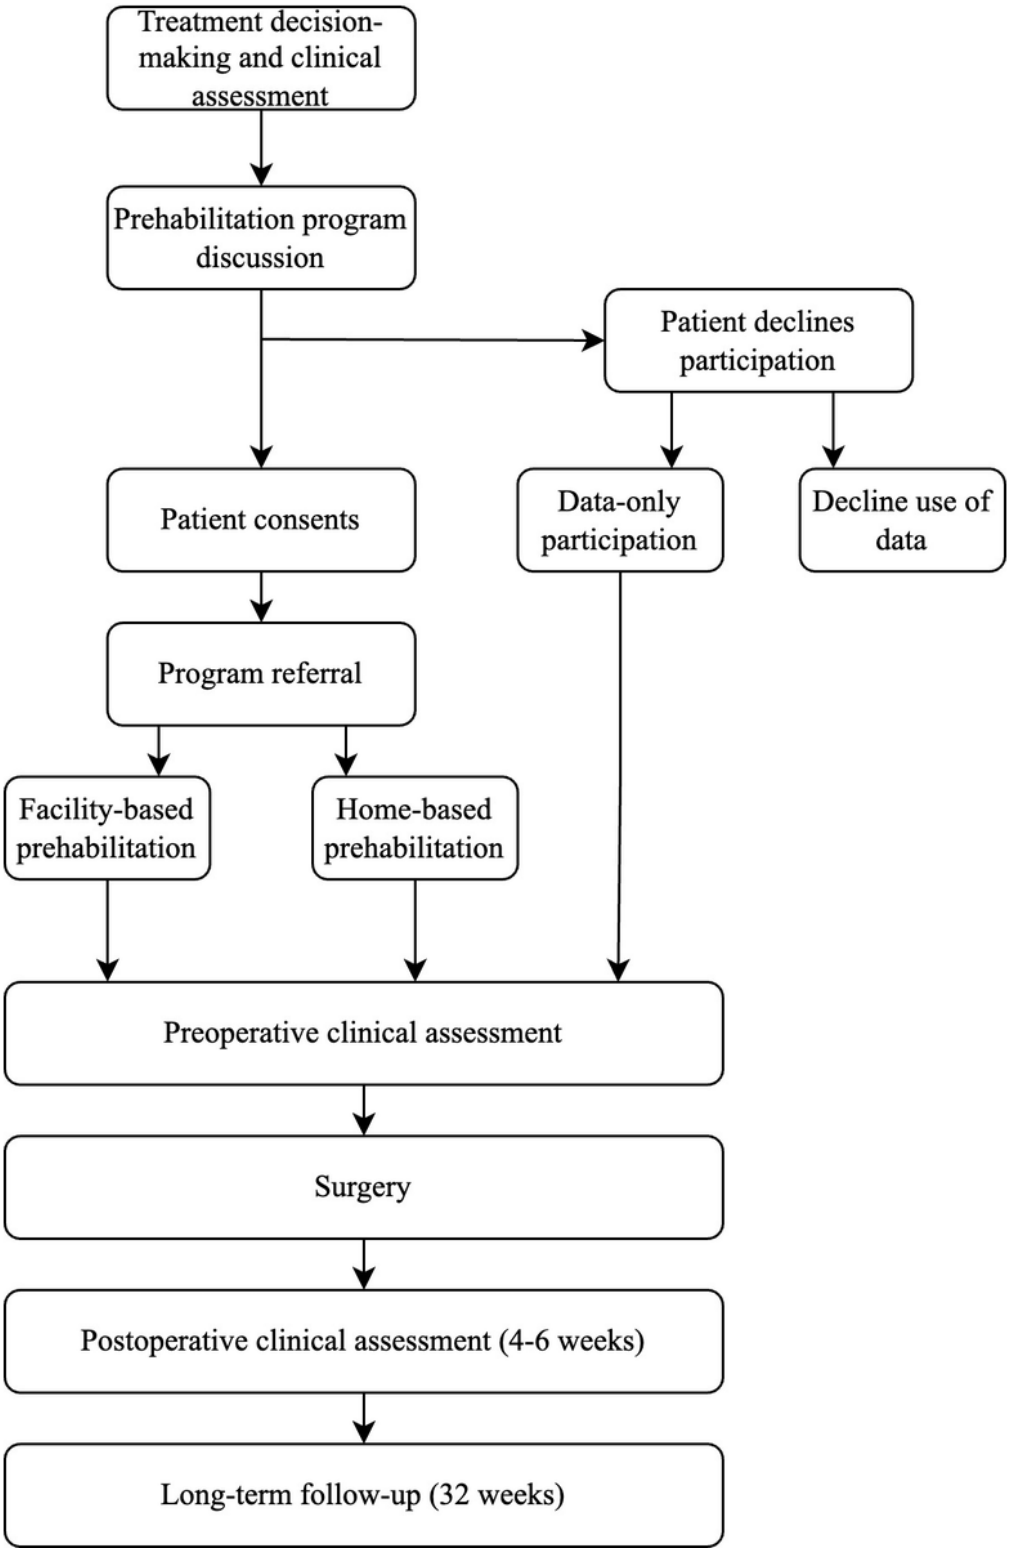
Methods

Design

This is a pilot, nonrandomized, pragmatic, repeated measures, mixed methods trial to assess the feasibility, implementation, and effectiveness of a clinically integrated, community-based, multimodal prehabilitation program for patients with lung and esophageal cancers in an urban academic health center in Halifax, Nova Scotia, Canada. Participant flow throughout the study is presented in Figure 1. This study aligns with the

TREND (Transparent Reporting of Evaluations of Nonrandomized Design) checklist (Multimedia Appendix 1) for nonrandomized trials [19].

Figure 1. Participant flow.



Participants

Based on a monthly surgical volume of 10 patients per month to the referring surgeon, assuming an enrollment rate of 25% while accounting for 20% attrition within a 16-month recruitment window, we will seek to recruit 64 participants (aged 18 years and older) diagnosed with lung or esophageal cancer (32 in the program and 32 who decline). This is based on the number of surgical candidates that the current surgeon sees in a 2-year period. Participants will be identified based on the following inclusion criteria: (1) confirmed diagnosis of lung or esophageal cancer; (2) treatment plan includes surgery (at least 2 weeks from the time of consent) [20]; (3) fluent in English; and (4) surgical oncologist approval. Exclusion criteria

include (1) unstable or symptomatic cardiac disease, musculoskeletal injury, or comorbid disease that precludes the ability to safely engage in physical activity or (2) significant cognitive limitations.

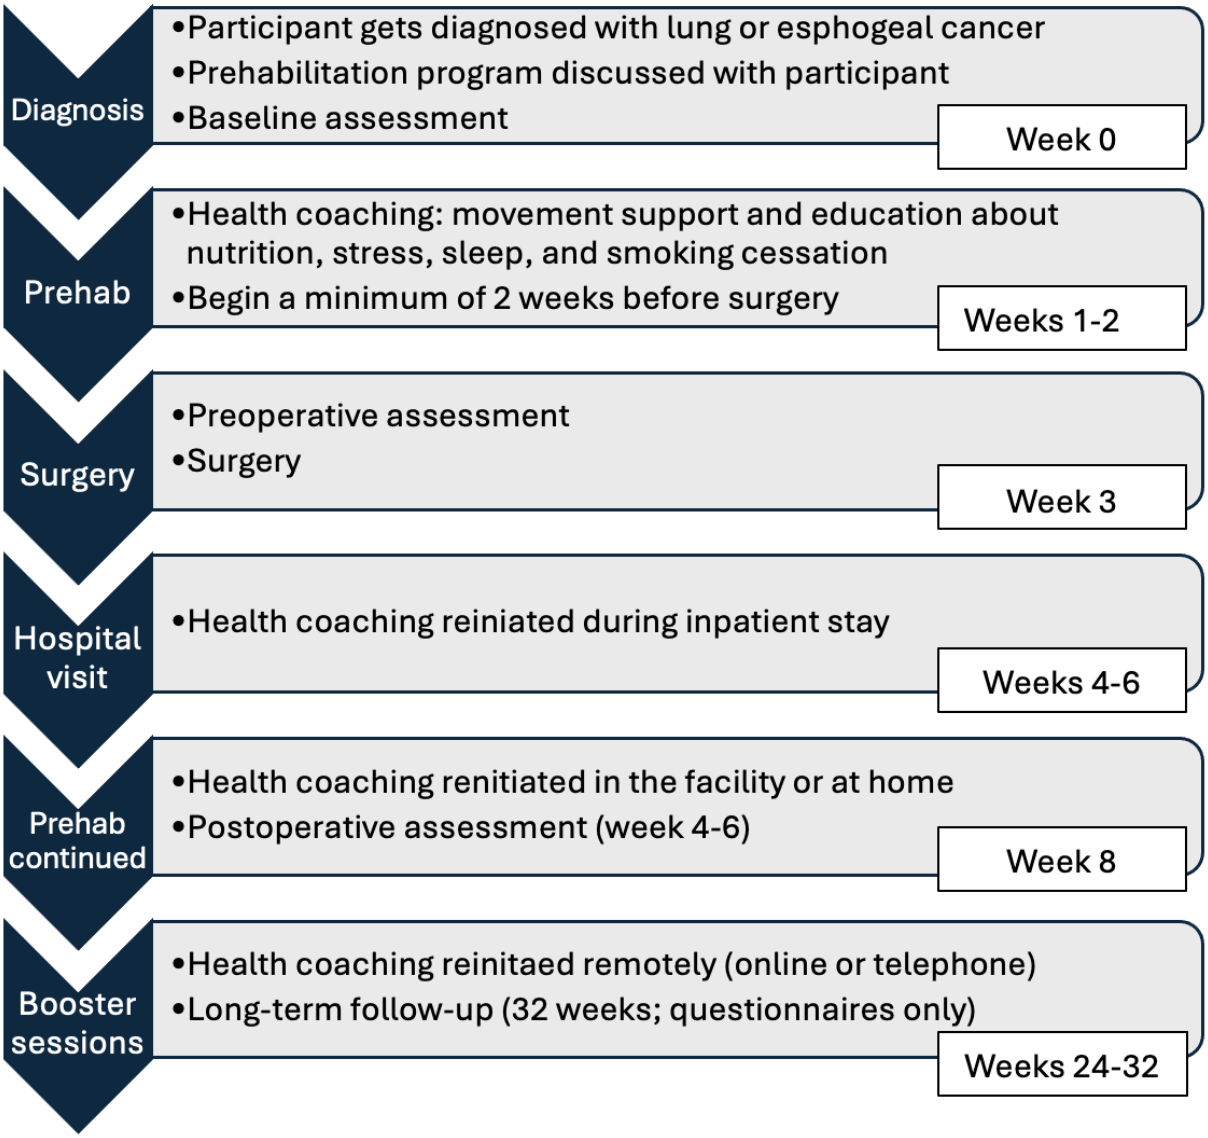
Enrollment and Assessment

Each potential participant will go through an assessment with the surgeon, including height, weight, blood pressure, heart rate, pulmonary function tests, grip strength, and a stair climb test as part of their clinical assessment. The thoracic surgeon will then raise the subject of prehabilitation with patients. At this point, patients will have the choice to participate in the prehabilitation program or not. If the participants do not agree to the study, they will continue with a standard of care. If a participant agrees to participate and provides written informed consent in accordance with the Nova Scotia Health Research Ethics Board, they will be referred to the research team and YMCA for immediate start of a prehabilitation program. Those who do not participate in prehabilitation will be used as a comparison group, through a waiver of consent; only those as part of the circle of care will pull these deidentified data for the research team.

Intervention

Participants will first have an appointment with a community-based, qualified exercise professional to discuss a tailored prehabilitation program. This will be dependent on a current functional fitness assessment (completed by the surgeon), goals of care, and surgery date. Participants will receive a handbook that will guide them through this process. The handbook will include a calendar of events, a guide to prehabilitation modalities (eg, movement, nutrition, sleep hygiene, stress management, and smoking cessation), publicly available resources (eg, Canada's Food Guide, CSEP 24-Hour Movement Guidelines, and Smoking Cessation guidelines), and helpful worksheets and other resources (Tobacco Free Nova Scotia Quit Line and mindfulness webinars). Participants will have the choice of delivery modality: either at home, virtual via Zoom (Zoom Video Communications), or at the nearest community-based YMCA. Both in-person and virtual programs will run in the same fashion. All participants will be given 2 resistance bands to assist with their at-home exercises. The intervention will last a total of approximately 8 weeks (Figure 2), depending on the time of surgery and postoperative follow-up. The intervention follows a tailored design, whereby the first 2-3 weeks provide more support, followed by weekly support and then biweekly support. This approach will help contribute to the autonomy of each patient. Following each counseling session, participants will engage in tailored movement sessions.

Figure 2. Timeline of prehabilitation intervention. Note that the "Prehab" phase may be longer than 1-2 weeks depending on the time from diagnosis to surgery. Prehab: prehabilitation.



Health Coaching

Participants will work with a qualified exercise professional who is trained in motivational interviewing (MI) to promote positive lifestyle habits. Participants will meet virtually or in person for counseling and movement sessions. Participants will receive 6 health coaching sessions prior to surgery (approximately 3×/week), with 5 additional wellness sessions after surgery (1×/weekly in the first month), and a follow-up (approximately 4-6 weeks after surgery). Health coaching will last 10-15 minutes, and the aim of these MI-informed behavioral counseling sessions is to develop personalized goals. Through MI techniques, qualified exercise professionals will use a shared decision-making approach with participants to promote evidence-based lifestyle modification, while using publicly available, evidence-informed resources to educate the participant on healthy and positive lifestyle behaviors. Following health coaching, the coach will lead the participant through a 15-45-minute movement routine. The booster sessions will provide health coaching over the phone or via Zoom only (Table 1).

Table 1. Overview of health coaching sessions.

Session	Week	Topic	Goal of session
Before surgery			
1	1	What to expect?	The goal is to have a clear understanding of what to expect from the diagnosis, surgery, and health coaching program. The qualified exercise professional will work with the participant to create a list of questions to discuss with their surgeon prior to their next visit. The qualified exercise professional will also start the process of what resources participants might need during their treatment, including Cancer Patient Pharmacare (which covers prescription cessation aids for example), Canadian Cancer Society patient supports (transportation supports), and other potential supportive services.
2	1	Understanding your body	The qualified exercise professional will go through how participants know their body the best, and things to look for when doing more movement. Key concepts of this session will be a rating of perceived exertion, use of our environment, and history of physical activity.
3	1	Movement + me	Participants will work with qualified exercise professionals to better understand what movement looks like for them and what type of movement they enjoy. Finding movement enjoyable is key to successful long-term movement.
4	2	Smoking cessation or sleep hygiene	If a participant reports current tobacco use, the qualified exercise professional will help the participant to understand the importance of smoking cessation as they prepare for surgery. This will include providing information about Tobacco Free NS and assisting with steps to access appropriate cessation resources. As well, participants will discuss sleep quality and the importance of sleep in preparation for and recovery from thoracic surgery.
5	2	Mindfulness	The qualified exercise professional will go through basic mindfulness attitudes, including patience, acceptance, and trust. The qualified exercise professional will review techniques for stress reduction and breathing.
6	2	Prepping for surgery	The qualified exercise professional will go through a reminder about things to bring with them to the hospital and talk about what to expect in the next few days. Participants will be reminded of the work they have done this far and be given a hospital date for their meet-up.
Surgery			
7	3	How are you feeling now?	The qualified exercise professional and participant will discuss how they are feeling and what supports the qualified exercise professional can offer to facilitate the transition from hospital to home setting.
8	4	Movement at home	The qualified exercise professional will assist the participant in better understanding movement at home and how they can make small movements as part of their everyday life. The focus of this session will be on doing small movement “snacks” and listening to their body.
9	5	Goal setting	Qualified exercise professionals will go through SMART[a] goals with the participants. This will include long- and short-term goals with an understanding of upcoming treatment and how that will affect goals.
10	6	Nutrition	The qualified exercise professional will assist the participant in the understanding of food as a whole and how important nutrition is when undergoing treatments for cancer, this will include tips from Canada’s Food Guide. If needed, the qualified exercise professional will also have resources for the food bank and how to access these types of services in their community.
11	8	Long-term planning: what is next?	The qualified exercise professional will discuss a long-term plan for the participant to sustain healthy lifestyle habits. They will go through their movement notes together and find a movement plan that will work for this participant, whether that be at home, at a local gym, or a more structured program.
Follow-up appointment with surgeon			
12	16	Booster session: where we are now?	The qualified exercise professional will discuss how the participant is feeling now and revisit goals. If participants require further support, the qualified exercise professional will also do anything within their scope and also refer to the Community Health Team resources, which offer support on many wellness topics and are free to all Nova Scotia residents.
13	24	Booster session: where we are now?	The qualified exercise professional will discuss how the participant is feeling now and revisit goals.
14	32	Booster session: where we are now?	The qualified exercise professional will discuss how the participant is feeling now and revisit goals.

[a]SMART: Specific, measurable, attainable, realistic, time orientated.

Movement Programming

All movement programming will be tailored to each individual participant’s current health status, goals, interests, and abilities. Each one-on-one movement session is expected to last 15-45 minutes and will include time for both warmup and cooldown. Participants will be instructed to begin at a light-to-moderate intensity (ie, 3-6 on a 10-point Borg Scale); systematically

progress (ie, periodized); and combine aerobic and resistance training programs for 15-45 minutes, 3 days/week. Should a participant feel that any movement is beyond their comfort level or ability, they will be instructed to inform the qualified exercise professional so that the movement can be modified to better suit their needs (Table 2).

Table 2. Outline of a movement programming[a].

	Description	Frequency	Intensity	Type	Time
Warmup	All sessions begin with a 5-minute warmup to gently increase heart rate and mobilize major muscle groups (RPE[b] 1-3/10).	—[c]	—	—	—
Aerobic	—	3-7× per week (3 supervised and 0-4 unsupervised)	MICT[d] (3-6 RPE) or HIIT[e] (7-9/10 RPE)	Rhythmic repetitive movements (eg, walking, marching, cycling)	10-15 minutes
Resistance	—	3× per week	4-7/10 RPE	Targeting major muscle groups including: • Legs (eg, sit to stand) • Back (eg, horizontal row) • Chest (eg, wall pushups) • Core (eg, dead bug) • Shoulders or arms (eg, shoulder press or bicep curl)	2 sets of 6-15 reps; 10-15 minutes
Balance	—	3-7× per week (3 supervised and 0-4 unsupervised)	4-7/10 RPE	Examples include single leg balance and tandem stance	2 × 30 seconds; 5 minutes
Flexibility	—	3-7× per week (3 supervised and 0-4 unsupervised)	4-7/10 RPE	Examples include hip flexor or quad stretch, hamstring stretch, and chest openers	2 × 20 seconds; 5 minutes
Locoregional	—	3-7× per week (3 supervised and 0-4 unsupervised)	4-7/10 RPE	Surgery-specific resistance and flexibility exercises (eg, swallowing exercises for esophageal participants)	2 × 20 seconds; 3-5 minutes
Cooldown	All sessions will conclude with a 5-minute cooldown to gently return heart rate to resting values (RPE 1-3/10).	—	—	—	—
Progression—aerobic	Sessions will begin at the lower limit of the desired range (eg, 3 sessions at 40% HRR[f]) and progress to the upper limit of the desired range (eg, 7 sessions at 70% HRR) as tolerated.	—	—	—	—
Progression—resistance, balance, and locoregional	Sessions will begin at the lower limit of the desired range (eg, 4/10 RPE) and progress to the upper limit of the desired range (eg, 7/10 RPE) by modifying repetitions, sets, or difficulty of exercises as tolerated.	—	—	—	—

[a]All programs will be tailored to each individual based on their functional level and environment.

[b]RPE: rating of perceived exertion.

[c]Not applicable.

[d]MICT: moderate intensity continuous training.

[e]HIIT; high intensity interval training.

[f]HRR: heart rate reserve.

Qualified Exercise Professional Training

Multiple YMCA-qualified exercise professionals will be trained in health coaching and MI to complete this study. This training will include (1) Thrive health services exercise oncology training [21], an exercise oncology-specific asynchronistic training module; (2) Health Coaching Certification [21], an evidence-based training that focuses on empowering health behavior change; and (3) completion of a full-day workshop on study protocol and MI techniques, including talks from experts in the field, individuals with lived experience of lung or esophageal cancer, and other health care professionals. Each counseling session will have a checklist and protocol for qualified exercise professionals to use outlining the targets and goals for each session. All qualified exercise professionals will be overseen by the YMCA clinical exercise physiologist who will offer advice and guidance on movement programming and health coaching sessions.

Outcome Measures

Feasibility (primary outcome) will include (1) recruitment feasibility—recruitment rate (the number of participants referred per month), enrollment rate (the number of enrolled participants divided by the number of referred participants), reasons for declining, and prehabilitation window (time between consent and surgery); and (2) intervention feasibility (adherence to the movement intervention, attrition, safety, study completion rate, and adverse events). The feasibility target for recruitment is a 25% enrollment rate. The feasibility target for adherence is 70% or more, measured by attendance to movement sessions with the qualified exercise professional. The feasibility target for attrition is 20% or less [22]. A timeline of feasibility measures is available in Table 3.

Table 3. Timeline of program measures[a].

[a]Pulmonary function test consists of tidal volume, forced vital capacity, vital capacity, and functional residual capacity. Vitals consist of blood pressure and pulse rate.

[b]5TSTS: 5 times sit to stand.

[c]FACT-L: Functional Assessment of Cancer Therapy—Lung.

[d]FACT-E: Functional Assessment of Cancer Therapy—Esophageal.

[e]FACIT-F: Functional Assessment of Chronic Illness Therapy—Fatigue.

[f]LOS: length of stay.

[g]ER: emergency department.

Participant outcome measures will include demographic information (age, sex, gender, socioeconomic status, race, marital status, educational level, and health knowledge), anthropometric measurements (height, weight, and BMI), medical information (surgery type, diagnosis, date of diagnosis, treatment status, and other chronic conditions), and patient-reported outcomes (PROs) that include quality of life (Functional Assessment of Cancer Therapy–Lung or Functional

Assessment of Cancer Therapy–Esophageal) [23,24] and fatigue (Functional Assessment of Chronic Illness Therapy–Fatigue) [25]. Both the Functional Assessment of Cancer Therapy–Lung or Functional Assessment of Cancer Therapy–Esophageal and Functional Assessment of Chronic Illness Therapy–Fatigue have been extensively validated and are reliable and widely used tools in the oncology setting [23]. Participants will have the option of completing surveys using the web-based (REDCap [Research Electronic Data Capture]; Vanderbilt University) database or using a pen and paper–based survey. A comprehensive assessment of functionality will be conducted in person in the clinic by the surgeon. Functional assessments are based on the Canadian Society of Exercise Physiology's Physical Activity Training for Health Protocol and include height, weight, resting heart rate and blood pressure, 5× chair sit-stand, stair climbing test, and grip strength. As part of standard of care, participants will undergo pulmonary function tests; these measures include tidal volume, forced vital capacity, vital capacity, and functional residual capacity.

The participants will be interviewed prior to the commencement of the program to better understand their perception of prehabilitation health coaching and to better understand their history with movement and healthy lifestyle behaviors. This will include questions that are based on past behaviors and future goals. This interview will be audio recorded and transcribed verbatim. A content analysis will be done using the Behavior Change Wheel and Theoretical Domains Frameworks [26,27]. This will aid in better understanding the behavior and barriers or facilitators to engage in the behavior. For sustained behavior change, participants need to have the Capability, Opportunity, and Motivation to perform the behavior [27]. Participants will also be interviewed at the end of the program to better understand their satisfaction with the program. This will also aid in understanding participants' perceptions of where they are regarding long-term behavior change. Postprogram interviews will be conducted to better understand their perspective on the program and how or if they found the program beneficial; these interviews will probe the understanding of sustained health behavior change and program satisfaction.

Postoperative outcomes include length of hospital stay and postoperative complications. The severity of complications will be graded according to the Clavien-Dindo classification [28,29]. Return to the emergency department within 90 days after the operation and 90-day mortality will also be assessed.

Statistical Analyses

The statistical analysis for this trial will be conducted with R (R Foundation for Statistical Computing). Participant characteristics will be summarized using descriptive statistics (mean, SD, frequency, and percentage). We will report on reasons for exclusion, attrition, and adverse events with frequency and percentages for each group. Safety will be determined by examining the total number of adverse events that occur over the duration of the program. Adherence to movement sessions will be summarized as a percentage (the number of movement sessions attended divided by the number of available movement sessions).

Baseline demographic and disease-related variables will be compared between prehabilitation and data-only participants using 1-way ANOVA for continuous variables and a chi-square test for categorical variables. The effectiveness analysis will include a linear mixed model to assess the difference in physical fitness and PROs from baseline (T0) to the preoperative (T1), postoperative (T2), 4-6 weeks postoperative (T3), and 32-week long-term follow-up (PROs only) time points, where the time point is the fixed effect and the individual participant is the random effect. A sensitivity analysis will be performed adjusting for sex, surgical type, and age. Linear mixed effect models will also be used to determine between-group differences. An α of .05 will be considered statistically significant. Point estimates and 95% CIs will be calculated for changes in the physical function and PROs at each timepoint and will also be used to provide important information for future sample size calculations. A Poisson regression will be used to estimate differences between groups for postoperative outcomes (ie, length of hospital stays, postoperative complications, return to emergency department, and mortality). Missing outcome data will be imputed using multiple imputation effects. Conclusions will be drawn using comparisons of each time point relative to the baseline.

Qualitative description is used to describe rather than interpret phenomena. Content analysis, the process of making sense of the meaning in the data will also be used during our thematic analysis. The research assistant will work with an experienced qualitative researcher to conduct multiple reviews of the transcripts and tapes (step 1) to familiarize themselves with the data. The analysis will be initiated as soon as the first interview is completed and continued concurrently with data collection. The analysis will examine what individual, structural, cultural, and institutional contexts are hypothesized to affect success. Additional codes will emerge to develop a thematic framework (step 2) that reflects the language and experiences of participants. An audit trial will be used to document the decision-making process. Sections of the transcripts will be charted into themes (step 3). Codes will be combined into themes during a series of research team meetings in which the relationships between behavior and the patient's capability, opportunity, and motivation to do said behavior will be explored and summarized. Analysts will review the codes and associate themes multiple times to check for potential biases, to ensure they reflect participants' words, and to improve and validate the interpretation (step 4) of the interviews. Additional interviews may be added when new themes emerge. Initial findings will be shared with a group of participants to help with interpretation and generate meaning from the data.

Ethical Considerations

This prehabilitation study includes human participants and was ethically approved by the Nova Scotia Health Research Ethics Board (REB# 1030020) in April 2024. All participants will go through a written informed consent procedure and will be aware that this study is completely confidential and voluntary. Participants will be given a small amount of money to offset the price of gas and parking when participating in an in-person program.

Author Reflexivity

This study brings together a multidisciplinary team with extensive expertise in research and clinical practice within the field of exercise oncology (JEL, DS, JC, and MRK); exercise measurement, evaluation, and prescription (JEL, DS, JC, and MRK); medical oncology (SS and AW); thoracic surgery (AW); policy implementation (LH and JP); and care experience (SS). The study team has a history of collaboration and has brought in key knowledge users to assist with the implementation of this project after the completion of research funding.

Results

Enrollment has begun in January 2025, with 2 participants enrolled in the health coaching program. It is estimated that it will take approximately 24 months to recruit all participants and collect all measures; analyses will take approximately 6 months; and writing the final manuscript will take approximately 6 months to complete. The full study is expected to be completed in approximately 3 years and be published in winter 2027.

Discussion

Principal Findings

The current standard of care for patients undergoing surgery does not include prehabilitation, although multiple randomized controlled trials have shown the efficacy of these programs [9,10,20,30]. Evidence is growing for the use of prehabilitation in standard of care, yet its implementation in clinical settings is still limited. BREATHE WELL will inform clinicians and knowledge users how structured prehabilitation programming using community settings and resources can bridge the gap between health care and the community. To maximize care pathways, it is imperative that those suited for community programs are triaged accordingly. Further, it is important to ensure that community-based resources are well equipped and trained to work with patients in prehabilitation to allow for sustained health behavior change and safe movement programming. Individuals living with and beyond cancer during and after treatment benefit from engaging in movement; however, they often lack the knowledge, resources, and guidance on how to do so safely and effectively [31-35]. By using an "exercise and educate" model focused on MI and health coaching, the emphasis will be on empowering participants to see the long-term benefits of behavior change and increase overall well-being for individuals. Also, previous community-based physical activity interventions with individuals living with and beyond cancer do see a longer-term increase in physical activity [11]. This could be due to familiarity with the environment and having increased support upfront, which can lead to better physical activity adherence. This study builds on previous evidence that prehabilitation is efficacious, yet its uptake into the standard of care is still lacking [14].

As part of this study, the intentional engagement of knowledge users including key health system partners, clinical care programs, and patients as team members will ensure high-quality evidence. It also provides an excellent infrastructure for rapid dissemination of findings into policy, practice, and clinical care. Knowledge translation initiatives will be ongoing throughout this research, including integrated and end-of-grant knowledge translation. We will regularly engage with all research team members, which includes key knowledge users (JP and LH) and patient partners (SS). The preliminary findings will be shared, when necessary, at team meetings, and interim research summary reports will be circulated via email and existing webinars and continuing education infrastructure established through our team members and collaborators. To support the further development of this project, we will generate an end-of-study summary report of key findings to policy and clinical partners. Findings will be disseminated to lung and esophageal cancer–specific audiences in Canada and internationally through conferences (eg, Canadian Association of Thoracic Surgeons Annual Meeting, American Association of Thoracic Surgeons Annual Meeting, Canada Cancer Research Alliance Annual Meeting, Canadian Society for Exercise Physiology Annual Meeting, and American Society of Clinical Oncology) and will be published in open access journals (eg, *BMC Health Services Research*) to enhance accessibility and potential for global reach and impact. This research will also be disseminated to patients and lay audiences through infographics to increase accessibility to a wider nonacademic audience.

There are several strengths to this study: (1) a pragmatic design allows for a deeper understanding of implementation and feasibility, which will aid in further understanding of prehabilitation in real-world settings; (2) the use of community-based facilities allows for a strong likelihood of not only system-level sustainability but also greater confidence for individuals to adhere to physical activity upon completion of the prehabilitation program; and (3) the use of a standard-of-care comparator group allows for preliminary effect estimates to understand if prehabilitation improves quality of care. However, this study is not without limitations. First, we have limited our sample to patients who have undergone thoracic surgery, which may not be generalizable to other populations with cancer. Second, the prehabilitation window is short (2-3 weeks), which precludes physiological changes. This is due to constraints from the diagnosis to the surgery date; if participants do have a longer window, they will be offered a longer presurgical program. However, with continued support after the surgery, participants will be supported to create long-term positive lifestyle changes and habits. Finally, this is a nonrandomized trial, which may decrease internal validity. However, the focus of this study is pragmatic in nature and the primary outcome is feasibility.

Conclusions

Prehabilitation is a key health intervention for those undergoing cancer surgery, with growing efficacy in the literature, yet the implementation of prehabilitation in real-world settings is lacking. BREATHE WELL will contribute to implementation science regarding approaches to support prehabilitation for surgical patients in a sustainable way that leverages the strengths of the health care and community setting.

Acknowledgments

The research team would like to acknowledge the continued support from the many administrative staff, Nova Scotia Health, and Dalhousie University, for their assistance in getting this research study off the ground. The study was funded by the Department of Surgery, Dalhousie University. The funder was not involved with the study design. The research team is focused on integrated knowledge translation and has used key support from patient partners (SS) and knowledge users (JC, JP, and LH) in the design, implementation, and dissemination of the study.

Data Availability

The original contributions presented in the study are included in the paper. Any further inquiries can be directed to the corresponding author. There are no data in the protocol paper.

Authors' Contributions

JEL, DS, JC, MRK, SS, JP, SS, and AW participated in conceptualization and funding acquisition. JEL, DS, JC, and AW collaborated on methodology. JEL wrote the first draft of the manuscript with assistance from DS and AW. All authors reviewed the final manuscript. AW supervised the full project.

Conflicts of Interest

None declared.

Abstract

Background: With the expected increase in the number of people needing care and the increasing shortage of skilled care workers, new care concepts are required. Therefore, digital assistive technologies (DATs), especially robotics, can improve the situation of people with different needs and create opportunities for participation. For a human-technology interaction to have a high level of usability, DAT's meaningfulness and effectiveness must be accessible to end users. Significant barriers to the use of DATs in health care are the lack of controllability and adaptivity, as well as control functions that are too complex.

Objective: The objective of this paper is to develop an interaction and control platform that is understandable to a layperson and has a programming interface for DAT interactions. The innovation consists of the expansion of usage and interaction options for carers of existing DAT in a more individual manner. This is to be achieved by combining modern interactive media, a modular software architecture, and already available DAT.

Methods: The project is planned as a mixed methods study with a longitudinal design, with multiple user involvements and measurement times in collaboration with 3 care facilities in Germany. When assessing technologies, the satisfaction of the basic human needs of competence, connection, and autonomy plays an important role in the actual use of the technology. These needs can be measured in the form of usability (System Usability Scale), intention to use (Technology Usage Inventory), and satisfaction with the carers' needs (Technology-Based Experience of Need Satisfaction). In the qualitative assessment, user experience is recorded using the think-aloud method and focus groups in order to obtain information about potential improvements of the platform.

Results: The EduXBot (Educational Exploration Robot Application Platform) project was initiated in January 2023 and is scheduled to conclude in December 2025, at which point the project's final results are expected to be available. The initial results were attained in the summer of 2024 when the final concept for the platform prototype was developed. In November 2024, an initial prototype of a functional platform for the simplified interaction and control of DAT was evaluated.

Conclusions: It is expected that the open DAT system architecture enables caregivers without any previous technical knowledge to assemble their individual DAT functional portfolio. The results of the project will provide low-threshold access to interaction options for existing DAT as well as expand the usage of such technologies in an individual and patient-centered way.

Introduction

Digital assistive technologies (DATs) have long been discussed as a way to address pressing health care challenges. On the one hand, these challenges are related to the aging of society and the associated increasing need for care services. On the other hand, the acute and future shortage of nurses makes it difficult to provide care for older adults and those who are sick [1-3]. The digital transformation of health care and the use of DAT could be an opportunity to address these challenges [4]. As the health care system in Germany is under pressure to respond to increasing care needs, one measure is to promote the digital transformation of the health care system [5-7]. However, preliminary work shows that DAT, such as mobile apps, telemedicine systems, and robotics, have not yet been implemented in care processes as sustainably as expected [8,9]. However, when used correctly, DAT can provide opportunities to reduce the burden on caregivers [10-13].

The term assistive technology is a generic term for assistive, adaptive, and rehabilitative devices, which, according to the World Health Organization [14], includes all assistive devices, such as crutches, bedpans, or wheelchairs. For the purposes of this study, the term is expanded to include digital technologies such as augmented or virtual reality technologies or robotic systems. A generally valid definition of DAT is difficult to formulate, however, because DAT can develop potential in different areas [15-17], the effects of which would then have to be demonstrated in a specific application.

Nursing can be described as a complex situation in which the patient must be approached individually and according to the situation. The advent of DAT presents a challenge to health care professionals, who must adapt these technologies to the diverse and individual needs of the patients they care for and integrate them into care processes that must be planned individually. Thanks to their training and professional experience, professional nurses are able to quickly understand these complex situations and make appropriate decisions. It is difficult for nurses to imagine that an algorithm-based system can learn their rules and principles and have the flexibility to know when to modify those rules or not apply them at all. Apart from this, nurses recognize that DAT could reduce the error rate for routine tasks that require high concentration, such as medication preparation or documentation [18].

In addition, ethical concerns play an important role in nurses' reluctance to use DAT. An aspect of the discussion is the change in the workflow that occurs with the integration of DAT. Nurses fear that the logic of the devices, which is different from their own, will cause additional stress or even make them feel influenced by others. Nurses also fear losing their jobs as technology takes over their activities. Last but not least, there is a fear of losing interpersonal contacts. A change in the psychosocial component of nursing work goes hand in hand with a reduction in the attractiveness of the profession for nurses and should, therefore, be avoided [18,19].

Previous work shows that technology development research has been approached from a technology-centered perspective. Reference to user interests is often only made in the context of raising awareness among target groups, identifying needs in the testing phase, or for a finished technology [20-22]. Participatory design approaches such as cocreation are a solution to foster usability and user acceptance. Cocreation is defined as a collaborative approach that involves end users and relevant stakeholders in all phases of a project [23]. Early involvement of end users can increase acceptance and have a positive impact on patient satisfaction and quality of care [24,25]. In addition, cocreation can increase the successful implementation of evidence-based interventions and policies through equal and deep involvement of end users [26,27].

In order for DAT to unfold its potential, it is necessary, on the one hand, to provide services that are tailored to the respective functional limitations of those in need of care so that the use of DAT can be planned and problem oriented [28,29]. This means that nurses also play a crucial role in the widespread use of DAT. According to a study by the Bertelsmann Foundation, the acquisition of knowledge about existing technical systems is a prerequisite for the use of DAT in care settings, as is the development of application skills on the part of nursing staff [30]. Preliminary work also shows that application knowledge and skills, as well as the opportunity to use DAT in relation to care problems, are beneficial for nurses' willingness to use DAT [31-34].

To fill this research gap, the EduXBot (Educational Exploration Robot Application Platform) project aims to develop and evaluate a technology-based interaction platform with a reduced complexity control interface as part of a cocreative, exploratory approach to facilitate the control of existing DAT by caregivers. The goal is to provide formal caregivers with a simplified way to use DAT to support caregiving. The aim of this feasibility study is to investigate to what extent a prototype for simplified control of already available DAT changes the willingness of nurses to use them in the nursing process. The collaborative project brings together developers from the field of technology research, nursing scientists, and business partners from the fields of project management for digital work environments and the development of digital formats for knowledge transfer. The cocreative nature of the project means that in addition to the scientific project staff, nurses will be involved as end users in every phase of the project. This ensures that the project goals are better achieved in terms of user needs and technical feasibility.

Methods

Conceptual Framework

The project aims at the participatory development and evaluation of a platform to promote the applicability of DAT in care settings. A feasibility study with a longitudinal design will be conducted based on a mixed methods approach. The main goal of the platform is a simplified application of DAT to support care processes. The development will be carried out in a participatory manner as a user-centered design (UCD) based on the suggestions of the "Motivation, Engagement, Thriving in User Experience" (METUX) model [35], which takes into account the expectations and experiences of the end users and promotes the intention to use (ITU) and thus the usability, relevance, and creativity of the platform, thus concretizing the overall implementation concept.

In practical implementation, the project is based on the theoretical model of UCD and follows the suggestions of the cocreative design cycle [36]. The UCD approach is used to cocreatively develop a more needs-based and more tailored end product based on the nurses' expert knowledge and to take possible consequences of implementation into account [36-38]. Positive effects are promised in terms of improving the identified outcomes as well as greater usability and user acceptance of technical products [39,40]. The cocreative design cycle is the process by which all relevant stakeholders are involved in the design and development of technologies. End users are actively involved in the design and development of solutions that meet their challenges. The result of the process is innovative and creative solutions that are useful, effective, and user centered, thereby promoting their actual use [41].

The user-centered and cocreative approach used in this study integrates 3 cycles (Figure 1) that incorporate the realities of end users (relevance cycle) and the scientific knowledge base (rigor cycle) into the development of technical products (design cycle) [42-45]. With this chosen approach, it is better possible to theorize, collect, and ultimately practically map the requirements for the technologies used in the study in the sense of determining needs. At the same time, collaboration between scientists and end users is more possible. Furthermore, end users can be more actively involved in product evaluation over the course of the test cycle. This ensures the functionality and, ultimately, the success in terms of improved applicability of a platform.

In the first step (relevance cycle), needs, functionalities, and application scenarios of and with nurses as end users are identified through focus groups. The selection of the DAT used in the project is based on the conditions of the cooperating institutions and the needs of the nursing staff. In order to clearly define nursing problems in the context of the learning scenarios, the concept of nursing need (see §14 Sozialgesetzbuch XI [Social Codebook XI]) is used. Based on this concept, DATs are selected that are already available and ready for use. These should cover a wide range and variety of technologies (from a mobile telepresence system to a complex humanoid robot).

Based on the results of this procedure, concrete scenarios will be outlined that are necessary for the implementation of a first demonstration model of the platform. In the next steps, the prototypes will be developed in 4 iterations with respect to usability, user acceptance, and satisfaction of basic psychological needs of the end users until the first prototype can be tested under simulated and real conditions in the facilities. The development of the prototype takes place schematically in 4 steps (Figure 2).

Figure 1. User-centered and cocreative design of the platform development (according to Farao et al [36]). DAT: digital assistive technology.

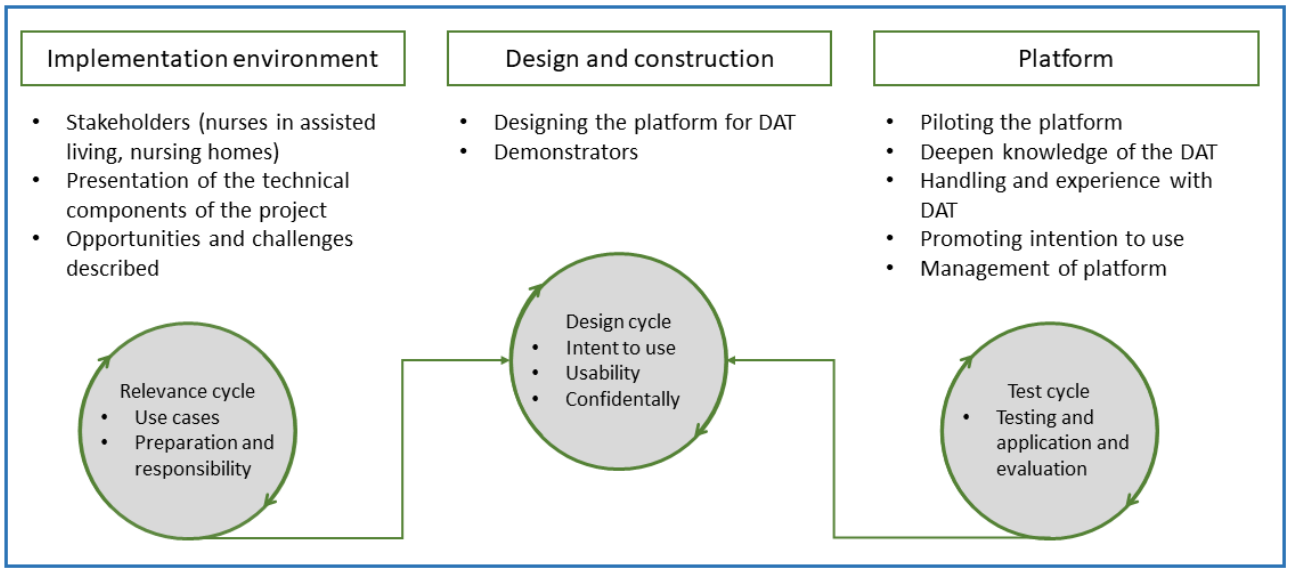

Figure 2. The development of the platform takes place in 4 steps. DAT: digital assistive technology.

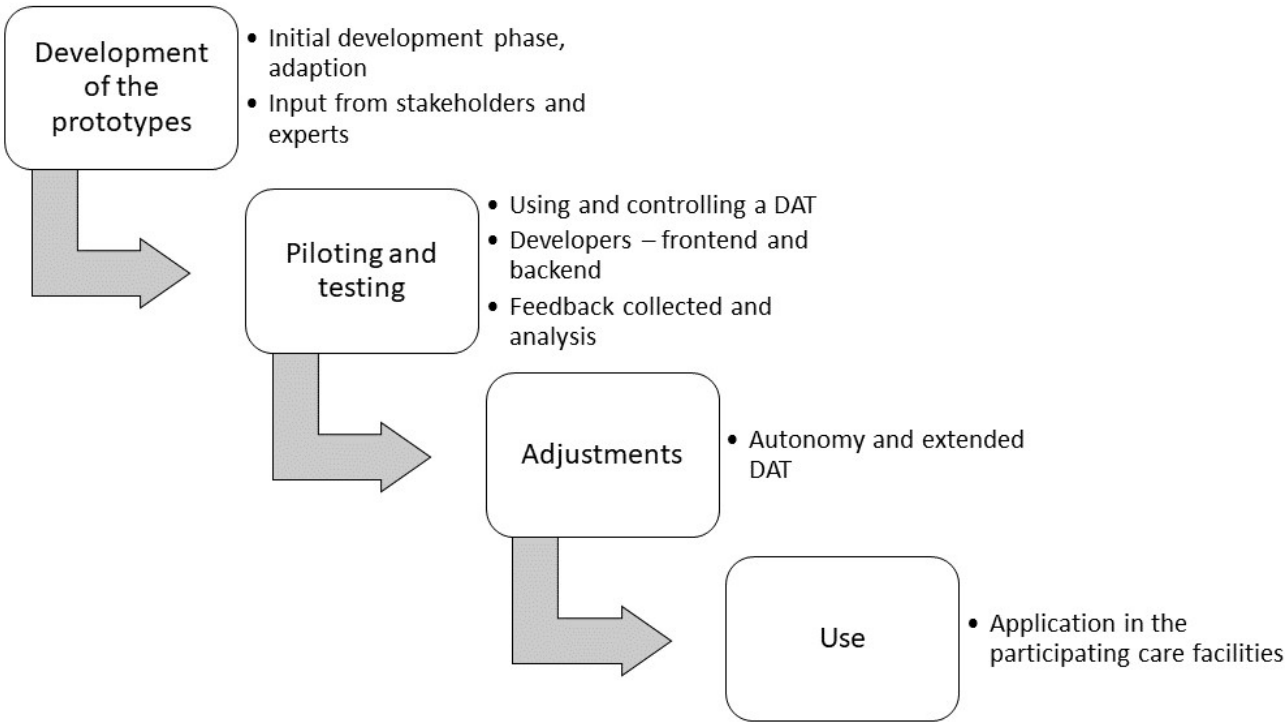
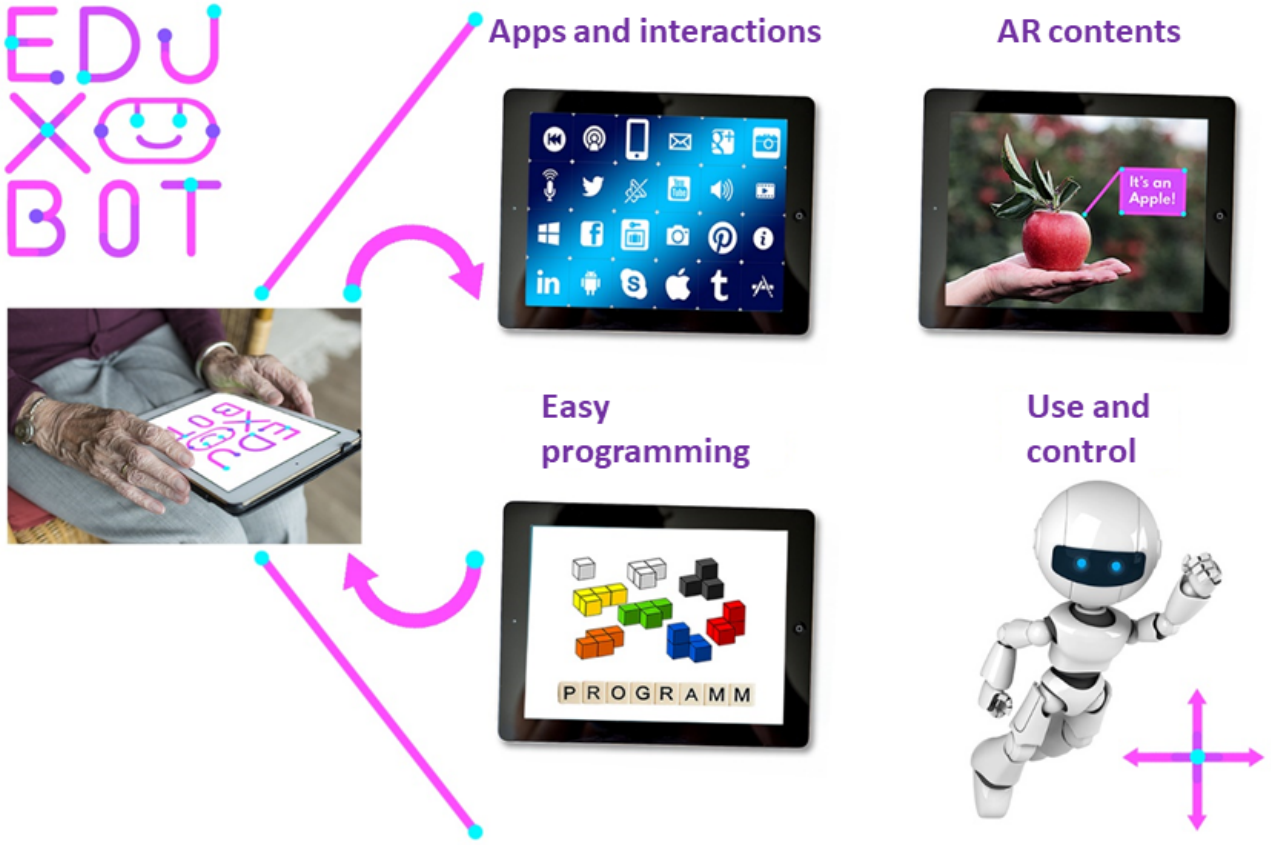


Technical Description

The innovation of the project does not lie in the development of new DAT per se but in the creation of extended usage and interaction possibilities for already available DAT. By combining modern interactive media and a modular software architecture, EduXBot aims to achieve the next level of DAT use in the care of people with disabilities, forced isolation, or restricted movement. The DAT should also promote an individual, programmable user interface for caregivers in an easier way to better meet the needs of those in need of care. EduXBot represents an experience and learning platform with 4 main functions (Figure 3): (1) programming (simplest type of programming), (2) community platform ("widget platform," users can share their apps), (3) using and controlling (easy way to interact, control, and use the DAT), and (4) augmented reality (AR) experience (experience and learn through AR content).

The multipart concept for using the platform then allows people with diverse previous technological knowledge to use DAT. That means EduXBot leads to the development of a layperson's iteration with the intention of human-technology interactions, which is developed in the form of a cocreative process together with the end users. EduXBot does not focus on the development of new care technologies that replace caregivers per se but rather on creating supportive interaction options that could relieve the burden on caregivers. The flexible and open system architecture of the platform supports this by keeping different DAT, sensors, and interaction systems available for different usage options. With the help of the development of low-threshold digital access options through an intuitive user interface with community and operator connections, informal support and supply networks are also strengthened as they enable participation in social networks.

Figure 3. The 4 main functions of the EduXBot platform. AR: augmented reality.



Study Design

Overview

EduXBot is a longitudinal feasibility study based on a mixed methods approach. The mixed methods approach combines aspects of quantitative and qualitative research in order to examine the research topic from different perspectives and to answer questions that could not be answered by a purely quantitative or purely qualitative study [46]. The researchers initiated the study with a quantitative phase, which was followed by a second qualitative phase that provided a more in-depth explanation of the initial results [47].

A total of 3 care institutions (1 inpatient, 1 outpatient, and 1 life-sustaining) that support people in their health care and daily life were recruited to participate in the project. The institutions were contacted as partner institutions in previous DAT research projects and agreed to participate in this project. Therefore, it can be assumed that the participating nurses are generally aware of the topic of DAT in nursing. The facility managers will be informed in detail about the project and will be asked to act as gatekeepers to motivate the nurses and relatives in their facility to participate in the research project.

Participants are invited to take part in the study as test subjects by the facilities with which they are affiliated. The participants are as varied as possible in terms of age, gender, length of professional experience, and so forth [48]. The inclusion of nurses from diverse backgrounds within the facilities serves to enhance the heterogeneity of the study sample, thereby contributing to the study's overall value. It should be noted that some participants may be unable to commit to the study due to scheduling conflicts or other commitments, while others may choose to withdraw (Textbox 1). It is essential to emphasize that no financial compensation is provided for participation in the study. However, those who elect to take part receive certain benefits, including complimentary refreshments during the workshop sessions and, upon request, recognition of their institution and name in the project acknowledgments.

Textbox 1. Description of the inclusion and exclusion criteria of the participants.

Inclusion criteria:

- The participants could be nurses
- The participants could be the support staff
- Currently in a facility that belongs to the project's practice partner
- Sufficient in written and spoken German

Exclusion criteria:

- Those who do not want to participate at the beginning or withdraw later

In the context of research involving human participants, it is imperative to consider pragmatic factors such as financial resources and the maximum feasible number of participants in accordance with the guidelines for designing and evaluating feasibility pilot studies [49]. According to the guideline, achieving saturation in a study occurs at 30 participants. Statistical principles suggest that 30 individuals are sufficient to ensure the normality of the sample size [50,51]. Therefore, the objective is to recruit a minimum of 30 caregivers. It is important to acknowledge that the implementation of blinding is not a viable option in this context, as the participants are required to actively engage with the technologies under study.

The primary objective of this study is to design the human-technology interaction between the platform and users in a manner that ensures a high level of usability for all users. The objective is to assess whether the accessible platform alters the intended use of DAT by offering a simplified application option for caregivers. This inquiry seeks to ascertain the potential for DAT to be integrated as a supplementary resource in the planning of individual care processes. The central question guiding this study is whether the EduXBot platform offers an interface that enhances the autonomy of caregivers' DAT use. The objective is to enhance usability by a minimum of one level over the course of the study. The primary objective is to ascertain the extent to which the platform affects the usability of DAT (System Usability Scale [SUS]), the intention to use it (Technology Usage Inventory [TUI]), and the satisfaction of caregivers' needs through technology (Technology-Based Experience of Need Satisfaction [TENS]).

The secondary objective is to develop a multilevel benefit concept for EduXBot. This will provide caregivers with different affinities for electronic media, as well as different levels of technical expertise, and will offer them windows of opportunity to use and experience the platform. The objective is to conduct a direct assessment of the EduXBot platform by the participating nurses and to evaluate the platform with the aim of continuously improving the content and application options of the platform. A secondary objective is to record user satisfaction in order to obtain information on potential improvements to the platform through the analysis of structured feedback. The collection of qualitative data will be facilitated through the implementation of think-aloud (TA) and focus group methods. The aim is to empower caregivers to articulate their subjective experiences and perceptions regarding the utilization of EduXBot in an unstructured manner.

The third objective is the long-term evaluation of the EduXBot platform, encompassing not only its readiness for implementation but also its potential for long-term integration, utilization, and management of DAT. A further objective is to examine the interrelationship between the perceived ITU, usability, and user acceptance of the platform, which is currently being developed for the application. The tertiary target variable is the long-term willingness to use DAT in a sustainable manner and to integrate the digital assistive support offering into the existing care provision framework.

The measurement times are based on the development process shown in Figure 2. This allows changes in improving ITU to be measured. Since there are different versions with different application scenarios, especially at TUI, Table 1 is intended to provide an overview of the measurement times and evaluation methods used.

Table 1. Different questionnaires are used at different measurement times.

Measurement time	Evaluation method
T0: Identification of functionalities and application scenarios	• TUI[a] original questionnaire (pre-post version) • Focus group
T1: Development of the prototypes	• TUI II parallel questionnaire (complete version) • Focus group
T2: Piloting and testing	• TUI II parallel questionnaire (complete version) • SUS[b] • TENS-Interface[c] • Focus group
T3: Adjustments	• TUI II parallel questionnaire (complete version) • SUS • TENS-Interface • Focus group
T4: Use	• TUI II parallel questionnaire (complete version) • SUS • TENS-Interface • Focus group

[a]TUI: Technology Usage Inventory.

[b]SUS: System Usability Scale.

[c]TENS-Interface: Technology-Based Experience of Need Satisfaction–Interface.

Quantitative Evaluation

The TUI is a valid measuring instrument that is based on the established Technology Acceptance Model [52] and its further developments [53]. It comprises 9 subscales, encompassing a total of 33 questions. These questions facilitate the estimation of technology use based on technology-specific and psychological factors. Each scale comprises 3-4 items, which are answered using a 7-point Likert scale. The intention to use scale uses a visual analog scale with a length of 10 cm. The subsequent Table 2 offers a comprehensive overview of the TUI scales.

Table 2. Description of the Technology Usage Inventory (TUI) scales according to Kothgassner et al [53].

Scale	Description
Curiosity	Curiosity and inquisitiveness of a person regarding a specific technology.
Technology anxiety	Independent of specific technology. Overwhelm, fear of using technology.
Interest	Independent of specific technology. Interest in technology and willingness to obtain information independently.
Usability	Perceived user-friendliness of a specific technology.
Usefulness	Perceived usefulness of a specific technology. Refers to support in everyday life.
Skepticism	Mistrust of a person regarding the use of a specific technology. Assessment of risk, danger, and disadvantages.
Accessibility	Perceived accessibility (in the sense of availability, procurability) of a specific technology.
Immersion	Can only be specified in connection with the corresponding technologies.
Intention to use	Intention to actually use a specific technology.

The internal consistencies of the scales can be rated as good overall (Cronbach α=0.70 to α=0.89). Furthermore, the TUI scales (with the exception of accessibility) have been found to be valid indicators of stress and relaxation based on heart rate and heart rate variability [53]. The wording of the individual questions can be adapted to the specific technology being evaluated, with the exception of the technology anxiety and interest scales. The TUI's modular design allows for the exclusion of individual scales contingent upon the investigative objective. For this study, for instance, the immersion scale was excluded, as no technology aimed at immersion was used.

This study uses the questionnaire at each measurement time (Table 1). Before the development of the platform, the original TUI questionnaire pre-post version was used to assess the caregivers' needs, functionalities, and DAT application scenarios. The "pre" version is administered before the introduction of the DAT, with the objective of collecting data on technology usage tendencies. The "post" version is administered after the introduction of the DAT, with the objective of establishing a baseline for measurement. Subsequent to these measurements, the TUI II parallel questionnaire (complete version) will be administered in its entirety. The

measurement enables the formulation of statements regarding changes in the ITU.

For the purpose of evaluation, a cumulative value was formulated for each scale. The cumulative value commences at 3 or 4, representing the lowest level of the construct, and, contingent on the number of items, ranges from 21 (3 items) to 28 (4 items) at the highest level. The ITU scale constitutes an exception in this regard. The scale is evaluated by measuring the distance from the right endpoint (full rejection) to the answer at the intersection of the line. The distance in millimeters was ascertained and added to all 3 items. The maximum scale value that can be attained is 300. The interpretation of test values is facilitated by the scale description. A high test value is indicative of a high level of the respective construct. In instances where the data does not conform to a normal distribution, it is advised to use stanines (standardized calibration scale with a minimum of 1 and a maximum of 9) and percentile ranks (relativizing the test characteristic value in relation to the reference population) [53]. Standard tables have been developed for this purpose (Table 3). Consequently, a statement regarding the proportion of participants who attained the same or lower values is attainable.

Table 3. Percentage ranks and stanines.

Percentile rank	Stanine	Percentage (%)
0-4	1	4
>4-11	2	7
>11-23	3	12
>23-40	4	17
>40-60	5	20
>60-77	6	17
>77-89	7	12
>89-96	8	7
>96-100	9	4

The SUS assesses the usability of a system as perceived subjectively by the user and is proven to be technology-independent; that is, it can be used for a wide range of systems and technologies [54,55]. The 10 items are divided into 5 positive and 5 negative statements and are each represented on a Likert scale from 0 to 5. The participants' answers result in the SUS item score, which must then be converted into the SUS overall score (from 0 to 100) [56].

The calculation of the overall SUS score entails the subtraction of 1 from the raw value of all odd items in the initial step, whereas the raw value of 5 is to be subtracted from the raw value of all even items. To illustrate this calculation, consider the following example. If item 1 had a raw score of 4, the calculated score would be 3 (obtained as 4 minus 1). For item 2, if the raw score was 2, the score was 3 (derived as 5 minus 2). Subsequently, the sum of these scores was calculated and multiplied by 2.5 to derive the overall SUS score [56].

The average overall score of all studies (68) can be used to interpret your overall score [55,56]. Bangor et al [57,58] also introduced a rating scale using adjectives and letters analogous to the American school grading system as an aid to interpretation (Table 4).

Table 4. Adjective scale of the System Usability Scale (SUS) overall score [54,55].

SUS[a] overall score	Area of acceptance	Adjective scale
90-100	Acceptable	Best imaginable
80-89	Acceptable	Excellent
68-79	Acceptable	Good
50-67	Marginal	Ok
35-49	Not acceptable	Poor
0-34	Not acceptable	Worst imaginable

[a]SUS: System Usability Scale.

Deci and Ryan's [59] assertion posits that the use of the platform is contingent upon the satisfaction of specific fundamental human needs, including autonomy, competence, and connectedness [35]. Psychology posits that the more fundamental psychological needs are met through interaction with the system, the more end users engage with technology [60]. The objective of the TENS-Interface questionnaire is to ascertain the extent to which direct interaction with a technology fulfills the fundamental psychological needs for autonomy, competence, and connectedness [35]. The questionnaires, initially developed in English, underwent translation into German under the guidance of a professional linguist for their

usage within the project. The translation process was guided by the "Translation Guidelines and Translation Documentation of the European Social Survey (ESS, 2020)" [61] with a focus on maintaining the validity and comprehensibility of the translation.

In the TENS-Interface, the items are each assigned to the basic needs of competence, autonomy, and relatedness. However, they are presented randomly in the questionnaire. The objective is to ascertain the extent to which direct interaction with a technology fulfills the fundamental psychological needs for autonomy, competence, and relatedness [35]. The application is designed to be universally accessible, ensuring autonomy of action, competence in handling, and a connection with the technology facilitated through the EduXBot platform interface. The collected data are then subjected to evaluation according to these objectives.

The descriptive statistics of the quantitative data are presented depending on the distribution, such as mean or median. Categorical data describing the sample are presented as absolute and relative frequencies. In order to answer the main question about the change in ITU, the difference between the measurement times of the individual test subjects, the facilities, and the overall sample is described as an absolute and relative mean difference. Possible further group differences are examined using the parameters "qualification" and "work experience." IBM SPSS is used as a tool for data management and data analysis.

Qualitative Evaluation

The TA methodology is used to qualitatively evaluate the platform. The idea is to ask subjects to express their thoughts and emotions out loud while testing the prototype in order to document them [62,63]. The advantage of this method is that it collects problems with the technology that has been tried by the end users, as retrospective surveys can lead to incomplete information about the problems with a technology. This means that TA protocols are helpful in understanding the thinking strategies of end users [64].

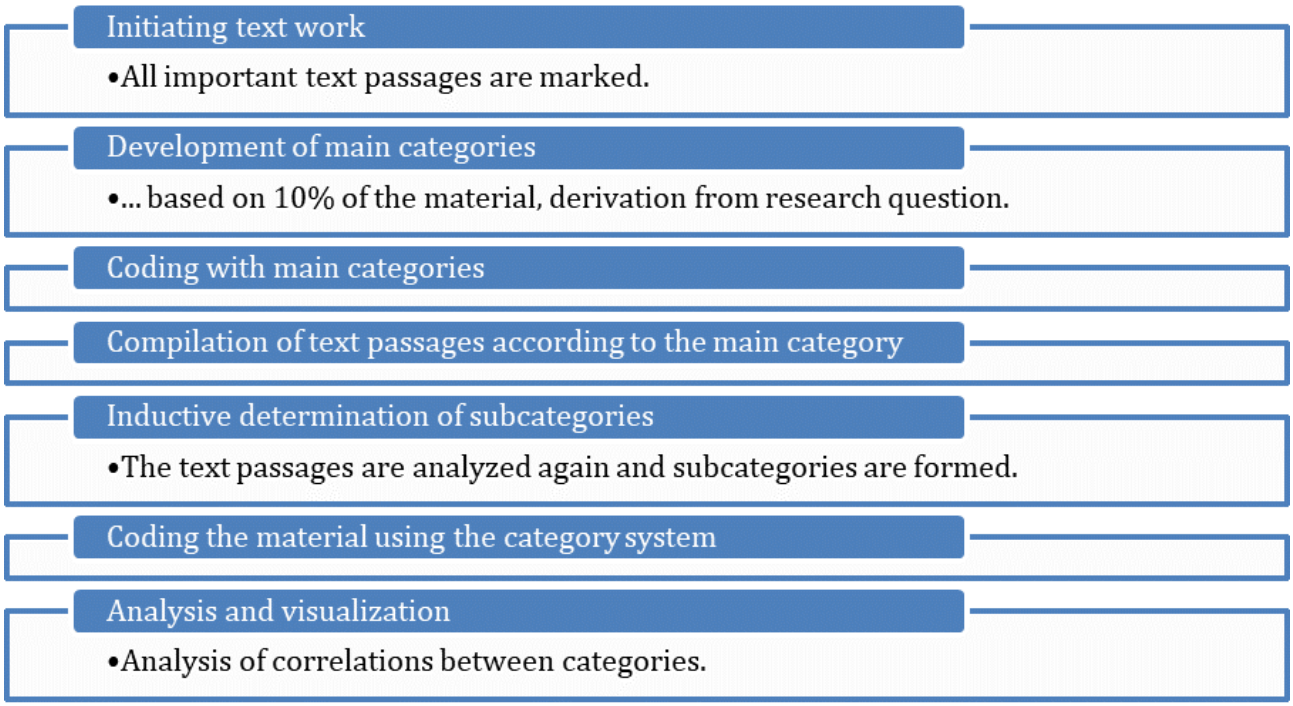
Testing sessions can be conducted on participants' own equipment or in a controlled environment. In protocols, participants think out loud as they complete a series of predetermined tasks. Participants are asked to say anything that comes to mind as they complete the task. This may include what they see, think, do, and feel. Sessions are often audio and video recorded so that developers can review what participants did and how they responded. Raw data comprise the verbalization of the thoughts, perceptions, and feelings that participants articulate as they complete a defined task. In a formal research protocol, all verbalizations are transcribed and then analyzed. In the context of usability testing, observers are asked to take notes on what participants say and do without trying to interpret their actions and words, and in particular, to note where they encounter difficulties [65].

The focus groups conducted during the iteration loops are partially structured with the help of guidelines Multimedia Appendix 1. The overall goal is to generate specific knowledge to answer the research question during the development process. The main factors that play a role are the adaptation of the selected application scenarios to the respective facilities as well as aspects of control and usability.

The composition of the focus groups is specifically based on theoretically based preselection in the sense of theoretical sampling according to the indicator caregiver [66]. In addition to these criteria, the most important thing is the willingness to talk about the respective needs and needs in the context of the platform development. No further criteria are defined in advance, but after the sample pool has been generated, the composition is determined exactly with regard to the contrasting of the groups. The number of participants in the focus groups is limited to 6 to a maximum of 10 people [67,68]. The selection of queries takes place according to the principle of theoretical sampling; achieving statistical representativeness is not intended [69].

All qualitative data were subjected to Kuckartz and Rädiker's [70] qualitative content analysis, which provides a structured framework for the content (Figure 4). Given the project's position within an emerging field of research, the material was coded inductively. This entailed the creation of categories based on the TA protocols and focus groups, thereby facilitating an exploratory evaluation of the material. This methodological approach enabled the systematic organization of the data material according to its content-related characteristics.

Figure 4. Steps of qualitative content analysis according to Kuckartz and Rädiker [70].



Ethical Considerations

All procedures involving human participants or human tissue will be performed in accordance with the ethical standards and principles of the institutional and national research committee of the 1975 Helsinki Declaration [71] and its later amendments or comparable ethical standards. Informed consent will be obtained from all participants. This study was approved by the Ethics Committee of the Medical Faculty of the Martin Luther University Halle-Wittenberg (approval 2023-190 of August 31, 2023). The study was registered in the German Register of Clinical Studies (DRKS00034195).

Results

The EduXBot project is funded by the Federal Ministry of Education and Research for a period from January 2023 to December 2025. During the summer of 2023, the practice partners were introduced to the project, and the application scenarios for a prototype design of the platform were cocreatively defined. The initial results were attained in the summer of 2024 when the final concept for the platform prototype was developed in collaboration with the target group. A total of 2 workshops were held in February and July 2024. An initial prototype of a functioning platform for the simplified interaction and control of DAT was evaluated in November 2024. The project is scheduled to conclude in December 2025, at which point the final results will be available. To ensure methodological quality, the Transparent Reporting of Evaluations with Nonrandomized Designs (TREND) statement [72] will be used for reporting the results.

Discussion

Principal Findings

The objective of this study is to design the human-technology interaction between an interaction and control platform and nurses in such a way that a process is created that ensures the high usability of DAT in nursing care. The central question guiding this study is whether the low-threshold platform changes the intended use of DAT through the simplified application options for nurses in order to integrate DAT as possible supplementary resources into individual nursing process planning. The objective is to assess whether the platform offers an interface that enhances the autonomy of nurses in using DAT. The evaluation will yield both quantitative and qualitative data, providing insights into the requirements of nurses as end users of DAT. The objective is to enhance the usability of the platform by at least one level over the course of the study.

Strengths and Limitations

The strengths of this study include the triangulation of quantitative and qualitative data. The potential for DAT to streamline individualized interventions in nursing care has implications for its intended use, which, in turn, affects its actual use in everyday work. The findings of this study will encompass practical, scientific, and societal ramifications, thereby paving the way for subsequent studies and interventions aimed at reducing nurses' workload. However, the study is not without limitations.

First, the number of participants is limited. For feasibility studies, the Guidelines for Designing and Evaluating Feasibility Pilot Studies [49] recommend basing the number of participants on practical factors such as availability and financial resources. In the event that the targeted number of 30 participants is not

attained, the evaluation will be conducted by combining quantitative and qualitative data in accordance with the methods outlined by Creswell and Plano Clark [47].

Second, the participating practice partners have previously engaged in other research projects, have been informed about the digital transformation, and have had experience with DAT. Conversely, participation in this study is voluntary, suggesting that nurses who are generally open to the topic are more likely to participate. The number of participating care facilities is limited to 3, which may limit the generalizability of the findings. While the inclusion of other professional groups, such as support staff, could be considered a valuable addition to the study, future research would benefit from the involvement of a more extensive range of care facilities and health care professionals to enhance the generalizability of the findings.

Conclusion

A scoping review of the state of the art of robotic interaction and control platforms in health care [73] reveals that only a limited number of feasibility or user studies have addressed the interaction and control of DAT by end users in a cocreative manner. The studies emphasize the necessity of end-user engagement to mitigate ethical concerns and ensure the relevance of the developed technologies to their intended beneficiaries [74-76]. A notable limitation of the existing studies is their exclusive focus on home care settings, resulting in a paucity of empirical findings for the domain of long-term inpatient care. In this context, the EduXBot project has been initiated to address this knowledge gap.

The implementation of technologies in nursing care practice is predicated on nurses' perception of their meaningful use. The generalization of the care process into standardized procedures is a challenging and complex scenario. The integration of individualized interactions further complicates the scenario, making it challenging for technical developers to meet the requirements and needs of the target group without the involvement of nursing professionals in the development process [77,78]. Caregivers play a pivotal role in research endeavors. Their expertise in the field, stemming from their in-depth understanding of diseases and their impact on patients, positions them as pivotal potential end users. By incorporating their insights, nurses can influence the development of technologies to align with their needs and requirements for interaction and control [79].

The dearth of development expertise among caregivers precludes them from programming the technologies independently. A potential solution to the usability issues of DAT is the development of a platform that provides an interface for nonprogrammers to create individual interventions using everyday controls and a few intuitive steps. This approach has the potential to ensure the sustainable implementation of DAT. EduXBot signifies an inaugural endeavor in this direction.

Acknowledgments

This work was created as part of the TDG (Translationsregion für digitale Gesundheitsversorgung)—project EduXBot (Educational Exploration Robot Application Platform) funded by the Federal Ministry of Education and Research via the WIR!—Wandel durch Innovation in der Region under funding FKZ 03WIR3118B. We acknowledge the financial support of the Open Access Publication Fund of the Martin-Luther-University Halle-Wittenberg.

Data Availability

The datasets generated during and/or analyzed during this study will be made publicly available upon completion of the study and can be obtained from the corresponding author on reasonable request.

Abstract

Background: In Mali, a lack of qualified human resources in primary health care and sexual and reproductive health and rights (SRHR) is one of the greatest barriers to the population's access to standard health services. Frontline professional training must be strengthened to respond to the needs of the population, particularly those of women and girls. Training must be conducted using an interdisciplinary and adapted approach to promote gender equality.

Objective: This study aims to identify the SRHR training needs among the community, educational actors, and primary health care providers.

Methods: A concurrent mixed methods design was adopted, using 2 methods. A quantitative method, through a cross-sectional analytical survey, will be conducted at the community level with university community health centers (CSCom-U) users and adolescents in CSCom-U health areas, as well as at the health education institution and community health centers levels with teachers, students, and interdisciplinary professional groups within the CSCom-U and district hospital maternity. Descriptive and inferential analyses will be conducted to process quantitative data. This research is at the stage of data analysis and interpretation. A qualitative method, based on 3 sources of data (focus groups, individual semistructured interviews, and document analysis), which involved the same targets as the quantitative component, with additional community actors such as Community Health Associations (Associations de santé communautaire) and Women's Service User Communities. A thematic analysis of the qualitative data using a mixed deductive and inductive method will be performed.

Results: *:* Field data collection took place from March to April 2022. Quantitative data from 3153 participants are being analyzed using SPSS. Qualitative data from 11 interviews and 27 focus groups were processed with Qualitative Data Analysis Miner. Data analysis is still ongoing.

Conclusions: This study will provide a better understanding of adolescents and SRHR user's service needs in terms of health services availability and quality and SRHR knowledge, issues related to student training quality, the level of adequacy between the training offered and the actual needs of the service recipients, and the level of preparation and ability of teachers to provide quality teaching taking gender equity into account. The recommendations drawn from this assessment will propose concrete actions to improve women and girls' health services provided by professionals, and to better adapt the future health professionals' profiles to the needs of communities, particularly those of women and girls.

KEYWORDS

mixed methods study; protocol; sexual and reproductive health and rights; Mali; primary health care providers; women and girls' health needs

Introduction

In Mali, the health system does not yet have sufficient capacity to meet the health needs of the population, especially those of women and girls. Primary health care (PHC), considered to be the foundation of sexual and reproductive health and rights (SRHR) service delivery, remains poor [1]. Each year, 33% of pregnant women give birth outside of a health facility, and the maternal death ratio is 440 out of 100,000 births [2]. Although 24% of Malian women aged between 15 and 49 years report having unmet family planning (FP) needs, only 15% of them use modern contraceptive methods [3]. Among women with unmet FP needs, 17% are oriented toward pregnancy spacing [3].

In rural areas, where approximately 75% of the Malian population live, access to PHC services is more difficult, thus creating substantial inequities [4]. There is a significantly higher fertility rate (6.8 vs 4.9 in urban areas), a lower proportion of prenatal care visits (37% vs 67% in urban areas), a higher proportion of deliveries outside a health facility (39% vs 7% in urban areas), as well as more limited access to FP (contraceptive prevalence rate for sexually active women not in a union is of 27% vs 44% in urban areas) [3]. This highlights that women and girls have poor access to nonstigmatizing SRHR services and information as well as insufficient bargaining power regarding their sexual and reproductive health [5,6]. In addition, gender-based violence (GBV), including domestic violence, is also widely common as 45% of women aged 15-49 years are survivors of physical or sexual violence [3]. However, this violence remains poorly documented due to several barriers such as low institutional commitment to integrating this issue, particularly in health reporting. There is also a lack of health professionals training and clinical screening tools for mental health problems, particularly for postpartum depression, GBV survivors, and people affected by armed conflict [7].

Health education institutions in Mali lack the human, material, and financial resources to fulfill their role in teaching PHC and SRHR care [8]. The gaps in undergraduate and continuing education contribute to the lack of skilled human resources in PHC and SRHR, particularly in rural areas [9]. Skills of frontline professionals need to be strengthened at the level of both institutional management and training, to respond to the population's needs using an interdisciplinary approach, to promote gender equality (GE), and, ultimately, to offer training tailored to the needs of the labor market.

To address these concerns, the Canadian consortium—which is composed of Santé Monde, the Cégep de Saint Jérôme and the Centre interdisciplinaire de développement international en santé from University of Sherbrooke and funded by Global Affairs Canada—has implemented the Local Teaching Communities for Healthy Women and Girls (Communautés locales d'enseignement pour les femmes et les filles en santé [CLEFS; French]) project. This project will operate for a 5-year period (2020-2025) in 5 different regions of Mali (Kayes, Koulikoro, Ségou, Sikasso, and the district of Bamako). The CLEFS project was developed in partnership with the Malian Ministries of Health, Higher Education, and Women's Promotion and with health training institutions in Mali (Faculty of Medicine and Odontostomatology [FMOS], National Institute for Training in Health Sciences [Institut National de Formation en Science de la Santé [INFSS]], and private schools), women's user committees, persons in charge at Community health associations (Associations de santé communautaire [ASACO]) for university community health centers (CSCom-U), as well as the Malian district hospitals to which the CSCom-U are attached. CSCom-U is a first-level health center in community settings offering a minimum package of health care. As community health centers with a university orientation, they also offer delocalized internships for medical students.

This project is based on the principle that health education institutions in Mali must fully integrate PHC and SRHR concepts into their curricula and pedagogical approaches to fulfill their social responsibility toward women's and girls' needs. This process involves collecting and analyzing data on the unmet needs of the beneficiaries, as well as those related to training and frontline health care system actors. In this context, the CLEFS project supported the Malian health training institutions (INFSS and FMOS) in conducting a participatory evaluation.

Methods

Research for the Continuous Improvement of PHC and SRH Training Programs

Improving care in SRHR requires going through all the steps of the training engineering process to ensure continuous improvement of health care services and related training. A key step is conducting a participatory evaluative study to identify the SRHR needs of the communities served by the CSCom-Us, with a focus on women and girls, as well as those of the various actors involved in training and in the provision of PHC services [10,11] to assess the adequacy between the real needs of the communities and the targeted output profiles in SRHR.

SRHR training needs for front-line care providers are those focusing on essential services such as comprehensive sexual health education, FP, antenatal, intrapartum, and postnatal care including emergency obstetric and newborn care, prevention and treatment of HIV and other sexually transmitted infections (STIs), postabortion care, and prevention, immediate services and referrals for cases of GBV, and finally prevention, detection, and management of reproductive cancers [12]. Training needs encompass a patient-centered approach that respects individual gender considerations and human rights.

This participatory approach will allow a better involvement and ownership of the needs assessment methodology by Malian professionals, as well as a better acceptance and use of the resulting findings. The results will reflect a concerted and consensual identification of SRHR needs and therefore an appropriate definition of the expected output profiles at the level of both undergraduate and continuing education.

Study Objectives

Overview

The main objective of this study is to depict the real and differentiated needs of Malian actors and primary care users related to SRHR to improve the training programs and services offered in this area.

This translated into the following specific objectives as follows: (1) to identify the SRHR needs of community actors and beneficiaries (adolescents and CSCom-U users); (2) to identify the SRHR training needs of students, trainers, and health professionals involved in training in terms of SRHR capacity building; and (3) to improve the curricula of nursing and obstetric practitioners in accordance with the needs of the health care professionals and specific needs of the populations served, in particular those of women and girls.

Overall Study Design

Using a participatory approach, this needs assessment adopts a concurrent mixed methods research design combining quantitative and qualitative methods [13]. It is based on the convergence of the analytical results performed for each method with all the actors concerned [14,15].

Method 1: Quantitative

Quantitative Study Design

Cross-sectional surveys were conducted in the 5 project intervention zones, namely the cercles of Sikasso, Kolokani, Baraouéli, Kayes, and Bamako in the regions of Sikasso, Koulikoro, Segou, Kayes, and Bamako. Note that a cercle is the second administrative division of Mali. Mali is composed of 8 regions and 1 capital district (Bamako), with each region divided into 49 cercles.

Three levels were considered as follows: (1) community level: targeting CSCom-U users and adolescents in the CSCom-U health areas; (2) health education institutions level (FMOS and the main INFSS and its regional branch schools [called Annex]) and CSCom-U targeting teachers, students/trainees as well as; and (3) groups of interdisciplinary professionals from CSCom-U and the maternity ward of district hospitals supported by the CLEFS project.

Participant Inclusion Criteria

The study participant inclusion criteria are as follows.

1. Female users: women of childbearing age between 15 and 49 years old who have resided in the household during the last 6 months before the survey.
2. Male users: male heads of household aged 20 years and older or their legal representative aged 20 years and older who have stayed in the household during the last 6 months.
3. Adolescents: unmarried girls and boys aged 15-19 years.
4. Interdisciplinary professional groups: consist of physicians, clinical supervisors, midwives, and obstetric nurses practicing in CSCom-U and district hospitals maternity units for at least 6 months prior to the survey.
5. Teachers: lecturers and supervisors on a temporary or contractual basis in the nursing care and obstetrical care programs at the INFSS or Annex schools and in the family/community medicine programs at the FMOS, who have been teaching for at least 1 year before the survey.
6. Students: students in the nursing care/obstetrical care streams of the INFSS and its Annex schools, as well as those of the Specialized Studies Diploma in Family/Community Medicine programs, from the 2nd year of teaching onwards—including trainees—with a proportional distribution between men and women and between the different years of study.

Sample Size and Techniques

Sample sizes of the different community targets and intervention zone were calculated separately based on the total number of households in the health areas and the size of the population targeted by the survey. Sample size was, considering the proportion of the phenomenon studied, at 50% and the CI at 95% [16]. The choice of 50% value allows us to have a sufficiently large sample to make inferences, regardless of the true value of the phenomenon studied in the real population. It was calculated using Epi Info7 software (Centers for Disease Control and Prevention) and was distributed proportionally to the size of the households in the selected villages.

Student and teacher sample size was calculated separately based on the total number of students in the nurse and obstetrical care stream at INFSS and its Annex schools and the number of family/community medicine and teachers involved in these streams at the 2 institutions. The calculation was done using the same method and the same software as the community-level actors in a separate way for the INFSS, the INFSS Annexes, and the FMOS. Thus, the calculated sample size (teachers and students) at the Annex schools' level was proportionally distributed based on the number of teachers and students in the different Annexes.

At the Community Level

A multistage sampling technique was used for selecting study participants (stratified random, clusters, and simple random).

Stratified random sampling was performed in the villages or sectors of the CSCom-U health catchment areas considered as natural strata (4 per CSCom-U). The lists of villages in the health catchment areas were established by CSCom-U. Strata were randomly drawn considering proportionality in this population by applying the systematic random method with a sampling step calculation. Once these strata were randomly drawn, the households within these villages or sectors were grouped into clusters (composed of a maximum of 40 households) using the segmentation method for each one. Thus, clusters were randomly selected, and the survey was conducted among the households in these clusters.

Another simple random draw was then conducted within households to select one woman of reproductive age in each household (if there are several) to answer the user survey questions. The head of the household or his/her representative who is 20 years or older was surveyed to answer questions about users. Adolescents (male/female [M/F]) meeting the criteria in the selected households, were also surveyed after a random draw if numerous. If the number of households expected to be surveyed was greater than the number of households in the selected cluster, another cluster was randomly selected to complete the total number of samples required for the survey.

At the Educational Institutions and CSCom-U Levels

A simple random draw without replacement was made from a list of all teachers of the Specialized Diploma of Family Medicine/Community Medicine and the INFSS and Annex schools to obtain the required sample size. Another simple random draw without replacement was also carried out based on the list of the students of the cycles and the level of teaching concerned to obtain the required sample size. The sample size was segregated by gender/level/profession. Randomly selected students were contacted to participate in the survey after obtaining their consent. If a student refused to participate in the survey, another number was randomly drawn to replace him/her until the total sample size was reached.

For the interdisciplinary focus groups in the CSCom-U and district hospitals, as the number of staff is not large, all physicians, midwives, and nurses with a role in SRHR who were available at the time of the team's visit and who gave their consent to participate were surveyed.

There is a low number of professionals in CSCom-U and maternity care. Therefore, all available and willing physicians, midwives, and nurses were solicited for the CSCom-U and district hospitals interdisciplinary professional focus groups.

Quantitative Data Collection and Management

To carry out the data collection, teams of external interviewers and trained supervisors were deployed on site. The interviewers were external individuals with expertise in conducting surveys and were recruited by the project team for the period of the data collection. They were responsible for carrying out the surveys among users, adolescents, and students. Due to the sensitivity of sexual and reproductive health issues, female interviewers conducted the surveys among female respondents and male interviewers among male ones.

Supervisors made up of members of the State's Technical Services and members of the FMOS, INFSS, and Association of Private Health Schools were responsible for verifying the conformity of investigators' work and supporting them when necessary. Their involvement strengthened the process of ownership of the continuous quality improvement approach from data collection to the presentation of evaluation results. This approach ensured the transfer of acquired skills to other stakeholders and replicated the continuous quality improvement process in their respective regions, with little or no outside technical assistance. Supervisors were also responsible for conducting the qualitative component.

The FMOS experts (Mali), in collaboration with the INFSS (Mali) and supported by the CLEFS project team (Canada), developed and customized questionnaires tailored to the various survey targets. These questionnaires were subsequently distributed to all stakeholders involved in the training needs assessment process for review, appropriation, and validation of the tools. Once validated, the tools were created on the Kobocollect platform (KoboToolbox software) and then deployed on tablets or smartphones to collect data. This method offers several advantages such as quickness, error avoidance, the obligation to answer all questions (better completeness of data), and reduction of outliers. All data collected on-site were sent daily to the Kobocollect account and extracted in an Excel file to be reviewed during the data collection.

Prior to data collection, a 3-day training was conducted for the entire evaluation team. This was followed by a 1-day pretest in an area outside of the project's intervention regions to assess its clarity and comprehensibility and to enable the methodology to be adjusted if needed.

Quantitative Data Analysis

Since the data were collected with tablets or smartphones, data entry was instantaneous. Data were extracted from the KoboCollect platform in Excel format, then processed, cleaned, and finally analyzed using Excel (Microsoft Corp) and SPSS software (version 27; IBM Corp).

Data analysis and interpretation are still ongoing. According to our research protocol, we will conduct descriptive analyses, such as examining proportions, averages, and SDs, to gain insights into sociodemographic characteristics. This includes

examining levels of knowledge, attitudes, practices, and perceptions regarding various aspects of SRHR, specifically FP, sexuality, STIs, HIV, prenatal care, childbirth, and GBV. The level of satisfaction and challenges related to the use of CSCom-U will also be analyzed. Access to information for CSCom-U users and adolescents regarding SRHR will also be measured.

The evaluation will also include an assessment of the satisfaction levels of students with the SRHR programs attended, the training environment and internships including safety aspects; students' sense of preparedness to face professional life; level of preparedness of teachers and health professionals to respond to the needs of students and interns and to train students able to respond to community needs.

Several inferential statistics will be used. For example, chi-square tests will be used to compare the proportions of the variables of interest and the student *t* test will be used to compare mean scores. Gender analyses will also be performed to understand gender specificities. The statistical significance level will be set at 5%. Multivariable regression analysis will be conducted afterwards if significant associations are found in bivariate analyses.

Method 2: Qualitative

Qualitative Study Design

Three groups (ie, multidisciplinary teams, community stakeholders, teaching teams, and students) were targeted for the qualitative component, which was conducted using 3 sources of data: focus groups, semistructured individual interviews, and a literature review.

Participant Selection and Method

Community Actors

Community actors mainly included the project's implementation partners, that is, ASACO members, women's user communities, youth groups, and community relays. This phase also reached users, adolescents, traditional birth attendants, traditional therapists, and community leaders. Targets were chosen according to a purposive sampling and snowball strategy until data saturation was reached according to the inclusion criteria previously identified in the sample of the quantitative component. To ensure a better representation of this population, we aim to select a variety of profiles in terms of age, gender, number of years in office, and as members of different associations.

At the community level, 6 focus groups were conducted as well as semistructured interviews per health area as follows: a mixed focus group (M/F) with members of each ASACO (8 to 12 people); a women's focus group with communities of women users (8 to 12 people); a mixed (M/F) focus group with youth groups, provided that heterogeneous youth groups exist in the localities. If not, or depending on cultural realities, homogeneous groups were conducted; a mixed focus group (M/F) with community relays of 8 to 12 people; a homogeneous focus group with women users of the SRHR services of the CSCom-U; a mixed focus group (M/F) with adolescents; and individual interviews with a traditional birth attendant or rural maternity officer and a traditional therapist per village/area, if available.

CScom-U and District Hospital Maternity Units' Multidisciplinary Teams

These multidisciplinary teams were composed of medical doctors, midwives, and obstetric nurses involved in the SRHR services. CSCom-U and maternity technical staff were not numerous and therefore all of them were involved.

Concerning the data, a mixed (M/F) focus group was organized at each CSCom-U and district hospital maternity unit to explore the following elements: the clinical skills of health professionals, the challenges, and issues they face in providing quality SRHR services to women and girls, their level of ability (training, tools, and equipment) to provide quality SRHR services as well as mental and environmental health issues. Discussions also focused on their ability to provide support and respond to the needs of trainees, including safety issues, and harassment.

Educational Institutions Actors

Overview

Two groups of actors were targeted at this level: teachers and students. They were chosen according to a purposive sample strategy and until data saturation was reached, according to the inclusion criteria already identified in the sample of the quantitative component. To ensure a better representativeness of this population, we selected a variety of profiles in terms of gender, seniority, level of study, teaching field, and type of teacher (lecturer and supervisors).

For the Teachers

Three mixed (M/F) focus groups (1/nursing, 1/obstetrical, and 1 family or community medicine specialty diploma) of 8 to 12 teachers were organized. Our objective was to better understand the level of preparation of the teachers in terms of pedagogy, teaching SRHR, their expectations, and the difficulties they face in teaching in the continuous improvement of programs.

For Students

A heterogeneous focus group for the nursing stream, a homogeneous focus group for the obstetrical stream, and a heterogeneous focus group for the family or community medicine specialty diploma of 8-12 students was organized. Our objective was the following: to identify the main challenges and issues related to the quality of training, the adequacy between training and the needs of the populations, the training environment, GBV, security aspects, and the consideration of their specific needs by teachers. To obtain quality information, students were selected from the 2nd year of training.

Document Analysis

In addition to the literature review, a documentary analysis was conducted and covered: the CSCom-U supervision reports, maternal death audits, CSCom-U and district hospitals activity reports, previous evaluation reports, etc. These reports helped to determine the needs already identified by the national or regional level at the CSCom-U and to understand the underlying problems related to SRHR.

Qualitative Data Collection and Management

Overview

Focus groups and individual interviews were conducted using interview guides tailored for each target group. They were developed by the project team in collaboration with key partners from FMOS and INFSS and validated by all stakeholders in the needs assessment process. The guides were inspired and adapted to the context and needs of the project based on existing guides such as the Demographic and Health Survey and covered the main themes explored (eg, SRHR knowledge and services offered) according to the actors of each target. The various individual interviews and focus groups were conducted by the survey supervisors, who are the project's supporting partners, that is, agents of the government's technical services, but also key partners. For the focus groups, a minimum of 2 people conducted them. One was responsible for facilitating the discussion and the other for managing the recording, taking notes, and making observations of the participants. For individual interviews, 1 or 2 people conducted them depending on the number of supervisors, one of them was responsible for asking the questions, and the other for taking notes and managing the recording.

At the Community Level

For the recruitment and data collection, our evaluation team informed ASACOs leaders as well as the Technical Directors of the Center of the evaluation process, the date, and the participants to be met. They then informed the other members of the ASACOs, the communities of women users, the youth groups, and the community relays and set up a schedule of visits and meetings with the different participants. The different discussion groups were conducted in the ASACO offices. ASACOs, with the support of the evaluation team, made the necessary arrangements to ensure the involvement of the participants and to respect data confidentiality.

Guidebooks were written in French, but were administered in Bambara, the most widely spoken national language of Mali. The observer took notes directly in French. Each focus group lasted a maximum of 120 minutes and was recorded after obtaining verbal or written consent from the participants. Discussions were fully transcribed as they occur in verbatim form and translated by interpreters when needed.

Individual interviews were conducted with traditherapists, traditional birth attendants, and community leaders and occurred in the villages or areas selected for the quantitative survey. Interviews were held after the ASACO leaders had informed the customary authorities and obtained the free and informed consent of the participants. Interviews lasted 45 to 60 minutes at most. The interviews were conducted in Bambara and verbatims were translated into French.

At CScom-U and District Hospital Maternity Units' Levels

The evaluation team informed the technical directors of the center and the district medical officer, who in turn informed the technical staff of the objectives of the evaluation, the people to be involved in the process, and the schedule for the evaluation team's visit. In collaboration with their ASACO, they made the necessary arrangements to encourage the participation of the people concerned as well as confidentiality during the data collection.

At the Health Education Institution Level

Under the guidance of the evaluation team, the administration of these institutions informed faculty and students of the evaluation process, objectives, and schedule. Together they organized the recruitment of faculty and students who wished to participate in the interviews. They provided a room for the team to ensure the confidentiality of the interviews. At the school level, interviews were conducted directly in French and notes were taken in French. They were also recorded after obtaining participants' consent.

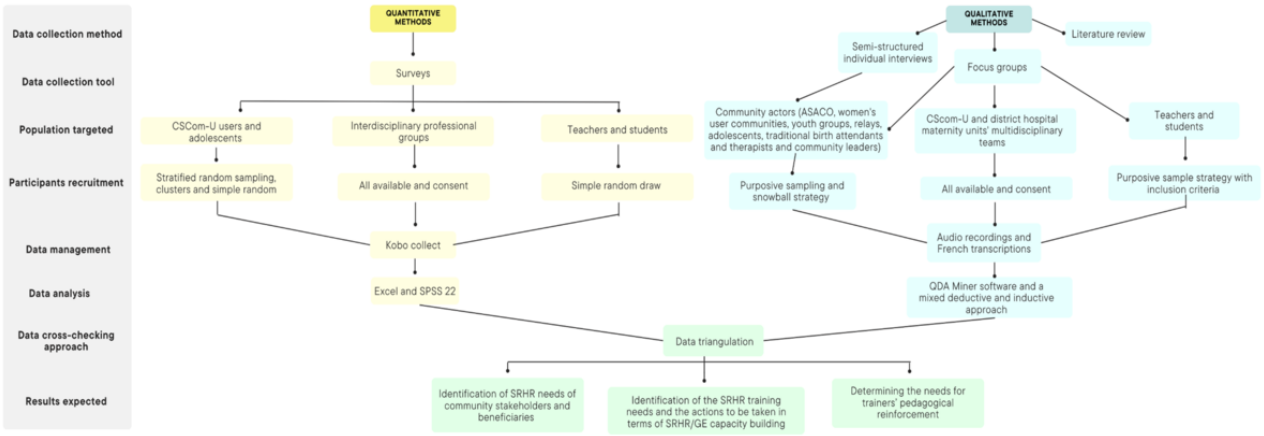
Qualitative Data Analysis Methods

Data analysis and interpretation are still ongoing. Qualitative data analysis will be conducted using an iterative process and will include the listening of audio recordings, successive readings of French transcriptions, team coding, team analysis, and participant validation. The project team will code the interviews using QDA (Qualitative Data Analysis; Provalis research) Miner software using a mixed deductive and inductive approach. This iterative method simultaneously makes sense of the data collected based on the state of knowledge, while potentially identifying new meanings. A brief list of initial codes based on the interview guides will serve as a coding grid a priori. It will be modified and enriched as the analysis proceeds. Coding will be controlled by a double coding technique performed by a member of the project team and the expert researchers. Parallel and independent coding will be done for the first few 4 interviews, followed by a comparison of the results. This process will be repeated until a consensus list of initial codes is obtained as well as intercoder fidelity greater than 90% [17].

Mixed Methods Integration

We will adopt a strategy using the matrix technique to summarize and present the QUAN and QUAL results [18]. First, the main statistical results (QUANT component) of the surveys will be presented by the participant group. Second, the themes emerging from the QUALI component (interviews and group discussions) will also be presented in a matrix by the participant group. This will enable us to look for similarities and divergences within and across participant groups, as well as patterns between different participant groups in each component of the study. Third, our integration strategy will focus on concordance as well as divergence between the main qualitative and quantitative findings [18,19]. Thus, we will develop a mixed methods matrix combining the main QUAN and QUAL results, organizing the data according to key themes and corresponding variables to enable comprehensive analysis and interpretation. This matrix will contain a row for each key qualitative theme (ie, needs related to GBV, FP, pregnancy and neonatal care, STI prevention and treatment, postabortion care, sexual health education, clinical support for GBV survivors, and SRHR capacity building needs for trainers), which will be compared or contrasted with the corresponding quantitative results for each theme (eg, knowledge and practice related to FP, STI prevention, and needs for trainers' pedagogical reinforcement; Figure 1).

Figure 1. Overview of the main stages of the research study. ASACO: Associations de santé communautaire; CSCom-U: university community health centers; SRHR: sexual and reproductive health and rights.



This approach is consistent with guidance on methods that advocate complementing quantitative analyses with in-depth data obtained from focus groups and individual interviews [20,21].

Evaluation Team Training and Formative Research

Overview

Prior to the data collection start-up, a 5-day training session on the use of the QDA Miner qualitative analysis software was organized for the evaluation team in Mali to strengthen their capacity to analyze qualitative data. This training was facilitated by a consultant supported by the University of Sherbrooke who was also in charge of making the software available.

A further 3 days' training on the KoboCollect software was provided to the evaluation team by the project's monitoring and evaluation technical advisor as required.

Prior to the teams' field deployment, a 4-day training session was held for all individuals involved in the needs assessment process. The training was provided by FMOS, INFSS, and the CLEFS project team and focused on the following.

Understanding the Roles and Responsibilities of Team Members

Following are the roles and responsibilities of the team members:

- The interviewer's responsibilities in terms of listening, paying attention, etc.
- The pitfalls to be avoided (nonjudgmental and noninterrupting)
- Setting up conditions to ensure data confidentiality
- Seeking free and informed consent to participation
- Respecting societal and cultural values.

Understanding and Translating the Different Tools to Be Used

The following will be ensured in understanding and translating the tools to be used:

- A detailed explanation of the tools to be administered
- An exchange to validate the translation of these tools into the national language so that any questions asked are understood and worded correctly.

Survey Methodology, Including On-Site Data Collection

The survey methodology involves the following:

- The process of identifying households and survey targets
- The process of obtaining participant consent and discussing the ethical aspects of the research process
- Data collection procedures, including digital data collection (eg, downloading, filling in and saving forms, and sending final versions).

Managing Sensitive Cases and Difficult Situations

Sensitive cases and difficult situations will be managed as follows:

- Training on how the evaluation team should act if respondents confide to us or seek our advice or support
- Following this 3-day theoretical training, a pretest was organized on the fourth day in a Bamako commune with a dozen people to identify and rectify any errors of understanding and phrasing before the team's deployment in the field.

Ethical Considerations

This study adheres to the ethical guidelines and principles relevant to human research. The ethical approval was granted by the Research Ethics Committees of the Malian FMOS (reference number: 20231 132 ICE/USTTB) and the University of Sherbrooke (reference number 2022-3261).

Prior to the teams' deployment, the ASACO's offices informed the local authorities in all villages or neighborhoods of the survey teams' presence. Once on site, the teams visited these authorities to obtain their approval to conduct survey activities in their villages or neighborhoods.

Informed consent to participate from all respondents was obtained at the beginning of the survey and all individuals were fully informed of the study's purpose, potential risks, and their right to refuse to participate, to withdraw at any time, or to not answer certain questions without any justification or prejudice.

If a participant wished to withdraw during or after the research, he or she had to contact the research team responsible whose contact details were provided on the consent form.

Confidentiality and anonymity of data were explained to the respondents. For minors, consent was also requested from parents or guardians. An informed consent form was developed outlining the objectives of the research, the voluntary and nonprofit nature of participation, data confidentiality and anonymity, and the approximate duration of participation. This form was shared by the collectors and its reading (in Bambara or French, as preferred) was mandatory and they were asked to devote time to explain it to the participants. The supervisors ensured that interviewers complied strictly with these instructions. All data are confidential and will be only used to achieve the project's results.

Identifiable information will not be disclosed in written publications and oral or poster presentations.

Results

Field data collection took place from March to April 2022. Quantitative data were collected using the KoboCollect application, and descriptive and bivariate analyses were carried out using SPSS software on a sample of 3153 participants. For qualitative data, 11 individual interviews and 27 focus groups were conducted and analyzed using QDA Miner software. Data analysis and interpretation are currently being finalized, and the first results should be submitted for publication in 2025.

Discussion

Overview

This research is one of the first to provide a holistic assessment and understanding of SRHR care needs across a continuum of services (from training, and provision to receiving care) covering the perspectives of various stakeholders at different levels (community, educational, and interdisciplinary health care professionals). It is also one of the first SRHR studies to be deployed in 5 regions (Bamako, Kayes, Koulikoro, Ségou, and Sikasso) across Mali.

Expected Findings and Outcomes

The results of the needs assessment will help us to better understand the needs of adolescents and users of SRHR services, not only in terms of availability, quality of services, and responsiveness of health care providers to their specific needs, but also in terms of SRHR information and knowledge.

Results will also help us gain a better understanding of the issues related to the quality of student training and supervision, and the adequacy between the training offered and the health care needs expressed by service users. They will also enable us to assess the readiness and skills of educators to provide quality SRHR teaching while considering GE.

Studies have demonstrated the effectiveness of training interventions in improving the attitudes and practices of health professionals regarding SRHR in low- and middle-income countries [11,22]. Therefore, recommendations resulting from this needs assessment will enable us to suggest concrete interventions for health care professionals and educators, allowing them to meet the community's needs—particularly those of women and girls.

Based on the results, we will design and implement a multifaceted strategy targeting the 3 levels (community, education, and health care providers).

In terms of training programs, the INFSS and FMOS will revise their curricula in line with the prioritized SRHR needs to fill the gaps in the existing modules. The plan is to integrate these needs into existing modules such as those concerning adolescent sexual and reproductive health, as well as care for GBV survivors and postabortion care, and to adopt interactive pedagogical methods to better prepare the future workforce in SRHR. In sum, the content of the existing curriculum modules will be repackaged to incorporate the priority needs and suggestions made by Malian participants and partners at the national, educational, and community levels.

Regarding the training needs, a package of interventions (training workshops and problem-solving exercises such as training on the management of GBV) will be developed, drawing directly on the results and recommendations of the study to enhance the teachers' and health care professionals' knowledge, skills and attitudes in providing SRHR services.

For community members, numerous interventions (eg, image kits, conferences, and training with peer educators on specific topics) will be codeveloped, prioritizing community involvement and ensuring that content will be oriented according to community acceptability and reflective of their needs.

Moreover, to bridge the gap between the study results and tangible impact in the field, the research findings will be disseminated through a variety of strategies and with numerous CLEFS project partners such as the relevant government actors, ASACO, community health centers, health professionals, and other community actors. This will enable key stakeholders to engage with the insights and facilitate the integration of the recommendations within their daily activities (practice and teaching).

This multifaceted strategy aims to ensure that the study results are effectively tailored to the Malian context and that they reach a wide range of stakeholders involved in PHC and in the provision of SRHR services. Having access to and using quality SRHR services are well linked to health care professionals' competencies, GE, and moreover to the well-being, community stability, and development [11,23].

Strengths and Limitations

Several strategies were used to ensure the credibility of this research as follows: triangulation of data sources (participants from 3 community levels, educational institutions, CSCom-U, and district hospital maternity wards), methods (document, focus groups, and interviews with different actors) and researchers (ie, triangulation of several analytical perspectives) to ensure consistency of the data and analysis; double coding for qualitative analysis; double member checking by sending preliminary results to participants belonging to the 3 target

groups to validate and rectify them if necessary; skeptical peer review by members of the research team who will question methods interpretations, and meanings throughout the process [24]; detailed, rich, and concrete description [25] of the study context to enable readers or research users to judge potential transferability to other contexts, as well as a detailed description of the methodological approach, including the research site and data collection methods; and sample diversification to promote a wider application.

The resulting recommendations will address multiple stakeholders' perceptions and needs, promoting alignment across various actors.

Finally, this research was developed through a collaborative and participatory approach, fostering an equitable partnership between research teams in Mali and the Canadian Consortium. Local researchers and partners led the selection of priority research questions and study design, ensuring that the research project reflected community priorities. Field researchers collected data while minimizing cultural bias, through an ongoing collaborative approach to interpretation between Malian and Canadian research teams. This approach involves local community representatives in several stages of the research process, including validation of tools, recruitment of participants and investigators, and validation of results analysis. To maximize the impact and accessibility of the research, results will be disseminated through many strategies. By focusing on local expertise and perspectives, this approach will promote greater ownership of the results by stakeholders.

However, some limitations were encountered during the data collection process. First, the inclusion criteria (15-19 years old and single) made access to adolescents in rural areas difficult. Most girls are already married by this age, and single girls often move to the city to work as domestic servants. Moreover, adolescents are rarely found at home, choosing instead to go to meeting places or sports activities. This required interviewers to seek them out in schools or conduct interviews in the evening. On the other hand, the availability of service users also posed a problem, requiring late-evening or late-day appointments. Finally, the complexity of the SRHR subject made the questionnaire lengthy, leading to a few complaints, although everyone completed the survey.

Conclusion

In summary, using a concurrent mixed methods study, this needs assessment will help provide essential knowledge on how to align the nursing and medical curriculum with the needs of different levels of stakeholders (community, education, and health care providers), increase the capacity of future and current health care providers to deliver appropriate SRH services, and ultimately address the needs of the Malian community, reduce inequities and promote social justice.

Acknowledgments

The authors would like to thank Massaba Kouyaté and Moussa Nianson Coulibaly for their contributions in the data collection stage. The authors would also like to thank the staff of the Centre interdisciplinaire de développement international en santé (CIDIS) at the Université de Sherbrooke for providing their expertise in the design of this protocol, as well as Global Affair Canada for its financial support.

Data Availability

The datasets generated and analyzed during this study are not publicly available due to ethical and privacy considerations but are available from the corresponding author on reasonable request, if approval is obtained from the relevant ethics committee and data sharing complies with institutional and legal guidelines.

Conflicts of Interest

None declared.

Abstract

Background: Attention-deficit/hyperactivity disorder (ADHD) is one of the most widespread neurobehavioral problems during childhood. A child's personal health record (PHR) plays an important role in the controlled routine monitoring of ADHD symptom improvement. Along with the advantages, the convenience offered by mobile technology, and the ubiquity of smartphones in contemporary society, there is a compelling need for PHR to be available in the form of a mobile app.

Objective: This study aims to identify stakeholder needs, followed by designing, developing, testing, and evaluating a mobile-based PHR in the context of pediatric ADHD management.

Methods: This study will adopt an action research design structured into 4 stages: diagnosing, planning, taking, and evaluating action. Stakeholders, including parents, pediatricians, occupational therapists, clinical psychologists, and teachers, will participate actively. In stage 1, stakeholder requirements for the mobile-based PHR will be explored through in-depth interviews, focus group discussions (FGDs), and document reviews. Thematic analysis will be used to identify key needs and challenges. In stage 2, a systematic literature review will be conducted to enhance user requirements analysis by synthesizing insights from existing mobile apps for pediatric ADHD management. A mobile-based PHR prototype will be designed and developed based on user requirements enhanced with systematic review results. In stage 3, the prototype will undergo a 6-week trial with participants to evaluate its functionality and address any identified issues. In stage 4, both quantitative and qualitative methods will be used to assess the app's usability and quality. The System Usability Scale (SUS) and the User Version of the Mobile App Rating Scale (uMARS) will be used for quantitative evaluation, while interviews and FGDs will be conducted for qualitative evaluation.

Results: This study commenced in October 2024. As of December 2024, 13 participants (n=5, 38.5%, parents; n=2, 15.4%, pediatricians; n=2, 15.4%, occupational therapists; n=2, 15.4%, clinical psychologists; and n=2, 15.4%, teachers) have been enrolled, meeting the minimum participant requirements for stage 1. Stage 1 was completed at the end of 2024, with stage 2 expected to be completed by September 2025, stage 3 by December 2025, and stage 4 by February 2026. The findings from each stage will inform iterative refinements to the mobile-based PHR. The final results, including usability and quality assessments, are anticipated for publication by the middle of 2026.

Conclusions: This study protocol outlines a pivotal initiative to enhance the management of pediatric ADHD. By using an action research methodology and actively engaging stakeholders, the study aims to contribute significantly to the field. The iterative cycles of the research seek to develop a mobile-based PHR that is not only user friendly but also effective and uniquely attuned to the diverse needs of those involved in pediatric ADHD care.

Introduction

Background

Attention-deficit/hyperactivity disorder (ADHD) is one of the most widespread neurobehavioral problems during childhood, with a worldwide prevalence of 5.29% [1,2]. The manifestation of ADHD occurs in 5.9% of youth and 2.5% of adults [3]. In the United States, an estimated 11%, equivalent to approximately 6.4 million children and adolescents aged 4-17 years, have received a diagnosis of ADHD [4]. Characterized by persistent patterns of inattention, hyperactivity, and impulsivity, ADHD manifests in various ways, affecting all aspects of a child's life [5,6]. The impact of ADHD extends beyond the immediate challenges of managing symptoms; it often disrupts academic performance, hinders peer relationships, and can contribute to emotional and behavioral difficulties [7-9]. Children with ADHD may face an increased risk of academic underachievement, low self-esteem, and a higher likelihood of engaging in risky behaviors [10-12]. Moreover, the condition places considerable stress on families and educators as they navigate the complexities of providing optimal support [13,14]. Recognizing the widespread prevalence and multifaceted impact of ADHD is crucial for developing targeted interventions and support systems that address the unique needs of affected children and related stakeholders.

Addressing the diverse needs of stakeholders in managing ADHD takes on added significance when considering the integration of personal health records (PHRs) into the care framework [15]. The PHR can serve as a central repository for health-related information, offering a comprehensive view of a child's medical history, treatment plans, symptoms improvement, and daily challenges associated with ADHD [16]. Within the context of pediatric ADHD management, routine and controlled monitoring of symptom improvement plays a pivotal role, and the PHR become instrumental in this process [17]. The PHR provides a structured platform for caregivers and related stakeholders to systematically monitor and analyze the child's response to therapeutic interventions [18]. By documenting the symptoms' progression, medication adherence, and the impact of various strategies, the PHR offers valuable insights that facilitate evidence-based decision-making [19]. Moreover, the ability to monitor symptoms in a controlled and consistent manner allows for a more nuanced and tailored approach to therapy adjustments, ensuring that interventions align closely with the child's unique needs [20]. The incorporation of the PHR into pediatric ADHD management not only enhances the accessibility of critical health information but also empowers stakeholders with a comprehensive tool for informed decision-making and the continual refinement of therapeutic strategies.

Although the idea of a PHR has historical roots in paper-based systems, health information technology now enables individuals to electronically store and manage their health information, granting them convenient access, whenever necessary [21]. In addition, with the ubiquity of smartphones in contemporary society, there is a compelling need for the PHR to be available in the form of a mobile app [22,23]. Furthermore, technological interventions for the assessment, monitoring, and treatment of neurodevelopmental disorders, including ADHD, are increasingly focused on mobile apps [24]. However, few apps related to ADHD provide information about their development processes, and none include evidence supporting their effectiveness [25].

The urgency to develop a mobile-based PHR specifically tailored for pediatric ADHD management stems from the growing demand for facilitating information sharing between stakeholders to promote the adoption of evidence-based practices in the management of children with ADHD [26]. The fragmentation of health care services, coupled with the dynamic nature of ADHD symptoms, necessitates a technological solution that can bridge communication gaps and empower those involved in the child's care [26,27].

Recognizing the imperative for a user-centric approach, the adoption of an action research methodology becomes paramount in the development of a mobile-based app [28-30]. Action research, designed to enhance the engagement of potential mobile app users in the entire research process, can foster awareness within the pediatric ADHD management stakeholders' context of how they experience and interact with technology [31,32]. This inclusive approach ensures that the resulting mobile app is not only technologically sound but also rooted in the practical experiences, preferences, and needs of those directly engaged in the daily challenges of pediatric ADHD management. Through iterative cycles, the action research methodology contributes to the development of an effective, user-friendly, and contextually relevant mobile-based PHR, ultimately advancing the landscape of pediatric ADHD management via the active participation of the stakeholders.

Objectives

The objectives of this study are to first identify the needs of stakeholders concerning the development of a mobile-based PHR for pediatric ADHD management. Based on the identified needs, a customized mobile app will be developed

collaboratively, with continuous input from the stakeholders to ensure the app addresses those needs effectively. Finally, the usability and quality of the mobile app will be rigorously tested and assessed, ensuring it aligns with the preferences and expectations of the stakeholders and functions as an effective tool for managing pediatric ADHD.

Methods

Study Design

This study will use an action research methodology in the form of a cycle with 4 stages (diagnosing action, planning action, taking action, and evaluating action), integrating both qualitative and quantitative designs [33,34]. The term "action research" in this paper refers to the same definition as "participatory action research," "participatory research," "interactive research," "collaborative inquiry/research," and "engaged scholarship" [35]. The action research design centers on doing "with" rather than doing "for" relevant stakeholders [36]. In this context, the participation of the relevant stakeholders becomes key to the implementation of action research.

Each stage in action research consists of an iterative process (plan, act, observe, reflect), involving the stakeholders at each step [37]. The stages of action research in this study can be succinctly observed in Figure 1.

Table 1 outlines the specific steps in each stage of action research, the measures used to track progress, and the timeline for each activity. Activities at each stage will be carried out, and their progress will be systematically monitored based on the table.

Figure 1. Stages of action research.

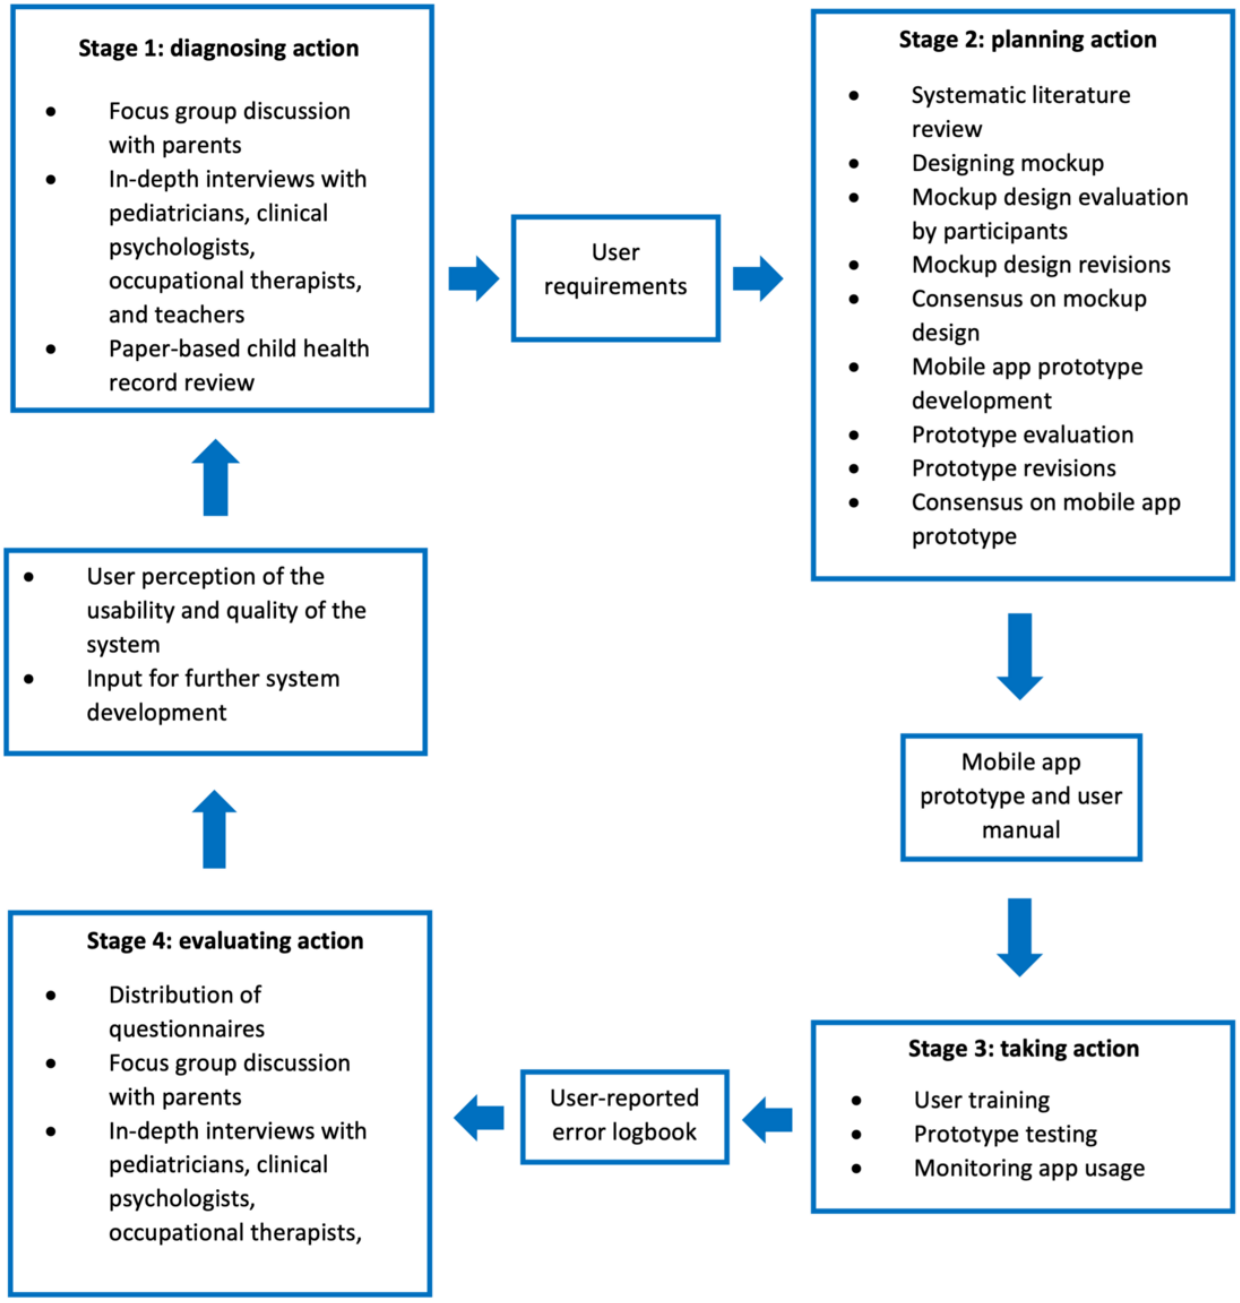

Table 1. Detailed steps and measures in each stage of the study.

Stage and steps	Measure(s)	Timeline
Stage 1: diagnosing action		
Conduct user requirement analysis through FGDs[a] with parents and interviews with pediatricians, occupational therapists, clinical psychologists, and teachers.	Number of participants, identified user needs	Months 1 and 2
Review paper-based documents managed by parents and related stakeholders.	Completeness of documentation analysis	Months 1 and 2
Stage 2: planning action		
Conduct a systematic literature review on the mobile-based app used for pediatric ADHD[b] management.	Number of reviewed studies, extracted key findings	Months 3-5
Design a mobile-based PHR[c] mockup.	Initial mockup completion	Month 6
Review and revise the mockup design based on participant feedback until consensus is reached.	Number of revisions, participant consensus	Month 7
Develop a prototype based on the final mockup design.	Initial prototype completion	Months 7-10
Review and revise the prototype based on participant feedback until consensus is reached.	Number of revisions, participant consensus	Months 11 and 12
Stage 3: taking action		
Conduct training and mentoring for participants on using the mobile-based PHR.	Participant attendance, knowledge gained	Month 13
Facilitate prototype trial usage among participants.	Number of users engaged	Months 14 and 15
Monitor app usage to identify challenges or technical issues.	Number of reported issues	Months 14 and 15
Stage 4: evaluating action		
Assess system usability using the SUS[d] questionnaire.	SUS score (range 0-100)	Month 15
Evaluate app quality using the uMARS[e] questionnaire.	Mean (SD) of uMARS scores	Month 15
Collect qualitative feedback via FGDs and interviews.	Identified feedback	Months 15 and 16
Summarize findings and provide recommendations for future development.	Final report completion	Months 17 and 18

[a]FGD: focus group discussion.

[b]ADHD: attention-deficit/hyperactivity disorder.

[c]PHR: personal health record.

[d]SUS: System Usability Scale.

[e]uMARS: User Version of the Mobile App Rating Scale.

Study Setting

This research will be conducted at Dr Sardjito Hospital, Special Region of Yogyakarta, Indonesia. This hospital was chosen as the research location because it is an educational and referral hospital with a pediatric health clinic specializing in social pediatrics and neurology, which is commonly referred to by patients with ADHD. As a tertiary hospital, it receives a significant number of pediatric patients with ADHD referred there each year. The hospital's comprehensive health care facilities and expertise in pediatric care, particularly in social pediatrics and neurology, make it an optimal environment for conducting this research.

This research will also be conducted in schools where children with ADHD receive formal education in Indonesia. These children are aged between 4 and 12 years [38]. Teachers who work with children with ADHD, including preschool and elementary school teachers, will be actively involved in the study. It is widely recognized that communication and active involvement of parents, health care providers, and teachers are essential for managing pediatric ADHD [39].

Stage 1: Diagnosing Action

Objective

The objective of stage 1 (diagnosing action) is to systematically identify and understand the diverse needs of stakeholders in relation to the development of a mobile-based PHR. This initial phase will be dedicated to diagnosing and comprehending the requirements of key stakeholders involved, including parents, pediatricians, occupational therapists, clinical psychologists, and teachers of children with ADHD. To develop high-quality apps, it is imperative to build the development process upon a comprehensive understanding of user requirements, derived from a methodology that actively involves users in the process [40]. Through a meticulous process involving document review,

focus group discussions (FGDs), and in-depth interviews, the stage will seek to uncover issues related to the recording of ADHD symptom development by parents and the PHR's role as a communication medium among parents, teachers, and health care professionals. The outcomes of this stage will include a comprehensive analysis of stakeholder needs, outlining specific requirements for the development of a mobile-based PHR.

Output

The output of this stage will be a document containing specific requirements for the development of a mobile-based PHR. These requirements include data needs, user groups and permissions, app features, functionalities, and expected technology specifications.

Participants

Stakeholders involved in the management of children with ADHD, including parents, pediatricians, occupational therapists, clinical psychologists, and teachers, will participate in this study [41,42]. Selection criteria for research participants are detailed in Table 2.

Involvement of parents or caregivers and teachers is related to the assessment of ADHD that requires evidence directly obtained from them regarding the core symptoms of ADHD, the duration of symptoms, the degree of functional impairment, and associated conditions [43].

We estimate that our study will need around 5 parents, 2 pediatricians, 2 occupational therapists, 2 clinical psychologists, and 2 teachers. This is the minimum number of participants; additional participants may be included during data collection until data saturation is achieved [44].

Table 2. Participant selection criteria.

Participants	Criteria
Parents	• Parents of children diagnosed with ADHD[a] (aged 4-12 years) who have received behavioral therapy and medication, with at least 1 year of experience in taking care of children with ADHD • Experienced in using mobile health apps • Own and actively use an Android- or iOS-based mobile phone with an internet connection
Pediatricians	• Pediatricians managing patients with ADHD whose parents are participating in the research, with a minimum of 2 years of experience in managing children with ADHD • Currently pursuing or have completed subspecialization in developmental pediatrics–social pediatrics or child neurology • Experienced in using electronic medical record systems or telemedicine or both
Occupational therapists and clinical psychologists	• Occupational therapists and clinical psychologists managing patients with ADHD whose parents are participating in the research, with a minimum of 2 years of experience in managing children with ADHD • Experienced in using electronic medical record systems or telemedicine or both
Teachers	• School teachers teaching children with ADHD whose parents are participating in the research, with a minimum of 2 years of experience in teaching children with ADHD • Own and actively use an Android- or iOS-based mobile phone with an internet connection

[a]ADHD: attention-deficit/hyperactivity disorder.

Data Collection

Data will be collected through a systematic approach, including FGDs with parents and in-depth interviews with pediatricians, occupational therapists, clinical psychologists, and teachers. The total number of interviews will be adjusted based on the number of participants involved. Participants will be selected using a purposive sampling method based on predetermined inclusion criteria to ensure representation of key stakeholders actively involved in managing pediatric ADHD. Comprehensive FGD and interview guides have been developed in Indonesian to facilitate semistructured sessions. The inquiry framework acknowledges the dynamic nature of discussions and interviews, allowing flexibility in question sequencing, particularly regarding follow-up inquiries, which may undergo alterations during the research [45]. The guides are designed to explore specific aspects described in Table 3.

The data collection process will follow a systematic procedure. Participants will be recruited through referrals from pediatricians specializing in ADHD to ensure a diverse and representative sample. In-depth interviews and FGDs will be conducted in a private and comfortable environment to encourage open and honest responses. Each session will begin with an introduction explaining the purpose of the study and obtaining consent for audio recording.

All interviews and FGDs will be audio-recorded with the participants' consent, and field notes will be taken to capture contextual details, nonverbal cues, and relevant observations during the sessions. Each in-depth interview session will be conducted for approximately 30-60 minutes, while each FGD session is expected to last from 60 to 120 minutes [46,47]. The semistructured nature of the interviews and FGDs will allow flexibility for follow-up questions and enable a deeper exploration of emerging themes during the discussions.

Table 3. Key aspects explored in stakeholder interviews and FGDs[a].

Aspect	Focus of exploration
Stakeholder needs	• Essential features required for a mobile-based PHR[b] • Information that needs to be recorded, monitored, and accessed (eg, symptom tracking, medication schedules, therapy progress)
Usability preferences	• Design expectations (eg, user-friendliness, interface layout) • Accessibility concerns, including navigation simplicity for parents and professionals
Data accessibility and security	• Preferences for access control (eg, who can input and view data) • Concerns about privacy and confidentiality of ADHD[c]-related information
Roles of stakeholders	• How each stakeholder envisions contributing to and using the PHR • Collaboration needs between parents, pediatricians, occupational therapists, clinical psychologists, and teachers in managing pediatric ADHD

[a]FGD: focus group discussion.

[b]PHR: personal health record.

[c]ADHD: attention-deficit/hyperactivity disorder.

As a methodological triangulation measure, paper-based child health records managed by parents will be reviewed to validate the essential data needs in the PHR [48]. Parents will be encouraged to present their manually recorded data, which reflects their needs in managing the care of children with ADHD. This will facilitate researchers in scrutinizing and documenting the various data types encapsulated within these records.

Data Analysis

Qualitative data from FGDs and in-depth interviews will be analyzed using thematic analysis following the 6-phase approach [49,50]: (1) familiarization with the data, where researchers immerse themselves in the data by reading and re-reading transcripts; (2) generating initial codes, involving systematic coding of significant features of the data across the entire dataset; (3) searching for themes, where codes are organized into potential themes; (4) reviewing themes to refine and ensure coherence and distinction between them; (5) defining and naming themes, focusing on capturing the essence of each theme; and (6) producing a report that involves a narrative that integrates the themes with supporting evidence from the data [51]. To address methodological rigor, aspects of reflexivity, confirmability, dependability, credibility, and transferability will be considered throughout the analysis process. Reflexivity will be addressed by creating fieldnote reflections, where researchers will document critical interpersonal dynamics affecting participants and their data, record and reflect on decisions made, and highlight moments of analytic insight to enhance transparency and self-awareness throughout the research process [52,53]. Confirmability will be ensured through detailed documentation of the analytic process, and peer debriefing dependability will be supported by maintaining a clear audit trail of the analysis process [54]. To enhance credibility, member checking with selected participants will be conducted, and investigator triangulation will be implemented with 2 researchers collaboratively reviewing and comparing the codes and resolving any differences through discussion for the same text unit [55]. Transferability will be facilitated by providing detailed descriptions of the study context and participant characteristics in this protocol [54]. The qualitative data will be organized using Open Code software version 4.03, ensuring systematic handling and transparency of the coding process [56,57].

Stage 2: Planning Action

Objective

Stage 2 (planning action) aims to design and develop a prototype of a mobile-based PHR that is agreed upon by all research participants. This stage will involve several key steps. First, a systematic literature review will be conducted on mobile apps used in pediatric ADHD management to enhance the user requirement analysis from stage 1 by thoroughly examining and synthesizing the existing literature. In the mobile app development process, understanding the efficient assessment of mobile apps, academic challenges, and other important aspects available in the existing literature is crucial [58]. The review will focus on identifying app features, purposes, target users, reported outcomes, and the measuring instruments used in previous studies. It will also address important considerations, such as the efficient assessment of mobile apps and academic challenges in the field. Next, a mockup design of the mobile-based PHR will be created based on the results of both the user requirement analysis and the systematic literature review. This mockup will be used to validate the user interface's usability [59].

Finally, a mobile app prototype will be developed based on the collective agreement of research participants on the finalized mockup design. The prototype will be developed in collaboration with a team of developers who will be recruited as part of the technical team for this study. The prototype will be built using Flutter, a framework that allows for the development of apps on both Android and iOS platforms, which together dominate the mobile app market [60-62].

Output

The outcome of this stage will be a mobile-based PHR prototype for both Android and iOS platforms, which has gained consensus

among all research participants and is ready for testing in the next stage. Furthermore, a user manual for the mobile app will be produced during this stage.

Participants

Participants in this stage will be stakeholders related to pediatric ADHD who have previously participated in stage 1. Participants in this stage will actively engage in the design and development process [63].

Data Collection

Data collection will involve several key steps. First, a systematic literature review will be conducted and documented following the PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses) 2020 guidelines [64]. To comprehensively explore the available literature on mobile apps for pediatric ADHD, a systematic search will be conducted across multiple databases, including PubMed, Scopus, Cochrane Library, and Google Scholar. The search strategy will involve a combination of MeSH (Medical Subject Headings) terms as controlled vocabulary terms and their relevant synonyms related to pediatric ADHD, mobile apps, and pediatric ADHD management stakeholders. MeSH terms used as keywords will include “parents,” “child,” “adolescent,” “family,” “caregivers,” “physicians,” “school teachers,” “pediatrics,” “mobile applications,” “smartphone,” “digital health” and “attention deficit disorder with hyperactivity.” The search strings will be tailored to the specific syntax and requirements of each database. The study/source selection process will follow a systematic and transparent approach. The process consists of 3 main steps. First, titles and abstracts of identified papers will be screened by 2 independent reviewers using predefined inclusion criteria. Any discrepancies will be resolved through discussion, and if necessary, a third reviewer will be consulted to facilitate consensus. Second, a full-text review of selected studies will assess their eligibility, with reasons for exclusion recorded and reported. Finally, relevant data will be extracted from the included studies. Subsequently, the data analysis will explore the apps’ features, purposes, reported outcomes, as well as variations in apps usage across different contexts and participant groups.

Information derived from the systematic literature review will be gathered and used to complement the results of the user requirement analysis, forming the foundation for the design and development of the mobile-based PHR. Next, the designed mockup will be presented to each participant for comprehensive feedback. Every discussion will be recorded, transcribed, and analyzed, with refinements made to the mockup design based on participant input. This iterative process will continue until a unanimous consensus is reached among all participants [65]. Finally, the approved mockup design will be transformed into a mobile-based app prototype. Similar to the mockup phase, the prototype will be discussed with each participant to gather further feedback The discussions will be recorded, transcribed, and analyzed, with subsequent revisions made to the prototype until a unanimous agreement is achieved among all participants.

Data Analysis

Data from the systematic literature review will be analyzed descriptively to map the user groups, as well as the apps’ features, purposes, and outcomes related to the implementation of mobile apps for pediatric ADHD. Additionally, participant feedback on the mockup design and prototype of the mobile-based PHR will be qualitatively analyzed, serving as a foundation for the continuous improvement and refinement of both the mockup design and the prototype.

Stage 3: Taking Action

Objective

Stage 3 (taking action) will involve the trial of the mobile-based PHR. The objective of this stage is for participants to actively use the mobile app in their daily activities while monitoring children with ADHD. Throughout this stage, technical challenges faced by users during the trial period will be identified to facilitate app improvements and refinements.

Output

The output of this stage will be a logbook document detailing the errors or technical challenges reported by users during the trial period. This logbook will serve as a comprehensive record of user feedback, documenting encountered issues and discrepancies. It will function as a crucial control document for the debugging process and for implementing necessary system refinements [66]. By systematically logging user-reported errors, the logbook will become a valuable resource for the iterative improvement process, ensuring that the mobile app prototype is continually enhanced and optimized based on real-world user experiences.

Participants

Participants in this stage will include individuals who have previously participated in stages 1 and 2, along with newly recruited parents of children diagnosed with ADHD. The number of newly recruited parent participants is anticipated to range between 20 and 80 individuals [67]. Eligibility criteria for participation require owning a smartphone compatible with either the Android or the iOS platform and having reliable internet access.

Data Collection

In this stage, participants will be asked to use the mobile-based PHR for 6 weeks before proceeding to the next stage [68]. During the trial period, app usage will be monitored, and users will be asked to report any system errors or technical issues encountered through the reporting form available in the mobile-based PHR. The reported data will be recorded and compiled into an error logbook. This monitoring will allow user issues to be addressed promptly, enabling the technical team to provide targeted support, as needed. To ensure participants use the mobile-based PHR consistently during the 6-week period and can test its entirety, they will be provided with detailed instructions during user training, as well as regular reminders and support throughout the period.

Data Analysis

The collected data will be descriptively analyzed by grouping similar types of errors or technical issues. Subsequently, app improvements and refinements will be implemented based on the analysis. Users will be informed of the implemented improvements and refinements through notifications in the mobile-based PHR.

Stage 4: Evaluating Action

Objective

Stage 4 (evaluating action) will focus on assessing the overall quality and usefulness of the mobile-based PHR from the user perspective. Unlike earlier stages, which focus on design, development, and refinement, this stage will primarily serve as a comprehensive evaluation of the outcomes of the previous stages. It will involve gathering feedback from participants on the effectiveness of the mobile-based PHR and identifying expectations for its further development.

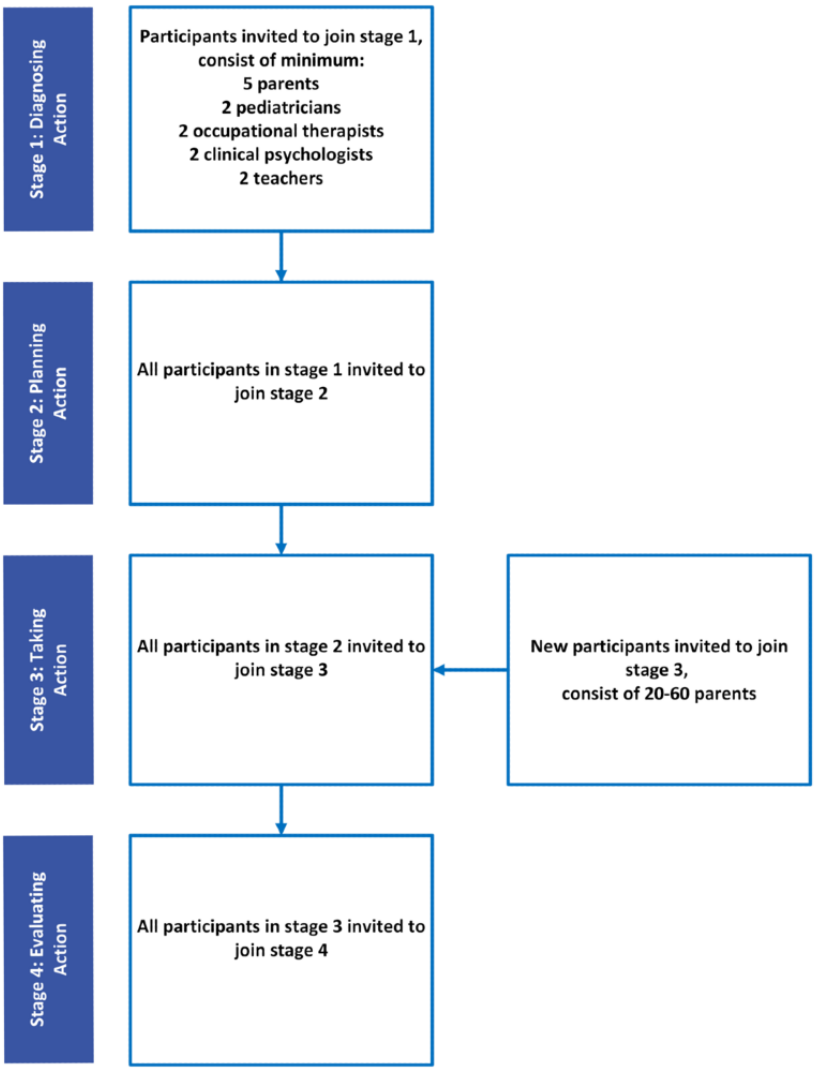
Output

The output of stage 4 will be a comprehensive evaluation report that summarizes participants' assessments regarding the usefulness and quality of the mobile-based PHR. Additionally, this stage aims to generate valuable feedback for future development.

Participants

The evaluation in stage 4 will involve both quantitative and qualitative assessments of the mobile-based PHR. Participants in stage 4 will consist of those who have participated from stage 1 to stage 3, as well as additional participants newly recruited in stage 3. Qualitative evaluations will be conducted exclusively with participants who have been involved from stage 1 to stage 3, as they can provide comprehensive and holistic feedback based on their entire experience. Meanwhile, quantitative evaluations in stage 4 will focus solely on parent participants, including both parents who participated from stage 1 to stage 3 and newly recruited parents in stage 3. The primary reason for focusing the quantitative assessment on parents is that they will be the main users of the mobile-based PHR, which is being designed to support the management and care of their children with ADHD. Figure 2 illustrates the sequential involvement of participants, starting from the initial recruitment in stage 1 through their continued engagement up to stage 4.

Figure 2. Participant flow diagram for the action research stages.



Data Collection

Quantitative data to assess the usefulness of the mobile-based PHR will be collected using the Indonesian version of the System Usability Scale (SUS) questionnaire [69]. The SUS consists of 10 statements, each scored on a Likert scale of 1-5, where a higher score indicates stronger agreement with the statement [70]. Additionally, quantitative data will be gathered to assess the quality of the mobile-based PHR using the User Version of the Mobile App Rating Scale (uMARS) questionnaire. The uMARS includes 20 items divided into 5 dimensions: engagement, functionality, aesthetics, information, and subjective quality. Each statement is scored on a 5-point Likert scale [71]. Qualitative data will also be collected through in-depth interviews and FGDs to gather comprehensive insights from participants' experiences during stage 3 (taking action). This approach will aim to uncover rich, contextual information regarding usability, satisfaction, challenges encountered, and participants' input and expectations for further development of the mobile-based PHR.

Data Analysis

Quantitative data obtained from the SUS questionnaire will be analyzed descriptively. The results will be summarized, totaled, and then multiplied by a coefficient of 2.5, yielding a final score within a range of 0-100 [70]. This score will be used to determine the percentile ranking. Data from the uMARS questionnaire will be analyzed through descriptive statistical analysis, calculating the mean (SD) to assess the quality of the mobile app. Scores ranging from 1 to 2 indicate "not acceptable," 2 to 3 indicate "poor," 3 to 4 indicate "acceptable," 4 to 5 indicate "good," and 5 indicate "excellent" quality [72]. Qualitative data from in-depth interviews and FGDs will be analyzed using thematic analysis [49].

Trustworthiness

The data in this research will be validated using the action research validation technique, which comprises coherence validation, discursive validation, and practical validation [35]. Coherence validation focuses on how various empirical, interpretative, and conceptual elements are integrated to mutually reinforce each other. The coherence validation technique that will be used in this research is triangulation, a method that will involve cross-referencing the results from FGDs and in-depth interviews regarding user requirements with the findings from the reviews of paper-based PHRs, particularly related to data that must be recorded in the PHR.

Discursive validation emphasizes dialogical and democratic validation in a forum. The discursive validation technique that will be used in this research is member checking, a method that involves returning the research findings to the participants for their review and validation. This iterative process will allow participants to confirm the accuracy and relevance of the data collected during in-depth interviews, FGDs, document reviews, and other research activities. By incorporating member checking, the study aims to ensure the credibility and trustworthiness of the research outcomes, as participants can provide feedback and insights, contributing to the overall validation and refinement of the research findings.

Practical validation focuses on testing in a real environment so that specific knowledge claims can gain sufficient trustworthiness. The practical validation method that will be used in this research is participant engagement, providing participants with an opportunity to actively use the mobile app prototype. Unlike a passive observation approach, participants will be directly involved in navigating and interacting with the prototype, offering insights into the user experience from a firsthand perspective. This hands-on engagement will ensure a more practical and realistic assessment of the mobile app's functionality and usability. By allowing participants to explore the prototype independently, the study aims to gather authentic feedback on the user interface, features, and overall performance, contributing to the refinement and enhancement of the mobile app based on the practical experiences of the end users.

The summary of the action research activities in each stage including output, activities, instrument, variable, participants, and validation methods are presented in Multimedia Appendix 1.

Ethical Considerations

The study has been approved by the Ethics Committee of the Faculty of Medicine, Public Health, and Nursing, Universitas Gadjah Mada (approval no: KE-FK-1257-EC-2023). To maintain ethical standards, we will provide comprehensive information regarding the study protocol to all potential participants. We will outline the purpose, procedure, and potential risks and benefits of their participation, especially in the context of action research [73]. Once they agree to participate, they will be required to provide signed informed consent. Confidentiality and privacy will be rigorously conducted throughout the research process, with measures in place to anonymize and secure sensitive information [74].

Results

This study was initiated in October 2024, with the research process divided into 4 distinct stages:

- Stage 1 (diagnosing action) will focus on identifying user requirements and challenges in managing ADHD care through stakeholder interviews, FGDs, and document reviews. As of December 2024, 13 participants were enrolled, comprising 5 (38.5%) parents, 2 (15.4%) pediatricians, 2 (15.4%) occupational therapists, 2 (15.4%) clinical psychologists, and 2 (15.4%) teachers, meeting the minimum target for participant numbers. This stage was completed at the end of 2024, providing key insights to guide subsequent stages.
- Stage 2 (planning action) will include a systematic literature review, user requirement validation, mockup design validation, and prototype development. The prototype development will be conducted in collaboration with a technical development team. This stage is projected to conclude by September 2025, delivering a finalized prototype for usability testing.
- Stage 3 (taking action) will focus on implementing and testing the prototype with participants during a 6-week trial

period. During this phase, system usage data, user feedback, and error reports will be collected and analyzed to refine the prototype. This stage is anticipated to be completed by the end of 2025.

- Stage 4 (evaluation action) will involve both qualitative and quantitative assessments of the mobile-based PHR. Qualitative evaluations will gather in-depth feedback from participants who have engaged in all stages, providing comprehensive insights into the user experience. Quantitative evaluations, targeting all parent participants, will assess the usability and quality of the mobile app through embedded questionnaires. This stage is expected to conclude in February 2026. The results of this study will be reported according to reporting guidelines provided for action research [75]. The final results are anticipated for publication by the middle of 2026.

Discussion

Summary

The landscape of future research in pediatric ADHD stands to evolve significantly, particularly in the development of effective electronic systems tailored for gathering crucial information to diagnose and monitor children and adolescents with ADHD [76]. As an innovative response to this research avenue, this study will contribute to this domain by using an action research approach that engages the stakeholders in pediatric ADHD management in all stages, including diagnosing, planning, taking, and evaluating action [77]. To the best of our knowledge, this is the first study that involves active participation and engagement with stakeholders, including parents, medical providers, and nonmedical providers, in the development of a mobile app related to pediatric ADHD management. This dynamic methodology will ensure that the mobile app developed is technologically effective, user-friendly, and contextually relevant.

The insights gleaned from this research will underscore the intricate challenges associated with managing pediatric ADHD and emphasize the critical role of collaborative and patient-centric interventions. These principal findings will pave the way for more targeted and contextually relevant interventions, fostering a deeper understanding of the intricacies involved in pediatric ADHD management.

Limitations

The scope of the study is confined to addressing the needs of stakeholders directly involved in the routine care of children with ADHD within tertiary hospital settings. Although this focus provides valuable insights into the specific challenges faced in such contexts, the findings may not be fully representative of the broader spectrum of ADHD management, especially in community or primary care settings. Additionally, the study's outcomes may be influenced by the regional or institutional characteristics of the selected tertiary hospitals, potentially limiting the generalizability of the results to a more diverse health care landscape. Despite these limitations, the study remains dedicated to refining and optimizing the care of children with ADHD within tertiary hospital environments, with the anticipation that the insights gained can contribute meaningfully to the broader discourse on pediatric ADHD management.

Conclusion

This study protocol outlines a pivotal initiative to enhance the management of ADHD in pediatric populations. By using an action research methodology and actively engaging stakeholders, including parents, medical providers, and nonmedical providers, the study aims to contribute significantly to the field. The iterative cycles of the research seek to develop a mobile-based PHR that is not only user-friendly but also effective and uniquely attuned to the diverse needs of those involved in pediatric ADHD care.

Acknowledgments

The authors would like to thank the Doctoral Program on Medical and Health Sciences of the Faculty of Medicine, Public Health and Nursing, Universitas Gadjah Mada, for support and facilitation during their doctoral study.

Data Availability

The datasets used and analyzed during this study will be made available from the corresponding author upon reasonable request after the completion of the study.

Authors' Contributions

DBS drafted the initial manuscript and finalized the manuscript. RS, DKN, and MSK provided feedback and contributed to revising the manuscript. All authors have read and approved the final version of the manuscript.

Conflicts of Interest

None declared.

Abstract

Background: The prevalence of sensory, cognitive, and mobility disabilities in Canada underscores the need to address environmental barriers. This study adapts and validates the Stakeholders' Walkability/Wheelability Audit in Neighborhoods (SWAN) tool to assess the challenges the built environment poses for individuals with disabilities, aiming to inform policy changes for accessibility and inclusivity.

Objective: This study aims to (1) adapt the SWAN tool for those with hearing, vision, or cognitive disabilities; (2) validate SWAN tool for researching environmental barriers for people with disabilities, including older adults; and (3) offer insights for policy changes in the built environment, contributing to literature and guiding future research.

Methods: The study uses a community-based research approach, carried out over 4 phases within an 18-month period in British Columbia. Phase 1 includes adapting and pilot-testing of the SWAN tool. In Phase 2, street intersections are identified for data collection using Geographic Information System tools and consultations with municipal officials. Phase 3 involves recruiting participants across four disability categories. The final phase includes analyzing the data and disseminating findings.

Results: Data collection concluded in September 2024, involving 80 eligible participants across four streams in preidentified hotspots. The results are expected to be published in March 2025. To date, data collection is ongoing, and we are currently in the process of data analysis.

Conclusions: This study will contribute to the growing body of research on built environment accessibility by adapting the SWAN tool for individuals with diverse disabilities. By identifying key barriers in urban spaces, the study aims to inform policy changes that will lead to more inclusive, accessible, and safe urban environments for all individuals.

Introduction

Overview

The number of people living with sensory (hearing and vision), cognitive, and mobility disabilities is increasing in Canada. In 2019, approximately 5% of people aged 15 years and older had a hearing disability, and in 2020, a total of 567,000 people were living with a cognitive disability [1]. About a quarter (24.1%) of the population living with disabilities are aged 65 years and older [2].

Mobility restrictions are not typically the result of a single cause but arise from an interaction of risk factors in various domains, both individual and environmental [3]. Historically, disability research primarily relied on the medical model, emphasizing the individual and their specific impairments or conditions [4]. However, in more recent times, disability models have shifted their focus toward understanding the dynamic interplay between individuals and their surrounding environment [5]. Environmental characteristics are hypothesized to limit or promote an individual's ability to complete purposeful actions and fulfill role expectations, affecting physical functioning and disability [3]. Lawton [6] proposed several dimensions of environment that are important for older adults: personal environment (family and friends), suprapersonal environment (ie, neighborhood racial or age composition), social environment (norms or values related to society or culture), and physical environment (eg, built environment). The physical environment is defined as the human-made or human-altered space in which individuals live out their daily lives [7] and is the focus of this paper. The built environment has a profound impact on the mobility of older adults and people living with disabilities, which can affect their health and quality of life [3,8-11]. This aligns with the International Classification of Functioning, Disability, and Health, which posits disability and functioning as outcomes that result from the interplay between health conditions (such as diseases, disorders, and injuries) and contextual factors, including the built environment.

For instance, individuals who are deaf or hard of hearing (DHH) feel less safe when navigating the pedestrian environment as they struggle to hear traffic on the road [12,13]. Persons living with mild cognitive impairment (MCI) often experience challenges with navigation of their own environment, which is heightened when communities do not integrate sufficient green spaces and landmarks (such as large shops, libraries, community centers, and senior centers) to help reduce the stress of wayfinding [14]. Moreover, people using mobility assistive technologies (MAT) may find it challenging to navigate the built environment, especially during rain and snow because of inadequate drainage or snow removal [10]. People with vision impairment (VI) also face difficulties due to the lack of accessibility in public spaces and transportation systems [11].

Limited research exists on the role of environmental factors on mobility and social participation of individuals with disabilities, creating a gap in the literature [3,8-11]. Environmental variables that can affect the experience of being mobile in a place, fall into 2 broad categories: macroscale, consisting of structural features such as street interconnectivity and land use mix [15,16]; and microscale, or details, such as aesthetics and sidewalk design, and maintenance [17]. While much research has concentrated on macroscale variables that define walkability [18], investigating microscale features is also valuable for understanding the mobility experience [19-22]. Microscale characteristics of the built environment can often be modified at a lower cost and within a shorter timeframe compared with restructuring macroscale designs [23].

Various audit tools have been developed and tested to evaluate the microscale qualities of the built environment, particularly at the street level, through on-site visits [24]. The Stakeholders' Walkability/Wheelability Audit in Neighborhoods (SWAN) is a microscale, user-led audit tool designed to evaluate both objective and subjective aspects of the built environment that affect the lives of older adults and individuals using mobility assistive devices, persons who are DHH, and persons living with MCI including dementia [25,26].

The SWAN tool is an adaptation of the SWEAT-R tool that captures the perspective of persons with disabilities [25]. Moreover, the development of the SWAN tool included a comprehensive literature review and incorporated aspects of other user-led tools, such as the Microscale Audit of Pedestrian Streetscapes [23,27], the Built Environment and Active Transport Neighborhood Assessment [28], and Jane's Walk: Walkability Checklist [29].

Previous research using the SWAN tool was primarily done with individuals with mobility disabilities using MAT [30]. To incorporate a wider variety of disability experiences, the SWAN tool has been adapted to accommodate individuals' living sensory disability (hearing and vision) as well as those with cognitive disabilities, including early stages of dementia and MCI. This adaptation enables these populations to systematically evaluate their neighborhoods.

Using a community-based participatory research approach, the SWAN tool was developed in collaboration with a committee of individuals with lived and professional experience, ensuring that diverse perspectives and needs are integrated into the research process. This approach promotes self-advocacy among participants and facilitates policy changes that are reflective of community needs [31].

Objectives

This study aims to (1) adapt the mobility tool for individuals living with hearing or vision as well as cognitive disability; (2) validate the tool for researching barriers in the built and social environment for persons with disabilities, including those with vision, hearing, cognitive, and mobility disabilities (including older adults); and (3) provide insights for decision-making and policy changes in modifying the built environment.

This protocol paper aims to contribute to existing literature and guide future studies on how individuals with cognitive, sensory, or mobility disabilities navigate the built environment. The goal is to fill knowledge gaps and provide evidence-based results for municipalities and communities to implement necessary policy changes for a safe and accessible living environment.

Methods

Overview

The research will be conducted over 4 phases within an 18-month period in British Columbia. Advisory committees including individuals with a variety of disabilities have been created to ensure the consideration of inputs or concerns of these individuals in the research project through a participatory research approach. These committees include individuals with mobility, visual, and hearing disabilities and early-stage dementia. The committees meet 2 to 3 times a year to provide feedback on the ongoing phases of the research project, which are presented below.

The first phase involves conducting a literature review, tool consolidation, and pilot-testing. Phase 2 entails identifying street intersections for data collection using Geographic Information System layers and discussions with municipal officials. Phase 3 involves collecting data across various streams of disabilities. The fourth phase includes data analysis and knowledge mobilization efforts.

Ethical Considerations

This study has been reviewed and approved by the ethics boards of Simon Fraser University and the University of British Columbia (H21-01234). To protect identities, names and any other information that might identify a participant will be removed from transcriptions and field notes. Any photos taken as part of data collection that could potentially identify individuals will be blurred. All data will be collected, managed, and stored in accordance with university research ethics procedures, and all data will be anonymized. We perceive that the risks for physical or emotional harm to the participants associated with the proposed research are minimal. The time and effort required by participants is minimal, and there is no deception or other manipulation of participants. Given that participants might share difficult experiences, which may lead to emotional and/or psychological distress, the researcher will make clear at the beginning and throughout the interview that participation is voluntary, and participants can withdraw their consent at any time without harm. Participation in this study is voluntary, and participants can decide to opt out. An honorarium of CAD $75 (approximately US $53) will be provided to participants.

Phase 1: SWAN Tool Development Process

Overview

To conduct the walking/wheeling audits with DHH individuals and those living with cognitive and vision disabilities, the original SWAN tool (that is, SWAN for MAT users) was adapted through reviewing the literature and consultations with persons with disabilities or persons with professional experience. Involving persons with disabilities and professionals with relevant experience fosters a more inclusive approach, ensuring that the tool reflects the diverse perspectives within the community. The incorporation of findings from both academic and gray literature allows for evidence-based adaptations, increasing the tool's validity and reliability for the target populations.

Literature Review

Relevant concepts pertaining to DHH individuals and those living with cognitive and vision disabilities, focusing on their experiences and interactions with the safety and accessibility of the outdoor built environment, were taken from reviews done by our study team [10,25,32,33]. This allowed for collating similar concepts to pinpoint areas where the tool may need expansion or clarification to better support these specific populations.

Content Comparison and Tool Consolidation

After developing the newly adapted tools, they were charted in Microsoft Excel alongside the original SWAN tool for content comparison, sequencing of questions, and language simplicity and consistency. Upon review of all tools, they were finalized as the Hearing and Mobility Tool, the Dementia Tool, and the Vision Tool.

Pilots

To test the functionality of the tools in the field, 4 pilots were conducted with persons with disabilities from the 4 populations of interest. These pilots served as an opportunity to try the tools with participants and gather feedback on the questions, content, process, and flow of data collection. Since data collection involves a walking/wheeling method, both the research team and participants experience this process in the field, allowing for adjustments to be made accordingly. During the pilot sessions, particular attention was given to ensuring the clarity and comprehensibility of the terminology used in the tools. This was done to ensure individuals with different levels of abilities could easily understand the features being inquired about.

Following the pilot session with individuals with vision disabilities, substantial adjustments were implemented to improve the tool's readability. These changes encompassed modifications to align the tool with the Canadian National Institute for the Blind standards, ensuring adherence to best practices for accessibility in both design and functionality. These adjustments, informed by participant feedback and collaboration with the Canadian National Institute for the Blind standards, are aimed at fostering a more user-friendly and inclusive experience for individuals with vision disabilities during data collection.

Phase 2: Identification of Data Collection Locations Through Community and Research Project Partnerships

Overview

To identify areas for data collection, the research team undertook a stepwise approach, namely (1) generating prioritized sites and (2) hosting an interactive community forum to finalize locations.

Intersections for Data Collection

The research team identified data collection areas in 6 partner municipalities across Metro Vancouver using open-source data and ArcGIS. They focused on pedestrian-involved collisions data, integrating additional layers such as transportation hubs (eg, sky train stations) and city center locations to create maps and identify "hotspots" for data collection. The outcome was maps highlighting 7 to 10 intersections in each municipality. Subsequently, the team met with municipal officials to discuss and prioritize 3 to 4 intersections for the data collection per municipality based on their feedback and guidance.

SWAN Community Forum

The second step involved hosting an interactive forum with persons with disabilities, community partners from senior centers, and municipal officials. The goal was to understand challenges at intersections and surrounding areas, examining barriers and facilitators to mobility. The forum also explored designing interventions based on evaluating these areas in relation to municipal priorities and funding.

Phase 3: Participant Recruitment, Coordination, and Data Collection

Overview

Finalizing the tool and confirming selected intersections enables the research team to proceed with participant recruitment for the 4 populations: individuals with cognitive, mobility, hearing, and vision disabilities, starting with those living with cognitive disabilities. In this study, we aim to collect data from 80 participants across various disability categories. The minimum sample sizes for each category are as follows: 30 participants using MAT, 15 individuals with MCI, 15 individuals who are DHH, and 20 individuals with VI. These numbers are selected to ensure sufficient data for validity and reliability tests. The larger sample size for participants using MAT reflects their greater prevalence compared with the other groups, allowing for a more comprehensive analysis of the effects of MAT in our study. All data collection will be concluded by September 2024. While our recruitment methods are committed to diversity and inclusion, we recognize the importance of providing specific details on participant demographics. By including a diverse range of participants in terms of age, gender, ethnicity, and disability type, we aim to gain a comprehensive understanding of the barriers and facilitators present within the built environment.

Recruitment

The research team will recruit participants from community centers, relevant organizations serving persons with disabilities, and health care connections. This ongoing process targets DHH individuals, those with hearing and vision disabilities, those with early stages of dementia or MCI, and MAT users. To streamline participant onboarding, a researcher will act as the central administrator. This individual will verify eligibility, review study details, consent, web-based online tool training, and COVID-19 protocols with participants before scheduling data collection sessions. Sessions will be scheduled based on participant and research team availability. The lead research assistant (RA) for each session will maintain communication with participants and ensure all necessary documents (SWAN tools, consent forms, and equipment) are ready for the efficient completion of the audits.

On-Site Preparation Research Team

On the day of data collection, the lead and accompanying RAs will arrive in advance to assess the presence and accessibility of public washrooms. Additionally, they will identify either an indoor or covered location for the completion of the SWAN Secondary Observation Form (SOF). This form will be filled out in the format of a 15- to 20-minute qualitative interview.

On-Site Preparation Participant

Before starting the audit with the participant, the lead RA will review the consent form to ensure the participant understands the study objectives, the use of collected data, and their right to withdraw. Next, a demographic form will be completed to contextualize the participant's answers. The participant will be oriented on the path of travel using a map of the intersections to be covered. The lead RA will accompany the participant throughout the walking/wheeling audit, providing assistance as needed or taking a more active role by reading questions aloud, based on the participant's preference.

SOF Content

The SOF includes open-ended questions similar to those in the SWAN tool, encouraging discussion and reflection from the participant. Responses will be either audio recorded or handwritten based on the participant's consent choice. By incorporating the secondary observation interview guide, the SWAN tool gains a more comprehensive understanding of participants' interactions with their neighborhoods.

Home and Community Environment Survey

During the data collection phase, 2 complementary tools will be used: the Home and Community Environment (HACE) tool and the SWAN tool. Participants can either complete these tools themselves or have assistance from a secondary RA. This dual approach enhances the validation process, providing a more thorough assessment of the research variables.

The HACE tool, designed as a self-report measure, will be directly administered by the participants. It aims to evaluate various factors within an individual's HACE that might influence their level of community participation. In this study, the HACE tool serves as an additional validation measure for the effectiveness of the SWAN tool [34].

The initial HACE prototype consisted of 44 items assessing the physical, attitudinal, and political aspects of HACEs. Specifically, questions related to the community mobility domain will be included in the SWAN project's data collection process.

Sidewalk Accessibility Index

The Sidewalk Accessibility Index (SI) serves as an indicator to assess the performance of sidewalks and public spaces, focusing on the needs and expectations of wheelchair users to define accessible routes within urban road networks. It considers

various variables that contribute to the comfort and safety of wheelchair users, weighted according to their perceptions [35].

In the SWAN project, the SI will be used as a complementary tool for validation purposes. During data collection, a secondary RA completes the SI, which gathers data on 4 key aspects related to sidewalks: evenness, maintenance, width, and surface quality. However, the SWAN project focuses solely on these sidewalk-specific factors and does not inquire about the suitability of pedestrian crossings.

Sidewalks and public spaces should provide an environment that meets the needs of all users, ensuring comfort and safety regardless of physical limitations, whether temporary or permanent. The SI variables are designed to describe aspects of comfort and safety related to pedestrian movement along the block and crossing street intersections.

Finalization of Data Collection

The participant will then be provided with an honorarium for their time spent, and if required, a discussion of a second data collection will take place to complete any outstanding segments. The lead RA is responsible for ensuring the completion of all documents along with uploading and storing data collected appropriately. Finally, a reflection form will be completed by the researchers to reflect on the data collection.

Phase 4: Data Analysis

Overview

The analysis will focus on validating the SWAN tool, which collects both quantitative and qualitative data. Objective and subjective scores will be calculated for its 5 domains. In order to verify the validity of the SWAN tool, 2 additional audit tools will be used to collect data, including HACE [34] and SI [35]. Walk score results for the audited area will also be compared with the SWAN result for further validation. Details on tool validation methods can be found in the section on tool validity. Additionally, the interrater reliability (IRR) of the SWAN tool will be assessed. More information is provided in the IRR section.

Quantitative data from SWAN and other tools will be entered and organized in Microsoft Excel. This includes coding and scoring based on the codebook and calculating domain scores within Excel. For further analysis, the R programming language in RStudio (Posit, PBC) will be used for IRR and tool validity assessments. Qualitative responses from the SOF will be entered and analyzed in NVivo software (Lumivero). More details on SOF analysis can be found in the *Qualitative Data Analysis* section. The specific steps of data analysis are outlined in the following sections.

Data Cleaning and Reorganization

After data are entered and prior to moving forward with the analysis, certain questions will be moved to their original domains. The questions were moved to a different domain for efficient data collection. Although they were physically sequential on site, they are better organized in a separate domain for analysis. For example, questions about street safety features were placed in the function of the street crossing domain during data collection but belong to the safety domain.

Weighting of Scores

The primary step in calculating scores for street segments involves assigning weights to both the domains and subdomains, ensuring a total cumulative score of 100 for all domains. These weights are determined through a comprehensive literature review and expert recommendations.

For individuals who are DHH, use medical assistance technology, and have cognitive disabilities, the domain weights remain consistent. However, there is a slight variation in the vision stream weighting, reflecting the unique needs of individuals with visual impairments. Specifically, the “appearance and maintenance” domain is considered less critical. Therefore, the vision stream receives a weight 5 points lower than other streams, which is then added to the “sidewalk functionality” subdomain.

“Functionality” and “safety” are deemed the most crucial domains for neighborhood accessibility for individuals with disabilities. Consequently, each of these domains will be assigned the highest weight. As shown in Table 1, functionality is divided into crossing functionality (20 points) and sidewalk functionality (15 points in vision stream, 10 points in other streams). The same weights will apply to safety subdomains, traffic safety at 20 (covering pedestrian and vehicle interaction safety), and personal safety at 10 (focusing on subjective safety perceptions).

Table 1. Domain and subdomain weights.

Domains and subdomains	Vision stream	Other streams
Functionality	30	35
Crossing functionality	20	20
Sidewalk functionality	10	15
Safety	30	30
Traffic safety	20	20
Personal safety	10	10
Land use and supportive features	20	20
Appearance and maintenance	15	10
Social aspect	5	5
Total	100	100

The "land use and supportive features" domain, recognized as the second most critical, will receive a weight of 20. "Appearance and maintenance" will be weighted at 10 for vision and 15 for all other streams, due to overlapping questions within the land use and supportive features domain. In contrast, the "social aspects" domain, with a limited set of 5 questions focusing on subjective assessments, will have the lowest weight.

Subsequently, a detailed review of questions within each domain and subdomain will extract essential concepts and elements. The assigned weight will then be evenly distributed among these identified concepts and elements to avoid undue emphasis on specific concepts. For instance, the 20 points allocated to the subdomain of crossing functionality will be evenly divided among concepts (eg, curb ramp, crosswalk, and pedestrian signal) within that subdomain. Finally, the weight assigned to each category of questions will be equally distributed among all questions within that category to ensure a balanced weighting process.

Objective Scores

There will be 3 steps to calculate the objective score for each domain. First, responses to questions will be converted into numeric codes based on the code book. Second, these codes will be multiplied by the question's weight to calculate the question's score. Third, the scores for all questions within a domain will be summed and divided by the maximum possible score for that domain. To make the aggregated objective score easier to understand, it will be multiplied by 100% for each domain.

Some questions in the SWAN tool are reverse-coded to avoid confusion. For instance, a positive response to the presence of a certain physical feature indicating a barrier (eg, "transition from the curb ramps into the crosswalk causes problems") would be scored as "1," though it is not a facilitator in this context. These questions were reverse-scored as needed to ensure the total score includes only true "Yes" scores.

In addition to the final objective score for each domain, a total score for the SWAN tool will be calculated by averaging the scores for each domain. This total score will facilitate comparisons between different audited segments.

Codebook

In the SWAN tool, response options typically include "Yes," "No," "Don't Know," and "Not Applicable," as shown in Table 2. However, for individuals with vision disabilities, an additional option, "Cannot detect," is provided for cases where the participant cannot clearly see the object but is aware of its existence. When participants with vision disabilities choose this option, it is treated as equivalent to selecting "No," as the object is not detectable or functioning properly for the user. During the coding process, a value of "1" will be assigned for the presence of an assessed environmental feature that enhances walkability/wheelability, and "0" for its absence. Reverse-coded questions, such as "The outdoor patio(s) is/are an obstacle to walking/wheeling," will use "0" to represent the presence of this barrier and "1" to denote its absence.

Table 2. Different types of questions and scoring rationale (missing data: n=99).

Type of question and possible responses	Code
General questions	
Yes	1 (0 in case of reverse coding)
No (cannot detect, specifically in the tool designed for vision impairment)	0 (1 in case of reverse coding)
Not applicable	98
Don’t know	97
Both sides questions	
Both sides	2 (0 in case of reverse coding)
One side	1
Neither side	0 (2 in case of reverse coding)
Not applicable	98
Don’t know	97
Directional questions	
One-way	1
Two-way	0
Not applicable	0
Don’t know	0

For items referring to “one side or both sides” of a street segment, they will be grouped together as a scale. For example, “Are there curb ramps/cuts present?” will be coded as “2” if they are present on both sides, “1” if present on only one side, and “0” if not present at all. The same approach applies to items with a positive or negative impact on walkability/wheelability.

In addition to general and 2-sided questions, the SWAN tool includes questions about the direction of traffic, with responses like “one-way” and “two-way”. Through a disability lens, “one-way” responses will be coded as “1” and “two-way” as “0” since crossing one-way streets is less complex.

Responses like “not applicable” and “don't know,” based on the data collection area and participants’ familiarity, will be excluded from the scoring system to ensure it accurately reflects walkability/wheelability factors.

Subjective Ratings

Participants in the SWAN tool provide subjective ratings using a 5-point Likert scale at the end of each domain. This scale ranges from “poor” (scored as “1”) to “excellent” (scored as “5”), reflecting their subjective experience of the assessed domain. These ratings are averaged and converted into percentages to indicate participants’ subjective perceptions of the audited segment. Comparing these subjective scores with the objective scores may reveal interesting findings.

Qualitative Data Analysis

As indicated, the qualitative data will be collected using the SOF which contains open-ended questions based on the 5 primary domains, and 4 subdomains in the SWAN tool. Qualitative data gathered using the SOF is intended to capture detailed insights from the participants regarding the built environment and their lived experiences. For instance, within the personal safety subdomain, participants will be asked the following “Are there things that make you feel safe or unsafe when walking/wheeling during the daytime?” Collectively, the SOF data and the photo commentary build the qualitative dataset connected to the SWAN tool.

The qualitative data will be analyzed by using both Braun and Clark’s [36] seminal multistep thematic analysis process and by drawing on later advances in their methodological framework [37]. Their original analytical process consists of six integrated phases including (1) data familiarization and review, (2) code development and comparison, (3) code consolidation and early theme exploration, (4) theme confirmation and mapping, (5) theme refinement and name creation, and (6) research findings write-up (Braun and Clark [36]). While the open-ended questions contained in the SOF are grounded in the conceptual domains of the SWAN tool, the qualitative analysis process will be both inductive and reflexive [36,37]. Therefore, the analysis will be guided by the data itself [36] and will aim to identify insights and interpretations of the data beyond known built environment barriers and facilitators while also embracing the subjectivity of the research team members [37]. The research team will also independently and collectively engage in reflexive journaling practices and group discussions throughout the qualitative analysis process [38]. These practices will help the research team examine their subjectivity and understand its connection to their analysis [39]. Last, this will also contribute to the quality of the analysis; specifically, the adoption of these reflexive methods will contribute to the equitable and fair representation of all participant perspectives [38].

Step 1: Data Familiarization and Review

The raw qualitative data will undergo initial transcription and cleaning using Otter.ai. Subsequently, the transcriptions will also be verified by several RAs. This process will not only

ensure a clear and reliable dataset for analysis but will also help the research team familiarize themselves with the data.

Step 2: Code Development and Comparison

After the data have been transcribed and cleaned the coding process will begin. This will include the development of early/open codes and exploration of the codes across transcripts [36]. Coding will be undertaken by individual research team members, however, will be complemented by group discussions to allow for exploration of the research team's subjectivity and interpretation of the data.

Step 3: Code Consolidation and Early Theme Exploration

Following the coding of the transcripts, the research team will work to consolidate the existing codes and explore relevant themes identified within the data [36]. This process will be collaborative as all research team members will aid in collating existing codes, and in the development of a preliminary thematic map/diagram.

Step 4: Theme Confirmation and Mapping

After the potential themes have been identified, the research team will work to solidify the themes. This will involve examining if the preliminary themes fully represent and reflect the data [36]. This process will be iterative and will potentially involve revisiting the coding process. This stage will not conclude until all team members agree that the analysis fully captures the data, and a cohesive thematic map has been developed.

Step 5: Theme Refinement and Name Creation

The research team will then work to ensure each theme is well-defined and succinct [36]. This process will also be iterative and will work to identify the relevance of each theme in relation to the broader goals of the SWAN tool.

Step 6: Write-Up of Research Findings

In the final step, the team will elaborate on each theme, discussing their significance with evidence from the data, including quotes. This comprehensive write-up will aim to convey theme frequency, and importance, within the research context.

IRR Analysis

The reliability of the SWAN will be determined by calculating IRR using the paired observer method. The IRR will compare the objective scores of older adults or persons with disability and the secondary RA. This will be calculated both in percentage agreement and Cohen κ to compare the results [40]. Percentage agreement is a straightforward measure that calculates the proportion of agreement between 2 observers as a percentage of the total observations; however, in 1960, Cohen [41] critiqued the use of percent agreement due to its inability to account for chance agreement. He introduced the Cohen κ, developed to account for the possibility that raters actually guess on at least some variables due to uncertainty [40]. Cohen suggested the κ result be interpreted as follows: values ≤0 as indicating no agreement, 0.01-0.20 as none to slight, 0.21-0.40 as fair, 0.41-0.60 as moderate, 0.61-0.80 as substantial, and 0.81-1.00 as almost perfect agreement [41].

Tool Validity

To validate the SWAN tool, correlation analyses will be conducted between its domains and other environmental audit tools used in data collection: HACE, SI, and Walkscore. HACE and SI scores will be normalized using formulas outlined in their respective papers [34,35], while Walkscores for the audited area will be obtained via web. After examining data distribution, the appropriate correlation analysis method, Pearson correlation, will be applied to assess associations between scores from different tools. Pearson correlation lies between –1 and 1. Values near 0 mean no (linear) correlation and values near SD 1 mean very strong correlation. The negative sign means that the 2 variables are inversely related, that is, as one variable increases the other variable decreases. The following table gives a guideline on the strength of the linear relationship corresponding to the correlation coefficient value [42].

As no comprehensive audit tool similar to SWAN was identified in existing literature, each additional audit tool was purposefully selected to assess the validity of specific SWAN domains. Therefore, SI will be compared with functionality, HACE with safety, and Walkscore with land use and supportive features. The matrix in Table 3 illustrates which SWAN domains or subdomains will be compared with measures from HACE, SI, and Walkscore tools.

Table 3. Similarity between the Stakeholders' Walkability/Wheelability Audit in Neighborhoods (SWAN) domains and subdomains and other tools.

Extra tools and measures used for tool validation	Domains and subdomains of the SWAN tool						
	Functionality		Safety		Land use and supportive features	Appearance and maintenance	Social aspect
	Street crossing	Sidewalk	Traffic safety	Pedestrian safety			
SI[a] (sidewalks)

[b]HACE: Home and Community Environment.

Results

Data collection concluded in September 2024, involving 80 eligible participants across 4 streams in preidentified hotspots. The results are expected to be published in March 2025. To date, data collection is ongoing, and we are currently in the process of data analysis.

Discussion

Expected Findings

By focusing on a diverse group of participants, including those using MAT, those living with MCI and VI, and those who are DHH, the study aims to provide a comprehensive understanding of the barriers and facilitators present within the built environment using the SWAN tool. As there are no validated tools to capture this population perspective while navigating the built environment, the anticipated findings are expected to contribute to the existing literature by validating the SWAN tool in diverse disability categories. We hypothesize that similar to prior research, functionality and safety will emerge as key factors influencing accessibility across all disability groups. Past studies have consistently shown that features like sidewalk width, smoothness, and the presence of safe crossings are fundamental to pedestrian mobility [3,8-11]. However, our approach considers physical features, by integrating subjective participant ratings and qualitative data collected through the SOF to capture subjective experiences. This dataset should provide a more comprehensive view of how the built environment influences community participation and social participation for individuals with disabilities.

A key strength of this study is its comprehensive inclusion of multiple disability types. This research adopts a holistic perspective, capturing the full spectrum of disability-related accessibility challenges.

One important aspect that was not fully addressed in this study was the inclusion of individuals who are deaf-blind. This population, which experiences both vision and hearing impairments simultaneously, faces unique challenges that were not directly captured in this phase of the research. Due to the complexity of their needs, the lack of comprehensive accessibility tools for this group, and the potential for logistical difficulties in coordinating data collection with deaf-blind individuals, this population was excluded from this study. However, their experiences are equally critical to understanding how the built environment affects individuals with multiple disabilities.

To ensure that the findings from this study reach a wide audience and have a meaningful impact, we have developed a comprehensive knowledge mobilization strategy. A central element of this plan is the community forum, which will provide an interactive space for people with disabilities, urban planners, local government officials, and other key stakeholders to engage

directly with the research findings. This forum will facilitate the exchange of experiences and insights from individuals with disabilities, offering a platform to share their lived experiences navigating urban spaces. Through this collaborative dialogue, we aim to raise awareness and generate actionable recommendations for improving the accessibility of urban environments.

Additionally, as part of the knowledge mobilization strategy, we will develop multimedia resources including games and videos to engage both the disability community and the general public in the study's outcomes. The games will simulate the various mobility challenges faced by individuals with disabilities, offering an immersive experience for users to understand and empathize with the barriers these individuals encounter. These interactive tools will be used as educational resources in community centers, schools, and public awareness campaigns to foster greater understanding and empathy.

Conclusion

This study introduces a new approach to assessing urban accessibility for individuals with various disabilities using the SWAN tool; by adopting a community-based methodology, the research emphasizes the importance of including diverse disability perspectives in evaluating the built environment. The anticipated findings will provide valuable insights into the barriers and facilitators that impact mobility, safety, and overall accessibility in urban spaces.

While the study's limitations include the exclusion of individuals who are deaf-blind and the focus on specific urban areas, these gaps present opportunities for future research. Expanding the participant pool and environments will strengthen the generalizability of the findings.

This work contributes new knowledge to the field by offering a comprehensive framework for urban accessibility that integrates both subjective and objective measures. It underscores the importance of inclusive design and offers practical implications for urban planners and policymakers striving to create more accessible, inclusive communities.

Abstract

Background: Acquired neurological diseases entail significant changes and influence the relationship between a patient and their significant other. In the context of long-term rehabilitation, those affected collaborate with health care professionals who are expected to have a positive impact on the lives of the affected individuals.

Objective: This study aims to examine the changes in the relationship between the patient and their loved ones due to acquired neurological disorders and the influence of health care professionals on this relationship.

Methods: Through sociogenetic type building, we will identify different types of patient-caregiver dyads and their effects on health care professionals and vice versa. The results will then be integrated into a model based on the theory of symbolic interactionism and Baxter's Relational Dialectics Theory.

Results: This study is not funded and was approved by the ethics committee of the German Society for Nursing Science, and it complies with the Declaration of Helsinki. The data collection started in June 2024 based on narrative couple interviews and is running. We assume that patients and their relatives will demonstrate heterogeneity as individuals, as well as in their interactions within the dyad, regarding certain orientations such as coping with illness, motivation for therapy, and coping strategies.

Conclusions: Our findings address a biopsychosocial perspective that enhances treatment approaches in neurological long-term care. Understanding the influence of professionals on dyadic couple relationships can improve rehabilitation effectiveness by tailoring therapeutic approaches to various patient types, relatives, and dyadic relationship constellations. This fosters patient- and family-centered therapy in line with holistic care.

Introduction

Scientific and Practical Relevance of the Project

Rehabilitation is effective for any person with a long-lasting disability at any stage of the illness. A patient-centered biopsychosocial rehabilitation approach involving a multidisciplinary team is particularly essential for individuals with neurological conditions, as they frequently experience lifelong limitations and require comprehensive, individualized support to enhance their quality of life and achieve maximum independence [1].

Neurological damage is acquired through stroke, traumatic central nerve injury, or traumatic brain injury. The resulting sudden loss of independence often leads to irreversible harm and is one of the main causes of lifelong support and home care needs. Strokes cause a high economic and health burden [2]. For example, the cost of stroke to health care systems in 32 countries totaled US $28.2 billion in 2017 [3]. This is why the Stroke Alliance for Europe emphasizes the need for European countries to invest in cost-effective stroke interventions to improve rehabilitation and the quality of life of stroke survivors [3]. The number of patients with traumatic brain injury in 2016 in Germany was 419,507 [4]. More than 4000 patients become long-term care cases due to severe permanent injuries, resulting in high costs and limited ability to work [5]. The rehabilitation process for neurological diseases is highly complex, depends on numerous influencing factors, and is vague concerning the results. The effectiveness of rehabilitation is highly dependent on its integration within a biopsychosocial framework and requires an individualized, person-centered approach [1]. Functional, cognitive, and psychological challenges directly impact the ability to perform daily tasks independently [6]. Acquired neurological damage leads to a loss of social roles for those affected and requires adaptation to the new living conditions [7]. In the context of illnesses, the individual coping strategies used vary greatly across the different patients [8]. Life orientations, goals, ideas, and expectations about one's own life and future development represent a relevant aspect of rehabilitative cooperation and success. Relatives of those who are directly affected not only experience trauma but also deal with the illness and its lasting personal consequences for themselves [9]. Individual processes take place within partnership dyads and domestic cohabitation. This is particularly relevant for Germany where 63% of people in need of care are cared for exclusively by relatives in a domestic setting. Nursing homes care for only 16% of people in need of long-term care in Germany [10].

Family Change Processes and Relationship Dynamics

In the partnership dyad between the person affected and the caregivers, dual roles arise as a spouse, patient, or caring relative [11]. Changes caused by a sudden loss of independence and the need for assistance due to a family member's illness impact power dynamics, role distributions, tasks, and decision-making between patients and their relatives. On the one hand, relatives provide their resources while on the other hand, they need help themselves. Within the framework of the existing family system, relatives thus have to face new challenges [9,12]. In this context, the rehabilitation process after acquired neurological damage is associated with fears, worries, and adaptations for many patients and their caregivers [13].

The therapeutic relationship significantly influences the rehabilitation process of neurological diseases and is of paramount importance [14,15].

Family caregivers play a central role in providing care, therapy, and social support, particularly in the case of lifelong disability due to acquired neurological damage [16]. According to recent international studies, the psychosocial effects of neurological damage have already been described for patients [12,17] and family caregivers of affected persons [18]. Studies also explore the dynamics between patients and therapists, as well as the relationships formed in patient-therapist interactions [12,19]. However, given the importance of biopsychosocial aspects in therapy and the close interactions affecting the well-being of patients and their relatives, there is a lack of studies on the influence of health care professionals on the dyadic relationship between patients and relatives in different phases of rehabilitation.

Our study addresses the following questions:

1. How does the dyadic relationship between persons with acquired central nervous chronic impairment and their significant others change over time and what does it mean for the therapeutic process?

2. How do relationships and relationship aspects influence the rehabilitation process?

3. What is the influence on the dyadic relationship that affects persons and their life partners which attributes to the health care professionals?

Furthermore, we want to discuss how health care professionals should react to the different situations and dyads in the rehabilitation process to enable the best possible quality of life from the perspective of the affected person and their life partner.

Underpinning Theories and Theoretical Approach

The theory of symbolic interactionism (SI) is based on the fundamental idea that actors influence each other within the framework of interaction processes and the resulting ongoing interpretations [20]. In relation to the object of the study, this means that 2 people enter a relationship with each other based on a "self" resulting from their history of interaction. The "self" is called into question by the sudden injury that leads to a long-term need for help, is no longer connectable in the strongly changed interaction, and needs a challenging adaptation.

Building on the understanding of SI, Leslie Baxter's Relational Dialectics Theory (RDT) focuses on forming a meaningful relationship between partners [21]. The relationship between the patient and the caregiver is established in dialogue and is subject to continuous change. Examples of dialectics within the dyadic relationship are integration-separation, stability-change, or expression-nonexpression. According to the RDT, these dialectics are natural and unavoidable in any relationship, and they play a crucial role in shaping how individuals communicate and interact [22]. This is particularly relevant to understand the changes within the couple relationship of patient and relative over time.

From a theoretical perspective, this study aims to increase the knowledge on the influence of changes in the couple's relationship on the rehabilitation process and vice versa, and consequently on the quality of life of patients and caregivers. Different types of patient-caregiver dyads can be identified and empirically validated based on theoretical approaches. This approach makes it possible to link empirically identified types back to the theory of SI [20], and the RDT [21], to support them empirically or to change, refute, or expand them. A major novelty of the study lies in the theoretical foundation of the

reciprocal effects of relational changes in acquired central nervous damage in rehabilitative processes and interaction with health care professionals.

From a practical perspective, standardized types of dyads can be recognized, and various rehabilitative approaches can be postulated at the practice level on a sociopsychological basis. This enables the enhancement of individual care for affected individuals, with a focus on improving their quality of life.

Methods

The study follows the Standards for Reporting Qualitative Research [23].

Approach, Sampling, and Recruitment

Approach

We use a qualitative approach, exploring how individuals maintain and shape their relationships in response to changed life situations within a domestic environment.

Sampling

Our sample consists of people with similar neurological conditions. Within the scope of the study, we include adult couples in which one person is chronically affected by an acquired neurological injury. Within these cases, disturbances, social status, age, and duration of affliction should be heterogeneous to ensure a high degree of diversity.

The inclusion criteria are (1) people who had an acquired central nervous system injury at least 6 months before and their partners, (2) the partnership existed before the injury and still exists at the time of the survey, (3) partners live together in a household, (4) participants have the capacity to give consent, (5) participants exhibit sufficient visual and hearing ability in order to understand the questions during the interview, (6) residence in Germany, and (7) sufficient understanding of German language.

Recruitment and Field Access

We recruit participants by displaying notices and flyers in public areas, including doctor's waiting rooms and neurological rehabilitation centers. This approach promotes voluntary participation. The study aims to achieve theoretical saturation without relying on predetermined statistical methods. Participants and their partners may choose the location for the interviews, which can be either through video call or in a place of their preference. The decision regarding the interview setting (face-to-face or online) is made by the concerned family dyads to avoid complicating the caregiving situation. No payment or reimbursement of expenses is provided for participation.

Data Collection Instruments and Data Processing

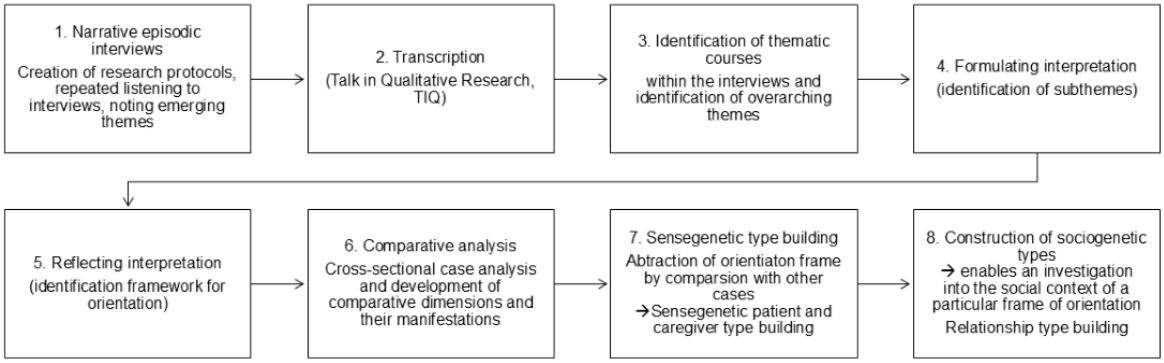
Narrative episodic joint couple interviews were conducted as part of this study. A deliberate decision was made to engage in dialogue with the spouses collectively, as this approach reflects the shared reality and facilitates negotiation processes between the individuals. Our research will deliberately consider the role of power dynamics within the interview setting, with a particular focus on the use of interruptions, attributions, accusations, and consents in relation to the discussed issues. This will be done in order to explicate the power structures and roles within the relationship and to analyze them in the context of the rehabilitation process. The couple's interviews will be recorded using an audio recording device. To meet the criterion of intersubjective traceability, the researcher will meticulously maintain posttranscripts and research diaries, which will document not only the content of the interview but also the researcher's personal feelings and reflections after each interview. This process will include active reflection on the researcher's role in the field, ensuring a transparent examination of potential biases and interactions.

The project uses the transcription system "Talk in Qualitative Research" for data processing, which was developed within the framework of the documentary method [24,25].

Data Analysis

The analysis of the narrative couple interviews is carried out according to Bohnsack's documentary method (Figure 1) [24]. The main researcher will systematically engage with the material, using a step-by-step immersion process to gradually extract insights and develop comparative horizons through case comparisons. This approach will ensure a thorough exploration of each case before proceeding to the next. The material and interpretations will be discussed with the research team using a 4-eyes principle and in workshops to gain diverse perspectives, validate findings, and enhance analytical rigor.

Figure 1. Methodical approach according to the documentary method.



Accordingly, the documentary method does not only remain at the level of an actor's reflexive knowledge but also allows access to practice-relevant action. This is pertinent in relation to the attitudes and behavior of those affected and their

caregiving relatives. By examining dyadic relationships retrospectively, the research seeks to understand how the meanings and dynamics within these relationships have developed and changed over time. The formulating textual interpretation summarizes what has already been interpreted by the actors in the research field. This forms the basis for the reflexive interpretation, which consists of a formal and a semantic interpretation.

Comparative Analysis and Type Formation

The reconstruction of the habitus based on biographical narratives is conducted with the objective of determining the extent to which the habitus interpretations developed from the initial sequence can be confirmed, differentiated, or expanded through the analysis of subsequent sequences of this case. This is achieved through a comparative contrast with thematically similar sequences from other cases [26]. In a comparative analysis, the horizons of the respective cases within this study (eg, attitudes of patients and caregiving relatives) are compared and related to each other [25]. In sense-genetic type formation, we work out different orientation frameworks for dealing with a problem, for example, coping strategies for illness, and typify them [26]. Building on this, sociogenetic typing includes social contexts within the partnership and the relationship with health care professionals (Figure 1 [24]).

A flowchart of the study procedure and work packages is provided in Figure 2.
